## 11 — Abstract —

12 We make progress on the fine-grained complexity of MAXIMUM-CARDINALITY MATCHING on  
13 graphs of bounded *clique-width*. Quasi linear-time algorithms for this problem have been recently  
14 proposed for the important subclasses of bounded-treewidth graphs (Fomin et al., SODA’17) and  
15 graphs of bounded modular-width (Coudert et al., SODA’18). We present such algorithm for  
16 bounded *split-width* graphs — a broad generalization of graphs of bounded modular-width, of  
17 which an interesting subclass are the distance-hereditary graphs. Specifically, we solve MAXIMUM-  
18 CARDINALITY MATCHING in  $\mathcal{O}((k \log^2 k) \cdot (m+n) \cdot \log n)$ -time on graphs with split-width at most  
19  $k$ . We stress that the existence of such algorithm was not even known for distance-hereditary  
20 graphs until our work. Doing so, we improve the state of the art (Dragan, WG’97) and we  
21 answer an open question of (Coudert et al., SODA’18). Our work brings more insights on the  
22 relationships between matchings and *splits*, *a.k.a.*, join operations between two vertex-subsets in  
23 different connected components. Furthermore, our analysis can be extended to the more general  
24 (unit cost)  $b$ -MATCHING problem. On the way, we introduce new tools for  $b$ -MATCHING and  
25 dynamic programming over *split decompositions*, that can be of independent interest.

34 Romania.

## 35 **1 Introduction**

36 The MAXIMUM-CARDINALITY MATCHING problem takes as input a graph  $G = (V, E)$  and  
37 it asks for a subset  $F$  of pairwise disjoint edges of maximum cardinality. This is a funda-  
38 mental problem with a wide variety of applications. Hence, the computational complexity  
39 of MAXIMUM-CARDINALITY MATCHING has been extensively studied in the literature. For  
40 instance, this was the first problem shown to be solvable in polynomial-time [11]. Cur-  
41 rently, the best-known algorithms for this problem run in  $\mathcal{O}(m\sqrt{n})$ -time on  $n$ -vertex  $m$ -edge

42 graphs [22]. Such superlinear running times can be prohibitive for some applications. In-  
 43 triguingly, MAXIMUM-CARDINALITY MATCHING is one of the few remaining fundamental  
 44 graph problems for which we neither have proved the existence of a quasi linear-time al-  
 45 gorithm, nor a superlinear time complexity (conditional) lower-bound. This fact has renewed  
 46 interest in understanding what kind of graph structure makes this problem difficult. Our  
 47 present work is at the crossroad of two successful approaches to answer this above question,  
 48 namely, the quest for improved graph algorithms on special graph classes and the much more  
 49 recent program of “FPT in P”. We start further motivating these two approaches before we  
 50 detail our contributions.

## 51 1.1 Related work

52 **Algorithmic on special graph classes.** One of our initial motivations for this paper was  
 53 to design a quasi linear-time algorithm for MAXIMUM-CARDINALITY MATCHING on *distance-*  
 54 *hereditary graphs* [1]. – Recall that a graph  $G$  is called distance-hereditary if the distances  
 55 in any of its connected induced subgraphs are the same as in  $G$ . – Distance-hereditary  
 56 graphs have already been well studied in the literature [1, 8, 17]. In particular, we can  
 57 solve DIAMETER in linear-time on this class of graphs [8]. For the latter problem on general  
 58 graphs, a conditional *quadratic* lower-bound has been proved in [24]. This result suggests  
 59 that several hard graph problems in P may become easier on distance-hereditary graphs.  
 60 Our work takes a new step toward better understanding the algorithmic properties of this  
 61 class of graphs. We stress that there exist linear-time algorithms for computing a maximum  
 62 matching on several subclasses of distance-hereditary graphs, such as: trees, cographs [26]  
 63 and (tent,hexahedron)-free distance-hereditary graphs [7]. However, the techniques used for  
 64 these three above subclasses are quite different from each other. As a byproduct of our main  
 65 result, we obtain an  $\mathcal{O}(m \log n)$ -time algorithm for MAXIMUM-CARDINALITY MATCHING on  
 66 distance-hereditary graphs. In doing so, we propose one interesting addition to the list of  
 67 efficiently solvable special cases for this problem.

68 **Split Decomposition.** In order to tackle with MAXIMUM-CARDINALITY MATCHING on  
 69 distance-hereditary graphs, we consider the relationship between this class of graphs and *split*  
 70 *decomposition*. A *split* is a join that is also an edge-cut. By using pairwise non crossing splits,  
 71 termed “strong splits”, we can decompose any graph into degenerate and prime subgraphs,  
 72 that can be organized in a treelike manner. The latter is termed split decomposition [6],  
 73 and it is our main algorithmic tool for this paper. The *split-width* of a graph is the largest  
 74 order of a non degenerate subgraph in some canonical split decomposition. In particular,  
 75 distance-hereditary graphs are exactly the graphs with split-width at most two [23].

76 Many NP-hard problems can be solved in polynomial time on bounded split-width graphs  
 77 (e.g., GRAPH COLORING, see [23]). Recently, with Coudert, we designed FPT algorithms for  
 78 polynomial problems when parameterized by split-width [5]. It turns out that many “hard”  
 79 problems in P such as DIAMETER can be solved in  $\mathcal{O}(k^{\mathcal{O}(1)} \cdot n + m)$ -time on graphs with  
 80 split-width at most  $k$ . However, we left this open for MAXIMUM-CARDINALITY MATCHING.  
 81 Indeed, our main contribution in [5] was a MAXIMUM-CARDINALITY MATCHING algorithm  
 82 based on the more restricted *modular decomposition*. Given this previous result, it was  
 83 conceivable that a MAXIMUM-CARDINALITY MATCHING algorithm based on split decom-  
 84 position could also exist. However, we need to introduce quite different tools than in [5] in  
 85 order to prove in this work that it is indeed the case.

86 **Fully Polynomial Parameterized Algorithms.** Our work with split-width fits in the re-  
 87 cent program of “FPT in P”. Specifically, given a graph invariant denoted  $\pi$  (in our case, split-

width), we address the question whether there exists a MAXIMUM-CARDINALITY MATCHING algorithm running in time  $\mathcal{O}(k^c \cdot (n+m) \cdot \log^{\mathcal{O}(1)}(n))$ , for some constant  $c$ , on every graph  $G$  such that  $\pi(G) \leq k$ . Note that such an algorithm runs in quasi linear time for any constant  $k$ , and that it is faster than the state-of-the-art algorithm for MAXIMUM-CARDINALITY MATCHING whenever  $k = \mathcal{O}(n^{\frac{1}{2c}-\varepsilon})$ , for some  $\varepsilon > 0$ . This kind of FPT algorithms for polynomial problems have attracted recent attention [5, 16, 19, 20, 21]. We stress that MAXIMUM-CARDINALITY MATCHING has been proposed in [21] as the “drosophila” of the study of these FPT algorithms in P. We continue advancing in this research direction.

Note that another far-reaching generalization of distance-hereditary graphs are the graphs of bounded *clique-width* [17]. In [5], we initiated the complexity study of MAXIMUM-CARDINALITY MATCHING – and other graph problems in P – on bounded clique-width graph classes. The latter research direction was also motivated by the recent  $\mathcal{O}(k^2 \cdot n \log n)$ -time algorithm for MAXIMUM-CARDINALITY MATCHING on graphs of treewidth at most  $k$ , see [13, 19]. Turning our attention on denser graph classes of bounded clique-width, we proved in [5] that MAXIMUM-CARDINALITY MATCHING can be solved in  $\mathcal{O}(k^4 \cdot n + m)$ -time on graphs with *modular-width* at most  $k$ . We stress that distance-hereditary graphs have *unbounded* treewidth and unbounded modular-width. Furthermore, clique-width is upper-bounded by split-width [23], whereas split-width is upper-bounded by modular-width [5]. As our main contribution in this paper, we present a quasi linear-time algorithm in order to solve some generalization of MAXIMUM-CARDINALITY MATCHING on bounded split-width graphs — thereby answering positively to the open question from [5], while improving the state-of-the-art. Our result shows interesting relationships between graph matchings and splits, the latter being an important particular case of the join operation that is used in order to define clique-width. The fine-grained complexity of MAXIMUM-CARDINALITY MATCHING parameterized by clique-width, however, remains open.

## 1.2 Our contributions

We consider a vertex-weighted generalization for MAXIMUM-CARDINALITY MATCHING that is known as the unit-cost  $b$ -MATCHING problem [12]. Roughly, every vertex  $v$  is assigned some input capacity  $b_v$ , and the goal is to compute edge-weights  $(x_e)_{e \in E}$  so that: for every  $v \in V$  the sum of the weights of its incident edges does not exceed  $b_v$ , and  $\sum_{e \in E} x_e$  is maximized. We prove a simple combinatorial lemma that essentially states that the cardinality of a maximum  $b$ -matching in a graph grows as a piecewise linear function in the capacity  $b_w$  of any fixed vertex  $w$ . This nice result (apparently never noticed before) holds for any graph. As such, we think that it could provide a nice tool for the further investigations on  $b$ -MATCHING. Then, we derive from our combinatorial lemma a variant of some reduction rule for MAXIMUM-CARDINALITY MATCHING that we first introduced in the more restricted case of modular decomposition [5]. Altogether combined, this allows us to reduce the solving of  $b$ -MATCHING on the original graph  $G$  to solving  $b$ -MATCHING on *supergraphs* of every its split components. We expect our approach to be useful in other matching and flow problems.

Overall, our main result is that  $b$ -MATCHING can be solved in  $\mathcal{O}((k \log^2 k) \cdot (m+n) \cdot \log \|b\|_1)$ -time on graphs with split-width at most  $k$  (Theorem 12). It implies that MAXIMUM-CARDINALITY MATCHING can be solved in  $\mathcal{O}((k \log^2 k) \cdot (m+n) \cdot \log n)$ -time on graphs with split-width at most  $k$ . Since distance-hereditary graphs have split-width at most two, we so obtain the first known quasi linear-time algorithms for MAXIMUM-CARDINALITY MATCHING and  $b$ -MATCHING on distance-hereditary graphs.

We introduce the required terminology and basic results in Section 2, where we also sketch the main ideas behind our algorithm (Section 2.3). Then, Section 3 is devoted to a

135 combinatorial lemma that is the key technical tool in our subsequent analysis. In Section 4,  
 136 we present our algorithm for  $b$ -MATCHING on bounded split-width graphs. We conclude  
 137 in Section 5 with some open questions. Due to space restrictions, some of the proofs are  
 138 omitted. Full proofs can be found in our technical report [9].

## 139 2 Preliminaries

140 We use standard graph terminology from [3]. Graphs in this study are finite, simple (hence  
 141 without loops or multiple edges), and connected – unless stated otherwise. Furthermore we  
 142 make the standard assumption that graphs are encoded as adjacency lists. Given a graph  
 143  $G = (V, E)$  and a vertex  $v \in V$ , we denote its neighbourhood by  $N_G(v) = \{u \in V \mid \{u, v\} \in$   
 144  $E\}$  and the set of its incident edges by  $E_v(G) = \{\{u, v\} \mid u \in N_G(v)\}$ . When  $G$  is clear  
 145 from the context we write  $N(v)$  and  $E_v$  instead of  $N_G(v)$  and  $E_v(G)$ . Similarly, we define  
 146 the neighbourhood of any vertex-subset  $S \subseteq V$  as  $N_G(S) = (\bigcup_{v \in S} N_G(v)) \setminus S$ .

### 147 2.1 Split-width

148 Let a *split* in a graph  $G = (V, E)$  be a partition  $V = U \cup W$  such that:  $\min\{|U|, |W|\} \geq 2$ ; and  
 149 there is a complete join between the vertices of  $N_G(U)$  and  $N_G(W)$ . A *simple decomposition*  
 150 of  $G$  takes as input a split  $(U, W)$ , and it outputs two subgraphs  $G_U = G[U \cup \{w\}]$  and  
 151  $G_W = G[W \cup \{u\}]$  where  $u, w \notin V$  are fresh new vertices such that  $N_{G_U}(w) = U$  and  
 152  $N_{G_W}(u) = W$ . The vertices  $u, w$  are termed *split marker vertices*. A *split decomposition*  
 153 of  $G$  is obtained by applying recursively some sequence of simple decompositions (*e.g.*, see  
 154 Fig. 1). We name *split components* the subgraphs in a given split decomposition of  $G$ .

■ **Figure 1** A graph and its split decomposition. Split marker vertices that correspond to a same simple decomposition are identified by two rectangles with the same color.

155 It is often desirable to apply simple decompositions until all the subgraphs obtained  
 156 cannot be further decomposed. In the literature there are two cases of “indecomposable”  
 157 graphs. Degenerate graphs are such that every bipartition of their vertex-set is a split. They  
 158 are exactly the complete graphs and the stars [6]. A graph is prime for split decomposition  
 159 if it has no split. We can define the following two types of split decomposition:

- 160 ■ **Canonical split decomposition.** Every graph has a canonical split decomposition  
 161 where all the subgraphs obtained are either degenerate or prime and the number of  
 162 subgraphs is minimized. Furthermore, the canonical split decomposition of a given graph  
 163 can be computed in linear-time [4].
- 164 ■ **Minimal split decomposition.** A split-decomposition is *minimal* if all the subgraphs  
 165 obtained are prime. A minimal split-decomposition can be computed from the canonical  
 166 split-decomposition in linear-time [6]. Doing so, we avoid handling with the particular  
 167 cases of stars and complete graphs in our algorithms. The set of prime graphs in any  
 168 minimal split decomposition is unique up to isomorphism [6].

169 For instance, the split decomposition of Fig. 1 is both minimal and canonical.

170 ► **Definition 1.** The *split-width* of  $G$ , denoted by  $sw(G)$ , is the minimum  $k \geq 2$  such that  
 171 any prime subgraph in the canonical split decomposition of  $G$  has order at most  $k$ .

172 We refer to [23] for some algorithmic applications of split decomposition. In particu-  
 173 lar, graphs with split-width at most two are exactly the distance-hereditary graphs, *a.k.a.*  
 174 the graphs whose all connected induced subgraphs are distance-preserving [1]. Distance-  
 175 hereditary graphs contain many interesting subclasses of their own such as *cographs* (*a.k.a.*,  
 176  $P_4$ -free graphs) and 3-leaf powers. Furthermore, since every degenerate graph has a split  
 177 decomposition where all the components are either triangles or paths of length three, every  
 178 component in a minimal split decomposition of  $G$  has order at most  $\max\{3, sw(G)\}$ .

179 **Split decomposition tree.** A split decomposition tree of  $G$  is a tree  $T$  where the  
 180 nodes are in bijective correspondance with the subgraphs of a given split decomposition  
 181 of  $G$ , and the edges of  $T$  are in bijective correspondance with the simple decompositions  
 182 used for their computation. More precisely, if the considered split decomposition is reduced  
 183 to  $G$  then  $T$  is reduced to a single node; Otherwise, let  $(U, W)$  be a split of  $G$  and let  
 184  $G_U = (U \cup \{w\}, E_U)$ ,  $G_W = (W \cup \{u\}, E_W)$  be the corresponding subgraphs of  $G$ . We  
 185 construct the split decomposition trees  $T_U, T_W$  for  $G_U$  and  $G_W$ , respectively. Furthermore,  
 186 the split marker vertices  $u$  and  $w$  are contained in a unique split component of  $G_W$  and  
 187  $G_U$ , respectively. We obtain  $T$  from  $T_U$  and  $T_W$  by adding an edge between the two nodes  
 188 that correspond to these subgraphs. The split decomposition tree of the canonical split  
 189 decomposition, resp. of a minimal split decomposition, can be constructed in linear-time [23].

## 190 2.2 Matching problems

191 A *matching* in a graph is a set of edges with pairwise disjoint end vertices.

► **Problem 1 (MAXIMUM-CARDINALITY MATCHING).**  
 192 **Input:** A graph  $G = (V, E)$ .  
**Output:** A matching of  $G$  with maximum cardinality.

193 The MAXIMUM-CARDINALITY MATCHING problem can be solved in  $\mathcal{O}(m\sqrt{n})$ -time [22].  
 194 We do not use this result directly in our paper. However, we do use in our analysis the  
 195 notion of *augmenting paths*, that is a cornerstone of most matching algorithms. Namely,  
 196 let  $G = (V, E)$  be a graph and  $F \subseteq E$  be a matching of  $G$ . A vertex is termed matched  
 197 if it is incident to an edge of  $F$ , and exposed otherwise. An  $F$ -augmenting path is a path  
 198 where the two ends are exposed, all edges  $\{v_{2i}, v_{2i+1}\}$  are in  $F$  and all edges  $\{v_{2j-1}, v_{2j}\}$   
 199 are not in  $F$ . We can observe that, given an  $F$ -augmenting path  $P = (v_1, v_2, \dots, v_{2\ell})$ , the  
 200 matching  $E(P)\Delta F$  (obtained by replacing the edges  $\{v_{2i}, v_{2i+1}\}$  with the edges  $\{v_{2j-1}, v_{2j}\}$ )  
 201 has larger cardinality than  $F$ .

202 ► **Lemma 2 (Berge, [2]).** A matching  $F$  in  $G = (V, E)$  is maximum if and only if there is  
 203 no  $F$ -augmenting path.

204 It is folklore that the proof of Berge's lemma also implies the existence of many vertex-  
 205 disjoint augmenting paths for small matchings. More precisely:

206 ► **Lemma 3 (Hopcroft-Karp, [18]).** Let  $F_1, F_2$  be matchings in  $G = (V, E)$ . If  $|F_1| = r$ ,  $|F_2| =$   
 207  $s$  and  $s > r$ , then there exist at least  $s - r$  vertex-disjoint  $F_1$ -augmenting paths.

208  **$b$ -Matching.** More generally given a graph  $G = (V, E)$ , let  $b : V \rightarrow \mathbb{N}$  assign a nonneg-  
 209 ative integer capacity  $b_v$  for every vertex  $v \in V$ . A  $b$ -matching is an assignment of nonneg-  
 210 ative integer edge-weights  $(x_e)_{e \in E}$  such that, for every  $v \in V$ , we have  $\sum_{e \in E_v} x_e \leq b_v$ . We

211 define the  $x$ -degree of vertex  $v$  as  $\deg_x(v) = \sum_{e \in E_v} x_e$ . Furthermore, the cardinality of a  
 212  $b$ -matching is defined as  $\|x\|_1 = \sum_{e \in E} x_e$ . We will consider the following graph problem:

► **Problem 2 ( $b$ -MATCHING).**

213 **Input:** A graph  $G = (V, E)$ ; an assignment function  $b : V \rightarrow \mathbb{N}$ .

**Output:** A  $b$ -matching of  $G$  with maximum cardinality.

214 For technical reasons, we will also use the following variant of  $b$ -MATCHING. Let  $c : E \rightarrow$   
 215  $\mathbb{N}$  assign a cost to every edge. The cost of a given  $b$ -matching  $x$  is defined as  $c \cdot x = \sum_{e \in E} c_e x_e$ .

► **Problem 3 (MAXIMUM-COST  $b$ -MATCHING).**

216 **Input:** A graph  $G = (V, E)$ ; assignment functions  $b : V \rightarrow \mathbb{N}$  and  $c : E \rightarrow \mathbb{N}$ .

**Output:** A maximum-cardinality  $b$ -matching of  $G$  where the cost is maximized.

217 ► **Lemma 4** ([14, 15]). *For every  $G = (V, E)$  and  $b : V \rightarrow \mathbb{N}$ ,  $c : E \rightarrow \mathbb{N}$ , we can solve*  
 218 *MAXIMUM-COST  $b$ -MATCHING in  $\mathcal{O}(nm \log^2 n)$ -time.*

219 *In particular, we can solve  $b$ -MATCHING in  $\mathcal{O}(nm \log^2 n)$ -time.*

220 There is a nonefficient (quasi polynomial) reduction from  $b$ -MATCHING to MAXIMUM-  
 221 CARDINALITY MATCHING that we will use in our analysis (e.g., see [25]). More precisely,  
 222 let  $G, b$  be any instance of  $b$ -MATCHING. The “expanded graph”  $G_b$  is obtained from  $G$  and  
 223  $b$  as follows. For every  $v \in V$ , we add the nonadjacent vertices  $v_1, v_2, \dots, v_{b_v}$  in  $G_b$ . Then,  
 224 for every  $\{u, v\} \in E$ , we add the edges  $\{u_i, v_j\}$  in  $G_b$ , for every  $1 \leq i \leq b_u$  and for every  
 225  $1 \leq j \leq b_v$ . It is easy to transform any  $b$ -matching of  $G$  into an ordinary matching of  $G_b$ ,  
 226 and vice-versa.

## 227 2.3 High-level presentation of the algorithm

228 In order to discuss the difficulties we had to face on, we start giving an overview of the FPT  
 229 algorithms that are based on split decomposition.

230 ■ We first need to define a vertex-weighted variant of the problem that needs to be solved  
 231 for every component of the decomposition separately (possibly more than once). This  
 232 is because there are split marker vertices in every component that substitute the other  
 233 remaining components; intuitively, the weight of such a vertex encodes a partial solution  
 234 for the union of split components it has substituted.

235 ■ Then, we take advantage of the treelike structure of split decomposition in order to solve  
 236 the weighted problem, for every split component sequentially, using dynamic program-  
 237 ming. Roughly, this part of the algorithm is based on a split decomposition tree. Starting  
 238 from the leaves of that tree (resp. from the root), we perform a tree traversal. For every  
 239 split component, we can precompute its vertex-weights from the partial solutions we  
 240 obtained for its children (resp., for its father) in the split decomposition tree.

241 **Our approach.** In our case, a natural vertex-weighted generalization for MAXIMUM-  
 242 CARDINALITY MATCHING is the unit-cost  $b$ -MATCHING problem [12]. Independently from  
 243 this work<sup>1</sup>, the authors in [20] proposed a new MAXIMUM-CARDINALITY MATCHING al-  
 244 gorithm on graphs of bounded modular-width that is also based on a reduction to  $b$ -  
 245 MATCHING. Unlike this work, the algorithm of [20] cannot be applied to the more gen-  
 246 eral case of bounded split-width graphs. Indeed, the main technical difficulty for the latter

<sup>1</sup> Our preliminary version of this paper was released on arXiv one day before theirs.

247 graphs – not addressed in [20] – is how to precompute efficiently, for every component of  
 248 their split decomposition, the specific instances of  $b$ -MATCHING that need to be solved. To  
 249 see that, consider the bipartition  $(U, W)$  that results from the removal of a split. In order  
 250 to compute the  $b$ -MATCHING instances on side  $U$ , we should be able (after processing the  
 251 other side  $W$ ) to determine the number of edges of the split that are matched in a final  
 252 solution. Guessing such number looks computationally challenging. We avoid doing so by  
 253 storing a partial solution for *every* possible number of split edges that can be matched.  
 254 However, this simple approach suffers from several limitations. For instance, we need a very  
 255 compact encoding for partial solutions – otherwise we could not achieve a quasi linear-time  
 256 complexity. Somehow, we also need to consider the partial solutions for *all* the splits that  
 257 are incident to the same component all at once.

258 This is where we use a result from Section 3, namely, that for every fixed vertex  $w$   
 259 in a graph, the maximum-cardinality of a  $b$ -matching is a piecewise-linear function in the  
 260 capacity  $b_w$  of this vertex. Roughly, in any given split component  $C_i$ , we consider all the  
 261 vertices  $w$  substituting a union of other components. The latter vertices are in one-to-  
 262 one correspondence with the strong splits that are incident to the component. We expand  
 263 every such vertex  $w$  to a module that contains  $\mathcal{O}(1)$  vertices for every straight-line section  
 264 of the corresponding piecewise-linear function. We want to stress that to the best of our  
 265 knowledge, the combination of dynamic programming over split decomposition with the  
 266 recursive computation of some piecewise-linear functions is an all new algorithmic technique.

### 267 3 Changing the capacity of one vertex

268 We first consider an auxiliary problem on  $b$ -matching that can be of independent interest.  
 269 Let  $G = (V, E)$  be a graph,  $w \in V$  and  $b : V \setminus w \rightarrow \mathbb{N}$  be a partial assignment. We denote  $\mu(t)$   
 270 the maximum cardinality of a  $b$ -matching of  $G$  provided we set to  $t$  the capacity of vertex  
 271  $w$ . Clearly,  $\mu$  is nondecreasing in  $t$ . Our main result in this section is that the function  $\mu$  is  
 272 essentially piecewise linear (Proposition 1). We start by introducing some useful lemmata.

273 ▶ **Lemma 5.**  $\mu(t + 1) - \mu(t) \leq 1$ .

274 ▶ **Lemma 6.** If  $\mu(t + 2) = \mu(t)$  then we have  $\mu(t + i) = \mu(t)$  for every  $i \geq 0$ .

275 ▶ **Lemma 7.** If  $\mu(t + 1) = \mu(t)$  then we have  $\mu(t + 3) = \mu(t + 2)$ .

276 These above results are obtained by studying vertex-disjoint augmenting paths in some  
 277 “expanded graphs”  $G_{b,t}$  (cf. Lemmata 2 and 3).

▶ **Proposition 1.** There exist integers  $c_1, c_2$  such that:

$$\mu(t) = \begin{cases} \mu(0) + t & \text{if } t \leq c_1 \\ \mu(c_1) + \lfloor \frac{t-c_1}{2} \rfloor = \mu(0) + c_1 + \lfloor \frac{t-c_1}{2} \rfloor & \text{if } c_1 < t \leq c_1 + 2c_2 \\ \mu(c_1 + 2c_2) = \mu(0) + c_1 + c_2 & \text{otherwise.} \end{cases}$$

278 Furthermore, the triple  $(\mu(0), c_1, c_2)$  can be computed in  $\mathcal{O}(nm \log^2 n \log \|b\|_1)$ -time.

279 **Proof.** Let  $c_1$  be the maximum integer  $t$  such that  $\mu(t) = \mu(0) + t$ . This value is well-defined  
 280 since  $\mu$  must stay constant whenever  $t \geq \sum_{v \in N_G(w)} b_v$  (saturation of all the neighbours).  
 281 Furthermore, by Lemma 5 we have  $\mu(t) = \mu(0) + t$  for every  $0 \leq t \leq c_1$ . Then, let  
 282  $t_{\max}$  be the least integer  $t$  such that, for every  $i \geq 0$  we have  $\mu(t_{\max} + i) = \mu(t_{\max})$ .  
 283 Again, this value is well-defined since we have the trivial upper-bound  $t_{\max} \leq \sum_{v \in N_G(w)} b_v$ .

■ **Figure 2** An example with  $(\mu(0), c_1, c_2) = (1, 1, 1)$ . Vertices are labeled with their capacity. Thin and bold edges have respective weights 0 and 1.

284 Furthermore, since  $\mu$  is strictly increasing between 0 and  $c_1$ ,  $t_{\max} \geq c_1$ . Let  $c'_2 = t_{\max} - c_1$ .  
 285 We claim that  $c'_2 = 2c_2$  is even. For that, we need to observe that  $\mu(c_1) = \mu(c_1 + 1)$  by  
 286 maximality of  $c_1$ . Using Lemma 7, we prove by induction  $\mu(c_1 + 2i) = \mu(c_1 + 2i + 1)$  for  
 287 every  $i \geq 0$ . The latter proves, as claimed,  $c'_2 = 2c_2$  is even by minimality of  $c'_2$ . Moreover,  
 288 for every  $0 \leq i < c_2$  we have by Lemma 6  $\mu(c_1 + 2i) < \mu(c_1 + 2(i + 1))$  (since otherwise  
 289  $t_{\max} \leq c_1 + 2i$ ). By Lemma 7 we have  $\mu(c_1 + 2i) = \mu(c_1 + 2i + 1)$ . Finally, by Lemma 5 we get  
 290  $\mu(c_1 + 2(i + 1)) \leq \mu(c_1 + 2i + 1) + 1 = \mu(c_1 + 2i) + 1$ , therefore  $\mu(c_1 + 2(i + 1)) = \mu(c_1 + 2i) + 1$ .  
 291 Altogether combined, it implies that  $\mu(c_1 + 2i) = \mu(c_1 + 2i + 1) = \mu(c_1) + i$  for every  $0 \leq i \leq c_2$ ,  
 292 that proves the first part of our result.

293 We can compute  $\mu(0)$  with any  $b$ -MATCHING algorithm after we set the capacity of  $w$  to  
 294 0. The value of  $c_1$  can be computed within  $\mathcal{O}(\log c_1)$  calls to a  $b$ -MATCHING algorithm, as  
 295 follows. Starting from  $c'_1 = 1$ , we multiply the current value of  $c'_1$  by 2 until we reach a value  
 296  $c'_1 > c_1$  such that  $\mu(c'_1) < \mu(0) + c'_1$ . Then, we perform a binary search between 0 and  $c'_1$  in  
 297 order to find the largest value  $c_1$  such that  $\mu(c_1) = \mu(0) + c_1$ . Once  $c_1$  is known, we can use  
 298 a similar approach in order to compute  $c_2$ . Overall, since  $c_1 + 2c_2 = t_{\max} \leq \sum_{v \in N_G(w)} b_v =$   
 299  $\mathcal{O}(\|b\|_1)$ , we are left with  $\mathcal{O}(\log \|b\|_1)$  calls to any  $b$ -MATCHING algorithm. Therefore, by  
 300 Lemma 4, we can compute the triple  $(\mu(0), c_1, c_2)$  in  $\mathcal{O}(nm \log^2 n \log \|b\|_1)$ -time. ◀

## 301 4 The algorithm

302 We present in this section a quasi linear-time algorithm for computing a maximum-cardinality  
 303  $b$ -matching on any bounded split-width graph (Theorem 12). Given a graph  $G$ , our algorithm  
 304 takes as input the split decomposition tree  $T$  of any minimal split decomposition of  $G$ . We  
 305 root  $T$  in an arbitrary component  $C_1$ . Then, starting from the leaves, we compute by  
 306 dynamic programming on  $T$  the *cardinality* of an optimal solution. This first part of the  
 307 algorithm is involved, and it uses the results of Section 3. It is based on a new reduction  
 308 rule that we introduce in Definition 8. Finally, starting from the root component  $C_1$ , we  
 309 compute a maximum-cardinality  $b$ -matching of  $G, b$  by reverse dynamic programming on  $T$ .  
 310 This second part of the algorithm is simpler than the first one, but we need to carefully  
 311 upper-bound its time complexity. In particular, we also need to ensure that some additional  
 312 property holds for the  $b$ -matchings we compute at every component.

### 313 4.1 Reduction rule

314 Recall that an edge between a rooted subtree and its parent in  $T$  corresponds to a split  
 315  $(U, W)$  of  $G$ . After we processed the side  $U$  (corresponding to this subtree) we account  
 316 for all the partial solutions found for  $G_U$  by transforming the split marker vertex  $u$  into a  
 317 *module*<sup>2</sup>, as follows:

<sup>2</sup> Recall that  $M$  is a module if for every  $x, y \in M$  we have  $N(x) \setminus M = N(y) \setminus M$ .

318 ► **Definition 8.** For any instance  $G = (V, E), b$  and any split  $(U, W)$  of  $G$  let  $C = N_G(W) \subseteq$   
 319  $U$ ,  $D = N_G(U) \subseteq W$ . Let  $G_U = (U \cup \{w\}, E_U)$ ,  $G_W = (W \cup \{u\}, E_W)$  be the corresponding  
 320 subgraphs of  $G$ . We define the pairs  $G_U, b^U$  and  $H_W, b^W$  as follows:

321 ■ **Figure 3** The reduction of Definition 8.

- 321 ■ For every  $v \in U$  we set  $b_v^U = b_v$ ; the capacity of the split marker vertex  $w$  is left  
 322 unspecified. Let  $(\mu^U(0), c_1^U, c_2^U)$  be as defined in Proposition 1 w.r.t.  $G_U, b^U$  and  $w$ .
- 323 ■ The *auxiliary graph*  $H_W$  is obtained from  $G_W$  by replacing the split marker vertex  $u$  by  
 324 a module  $M_u = \{u_1, u_2, u_3\}$ ,  $N_{H_W}(M_u) = N_{G_W}(u) = D$ ; we also add an edge between  
 325  $u_2, u_3$ . For every  $v \in W$  we set  $b_v^W = b_v$ ; we set  $b_{u_1}^W = c_1^U$ ,  $b_{u_2}^W = b_{u_3}^W = c_2^U$ .

326 See Fig. 3 for an illustration. We will show throughout this section that our gadget  
 327 somewhat encodes all the partial solutions for side  $U$ . Formally, the following relationship  
 328 holds between solutions for  $G, b$  and solutions for  $H_W, b^W$ :

► **Proposition 2.** Given a graph  $G = (V, E)$  and a capacity function  $b$ , let  $(U, W)$  be a split of  
 $G$  and let  $H_W, b^W$  be as in Definition 8. If  $x$  and  $x^W$  are maximum-cardinality  $b$ -matchings  
 for the pairs  $G, b$  and  $H_W, b^W$ , respectively, then we have:

$$\|x\|_1 = \|x^W\|_1 + \mu^U(0) - c_2^U$$

329 In what follows, we prove the first direction of Proposition 2 using classical flow tech-  
 330 niques. We postpone the proof of the other direction since, for that one, we need to prove  
 331 intermediate lemmata that will be also used in the proof of Theorem 12.

332 ► **Lemma 9.** Let  $x$  be a  $b$ -matching for  $G, b$ . There exists a  $b$ -matching  $x^W$  for  $H_W, b^W$   
 333 such that  $\|x^W\|_1 \geq \|x\|_1 + c_2^U - \mu^U(0)$ .

334 The following Sections 4.2 and 4.3 detail the intermediate results that we will use in  
 335 order to prove the other direction of Proposition 2 (as well as Theorem 12).

## 336 4.2 $b$ -matchings with additional properties

337 We consider an intermediate modification problem on the  $b$ -matchings of some “auxiliary  
 338 graphs” that we define next. Let  $C_i$  be a split component in a given split decomposition  
 339 of  $G$ . The subgraph  $C_i$  is obtained from a sequence of simple decompositions. For a given  
 340 subsequence of the above simple decompositions (corresponding to the edges between  $C_i$   
 341 and its children in  $T$ ) we apply the reduction rule of Definition 8. Doing so, we obtain a pair  
 342  $H_i, b^i$  with  $H_i$  being a supergraph of  $C_i$  obtained by replacing some split marker vertices  
 343  $u_{i_t}$ ,  $1 \leq t \leq \ell$ , by the modules  $M_{i_t} = \{u_{i_t}^1, u_{i_t}^2, u_{i_t}^3\}$ . By construction  $u_{i_t}^2, u_{i_t}^3$  are adjacent  
 344 and they have the same capacity.

345 We seek for a maximum-cardinality  $b$ -matching  $x^i$  for the pair  $H_i, b^i$  such that the fol-  
 346 lowing properties hold for every  $1 \leq t \leq \ell$ :

- 347 ■ (**symmetry**)  $\deg_{x^i}(u_{i_t}^2) = \deg_{x^i}(u_{i_t}^3)$ .
- 348 ■ (**saturation**) if  $\deg_{x^i}(u_{i_t}^1) < c_{i_t}^1$  then,  $\deg_{x^i}(u_{i_t}^2) = x_{\{u_{i_t}^2, u_{i_t}^3\}}^i$ .

349 We prove next that for every fixed  $t$ , any  $x^i$  can be processed in  $\mathcal{O}(|E_{u_{i_t}}(C_i)|)$ -time so that  
 350 both the saturation property and the symmetry property hold for  $M_{i_t}$ . However, ensuring  
 351 that these two above properties hold *simultaneously* for every  $t$  happens to be trickier. We  
 352 manage to do so by reducing to MAXIMUM-COST  $b$ -MATCHING (*i.e.*, internal edges in the  
 353 modules are assigned a larger cost than the other edges).

354 ► **Lemma 10.** *In  $\mathcal{O}(|V(H_i)| \cdot |E(H_i)| \cdot \log^2 |V(H_i)|)$ -time, we can compute a maximum-*  
 355 *cardinality  $b$ -matching  $x^i$  for the pair  $H_i, b^i$  such that both the saturation property and the*  
 356 *symmetry property hold for every  $M_{i_t}$ ,  $1 \leq t \leq \ell$ .*

### 357 4.3 Merging the partial solutions together

358 Finally, before we can describe our main algorithm (Theorem 12) we need to consider the  
 359 intermediate problem of merging two partial solutions. Let  $(U, W)$  be a split of  $G$  and  
 360 let  $G_U = (U \cup \{w\}, E_U)$ ,  $G_W = (W \cup \{u\}, E_W)$  be the corresponding subgraphs of  $G$ .  
 361 Consider some partial solutions  $x^U$  and  $x^W$  obtained, respectively, for the pairs  $G_U, b^U$  and  
 362  $G_W, b^W$  (for some  $b^U, b^W$  to be defined later). Assuming an appropriate data-structure for  
 363  $b$ -matchings, this merging stage can be solved with a greedy algorithm.

364 ► **Lemma 11.** *Suppose that  $b^U$  (resp.,  $b^W$ ) satisfies  $b_v^U \leq b_v$  for every  $v \in U$  (resp.,  $b_v^W \leq b_v$   
 365 for every  $v \in W$ ). Let  $x^U, x^W$  be  $b$ -matchings for, respectively, the pairs  $G_U, b^U$  and  $G_W, b^W$   
 366 such that  $\deg_{x^U}(w) = \deg_{x^W}(u) = d$ .*

367 *Furthermore, for any graph  $H$  let  $\varphi(H) = |E(H)| + 4 \cdot (sc(H) - 1)$ , with  $sc(H)$  being the  
 368 number of split components in any minimal split decomposition of  $H$ <sup>3</sup>.*

369 *Then, in at most  $\mathcal{O}(\varphi(G) - \varphi(G_U) - \varphi(G_W))$ -time, we can obtain a valid  $b$ -matching  $x$   
 370 for the pair  $G, b$  such that  $\|x\|_1 = \|x^U\|_1 + \|x^W\|_1 - d$ .*

371 Overall, since there are at most  $n - 2$  components in any minimal split decomposition of  
 372  $G$  [23], the merging stages take total time  $\mathcal{O}(\varphi(G)) = \mathcal{O}(n + m)$ .

### 373 4.4 Main result

374 We are now ready to prove Proposition 2. This algorithmic proof is the cornerstone of our  
 375 main result.

**Proof of Proposition 2.** We have  $\|x^W\|_1 \geq \|x\|_1 - \mu^U(0) + c_2^U$  by Lemma 9. In order to  
 prove the converse inequality, we can assume w.l.o.g. that  $x^W$  satisfies both the saturation  
 property and the symmetry property w.r.t. the module  $M_u$  (otherwise, by Lemma 10, we  
 can process  $x^W$  so that it is the case). We partition  $\|x^W\|_1$  as follows:  $\mu^W = \sum_{e \in E(W)} x_e^W$ ,  
 $c'_1 = \deg_{x^W}(u_1) \leq c_1^U$  and  $c'_2 = \deg_{x^W}(u_2) - x_{\{u_2, u_3\}}^W = \deg_{x^W}(u_3) - x_{\{u_2, u_3\}}^W \leq c_2^U$ . Since we  
 assume that  $x^W$  satisfies both the saturation property and the symmetry property w.r.t.  $M_u$ ,  
 we have  $c'_2 > 0$  only if  $c'_1 = c_1^U$ . Furthermore, we observe that  $u_2$  and  $u_3$  must be saturated  
 (otherwise, we could increase the cardinality of the  $b$ -matching by setting  $x_{\{u_2, u_3\}}^W = c_2^U - c'_2$ ).  
 Therefore, we get:

$$\|x^W\|_1 = \mu^W + c'_1 + 2c'_2 + (c_2^U - c'_2) = \mu^W + c'_1 + c'_2 + c_2^U.$$

376 We define  $b_u^W = b_w^U = c'_1 + 2c'_2$ . Then, we proceed as follows (see Fig. 4 for an illustration).

<sup>3</sup> We recall that the set of prime graphs in any minimal split decomposition is unique up to isomorphism [23].

■ **Figure 4** The construction of  $x'$ . Vertices with capacity greater than 1 are labeled with their capacity. Thin and bold edges have respective weights 0 and 1.

377 ■ We transform  $x^W$  into a  $b$ -matching for the pair  $G_W, b^W$  by setting  $x_{\{u,v'\}}^W = x_{\{u_1,v'\}}^W +$   
 378  $x_{\{u_2,v'\}}^W + x_{\{u_3,v'\}}^W$  for every  $v' \in N_{G_W}(u) = D$ . Note that we have  $\text{deg}_{x^W}(u) = b_u^W = c'_1 +$   
 379  $2c'_2$ . Furthermore, the cardinality of the  $b$ -matching has decreased by  $x_{\{u_2,u_3\}}^W = c_2^U - c'_2$ .

380 ■ Let  $x^U$  be a  $b$ -matching for the pair  $G_U, b^U$  of maximum cardinality  $\mu^U(c'_1 + 2c'_2)$ . Since  
 381  $c'_1 \leq c_1^U$ ,  $c'_2 > 0$  only if  $c'_1 = c_1^U$ , and  $c'_2 \leq c_2^U$ , the following can be deduced from  
 382 Proposition 1:  $\|x^U\|_1 = \mu^U(c'_1 + 2c'_2) = \mu^U(0) + c'_1 + c'_2$ ; and the split marker vertex  $w$   
 383 is saturated in  $x^U$ , i.e.,  $\text{deg}_{x^U}(w) = b_w^U = c'_1 + 2c'_2$ .

384 Since we have  $\text{deg}_{x^W}(u) = \text{deg}_{x^U}(w) = c'_1 + 2c'_2$ , we can define a  $b$ -matching  $x'$  for the pair  $G, b$   
 385 by applying Lemma 11. Doing so, we get  $\|x\|_1 \geq \|x'\|_1 = \|x^U\|_1 + (\|x^W\|_1 - (c_2^U - c'_2)) -$   
 386  $(c'_1 + 2c'_2) = \mu^U(0) + c'_1 + c'_2 + \|x^W\|_1 - (c_2^U + c'_1 + c'_2) = \|x^W\|_1 + \mu^U(0) - c_2^U$ . ◀

387 We finally prove (in a similar way as above) the main result in this paper.

388 ▶ **Theorem 12.** For every pair  $G = (V, E), b$  with  $\text{sw}(G) \leq k$ , we can solve  $b$ -MATCHING in  
 389  $\mathcal{O}((k \log^2 k) \cdot (m + n) \cdot \log \|b\|_1)$ -time.

390 Setting  $b_v = 1$  for every  $v \in V$ , we obtain the following implication of Theorem 12:

391 ▶ **Corollary 13.** For every graph  $G = (V, E)$  with  $\text{sw}(G) \leq k$ , we can solve MAXIMUM-  
 392 CARDINALITY MATCHING in  $\mathcal{O}((k \log^2 k) \cdot (m + n) \cdot \log n)$ -time.

## 393 5 Open questions

394 We presented an algorithm for solving  $b$ -MATCHING on distance-hereditary graphs, and  
 395 more generally on any graph with bounded split-width. In contrast to our result, we stress  
 396 that as already noticed in [20], MAXIMUM-WEIGHT MATCHING cannot be solved faster  
 397 on complete graphs, and so, on distance-hereditary graphs, than on general graphs. An  
 398 interesting open question would be to know whether  $b$ -MATCHING can be solved in *linear*  
 399 time on bounded split-width graphs. In a companion paper [10], we prove with a completely  
 400 different approach that MAXIMUM-CARDINALITY MATCHING can be solved in  $\mathcal{O}(n + m)$ -  
 401 time on distance-hereditary graphs. However, it is not clear to us whether similar techniques  
 402 can be used for bounded split-width graphs in general.
