20 **Abstract**

21 With more than 5,000 species, Conoidea is one of the most diversified superfamilies of
22 Gastropoda. Recently, the family-level classification of these venomous predator snails
23 has undergone substantial changes, on the basis of a phylogenetic tree reconstructed
24 combining partial mitochondrial and nuclear gene sequences, and up to 16 families are
25 now recognized. However, phylogenetic relationships among these families remain
26 largely unresolved. Here, we sequenced 20 complete or nearly complete mitochondrial
27 (mt) genomes, which were combined with mt genomes available in GenBank to
28 construct a dataset that included representatives of 80% of the known families, although
29 for some we had only one species or genus as representative. Most of the sequenced
30 conoidean mt genomes shared a constant genome organization, and observed
31 rearrangements were limited exclusively to tRNA genes in a few lineages. Phylogenetic
32 trees were reconstructed using probabilistic methods. Two main monophyletic groups,
33 termed “Clade A” and “Clade B”, were recovered with strong support within a
34 monophyletic Conoidea. Clade A (including families Clavatulidae, Horaiclavidae,
35 Turridae s.s., Terebridae, Drilliidae, Pseudomelatomidae, and Cochlespiridae) was
36 composed of four main lineages, one of which was additionally supported by a
37 rearrangement in the gene order. Clade B (including families Conidae, Borsoniidae,
38 Clathurellidae, Mangeliidae, Raphitomidae, and Mitromorphidae) was composed of five
39 main lineages. The reconstructed phylogeny rejected the monophyly of Clavatulidae,
40 Horaiclavidae, Turridae, Pseudomelatomidae, and Conidae, indicating that several of
41 the currently accepted families may be ill-defined. The reconstructed tree also revealed
42 new phylogenetic positions for genera characterized as tentative (*Gemmuloborsonia*,
43 *Lucerapex*, and *Leucosyrinx*), enigmatic (*Marshallena*) or challenging to place
44 (*Fusiturris*), which will potentially impact the classification of the Conoidea.

46 **1. Introduction**

47 The Conoidea is the most diverse of the seven superfamilies included in the order
48 Neogastropoda (Cunha et al., 2009; Osca et al., 2015; Bouchet et al., 2017). The
49 conoidean snails are characterized by a venom gland, which allow their species to
50 actively capture preys or deter predators, usually with the aid of a specialized radular
51 system (Dutertre et al., 2014). These evolutionary novelties are hypothesized to have
52 favored the extreme diversification of the group, which has successfully colonized the
53 marine realm from polar regions to tropical latitudes, and from the shore to the very
54 deep sea (Kantor et al., 2016). Although still debated, the origin of the group could be
55 dated in the Early Cretaceous, Berriasian age, about 139.8-145.0 million years ago
56 (Murphy and Rodda, 1960; Kotetishvili, 1989), and they diversified since into 16 extant
57 recognized families, 382 accepted genera and more than 5,000 extant recognized
58 species (WoRMS; Bouchet and Gofas, 2015). Shell collectors count the Conoidea, and
59 more precisely the family Conidae (cone snails) among their favorites for their beautiful
60 and colored shells whereas toxicologists study their venom since the late 1970's for
61 their potential therapeutic applications (Prashanth et al., 2014).

62 The past century classifications of Conoidea were based solely on shell, radula and
63 anatomical characters (Powell, 1966; McLean, 1971; Taylor et al., 1993; see Puillandre
64 et al. 2008 for a historical review). More recently, molecular data have helped clarifying
65 the phylogenetic relationships within Conoidea, although most of the work focused
66 primarily on cone snails (Puillandre et al., 2011). Puillandre et al. (2008) performed the
67 first thorough molecular study on Conoidea based on partial mitochondrial (mt) and
68 nuclear gene sequences and including a fair representation of the main clades at the
69 family-level, later completed by Puillandre et al. (2011); see a summary of the resulting
70 phylogenetic hypotheses in Fig. 1. The conclusions of the two studies emphasized the

71 high diversity of deep lineages, recognized at the family level, and lead to the current
72 classification in 16 families (Bouchet et al., 2011): Borsoniidae, Bouchetispiridae,
73 Clathurellidae, Clavatulidae, Cochlespiridae, Conidae, Conorbidae, Drilliidae,
74 Horaiclavidae, Mangeliidae, Mitromorphidae, Pseudomelatomidae, Raphitomidae,
75 Strictispiridae, Terebridae, and Turridae. However, despite these seminal works,
76 phylogenetic relationships among these families remain largely unresolved, and the
77 monophyly of some of them is controversial.

78 Mitochondrial genomes have been used with success to reconstruct phylogenetic
79 relationships in different molluscan groups, including Polyplacophora (Irisarri et al.,
80 2014), Cephalopoda (Kawashima et al., 2013; Strugnell et al., 2017; Uribe and Zardoya,
81 2017), and Bivalvia (Glöckner et al., 2013; Williams et al., 2017). Within Gastropoda,
82 mt genomes have been used to reconstruct the phylogenetic relationships within the
83 main clades: Neritimorpha (Uribe et al., 2016a), Vetigastropoda (Lee et al., 2016; Uribe
84 et al., 2016b; Uribe et al., 2017b), Heterobranchia (White et al., 2011; Sevigny et al.,
85 2015), and Caenogastropoda (Cunha et al., 2009; Osca et al., 2015).

86 Within Caenogastropoda, phylogenetic inference based on mitogenomes has proven
87 to be particularly effective at the subgeneric (Abalde et al., 2017a; Abalde et al., 2017b)
88 and the generic (Uribe et al., 2017a; Wang et al., 2017) levels, showing less efficiency
89 at more inclusive taxonomic levels (Cunha et al., 2009; Osca et al., 2015) mostly due to
90 saturation and long branch attraction biases, but also in some instances associated to
91 limited taxon sampling. As of January 2018, the mt genomes available in GenBank
92 (<https://www.ncbi.nlm.nih.gov>) represented seven conoidean families: Conidae,
93 Borsoniidae, Mangeliidae, Clathurellidae, Clavatulidae, Terebridae, and Turridae. These
94 sequence data covered less than half of the currently recognized families within
95 Conoidea, and therefore, our primary goal was to sequence additional mitogenomes in

96 order to increase the family coverage and better represent the diversity of the group. The
97 new taxon sampling was aimed at improving resolution of phylogenetic relationships,
98 and thus, providing a robust framework for further evolutionary studies of the group.

99

100 **2. Materials and methods**

101 *2.1. Samples and DNA extraction*

102 The list of samples analyzed in this study is provided in Table 1. All newly sequenced
103 samples were collected during two expeditions of the Muséum National d'Histoire
104 Naturelle (Paris), namely Atimo Vatae (Madagascar, 2011) and Papua Niugini (Papua
105 New Guinea, 2012) (expeditions.mnhn.fr). Specimens out of the shell (Galindo et al.,
106 2014) were stored in 99% ethanol. DNA was isolated from 30–60 mg of muscle from
107 the foot following a standard phenol-chloroform extraction (Sambrook et al., 1989).

108 *2.2. PCR amplification and sequencing*

109 Fragments of the mt *cox1* gene were amplified by standard PCR (reaction conditions
110 described in Uribe et al. 2017a) using universal primers (Folmer et al., 1994) and
111 sequenced by the Sanger method. The new sequences were used to design specific
112 primers (see the complete list in Suppl. Mat 1), which were combined with previously
113 published *cox3* (forward), *rrnL* (forward and reverse), and *trnF* (reverse) primers (Uribe
114 et al., 2017a) to amplify by long-PCR reactions the complete or nearly complete
115 (without control region) mt genomes in several overlapping fragments (Table 1). The
116 long-PCR reaction protocol and profiles are described by Uribe et al. (2017a).

117 The long-PCR products were purified by ethanol precipitation. The overlapping

118 fragments from the same mt genome were pooled together in equimolar concentrations
119 and subjected to massive parallel sequencing. For each mt genome, a separate indexed
120 library was constructed using the NEXTERA XT DNA library prep kit (Illumina, San
121 Diego, CA, USA) and run in an Illumina MiSeq platform (v.2 chemistry; 2 x 150
122 paired-end) at Sistemas Genómicos (Valencia, Spain). Only in one case (sample
123 MNHN-IM-2013-9848, *Otitoma* sp), the Ion-Torrent platform at Service de
124 Systématique Moléculaire (UMS 2700 CNRS-MNHN, Paris, France) was used to
125 complete the corresponding mt genome.

126 *2.3. Genome assembly and annotation*

127 The reads corresponding to the different PCR-amplified mt genomes were sorted using
128 the library indices. Assembly of the mt genomes was performed using the TRUFA
129 webserver (Kornobis et al., 2015). Briefly, removal of adapters, read trimming, and
130 quality check were performed using SeqPrep (John, 2011), FastQC v. 0.10.1 (Andrews,
131 2010), and PRINSEQ v. 0.20.3 (Schmieder and Edwards, 2011) programs, respectively,
132 with default parameters. The *de novo* assemblies were carried out using Trinity r2012–
133 06–08 (Grabherr et al., 2011), and searching for contigs with a minimum length of 3 kb.
134 To overlap the assembled contigs and measure the mean depth of coverage of each mt
135 genome, we used the methods described in Uribe et al. (2017a).

136 The new mt genomes were annotated using the MITOS (Bernt et al., 2013)
137 webserver. The annotated 13 mt protein-coding genes were further corroborated by
138 identifying the corresponding open reading frames using the invertebrate mt genetic
139 code. The two ribosomal RNA (rRNA) genes were identified by sequence comparison
140 with other reported gastropod mt genomes, and assumed to extend to the boundaries of
141 adjacent genes (Boore et al., 2005). The transfer RNA (tRNA) genes were further

142 identified with tRNAscan-SE 1.21 (Schattner et al., 2005), which infers cloverleaf
143 secondary structures (with a few exceptions that were determined manually).

144 *2.4. Sequence alignment*

145 The 13 protein coding and two rRNA genes of the complete or nearly complete mt
146 genomes were aligned with orthologous genes of conoidean mt genomes available in
147 GenBank (Table 1). Mitogenomes from closely related neogastropod groups (Cunha et
148 al., 2009; Osca et al., 2015) were downloaded from GenBank and used as outgroups:
149 *Amalda northlandica* (Olivoidea), *Babylonia areolata* (Muricoidea: Babyloniiidae),
150 *Rapana venosa* (Muricoidea: Muricidae), *Columbella adansoni* (Buccinoidea:
151 Columbellidae), *Nassarius reticulatus* (Buccinoidea: Nassariidae), and *Galeodea
152 echinophora* (Tonnaidea). Two concatenated matrices were constructed, one with
153 protein coding plus rRNA genes at the nucleotide level (NT) and the other with protein
154 coding genes at the amino acid level (AA). In order to construct these datasets, the
155 nucleotide sequences of each of the protein coding and rRNA genes were aligned
156 separately. The alignment of the nucleotide sequences of the protein coding genes was
157 guided by the alignment of the deduced amino acid sequences in Translator X (Abascal
158 et al., 2010) using MAFFT v5 (Katoh et al., 2005). The nucleotide sequences of each of
159 the rRNA genes were aligned using MAFFT v7 server (Katoh et al., 2017) with default
160 parameters. All poorly aligned sites were removed using GBlocks, v.0.91b (Castresana,
161 2000) with the following settings: minimum sequence for flanking positions: 85%;
162 maximum contiguous non-conserved positions: 8; minimum block length: 10; gaps in
163 final blocks: no.

164 *2.5. Phylogenetic analyses*

165 Phylogenetic relationships within superfamily Conoidea were inferred using
166 maximum likelihood (ML; Felsenstein, 1981) and Bayesian inference (BI; Huelsenbeck
167 and Ronquist, 2001). The phylogenetic analyses of the NT matrix were conducted using
168 IQ-TREE v1.6.1 (Nguyen et al., 2014) for ML and MrBayes v3.1.2 (Ronquist and
169 Huelsenbeck, 2003) for BI. The unpartitioned best-fit models of nucleotide substitution
170 were identified using IQ-TREE Model Selection (Trifinopoulos et al., 2016) using +R
171 option (FreeRate model) that generalizes the +G model by relaxing the assumption of
172 Gamma-distributed rates. ML searches were run using a combination of rapid hill-
173 climbing approaches and the stochastic perturbation method with 1,000 ultrafast
174 bootstraps (UFB). The UFB values < 70%, between 70-94%, and \geq 95% were
175 considered to indicate non-significant, moderate, and high statistical support,
176 respectively (Minh et al., 2013). The MrBayes analysis was run with four simultaneous
177 Markov chains for six million generations, sampling every 1,000 generations, and
178 discarding the first 25% generations as burn-in (as judged by plots of ML scores and
179 low SD of split frequencies) to prevent sampling before reaching stationarity. Two
180 independent runs were performed to increase the chance of adequate mixing of the
181 Markov chains and of detecting failure to converge. Node support in the BI analysis was
182 assessed based on Bayesian Posterior Probabilities (BPP); values < 0.90, between 0.90–
183 0.94, and \geq 0.95 were considered to indicate non-significant, moderate, and high
184 statistical support, respectively.

185 Additionally, a BI analysis was conducted with PhyloBayes (Lartillot et al., 2013)
186 using the AA matrix, with two independent MCMC chains until convergence, sampling
187 every cycle, and without constant sites ($-dc-$ option) using the site-heterogeneous
188 mixture CAT model (Lartillot and Philippe, 2004), which is helpful in ameliorating the
189 well-known long branch attraction (LBA) bias (Felsenstein, 1978). Convergence of

190 analyses was checked *a posteriori* using the convergence tools implemented in
191 PhyloBayes (maxdiff < 0.125, maximum discrepancy < 0.1 and effective size > 100).
192 Node support was assessed based on BPP.

193

194 **3. Results**

195 Twenty complete or nearly complete (without control region) mt genomes were newly
196 sequenced and assembled, representing ten conoidean families. The length, the presence
197 of rearrangements, the GenBank accession number, the number of reads and the mean
198 depth of coverage for each mt genome are provided in Table 1. Most mt genomes were
199 amplified typically in two or three overlapping fragments (see primer information in
200 Suppl. Mat. 1). The Illumina MiSeq sequencing generated a total of 1,305,206 reads.
201 For one sample (*Otitoma* sp., MNHN-IM-2013-9848), the Illumina sequencing was
202 complemented with IonTorrent technology, adding 12,689 reads to the final assembly
203 for a total of 28,966 reads and a mean depth of coverage of 240x (Table 1). Of the
204 remaining mt genomes, those of *Gemmuloborsonia moosai* and *Pinguigemmula* sp.
205 received the minimum (23,023 and 148x) and maximum (157,709 and 1,557x) reads
206 and mean depth of coverage, respectively (Table 1).

207 *3.1. Mitogenomic organization*

208 Most of the conoidean mitogenomes share the same gene order, where all genes are
209 disposed in the major strand, with the exception of the *trnM*, *trnY*, *trnC*, *trnW*, *trnQ*,
210 *trnG*, *trnE* gene cluster (MYCWQGE) and the *trnT* gene (see Conoidea consensus order
211 Fig. 2a). Three events of gene rearrangement were detected: (1) the mt genomes of
212 *Clionella kraussii* and *Clavatula tripartita* (Clavatulidae), and of the two *Anguloclavus*

213 species (Horaiclavidae) showed a translocation of the *trnS* (tca) gene from the 3' end to
214 the 5' end of the *cob* gene (in yellow, Fig. 2b); (2) the mt genome of *Gemmuloborsonia*
215 *moosai* (Clavatulidae?) shows a translocation of the *trnF* gene from the 3' end of the
216 *nad5* gene to the 5' end of the *nad4L* gene (Fig. 2c); and (3) the most conspicuous
217 change occurred in the mt genome of *Cochlespira* sp. (Cochlespiridae) affecting the
218 relative position and order of the *trnK*, *trnA*, *trnR*, *trnN*, and *trnI* (KARNI) gene cluster
219 (Fig. 2d). The remaining features of each mt genome (stop and start codons, overlapping
220 genes, intergenic non-coding regions and encoding strands) are provided in Suppl. Mat.
221 2.

222 *3.2. Phylogenetic relationships*

223 The ML ($-\ln L = 24.87648$; using GTR+R7+F model) and BI ($-\ln L = 24.66123$ for run
224 1; $-\ln L = 24.66121$ for run 2; using GTR+I+G model) analyses using the NT dataset
225 (13,014 positions; matrix available in Suppl. Mat. 3) provided almost identical
226 topologies, which only differed in the relative position of *Fusiturris similis*
227 (Clavatulidae) (see yellow inset in Fig. 3). The monophyly of the Conoidea was
228 recovered with maximal support. The phylogenetic tree recognized two strongly
229 supported main lineages, hereinafter referred to as Clade A and Clade B, respectively
230 (Fig. 3), Clade A included the families Clavatulidae, Turridae s.s., Terebridae,
231 Horaiclavidae, Drilliidae, Pseudomelatomidae and Cochlespiridae (Fig. 3). The genera
232 *Cochlespira* (Cochlespiridae) and *Marshallena* (tentatively assigned to Horaiclavidae in
233 Bouchet et al., (2011)) grouped together with maximal statistical support and were sister
234 to the rest of Clade A, which was composed of three moderately to highly supported
235 main lineages: (1) two genera of Pseudomelatomidae (*Inquisitor* and *Otitoma*) were
236 sister to a clade having the genus *Leucosyrinx* (tentatively assigned to

237 Pseudomelatomidae in Bouchet et al., (2011)) sister to the genus *Splendrillia*
238 (Drilliidae). All these phylogenetic relationships received high statistical support; (2)
239 the genera *Lucerapex* (tentatively attributed to Turridae in Bouchet et al., (2011)) and
240 *Gemmuloborsonia* (tentatively attributed to Clavatulidae in Bouchet et al., (2011))
241 formed a strongly supported clade, which was sister, with high BPP and moderate UFB
242 support, to another moderately to highly supported clade having the genus *Oxymeris*
243 (Terebridae) sister to genera *Iotyrris* and *Pinguigemmula* (Turridae s.s.); and (3) a clade
244 with different topologies in the ML and BI analyses. The ML tree recovered with
245 moderate support (73%) the genus *Anguloclavus* (Horaiclavidae) sister to a clade
246 including *Fusiturris* (tentatively attributed to Clavatulidae in Bouchet et al. (2011)),
247 which was sister to *Clionella* + *Clavatula* (both Clavatulidae). In contrast, the BI tree
248 recovered with maximal support *Fusiturris* sister to *Anguloclavus* (see yellow inset in
249 Fig. 3).

250 Clade B included the families Mangeliidae, Raphitomidae, Mitromorphidae,
251 Conidae, Borsoniidae, and Clathurellidae (Fig. 3). Clade B could be further subdivided
252 into four main lineages: (1) *Mitromorpha* (Mitromorphidae) was the single
253 representative of this lineage; (2) Mangeliidae was sister to Raphitomidae with
254 moderate to high statistical support; (3) *Glyphostoma* (Clathurellidae) was the single
255 representative of this lineage; (4) the Borsoniidae were sister to genus *Profundiconus*
256 (Conidae) with high statistical support; and (5) all analyzed Conidae but *Profundiconus*
257 were grouped together with moderate to high statistical support (Fig. 3). The BI analysis
258 supported with maximal BPP a sister group relationship between lineages 1 and 2 and
259 between lineages 3 and 4+5 (Fig. 3).

260 The phylogeny reconstructed using the AA matrix (3,648 positions long) and the
261 CAT-GTR model, converged at ten million of generations (maxdiff: 0.0666 and

262 meandiff: 0.0052). The reconstructed tree also recovered the monophyly of Conoidea as
263 well as Clade A and Clade B (see Suppl. Mat. 4). Internal phylogenetic relationships
264 within both clades were compatible with the NT-based tree but largely unresolved.

265

266 **4. Discussion**

267 The primers anchoring in *cox3*, *rrnL*, and *trnF* genes (Uribe et al., 2017a) combined
268 with the specific primers designed for *cox1* allowed consistent long PCR amplification
269 of 20 mt genomes across the diversity of families within Conoidea. The number of reads
270 and mean depth of coverage for each mt genome were high and at the same level of
271 those previously reported for gastropod mitogenomes obtained with the same next
272 generation sequencing technology (Abalde et al., 2017a; Abalde et al., 2017b; Uribe et
273 al., 2017a). After adding the conoidean mitogenomes available in GenBank, our dataset
274 included 13 out of the 16 recognized families of Conoidea (only the Bouchetispiridae,
275 Conorbidae and Strictispiridae were missing). For the Borsoniidae, Clavatulidae,
276 Horaiclavidae, Raphitomidae, Mangeliidae and Pseudomelatomidae, only one genus
277 was previously available in GenBank, and our study extended the sampling to
278 additional genera. For Terebridae, Drilliidae, Cochlespiridae, Clathurellidae, and
279 Mitromorphidae, still only one genus is available for phylogenetic inference after the
280 present work. Therefore, the monophyly of these families still requires further
281 validation.

282 The gene order determined in most of the newly sequenced mt genomes conformed
283 to the consensus genome organization of the Caenogastropoda (Osca et al., 2015),
284 including previously reported Conoidea. Three alternative gene orders (two of them not
285 previously reported) were found and were limited to translocations of tRNA genes, the

most common mobile elements in the mt genome (Boore, 1999). One rearrangement, involving the translocation of *trnS* (tca) to the 5' end of the *cob* gene is shared by *Fusiturris* (Cunha et al., 2009), *Clavatula*, *Clionella*, and *Anguloclavus*, suggesting that it occurred in the common ancestor of these genera and could be considered a molecular synapomorphy, which is in full agreement with the recovered (highly supported) clade in the phylogeny. The translocation of the *trnF* gene in the mt genome of *Gemmuloborsonia moosai* could be linked to the well-known instability associated to genes adjacent to control regions (Gissi et al., 2008; San Mauro et al., 2014). The KARNI cluster is generally conserved across distant classes of mollusks including Polyplacophora (Irisarri et al., 2014), Cephalopoda (Yokobori et al., 2004), and within the Gastropoda, in Neomphalina (Nakagawa et al., 2014), Vetigastropoda (Lee et al., 2016; Uribe et al., 2016b; Uribe et al., 2017b), Neritimorpha (Castro and Colgan, 2010; Arquez et al., 2014; Uribe et al., 2016a) and several Caenogastropoda (Osca et al., 2015). However, at least two gene rearrangements broke up this cluster in the mt genome order of *Cochlespira* sp.: first, either the whole cluster except the *trnI* gene or without both the *trnI* and *trnN* genes was translocated from the 3' end of the *cox3* gene to the 3' end of the *nad3* gene; then, the *trnN* gene was secondarily translocated to the 5' end of the *trnK* gene. The alteration of the KARNI cluster has been also reported in several Gastropoda such as Turbinidae (*Lunella*, *Bolma*, and *Astralium*; Williams et al., 2014; Lee et al., 2016; Uribe et al., 2016b), Fissurellidae (*Diodora* and *Fissurella*; Uribe et al., 2016b), Haliotoidea (*Haliotis*; Maynard et al., 2005), and in other mollusks such as Chaetodermomorpha (*Scutopus*; Osca et al., 2014).

Thus far, phylogenetic analyses based on mt genomes focused primarily either on a single family within the Conoidea, the Conidae (Abalde et al., 2017a; Abalde et al., 2017b; Uribe et al., 2017a), or, on the contrary, at a more inclusive taxonomic level, on

311 the relative position of Conoidea within the Neogastropoda (Cunha et al., 2009). Our
312 study is the first filling the gap in between by specifically targeting the relationships at
313 the family level within the Conoidea. For that, we focused on ensuring broad taxon
314 coverage of the diversity of the superfamily, and sequenced 20 new mt genomes,
315 representing 10 different families, which combined with available mt genomes from
316 GenBank, allowed us to cover 80% of the currently accepted families of Conoidea.
317 However, for some of the families we had only one genus as representative, which
318 impeded us to test their monophyly. This is not trivial as the conoidean families are
319 highly diverse, and it is challenging the definition of all their members. In fact, in our
320 phylogenetic analyses, some of the families with more than one genus resulted non-
321 monophyletic. Therefore, the present phylogeny needs to be treated as ongoing and will
322 need in the future to be completed with many more genera per family.

323 The monophyly of Conoidea was previously recovered using the concatenation of
324 partial gene sequences with moderate to strong statistical support (Puillandre et al.,
325 2008; 2011). Here, it is further confirmed with maximal support in both the NT
326 (UFB=100 /BPP=1) and AA (BPP=1) phylogenetic analyses. Within the Conoidea, the
327 two main clades, designated as Clade A and Clade B following Puillandre et al. (2008),
328 and named Turroidea and Conoidea, respectively, by Tucker and Tenorio (2009), were
329 also recovered here with strong (UFB=98/BPP=1 with the NT matrix and BPP=0.95
330 with the AA matrix) and maximal support, respectively. In general, and not surprisingly
331 as both studies are based on mitochondrial data only, our analyses are congruent with
332 the phylogenetic relationships obtained within Clade A and Clade B by Puillandre et al.
333 (2011), but clearly improving the statistical support of many of the internal nodes, and
334 thus increasing the resolution of the overall tree. Most contradictions between our tree
335 and published trees (Puillandre et al., 2008, 2011) concern previously unsupported

336 relationships; only the few supported contradictions between our and previous
337 phylogenies are discussed in detail below.

338 Within Clade A, the genus *Cochlespira* (Cochlespiridae), here grouped with the
339 newly sequenced taxa *Marshallena* in the NT-based phylogenetic analyses, is sister to
340 the remaining Conoidea, a relationship already found by Puillandre et al. (2011).
341 *Marshallena* is a deep-water genus from the Indo Pacific, initially assigned to
342 Turriculinae and Cochlespirinae in older classifications (Powell, 1966; Taylor et al.,
343 1993; Bouchet et al., 2005), and more recently tentatively included in Horaiclavidae
344 (Bouchet et al., 2011). Our results favor the close relationship of *Marshallena* and
345 Cochlespiridae. However, these two lineages show relatively long branches and their
346 sister group relationship could be a LBA artifact (Felsenstein, 1978). In fact, this sister
347 group relationship is not recovered in the AA-based phylogenetic analysis using the
348 CAT model (site-heterogeneous mixture), which is recognized as a better model to
349 ameliorate LBA artifacts (Lartillot et al., 2007; Philippe et al., 2009; Irisarri et al.,
350 2014). Discerning whether *Cochlespira* (Cochlespiridae) and *Marshallena* are sister
351 lineages or not awaits future phylogenetic studies with a denser sampling of the related
352 taxa. With regards to the remaining taxa within Clade A, our results confirm the
353 presence of three main lineages as already suggested in Puillandre et al. (2011):
354 *Splendrillia* (Drilliidae) + Pseudomelatomidae, *Oxymeris* (Terebridae) + Turridae, and
355 *Anguloclavus* (Horaiclavidae) + Clavatulidae (here further reinforced by the sharing of
356 a specific mt genome rearrangement and by an amino acid insertion in the ATPase 6
357 protein after position 42; see Suppl. Mat. 5). The first two clades were also strongly
358 supported by the AA-based phylogenetic analysis. A sister group relationships of
359 *Oxymeris* + Turridae and *Anguloclavus* + Clavatulidae to the exclusion of *Splendrillia* +
360 Pseudomelatomidae received moderate to high support. In Bouchet et al. (2011), several

361 taxa within Clade A were tentatively attributed to a particular family, based on the
362 molecular tree obtained by Puillandre et al. (2011). However, our results raise serious
363 doubts about some of these assignations. According to our results, *Gemmuloborsonia* is
364 not closely related to Clavatulidae, but more likely to Turridae and Terebridae;
365 *Lucerapex* does not cluster with Turridae but it is closely related to *Gemmuloborsonia*;
366 and *Leucosyrinx* is sister to *Splendrilla* (Drilliidae) with strong support, and thus
367 cannot be assigned to Pseudomelatomidae without making this taxon paraphyletic.
368 Finally, the relative phylogenetic position of *Fusiturris similis* could not be confidently
369 resolved beyond determining its close affinity to *Anguloclavus* and Clavatulidae. This
370 species was sister to *Clavatula* and *Clionella* in the ML analysis, which would confirm
371 its assignation to Clavatulidae by Bouchet et al. (2011), but sister to *Anguloclavus*
372 (Horaiclavidae) in both (NT and AA) BI analyses. Given the shell variability in both
373 Clavatulidae and Horaiclavidae, it is difficult to determine to which family *Fusiturris*
374 would be more similar. Furthermore, the radula of *Fusiturris* is unique in Conoidea
375 (Powell, 1966), and does not match neither the ones of the Clavatulidae nor the one of
376 the Horaiclavidae

377 Clade B showed poor resolution in the deeper nodes, similar to previously published
378 phylogenetic analyses based on concatenated partial gene sequences (Puillandre et al.,
379 2008; Puillandre et al., 2011). However, this lack of resolution was rather evident in the
380 ML and AA BI analyses but not in the NT BI analysis, which rendered maximal support
381 for a sister relationship between *Mitromorpha* (Mitromorphidae) and clade including
382 Raphitomidae + Mangellidae and between *Glyphostoma* (Clathurellidae) and a clade
383 including Borsoniidae and paraphyletic Conidae. Both *Mitromorpha* and *Glyphostoma*
384 showed relatively long branches and were the only representatives of their
385 corresponding families, so their relative phylogenetic positions should be interpreted

386 with caution and as tentative (the families Mitromorphidae, Raphitomidae, and
387 Mangelidae were also found closely related in Puillandre et al., 2011). The genus
388 *Profundiconus* did not group with other Conidae but instead was placed as sister to
389 Borsoniidae with high support in the NT (ML and BI) analyses, and as sister to
390 Mitromorphidae with low support in the AA phylogenetic analysis. A recent
391 phylogenetic analysis also based on mt genomes and focusing on the Conidae (Uribe et
392 al., 2017a), recovered this family as a monophyletic group with high support, placing
393 *Profundiconus* as sister to all remaining Conidae. However, the sampling of other
394 conoidean families in this study was too limited to thoroughly test the monophyly of the
395 cone snails and set definitively the controversy. In other studies (Puillandre et al., 2011;
396 Kantor et al., 2012) with denser taxon sampling but based on partial gene sequences, the
397 monophyly of the Conidae was not supported, except in the Bayesian tree of Puillandre
398 et al., (2011), in which the posterior probability was 0.97. The genus *Profundiconus*
399 includes species that live exclusively in the deep sea and show a typical cone-shape
400 shell. Therefore, it was considered until now a true member of the Conidae. Pending
401 further confirmation, our results would thus suggest that the cone shell shape, distinctive
402 of the Conidae and used until now as a synapomorphy to recognize the members of
403 these well-known seashell group, would be present in two divergent lineages, either
404 evolving in the ancestor of the Conidae + Borsoniidae clade, and then lost secondarily
405 in the Borsoniidae, or appearing twice independently during the evolutionary history of
406 Conoidea. Discerning between these alternative hypotheses requires a denser taxon
407 sampling, especially for the Borsoniidae, whose monophyly, here highly supported, was
408 actually not supported in Puillandre et al. (2011).

409

410 **5. Conclusions**

411 With mitogenomes available for 80% of the valid families of Conoidea, we proposed
412 here the most complete and resolved phylogenetic tree for the group at the family level
413 to date. However, several of the families were represented by a single genus and others
414 resulted non-monophyletic. Hence, the need of completing the present phylogeny with a
415 more thorough sampling at the genus level in the future. Most of the phylogenetic
416 relationships recovered here are congruent with previously published hypotheses, and
417 received stronger statistical support. However, the relative phylogenetic position of
418 *Fusiturris* with regards to *Anguloclavus* (Horaicalvidae) and Clavatulidae awaits final
419 resolution. Additionally, striking results further emerged such as e.g., the potential close
420 relationship of the *Cochlespira* and *Marshallena*, *Splendrillia* and *Leucosyrinx*,
421 *Gemmuloborsonia* and *Lucerapex*, and the non-monophyly of the cone snails due to the
422 sister group relationship of *Profundiconus* and Borsoniidae. The sequencing of mt
423 genomes, if not resolving the entire conoidean tree, helps providing a tentative
424 backbone, which needs to be further confirmed and resolved using nuclear sequence
425 data. In the past, nuclear genes have been difficult to amplify and sequence compare to
426 mtDNA but this is drastically changing in recent years with new available technology
427 such as exon-capture techniques (Bi et al., 2012; Hugall et al., 2015; Bragg et al., 2016),
428 which are particularly promising for non-model systems and broad divergences. The
429 increase in sequence data needs to be accompanied in parallel by a denser taxonomic
430 coverage. This later issue is not the least: obtaining representatives of all the known
431 conoidean families (and of sufficient genera to test their monophyly) in good
432 preservation conditions for its use with new genome-scale techniques is already an
433 important challenge, which will become cumbersome in the near future given the
434 potential high rate of discovery of unknown lineages in the group, especially in the
435 deep-sea, as the case of the family Bouchetispiridae tends to suggest.

437 **6. Acknowledgements**

438 The newly sequenced material originates from two MNHN expeditions, conducted in
439 the context of the “Our Planet Reviewed” programme with Pro-Natura International
440 (ATIMO VATAE to South Madagascar in partnership with Université de Tuléar;
441 PAPUA NIUGINI 2012 to Papua New Guinea, in partnership with University of Papua
442 New Guinea and the National Fisheries College). The organizers thank the Total
443 Foundation, Prince Albert II of Monaco Foundation, Stavros Niarchos Foundation,
444 Fondation EDF, Vinci Entrepose Contracting and Richard Lounsbery Foundation for
445 their support to these expeditions. We are indebted to Barbara Buge, José Utge, Agnès
446 Dettaï and Laetitia Aznar-Cormano (MNHN, Paris), and Samuel Abalde (MNCN,
447 Madrid) for technical assistance in the laboratory. We are grateful to Jesús Marco and
448 Aida Palacios, who provided access to the supercomputer Altamira at the Institute of
449 Physics of Cantabria (IFCA-CSIC), and member of the Spanish Supercomputing
450 Network, for performing phylogenetic analyses. This work was supported by the
451 Spanish Ministry of Science and Innovation (CGL2013-45211-C2-2-P and CGL2016-
452 75255-C2-1-P to RZ; BES-2011-051469, EEBB-I-15-10150 and EEBB-I-14-08866 to

673 **Legends to figures**

674 Figure 1. Summary of the two published phylogenetic trees of the conoidean snails. A:
675 Puillandre et al., (2008); B: Puillandre et al., (2011). All nodes with Posterior
676 Probability < 0.95 were collapsed. The asterisk highlights a family described
677 by Kantor et al., (2012) closely related with Mitromorphidae, not included in
678 Puillandre et al., (2011).

679 Figure 2. Gene orders of conoidean mt genomes. The protein-coding genes are in blue,
680 the rRNAs in red, the tRNAs in black, and the control region (CR) in grey. The
681 genes encoded in the major and minor strands are in top and bottom positions,
682 respectively. The translocations are indicated in yellow, each arrow
683 corresponding to an independent event. The numbers 1 and 2, below the *trnL*
684 genes, correspond to the anticodons (cta) and (tta) respectively. The numbers 1
685 and 2, over the *trnS* genes, correspond to the anticodons (tca) and (agc)
686 respectively.

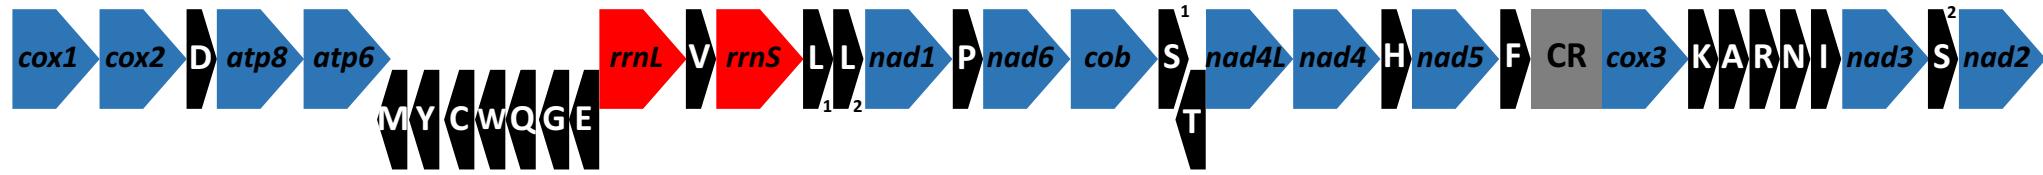

687 Figure 3. Phylogenetic relationships of the Conoidea based on complete mt genomes
688 based on protein coding genes and rRNAs. The reconstructed ML phylogram is
689 shown. The yellow inset indicates the alternative topology found in BI
690 analyses. The red inset indicates a tRNA gene order rearrangement, which is a
691 synapomorphy of the corresponding clade. The red and blue asterisks represent
692 the relative position in the tree of tRNA gene rearrangements C and D of Fig.
693 2, respectively. Numbers at nodes are support values for ML (UFB > 70)/BI
694 (BPP > 0.90). The grey color in the tree applies to outgroup taxa. Scale bar
695 indicates the number of substitutions/site. Shells A–S correspond to the
696 samples included in the analyses (vouchers in Table 1), only the B and E shells

697 do not correspond to a sequenced sample but to a conspecific specimen. A.

Table 1. Mitogenomes analyzed in this study. Complete mt genomes are indicated with an asterisk (*). The length of each mt genome is indicated in base pairs (bp). The NCBI accession number of each mt genome, as well as the number of total reads (No. Reads) with its corresponding mean depth of coverage (X) are also indicated. In parenthesis the number of reads from IonTorrent technology are shown. The crosses (†) indicate samples with shell picture (either the actual specimen used for sequencing or, when a voucher number is not indicated, a conspecific one) in Fig. 2.

Supplementary Material 4

Phylogenetic tree based on the 13 mitochondrial protein-coding genes analyzed at the amino acid level with the CAT+GTR model in PhyloBayes. Branch support is shown as Bayesian posterior probabilities (BPP). The nodes with BPP values below 0.95 are not shown. Scale bar indicates the number of substitutions/site. The grey color in the tree indicates outgroup taxa.

127

Alignment showing the beginning of the *atp6* gene in different species of Conoidea. An insertion of three nucleotides (one amino acid in the open reading frame) is found at position 127 in several species from the same clade in the reconstructed phylogeny. The inserted codon translates into Proline in *Clionella kraussii*, *Clavatula tripartito*, and *Fusiturris similis*, and into Alanine in the two species of *Anguloclavus*.
