Abstract. MegaM@Rt2 is a large European project dedicated to the provisioning of a model-based methodology and supporting tooling for system engineering at a wide scale. It notably targets the continuous development and runtime validation of such complex systems by developing the MegaM@Rt2 framework to address a large set of engineering processes and application domains. This collaborative project involves 27 partners from 6 different countries, 9 industrial case studies as well as over 30 different tools from project partners (and others). In the context of the project, we opted for a pragmatic model-driven approach in order to specify the case study requirements, design the high-level architecture of the MegaM@Rt2 framework, perform the gap analysis between the industrial needs and current state-of-the-art, and to plan a first framework development roadmap accordingly. The present paper concentrates on the concrete examples of the tooling approach for building the framework architecture. In particular, we discuss the collaborative modeling, requirements definition tooling, approach for components modeling, traceability and document generation. The paper also provides a brief discussion of the practical lessons we have learned from it so far.

Keywords: Model-Driven Engineering, Requirement Engineering, Architecture, UML, SysML, Traceability, Document Generation, Modelio

1 Introduction

MegaM@Rt2 is a three-years project, funded by European Components and Systems for European Leadership Joint Undertaking (ECSEL JU) under the H2020 European program, that started in April 2017 [1]. The main goal is to create an integrated framework incorporating methods and tools for continuous system engineering and runtime V&V [2, 8]. The underlying objective is to develop and apply scalable model-based methods and tools in order to provide improved productivity, quality, and predictability of large and complex industrial systems [9].

One of the main challenges is to cover the needs coming from diverse and heterogeneous industrial domains, going from transportation [3] and telecommunications to logistics. Among the partners providing use cases in the project, we can cite Thales, Volvo Construction Equipment, Bombardier Transportation and Nokia. These organizations have different product management and engineering practices, as well as regulations and legal constraints. This results in a large and complex catalog of requirements to be realized by the architecture building blocks at different levels of abstraction. Thus, the development of the MegaM@Rt2 framework is based on a feature-intensive architecture and a related implementation roadmap.

The MegaM@Rt2 framework plans to integrate more than 30 tools implementing the above mentioned methods and satisfying requirements of the case studies. The tools features are grouped in three conceptual tool sets:

1. MegaM@Rt Systems Engineering Tool Set regroups a variety of current engineering tools featuring AADL, EAST-ADL, Matlab/Simulink, AUTOSAR, Method B or Modelica, SysML and UML in order to precisely specify both functional and non-functional properties. Moreover, system level V&V and testing practices will also be supported by this tool set.
2. MegaM@Rt Runtime Analysis Tool Set seeks to extensively exploit system data obtained at runtime. Different methods for model-based V&V and model-based testing (MBT) will be rethought and/or extended for runtime analysis. Model-based monitoring will allow to observe executions of a system (in its environment) and to compare it against the executions of corresponding model(s). Monitoring will also allow a particular system to be observed under controlled conditions, in order to better understand its performance.
3. MegaM@Rt Model & Traceability Management Tool Set is a key part of the framework as it is dedicated to support traceability between models across all layers of the system design and execution (runtime). This can go from highly specialized engineering practices to low-level monitoring. Relying on the unification power of models, it should provide efficient means for describing, handling and keeping traceability/mapping between large-scale and/or heterogeneous software and system artifacts.

Model-based approaches for specification have been developed consistently during almost two decades [4]. Automated document generation was one of the first benefit offered by the Model-driven Architecture (MDA) [10, 4]. Indeed, models as the first-class entities of the engineering process should contain all the necessary information for the design documentation. However, several challenges arise. First, the architect team should decide the right organization for the global architecture model. Second, it should be carefully planned which level of details is appropriate for the design of the individual contributions. Third, it should be considered that the architecture model will be used during 3 years of the project for numerous purposes, and thus needs to be prepared to accommodate for changes in methodology. Fourth, several documents need to be generated by extracting the relevant information from all over the architecture model.

In this paper, we present our experience on providing and utilizing model-based tool support for defining MegaM@Rt2 framework architecture, to identify the solution to be implemented in the context of the project and to obtain a corresponding roadmap for the development of architecture components throughout the project.

2 Architecture specification approach

We adopted a practical approach for the architecture specification that is particularly adapted to collaborative projects such as MegaM@Rt2, integrating tools coming from several parties [5, 6]. As modeling language, we took a Systems Modeling Language (SysML) [11] subset for requirements specification and a Unified Modeling Language (UML) [12] subset for the high-level architecture specification. The approach to define the MegaM@Rt2 framework architecture is depicted in Fig. 1. We splitted the architecture model in several parts, dividing the responsibilities among: the Work Package (WP) leaders, the tool providers and the case study providers, as detailed in the following list:

- Requirements/Purposes are specified using SysML
 - Case Study Requirements are specified by case study providers,
 - Framework Requirements are specified by WP leaders, refining the Case Study Requirements
 - Tool Purposes are specified by tool providers with the aim to realise a specific subset of the Framework Requirements
- Architecture is specified in UML
 - Conceptual Tool Set is specified by the WP leaders and represents the basic architecture of the MegaM@Rt2 Framework
 - Tool Set Component is each tool instance, specified by tool providers, implementing part of the MegaM@Rt2 Framework functionalities
 - Common Interfaces - specified by tool providers,
 - Common deployment frameworks - specified by tool providers

In addition, to support the integration of each Tool Set Component into the MegaM@Rt2 Framework, the following additional elements has been identified:

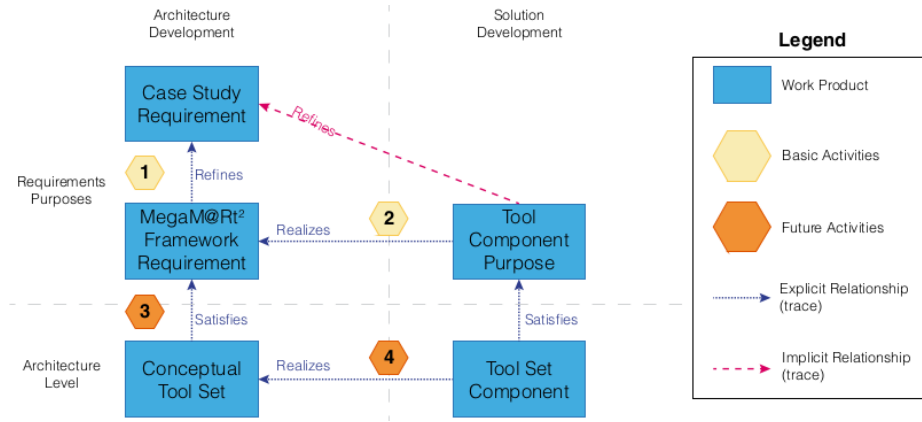

Fig. 1. Overview of the Architecture and Development process in MegaM@Rt2.

- Common Interfaces, specified by tool providers, to support data and model exchange between tools
- Common Deployment Frameworks, specified by tool providers, to highlight possible issues related to hardware and software platforms

At the Requirements/Purposes level, the needs of industrial partners have been collected and classified by means of Case Study Requirements, from which we specified (Activity 1) the MegaM@Rt2 Framework Requirements. For the latter, we identify (Activity 2) a set of Tool Component Purposes that will realize the case study requirements. At the Architecture level, each Conceptual Tool Set component and the relevant interfaces are identified (Activity 3) to satisfy framework requirements. Then, for the Conceptual Tool Set we specify (Activity 4) concrete Tool Set Components to realize the desired functionality. Those Tool Set Components expose features (i.e. purposes) that are progressively available, during the project time frame, based on specific development plan. The roadmap is defined as the set of tools components purposes available at each project milestone.

3 Tooling approach

Appropriate tooling support is important for the success of the model-driven engineering process shown in Fig. 1. In order to provide tool support for our architecture specification approach, we selected the Modelio and Constellation tools provided by one of the project participants: the SOFTEAM partner.

When collecting inputs of 50 users, it was important to provide guidelines and diagram templates. Otherwise, the integration work may become extremely challenging. As such, we defined a set of template diagrams both for specifying requirements and for collecting tool purposes. Users were able to clone these templates inside the model to describe their concrete tools.

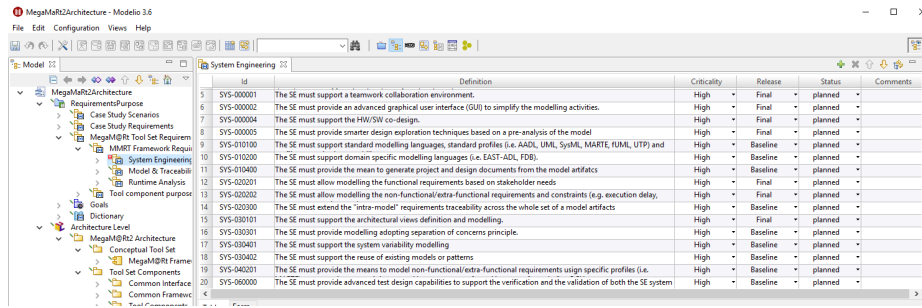

Fig. 2. Requirements editing with Modelio.

In the next subsections we are providing more details on how different features of the tool were used to support our approach.

3.1 Architecture specification

Modelio is an MDE workbench supporting standard modeling languages such as UML, SysML among others. All the modeling notations can be used in the same global model repository which is important for model traceability and management.

Requirements modeling. In our approach, requirements originated from different sources, i.e. from 9 case study providers and 22 tool providers. In order to have an uniform approach for requirement specification that would facilitate gap analysis and roadmap identification, we defined requirement templates that were used to define the expected properties to be collected, such as criticality for the case study requirements and *planned release* date for tool purposes.

Modelio allowed us to edit requirements in both diagram view and tabular view (see Fig. 2). The requirements were manually edited or automatically imported from other documents, e.g. MS Excel.

Architecture modeling. On the architecture level, we used Class and Deployment diagrams. We limited modeling to a subset of UML to enforce the common understanding of the architecture and simplify editing. In particular, we choose to use UML Components, Interfaces, Associations, Generalizations and Dependencies.

For tool components, we set a template for the architecture specification that included class diagram to specify functional interfaces, tool components subordinates and the relation to the conceptual tool set in the framework, and deployment diagrams to identify the execution environment of the tool component. In addition, Package diagrams have been used to define the high level structure of the MegaM@Rt2 framework architecture.

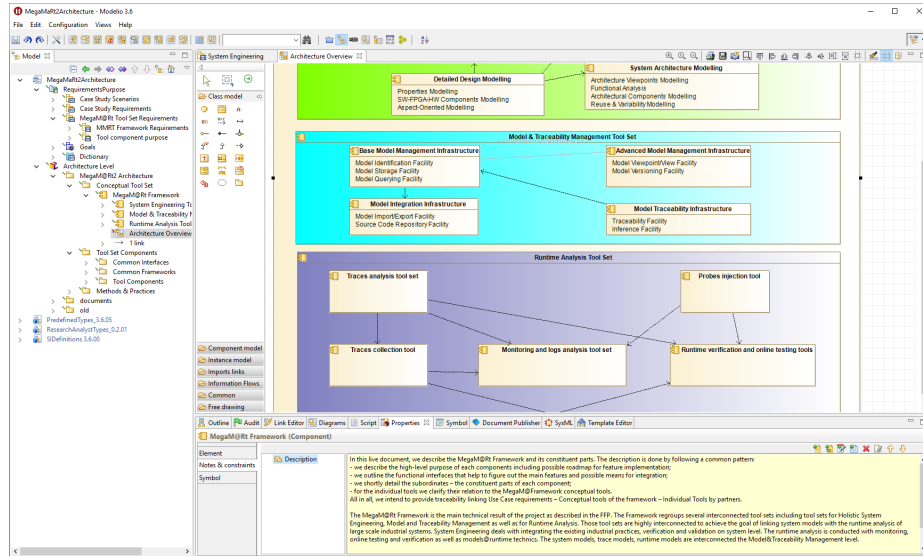

Fig. 3. Editing architecture and documentation with Modelio.

For instance, Fig. 3 shows that the MegaM@Rt2 framework architecture is composed of three parts corresponding to the three WPs of the project: System Engineering, Runtime Analysis, and Model and Traceability Management, respectively.

In Modelio, the documentation (Fig. 3) can be added in the textual notes or attached as separate documents. Both plain text and rich text notes are supported. In our work, we deliberately restricted editing to plain text notes to make sure that the generated documents are formatted correctly.

Fig. 4. Example: Traceability links among the tool set, framework and case study requirements.

Requirements traceability. Once the requirements have been specified, for each tool component we defined a traceability matrix to link case study requirements to framework requirements, and respectively framework requirements to tool purposes as depicted as described by Activities 1 and 2 of the modeling approach in Fig. 1. This allowed us to use instant traceability diagrams, as the one in Fig. 4, to visualise the whole set of dependencies for a given requirement. This proved beneficial not only for the requirement analysis and toolset integration planning, but also for identify common interfaces for tool components and visualise gaps for the requirements analysis.

Generating documents. Modelio offers fairly flexible model query and document generation facilities that were used for editing and maintaining four specifications in the project. The template editor (Fig. 5) was particularly useful to implement custom extraction of model elements in order to create specific sections of the document.

In the example below, the template specifies that the generator will search for a Tool Components package, look at all the UML components to generate a tool section. This document section will include introductory paragraph, Purpose subsection, subsections for all class and deployment diagrams as well as section on the owned interfaces.

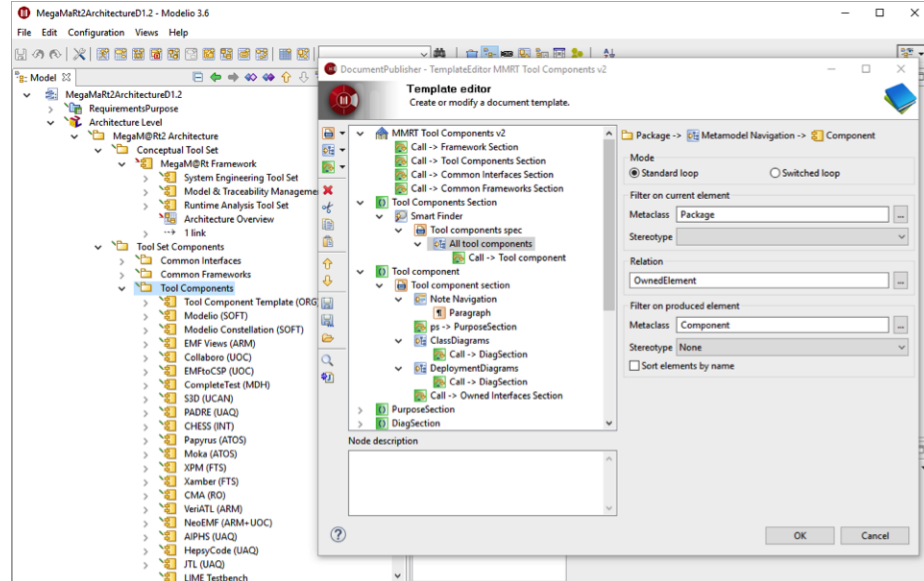

Fig. 5. Example: Custom document generation template for individual tools section.

When editing the architecture model, it is quite useful to see the generation result. Thus, along with developing custom document templates, we integrated the document generation to the Modelio interface. That way regular users could call the document generation directly from the tool using a context menu (Fig. 6).

3.2 Collaborative model editing

Modelio Constellation [7] is the model sharing, collaborative editing, versioning and configuration management facility that allow hundreds of modellers to work together on the same common and shared model. Indeed, authoring an architecture deliverables in MegaM@Rt2 project required contributions of 27 partners. Thus, around 50 users worked together on the single model. On the regular basis, users connected to the Constellation server, synchronised the local model with the central repository, edited the architecture and generated the documents with always updated templates. The documentation templates and user interfaces for document generation were developed continuously and had to be rolled out to the whole large team of modellers without interrupting the work process. It was important to provide versioning and conflict resolution when editing touched the common artifacts. Last but not least, several different deliverable were generated out of the same model. Therefore, the branching facility allowed to fix the state when the deliverable were released.

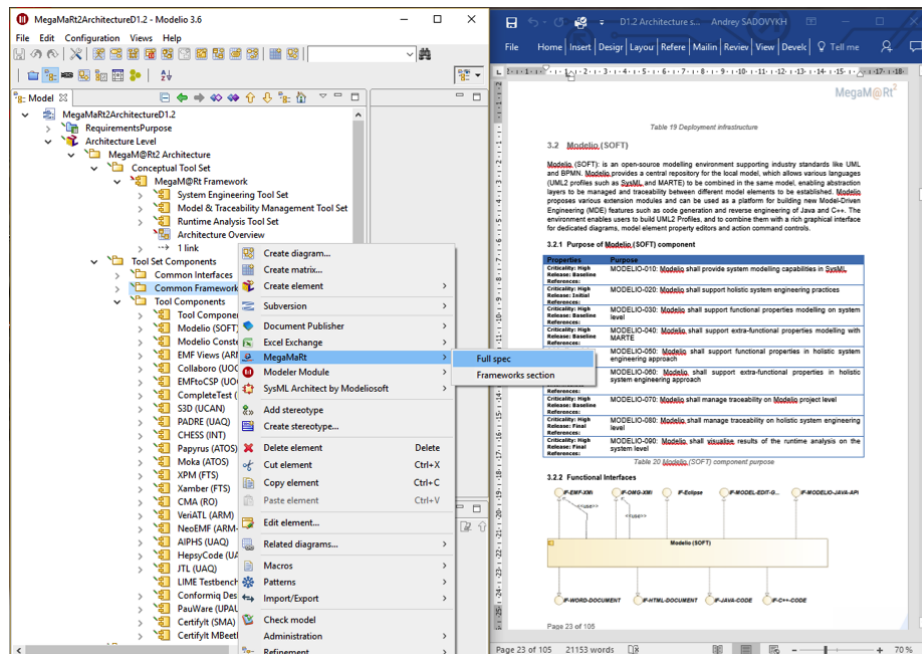

Fig. 6. Example: Architecture document generated with Modelio Document Publisher.

4 Conclusions

In this paper, we presented the tool support we used in order to identify and specify the architecture of the MegaM@Rt2 framework using model-driven principles and practices. Our approach enforced the coordination and collaboration among many different stakeholders and thus manageability of this complex project. Indeed, the main benefits of our model-driven approach are that all information was collected from different stakeholders and stored using one single model using a single tool.

This model was used as a central repository, that every project partner can access and update using model versioning techniques. In addition, having all the information in one single place, allowed us not only to constantly monitor the status of the process and to trace the requirements of the framework components, but also to easily generate necessary artefacts (such as documents, tables, diagrams) from the model, whenever needed.

However, using a model-based approach also had some challenges and limitations.

The first of such challenge was that different project participants had different levels of familiarity with modeling tools in general and with Modelio and Constellation in particular. This issue has been addressed by providing several project-wide online webinars along with proper documentation on describing how the tools can be used to support the architecture specification approach. The Modelio support team was helpful in solving the licensing issues, helping with installation and resolving model versioning conflicts.

A second challenge came from the fact that 50 modellers worked collaboratively with the models which could trigger inconsistencies, conflicts and omissions in the collected information. Using the Constellation tool we were able to support model versioning and collaborative modeling. In addition, we splitted the model in several parts corresponding to each work package and we provided clear guidelines on how the work is organized.

A third challenge came from the limitations of the selected tools. For instance, there were different restrictions on how the styling of the documents generated from the models could be configured and how the information could be visualized using different types of diagrams. Manual effort is also required to create document templates and configure the document generators. However, once the generators were created they could be reused easily and effectively.

In addition to the above challenges, some industrial partners were already using an existing company-wide tool chain that is not part of our project consortium. In this case, they still gave their requirements, which were mapped to MegaM@Rt tool set capabilities. However, in such cases, the industrial partners had an additional validation of the acceptance of their requirements using both the MegaM@Rt tool set capabilities as well as the capabilities of their in-house tool set.

Overall, the experience with Modelio and Constellation was mostly positive and the tool will be further used in other architecture deliverables at later stages of the project and as the reference document.

Acknowledgement. This project has received funding from the Electronic Component Systems for European Leadership Joint Undertaking under grant agreement No. 737494. This Joint Undertaking receives support from the European Union’s Horizon 2020 research and innovation program and from Sweden, France, Spain, Italy, Finland and Czech Republic.
