Luenberger observers for non autonomous nonlinear systems

Pauline Bernard and Vincent Andrieu

Abstract—We show how the (initial) Luenberger methodology presented in [1] for linear systems can be used to design causal observers for controlled nonlinear systems. Their implementation relies on the resolution of a time-varying PDE, the solutions of which transform the dynamics into linear asymptotically stable ones. We prove the existence and injectivity (after a certain time) of such transformations, under standard observability assumptions as such as differential observability or backward-distinguishability. We show on examples how this PDE can be solved and how the observability assumptions can be checked. Also, we show that similarly to the high gain framework, it is possible to use a time-independent transformation when the system is observable for any input and strongly differentially observable of order the dimension of the system.

Index Terms—observer, Kazantzis-Kravaris, Luenberger

I. INTRODUCTION

A. Context

Online estimation of the state of a dynamical system is crucial in practice, especially for monitoring or control purposes. However, very few general observer design methods exist for nonlinear time varying systems or for nonlinear systems with dynamics depending on an exogenous input. Some, such as the popular extended Kalman filters ([2]) rely on linearization methods, but thus provide only local convergence. Others consist in finding a reversible input-independent change of coordinates, which transforms the dynamics into a more favorable form such as state-affine time-varying forms ([3],[4] among others), for which a Kalman filter can be used, or a triangular form ([5],[6]) for which a high gain observer can be used. But the existence of such a change of coordinates usually requires restrictive assumptions on the system, such as the so-called uniform observability for triangular forms, or can be applied to some particular classes of nonlinear systems (see for instance the Immersion & Invariance approach in [7]).

On the other hand, if we allow the transformation to depend on the input, the range of possibilities widens. For instance, the transformation obtained by considering the output and a certain number of its derivatives, transforms the dynamics into the so-called phase-variable form ([8],[9]) under the ACP(N) condition ([9]), which roughly says that the Nth-derivative of the output can be expressed in a “Lipschitz” way in terms of the first N − 1 ones. In this case, a classical high gain observer can be used. But a drawback of this transformation is that it involves the input’s time derivatives (appearing when differentiating the output), which may make this solution unsuitable for practical applications.

In a completely independent line of research, some researchers have tried to reproduce Luenberger’s initial1 methodology presented in [1] for linear systems on nonlinear systems. Indeed, initially, Luenberger’s method consisted in transforming the system into a linear asymptotically stable one for which a trivial observer (made of a copy of the dynamics) exists. The extension of such a method to autonomous nonlinear systems was proposed and analyzed in a general context by [10], and rediscovered later by [11] where a local analysis close to an equilibrium point was given under conditions then relaxed in [12]. The localness as well as most of the restrictive assumptions were finally by-passed in [13], leading to the so-called Kazantzis-Kravaris-Luenberger (KKL) observers.

In this paper, we want to extend the use of those Luenberger observers to non autonomous systems. By non autonomous systems, we mean systems which may be time varying or which may depend on exogeneous signals. Exactly as in the high gain framework two paths are possible when considering exogenous inputs : either we keep the stationary transformation obtained for some constant value of the input (typically u = 0) and hope the additional terms due to the presence of the input do not prevent convergence. Or we take a transformation taking into account (implicitly or explicitly) the input.

As far as we know, no result concerning this problem exists in the literature apart from [14],[15] which follows and extends [16]. The idea pursued in [14] belongs to the first path : the transformation is stationary and the input is seen as a disturbance which must be small enough. Although the construction is extended in a cunning fashion to a larger class of inputs, namely those which can be considered as output of a linear generator model with small external input, this approach remains theoretic and restrictive. On the other hand, in [15], the author rather tries to use a time-varying transformation but its injectivity is proved only under the so-called “finite-complexity” assumption, initially introduced in [16] for autonomous systems. Unfortunately, this property is very restrictive and hard to check. Besides, no indication about the dimension of the target form is given and the transformation cannot be computed online because it depends on the whole past trajectory of the output.

That is why, in this paper, we endeavor to give results of existence and injectivity of the transformation under more standard observability assumptions and keeping in mind the practical implementation of this method. Preliminary results presented in [17] showed that any system which can’t blow up in finite backward time can be transformed through a time-varying transformation into a Hurwitz asymptotically stable

1We write “initial” insofar as what is nowadays usually called ”Luenberger observer” differs from what is in [1].
form and the injectivity of this transformation is achieved under a differential observability condition. We complete here this result by showing that injectivity can actually be ensured under a weaker backward observability condition for “almost any” choice of the eigenvalues of the target Hurwitz form with sufficiently large dimension. We also show that it is possible to take a stationary transformation in the case of instantaneously uniformly observable systems whose order of differential observability equals the system’s dimension.

B. Problem statement

Consider a general system of the form

\[ \dot{x} = f(x, u), \quad y = h(x, u) \tag{1} \]

where \( x \) is the state in \( \mathbb{R}^d_x \), \( y \) the output in \( \mathbb{R}^d_y \), \( f \) a continuously differentiable \( C^1 \) function, \( h \) a continuous function, and \( u : [0, +\infty) \rightarrow U \subset \mathbb{R}^{d_u} \) in a set \( U \subset \mathcal{L}_\infty^{\infty}([0, +\infty)) \) of considered inputs. We denote \( X(x, t; s; u) \) the value at time \( s \) of the (unique) solution to system (1) with input \( u \), initialized at \( x \) at time \( t \), and \( Y(x, t; s; u) \) the corresponding output function at time \( s \). We consider a subset \( \mathcal{X}_0 \subset \mathbb{R}^{d_x} \) containing all the possible initial conditions for the system. We introduce the following assumption:

Assumption 1. Solutions to System (1) initialized in \( \mathcal{X}_0 \) are well defined in positive time and belong to an open set \( \mathcal{X} \). In other words, for all \( u \in \mathcal{U} \), for all \( x_0 \in \mathcal{X}_0 \), and for all \( s \in [0, +\infty) \), \( X(x_0; 0; s; u) \) is well defined and is in \( \mathcal{X} \).

In this paper, we want to design an observer for system (1), via the Luenberger-like methodology developed in [1], [10], [11], [13]. We assume the inputs and outputs are known in a causal way, namely the observer can use only their past or current values, i.e., at time \( t \), \( u|_{[0,t]} \) and \( y|_{[0,t]} \) only. The idea is to transform system (1) into a Hurwitz form

\[ \dot{\xi} = A\xi + By \tag{2} \]

with \( A \) Hurwitz in \( \mathbb{R}^{d_x \times d_x} \), \( B \) a matrix in \( \mathbb{R}^{d_x \times d_y} \), for some strictly positive integer \( d_x \), i.e., for each \( u \in \mathcal{U} \), find a transformation\(^5\) \( T : \mathcal{X} \times [0, +\infty) \rightarrow \mathbb{R}^{d_x} \) such that for any \( x \) in \( \mathcal{X} \) and any time \( t \) in \( [0, +\infty) \),

\[ \frac{\partial T}{\partial x}(x, t)f(x, u(t)) + \frac{\partial T}{\partial t}(x, t) = AT(x, t) + B(h(x, u(t)) \tag{3} \]

Indeed, implementing the dynamics (2) with any initial condition would then provide an asymptotically converging estimate of \( T(X(x_0, 0; s; u), s) \). If \( T(\cdot, s) \) is besides injective (at least after a certain time), one could deduce an estimate for the system solution \( X(x_0, 0; s; u) \).

More precisely, the following theorem is proved in [17]:

**Theorem 1** (17). Assume Assumption 1 is satisfied. Consider a strictly positive integer \( d_x \), a Hurwitz matrix \( A \) in \( \mathbb{R}^{d_x \times d_x} \), and a matrix \( B \) in \( \mathbb{R}^{d_x \times d_y} \). Suppose that for any input \( u \) in \( \mathcal{U} \), there exists a function \( T : \mathcal{X} \times [0, +\infty) \rightarrow \mathbb{R}^{d_x} \) such that

1. \( T \) is a \( C^1 \) solution to PDE (3) on \( \mathcal{X} \times [0, +\infty) \);
2. there exists a time \( \bar{t} \geq 0 \) and a concave \( K^\infty \) function \( \rho_T \) such that for all \( (x_1, x_2) \) in \( \mathcal{X}^2 \) and all \( t \geq \bar{t} \),

\[ |x_1 - x_2| \leq \rho_T(|T(x_1, t) - T(x_2, t)|) \]

i.e. \( T \) becomes injective uniformly in time and in space after a certain time \( \bar{t} \).

Then, there exists a function \( T^* : \mathbb{R}^{d_x} \times [0, +\infty) \rightarrow \mathbb{R}^{d_x} \) such that for any \( x_0 \) in \( \mathcal{X}_0 \) and any \( \xi_0 \) in \( \mathbb{R}^{d_x} \), the (unique) solution \((X(x_0, 0; s; u), \xi(\xi_0, 0; s; u, y_{x_0}))\) to

\[ \dot{x} = f(x, u), \quad y = h(x, u), \quad \dot{\xi} = A\xi + By, \quad x = T^*(\xi, t) \tag{4} \]

verifies

\[ \lim_{s \rightarrow +\infty} |X(x_0, 0; s; u) - X(s)| = 0 \]

with

\[ X(s) = T^*(\xi_0, 0; s; u, y_{x_0}), s \).

We conclude that it is sufficient to find a solution \( T \) to PDE (3) that becomes injective uniformly in time and in space at least after a certain time to obtain an observer for system (1).

In Section II, we show that the existence of the time-varying transformation \( T \) itself is achieved under mild assumptions, and that its injectivity can be ensured by observability assumptions, similar to those presented in [13] for autonomous systems. Then, in Section III, we show on practical examples how an explicit expression for such a transformation can be computed. Finally, in Section IV, we prove that, similarly to [5], [6] for a high gain design, in the case of a uniformly observable (see [18, Definition 1]) input-affine system whose drift system is strongly differentially observable of order \( d_x \) (see [18, Definition 2]), a Luenberger-type observer can be built with a stationary transformation \( T : \mathcal{X} \rightarrow \mathbb{R}^{d_x} \).

**Notations**

1. Since \( h \) (resp. \( Y \)) takes values in \( \mathbb{R}^{d_y} \), we denote \( h_i \) (resp. \( Y_i \)) its \( i \)th-component.
2. For some integer \( m \) which we choose later in Assumptions 3, any solution \( x \) to system (1) with some \( C^{m+1} \) input \( u \), is such that \((x, u, \dot{u}, ..., u^{(m)})\) is solution to the extended system

\[ \dot{x} = f(x, u), \quad \dot{u} = \nu, \quad \nu_i = u^{(i)} \]

\[ i = 0, 1, ..., m \].
with input \( u^{(m+1)} \). We denote \( \pi_m = (u, \dot{u}, ..., u^{(m)}) \), \( \varphi_m = (\nu_0, ..., \nu_m) \), \( \bar{f} \) the extended vector field
\[
\bar{f}(x, \varphi_m, u^{(m+1)}) = \left( f(x, \nu_0), \nu_1, ..., \nu_m, u^{(m+1)} \right)
\]
and \( \bar{h} \) the extended measurement function
\[
\bar{h}_i(x, \varphi_m) = h_i(x, \nu_i) .
\]
Note that while \( \varphi_m \) is an element \( \mathbb{R}^{d_u(m+1)} \), \( \pi_m \) is a function defined on \([0, +\infty)\) such that \( \pi_m(s) = (u(s), \dot{u}(s), ..., u^{(m)}(s)) \) is in \( \mathbb{R}^{d_u(m+1)} \) for all \( s \) in \([0, +\infty)\). We denote \( \overline{U}_m \) a subset of \( \mathbb{R}^{d_u(m+1)} \) such that for all \( u \) in \( U \), \( \varphi_m((0, +\infty)) \subset \overline{U}_m \). For \( 1 \leq i \leq d_y \), the successive time derivatives of \( Y_i \) are related to the Lie derivatives of \( h_i \) along the vector fields \( f \), namely for \( j \leq m \)
\[
\frac{\partial Y_i}{\partial s^j}(x, t; s; u) = L_f^j \bar{h}_i(x, t; s; u, \varphi_m(s)) .
\]

II. TIME-VARYING TRANSFORMATION

We make the following assumption:

**Assumption 2.** Solutions to System (1) initiated from \( X \) do not blow-up in finite backward time, namely for any \( u \) in \( U \), any \( (x, t) \) in \( X \times [0, +\infty) \) and any \( s \) in \([0, t] \), \( X(x, t; s; u) \) is defined.

The existence of a \( C^1 \) time-varying solution to PDE (3) is achieved thanks to the following lemma:

**Lemma 1** ([17]). Consider a strictly positive number \( d_x \), a Hurwitz matrix \( A \) in \( \mathbb{R}^{d_x \times d_x} \), a matrix \( B \) in \( \mathbb{R}^{d_y \times d_x} \), and an input \( u \) in \( U \). Under Assumption 2, the function \( T^0 \) defined on \( X \times [0, +\infty) \) by
\[
T^0(x, t) = \int_0^t e^{A(t-s)} B Y(x, t; s; u) \, ds
\]
is a \( C^1 \) solution to PDE (3) on \( X \times [0, +\infty) \).

When Assumption 2 does not hold, it may still be possible to construct a function \( T^0 \) solution to PDE (3) on \( X \times [0, +\infty) \). This is the case if there exists a subset \( \chi' \subset \chi \) from which no solution blows up at infinity in backward time before leaving the set \( \chi' \). Indeed, any modified dynamics
\[
\dot{x} = \chi(x) f(x, u) ,
\]
with a \( C^\infty \) function \( \chi : \mathbb{R}^d_x \to \mathbb{R} \) satisfying
\[
\chi(x) = \begin{cases} 1 , & \text{if } x \in \chi(\chi') \\ 0 , & \text{if } x \notin \chi' \end{cases}
\]
is then backward complete and satisfies Assumption 2, and the PDE associated to system (6) is the same as PDE (3) on \( X \times [0, +\infty) \). In particular, we deduce:

**Corollary 1.** Assume \( X \) is bounded. Consider a strictly positive number \( d_x \), a Hurwitz matrix \( A \) in \( \mathbb{R}^{d_x \times d_x} \), a matrix

\footnote{Following what has been done for the function \( T \), to simplify the presentation, the dependance on \( u \) of the function \( T^0 \) has been dropped.}

\footnote{This property is named completeness within \( \chi' \) in [13].}

\( B \) in \( \mathbb{R}^{d_y \times d_x} \), and an input \( u \) in \( U \). There exists a \( C^1 \) function \( T^0 \) solution to PDE (3) on \( X \times [0, +\infty) \).

In the extreme scenario where Assumption 2 does not hold even for system (6), it could also be relaxed by considering an output dependent time rescaling as in [13, Section 2.6] when the system has some (backward) unbounded observability property.

Note that extending directly what is done in [16], [13] would rather lead us to the solution
\[
T^\infty(x, t) = \int_0^t e^{A(t-s)} B Y(x, t; t; u) \, ds .
\]
The drawback is that some assumptions about the growth of \( Y \) have to be made to ensure its continuity, unless \( Y \) is bounded backward in time. As for the \( C^1 \) property, and even if the solutions are bounded backward in time, it is achieved only if the eigenvalues of \( A \) are sufficiently negative. In fact, it is not absolutely needed that the solution be \( C^1 \), one could look for continuous solutions to
\[
\lim_{\delta \to 0} T(X(x, t; t; t+\delta; u), t) - T(x, t) = AT(x, t)+Bh(x, u(t))
\]
instead of PDE (3). The major disadvantage of this solution is that \( T^\infty \) is not easily computable since it depends on the values of \( u \) on \( (-\infty, t] \). Nevertheless, it may still be useful. For example, that is the solution chosen in [19] for the specific application of a permanent synchronous motor, where it is proved to be injective.

Unlike \( T^\infty \), \( T^0 \) depends only on the values of the input \( u \) on \( [0, t] \). Therefore, it is theoretically computable online. However, for each couple \( (x, t) \), one would need to integrate backwards the dynamics (1) until time 0, which is quite heavy. If the input \( u \) is known in advance (for instance \( u(t) = t \)) it can also be computed offline. We will see in Section III on practical examples how we can find a solution to PDE (3) in practice, without relying on the expression \( T^0 \).

We finally conclude that a \( C^1 \) time-varying transformation into a Hurwitz form always exists under the mild Assumption 2, but the core of the problem is to ensure its injectivity.

A. Injectivity with strong differential observability

**Assumption 3.** There exists a subset \( S \) of \( \mathbb{R}^d \) such that :

1) For any \( u \) in \( U \), any \( x \) in \( X \) and any time \( t \) in \([0, +\infty) \), \( X(x, t; s; u) \) is defined in \( S \) for all \( s \) in \([0, t] \).

2) The quantity
\[
M_f = \sup_{x \in S, t \in [0, t]} \left| \frac{\partial f(x, u_0)}{\partial x} \right|_{u_0 \in U}
\]
is finite.

3) There exist \( d_y \) integers \( (m_1, \ldots, m_{d_y}) \) such that the functions
\[
H_i(x, \varphi_m) = \left( \bar{h}_1(x, \varphi_m), L_{T}^{m_1-1} \bar{h}_1(x, \varphi_m), \ldots, L_{T}^{m_{d_y}} \bar{h}_i(x, \varphi_m) \right)
\]
is well defined on \( S \times \mathbb{R}^{d_u(m+1)} \) with \( m = \max_i m_i \) and \( 1 \leq i \leq d_y \) verify :
- for any \( \nu_m \) in \( \overline{U}_m \), \( H(\cdot, \nu_m) \) is Lipschitz on \( S \).
- there exists \( L_H \) such that the function
  \[
  H(x, \nu_m) = \left( H_1(x, \nu_m), \ldots, H_i(x, \nu_m), \ldots, H_{d_y}(x, \nu_m) \right)
  \]
  verifies for any \((x_1, x_2)\) in \( S^2 \) and any \( \nu_m \) in \( \overline{U}_m \)
  \[
  |x_1 - x_2| \leq L_H |H(x_1, \nu_m) - H(x_2, \nu_m)|
  \]
  namely \( H \) is Lipschitz-injective on \( S \), uniformly with respect to \( \nu_m \) in \( \overline{U}_m \).

4) For all \( 1 \leq i \leq d_y \), there exists \( L_i \) such that for all \((x_1, x_2)\) in \( S^2 \) and for all \( \nu_m \) in \( \overline{U}_m \)
  \[
  \left| L_{Hi}^m(x_1, \nu_m) - L_{Hi}^m(x_2, \nu_m) \right| \leq L_i |x_1 - x_2|
  \]
  namely \( L_{Hi}^m(x, \nu_m) \) is Lipschitz on \( S \), uniformly with respect to \( \nu_m \) in \( \overline{U}_m \).

**Theorem 2** ([17]). Suppose Assumption 3 is satisfied. For all integer \( 1 \leq i \leq d_y \) and \( m_i \) defined in Assumption 3, consider a Hurwitz matrix \( A_i \) in \( \mathbb{R}^{m_i \times m_i} \) and a vector \( B_i \) in \( \mathbb{R}^{m_i} \) such that the pairs \((A_i, B_i)\) is controllable. Denote \( m = \max_i m_i \).

There exists a strictly positive real number \( \tilde{k} \) such that for all \( k \geq \tilde{k} \) and for all \( \nu_m \) in \( \overline{U}_m \), there exists \( \nu_{k,u} \) such that any \( C^1 \) solution \( T \) to PDE (3) on \( X \times [0, +\infty) \) with
- \( d_y = \sum_{i=1}^{d_y} m_i \)
- \( A \) in \( \mathbb{R}^{d_x \times d_y} \) and \( B \) in \( \mathbb{R}^{d_c \times d_y} \) defined by
  \[
  A = \begin{pmatrix}
  kA_1 \\
  \vdots \\
  kA_i \\
  \vdots \\
  kA_{d_y}
  \end{pmatrix}, 
  B = \begin{pmatrix}
  B_1 \\
  \vdots \\
  B_i \\
  \vdots \\
  B_{d_y}
  \end{pmatrix}
  \]
  - \( T(\cdot, 0) \) Lipschitz on \( X \)

is such that \( T(\cdot, t) \) is injective on \( X \) for all \( t \geq \tilde{k}_{k,u} \), uniformly in time and in space. More precisely, there exists a constant \( L_k \) such that for any \((x_1, x_2)\) in \( X^2 \), any \( u \) in \( \mathcal{U} \) and any time \( t \geq \tilde{k}_{k,u} \)
  \[
  |x_1 - x_2| \leq L_k |T(x_1, t) - T(x_2, t)|.
  \]

Besides, for any \( t \geq \tilde{k}_{k,u} \), \( T(\cdot, t) \) is an injective immersion on \( X \).

Note that the additional assumption “\( T(\cdot, 0) \)” Lipschitz on \( X^\nu \)” is not very restrictive because the solution \( T \) can usually be chosen arbitrarily at initial time 0 (see examples in Section III).

In particular, the elementary solution \( T^0 \) found in Lemma 1 is the zero constant function at time 0 and thus clearly verifies this assumption.

Applying successively Lemma 1, Theorem 2 and Theorem 1, we conclude that under Assumption 3, it is possible to write an observer for system (1) by choosing any \((A_i, B_i)\) controllable and \( k \) sufficiently large.

**Remark 1.** It is important to note that \( \tilde{k} \) does not depend on \( u \), thanks to the fact that \( L_H, M_f \) and \( L_i \) given by Assumptions 3.2, 3.3, 3.4 are the same for all \( \nu_m \) in \( \overline{U}_m \).

However, the time \( \tilde{k}_{k,u} \) after which the solution becomes injective a priori depends on \( k \) and \( u \). This is not a problem in practice since we only want to be sure that for \( k \) sufficiently large, any solution will become injective after a certain time.

If we want this time \( \tilde{k}_{k,u} \) to be uniform in \( u \), the Lipschitz constants of \( H(\cdot, \nu_m(0)) \) and of \( T(\cdot, 0) \) must be the same for all \( u \) in \( \mathcal{U} \).

**Remark 2.** If we choose \( m = \max_i m_i \) sufficiently large distinct strictly positive real numbers \( \lambda_j \), and take \( A_i = -\text{diag}(\lambda_1, \ldots, \lambda_{m_i}) \) and \( B_i = (1, \ldots, 1)^\top \), then, the PDEs to solve are simply
  \[
  \frac{\partial T_{\lambda_i}}{\partial x}(x, t)f(x, u(t)) + \frac{\partial T_{\lambda_i}}{\partial t}(x, t) = -\lambda T_{\lambda_i}(x, t) + h_i(x, u(t))
  \]
for each \( 1 \leq i \leq d_y \) and \( \lambda \) in \( \{\lambda_1, \ldots, \lambda_{m_i}\} \). Then, one take
  \[
  T(x, t) = \left( T_{\lambda_1}, \ldots, T_{\lambda_{m_i}}, 1, \ldots, T_{\lambda_{d_y}} \right).
  \]

**Remark 3.** Under Assumption 3.3, 3.4, the system could also be transformed via \( H \) into a Lipschitz phase-variable form of dimension \( d_y \times \max_i m_i \geq \sum_{i=1}^{d_y} m_i \) ([20], [8]) and a high gain observer could be used. If we wanted to use only \( m_i \) derivatives for each output and obtain an observer of dimension \( \sum_{i=1}^{d_y} m_i \), each \( L_{Hi}^m \) would have to satisfy an additional triangularity assumption. But in any case, the crucial difference with the Luenberger observer presented in this chapter is that unlike \( H \), the transformation used here does not require the computation of the derivatives of the input (see examples in Section III).

In order to check Assumption 3 more easily in practice, we prove the following result :

**Lemma 2** ([17]). Assume that \( S \) is compact and there exist \( d_y \) integers \((m_1, \ldots, m_{d_y})\) such that \( \overline{U}_m \) with \( m = \max_i m_i \) is compact and for any \( \nu_m \) in \( \overline{U}_m \), \( H(\cdot, \nu_m) \) in (8) is a well defined injective immersion\(^8\) on \( S \). Then, Assumptions 3.2, 3.3, 3.4 are satisfied.

In other words, since the additional assumption “\( T(\cdot, 0) \)” Lipschitz on \( S^\nu \)” made in Theorem 2 is automatically verified when \( S \) is compact (\( T \) is \( C^1 \)), the result of Theorem 2 holds under the only assumptions of Lemma 2 if \( S \) satisfies Assumption 3.1.

### B. Injectivity with backward distinguishability

In the previous section, we have shown that finding an injective transformation into an Hurwitz form is possible under a strong differential observability property, namely that the function \( H(\cdot, \nu_m) \) made of each output and a certain number of its derivatives is an injective immersion. We investigate in this section if injectivity is still ensured when we have only a weak differential observability (i.e. \( H(\cdot, \nu_m) \) is injective but not an immersion) or even only backward-distinguishability as in [13, Theorem 3] for autonomous systems.

\(^8\) \( H(\cdot, \nu_m) \) is injective on \( S \) and \( \frac{\partial H}{\partial x}(x, \nu_m) \) is full-rank for any \( x \) in \( S \)
Theorem 3. Take \( u \) in \( \mathcal{U} \). Assume that for this input, system (1) is backward-distinguishable on \( \mathcal{X} \) in time \( t_u \), i.e. for any \( t \geq t_u \) and any \((x_a, x_b)\) in \( \mathcal{X}^2\),
\[
Y(x_a, t; s; u) = Y(x_b, t; s; u) \quad \forall s \in [t - t_u, t] \implies x_a = x_b.
\]
Assume also that Assumption 2 holds. Then, there exists a set \( \mathcal{R} \) of zero-Lebesgue measure in \( \mathcal{C}^{d_x + 1} \) such that for any \((\lambda_1, \ldots, \lambda_{d_x + 1})\) in \( \Omega^{d_x + 1} \), and any \( t \geq t_u \), the function \( T^0 \) defined in (5) with
\[
d_t = d_y \times (d_x + 1)
\]
and
\[
\begin{pmatrix}
\hat{A} \\
\vdots \\
\hat{A}
\end{pmatrix},
\begin{pmatrix}
\hat{B} \\
\vdots \\
\hat{B}
\end{pmatrix}
\]
is such that \( T^0(\cdot, t) \) is injective on \( \mathcal{X} \) for \( t > t_u \).

Note that the assumption of backward-distinguishability in finite time is in particular verified when the system is instantaneously backward-distinguishable, and a fortiori when the map made of the output and its derivatives up to a certain order is injective, namely the system is weakly differentially observable.

Of course, if \( T^0 \) has been built with system (6) instead of (1) to satisfy Assumption 2, the assumption of backward distinguishability needed here should hold for system (6), namely the outputs should be distinguishable in backward time before the solutions leave \( \mathcal{X} \).

Proof. Let us define for \( \lambda \) in \( \mathbb{C} \), the function \( T^0_\lambda : \mathcal{X} \times \mathbb{R}^+ \to \mathbb{C}^{d_x} \)
\[
T^0_\lambda(x, t) = \int_0^t e^{-\lambda(t-s)} Y(x, t; s; u) \, ds.
\]
Given the structure of \( A \) and \( B \), and with a permutations of the components,
\[
T^0(x, t) = \left(T^0_{\lambda_1}(x, t), \ldots, T^0_{\lambda_{d_x + 1}}(x, t)\right).
\]
We need to prove that \( T^0 \) is injective for almost all \((\lambda_1, \ldots, \lambda_{d_x + 1})\) in \( \Omega^{d_x + 1} \) (in the sense of the Lebesgue measure). For that, we define the function
\[
\Delta T(x_a, x_b, t, \lambda) = T^0_\lambda(x_a, t) - T^0_\lambda(x_b, t)
\]
on \( T \times \Omega \) with
\[
\Omega = \{ (x_a, x_b, t) \in \mathcal{X}^2 \times (t_u, +\infty) : x_a \neq x_b \}.
\]
We are going to use the following lemma whose proof\(^9\) can be found in [13]:

\(^9\)More precisely, the result proved in [13] is for \( \mathcal{T} \) open set of \( \mathbb{R}^{2d_x} \) instead of \( \mathbb{R}^{2d_x + 1} \). But the proof turns out to be still valid with \( \mathbb{R}^{2d_x + 1} \) because the only constraint is that the dimension of \( \mathcal{T} \) be strictly less than \( 2(d_x + 1) \).

Lemma 3 (Coron’s lemma). Let \( \Omega \) and \( \mathcal{T} \) be open sets of \( \mathbb{C} \) and \( \mathbb{R}^{2d_x + 1} \) respectively. Let \( \Delta T : \mathcal{T} \times \Omega \to \mathbb{C}^{d_y} \) be a function which is holomorphic in \( \lambda \) for all \( x \) in \( \mathcal{T} \) and \( C^1 \) in \( x \) for all \( \lambda \) in \( \Omega \).

If for any \((x, \lambda)\) in \( \mathcal{T} \times \Omega \) such that \( \Delta T(x, \lambda) = 0 \), there exists \( i \in \{1, \ldots, d_y\} \) and \( k > 0 \) such that \( \partial^k \Delta T \bigm| \partial \lambda^k (x, \lambda) \neq 0 \), then the set
\[
\mathcal{R} = \bigcup_{x \in \mathcal{T}} \{ (\lambda_1, \ldots, \lambda_{d_x + 1}) \in \Omega^{d_x + 1} : \Delta T(x, \lambda_1) = \ldots = \Delta T(x, \lambda_{d_x + 1}) = 0 \}
\]
has zero Lebesgue measure in \( \mathbb{C}^{d_x + 1} \).

In our case, \( \Delta T \) is clearly holomorphic in \( \lambda \) and \( C^1 \) in \( x \). Since for every \( x \) in \( \mathcal{T} \), \( \lambda \mapsto \Delta T(x, \lambda) \) is holomorphic on the connex set \( \mathbb{C} \), its zeros are isolated and admit a finite multiplicity, unless it is identically zero on \( \mathbb{C} \). Let us prove that \( \lambda \mapsto \Delta T(x, \lambda) \) can’t be identically zero on \( \mathbb{C} \). If it was the case, we would have in particular for any \( \omega \) in \( \mathbb{R} \)
\[
\int_{-\infty}^{+\infty} e^{-\omega \tau} g(\tau) \, d\tau = 0
\]
with \( g \) the function
\[
g(\tau) = \begin{cases} Y(x_a, t; t - \tau; u) - Y(x_b, t; t - \tau; u) , & \text{if } \tau \in [0, t] \\ 0, & \text{otherwise} \end{cases}
\]
which is in \( L^2 \). Thus, the Fourier transform of \( g \) would be identically zero and we deduce that necessarily we would have
\[
Y(x_a, t; t - \tau; u) - Y(x_b, t; t - \tau; u) = 0
\]
for almost all \( \tau \) in \([0, t]\) and thus for all \( \tau \) in \([0, t]\) by continuity. Since \( t \geq t_u \), it would follow from the backward-distinguishability that \( x_a = x_b \) but this is impossible because \( (x_a, x_b, t) \) is in \( \mathcal{T} \). We conclude that \( \lambda \mapsto \Delta T(x, \lambda) \) is not identically zero on \( \mathbb{C} \) and the assumptions of the lemma are satisfied. Thus, \( \mathcal{R} \) has zero measure and for all \((\lambda_1, \ldots, \lambda_{d_x + 1})\) in \( \Omega^{d_x + 1} \), \( T^0 \) is injective on \( \mathcal{X} \), by definition of \( \mathcal{R} \).

Remark 3. The function \( T \) proposed by Theorem 3 takes complex values. To remain in the real frame, one should consider the transformation made of its real and imaginary parts, and instead of implementing for each \( i \in \{1, \ldots, d_y\} \) and each lambda \( \xi_{\lambda, i} = -\lambda \xi_{\lambda} + y_i \)
\[
\text{in } \mathbb{C}, \text{ one should implement }
\]
\[
\tilde{\xi}_{\lambda, i} = \begin{pmatrix} -\Re(\lambda) & -\Im(\lambda) \\ \Im(\lambda) & -\Re(\lambda) \end{pmatrix} \xi_{\lambda, i} + \begin{pmatrix} y_i \\ 0 \end{pmatrix}
\]
in \( \mathbb{R} \). Thus, the dimension of the observer is \( 2 \times d_y \times (d_x + 1) \) in terms of real variables.

Remark 4. It should be noted that Theorem 3 gives for each \( u \) in \( \mathcal{U} \) a set \( \mathcal{R}_u \) of zero measure in which not to choose the \( \lambda_i \), but unfortunately, there is no guarantee that \( \bigcup_{u \in \mathcal{U}} \mathcal{R}_u \) is also of zero-Lebesgue measure.

Remark 6. Unlike Theorem 2 which proved the injectivity of any solution \( T \) to PDE (3), Theorem 3 proves only the
injectivity of $T^0$. Note though that as shown at the beginning
of the proof of Theorem 2 (see [17]) by the “variation of
constants” formula, any solution $T$ verifies
\[
T(x,t) = e^{At} T(X(x,t;0;u),0) + T^0(x,t)
\]
with Hurwitz, and thus tends to the injective function $T^0$.
We can thus expect $T$ to become injective after a certain time,
under some appropriate uniformity assumptions. In particular,
this is the case if for all $x$ in $\mathcal{X}$ and all $t \geq 0$, $X(x,t;0;u)$
is in a set $S$ for which there exists a class $K$ function $\rho$ such
that for all $(x_a,x_b) \in S \times S$, 
\[
|T(x_a,0) - T(x_b,0)| \leq \rho(|x_a - x_b|) ,
\]
\[
|T^0(x_a,0) - T^0(x_b,0)| \leq \rho(|x_a - x_b|) ,
\]
and a positive real number $\ell$ such that for all $t \geq 0$, 
\[
|T^0(x_a,t) - T^0(x_b,t)| \geq \ell \rho(|x_a - x_b|).
\]
In that case,
\[
|T(x_a,t) - T(x_b,t)| \geq (\ell - 2 |e^{At}|) \rho(|x_a - x_b|).
\]
Hence, injectivity on $\mathcal{X}$ is obtained after a certain time. The
part first is about uniform (in space) continuity, which is
satisfied as soon as $S$ is bounded, and the second part is about
injectivity (in space and in time). In fact, a way of ensuring the
injectivity is to take, if possible, a solution $T$ with the
boundary condition
\[
T(x,0) = 0 \quad \forall x \in S ,
\]
because in that case, necessarily, $T = T^0$.

It is also interesting to remark that in the case where $T$ is
initialized along (11), and the observer state is initial at $x_0 = 0$, we have for all time $s$
\[
\Xi(x_0,0;u,y_{x_0}) = T(X(x_0,0;u),s)
\]
i.e. finite-time convergence is achieved as soon as $T(\cdot,t)$
becomes injective.

We conclude from this section that as soon as no blow-
up in finite-time is possible, there always exists a time-varying
solution to PDE (3) which is injective under standard
observability assumptions. It follows that the only remaining
problem to address is the computation of such a solution
without relying on the expression (5). This is done in the
following section through practical examples.

III. EXAMPLES
A. Linear dynamics with polynomial output
Consider a system of the form\textsuperscript{10}
\[
\dot{x} = A(u,y)x + B(u,y) , \quad y = C(u)P_d(x)
\]
with $P_d : \mathbb{R}^{d_x} \rightarrow \mathbb{R}^{d_y}$ a vector containing the $k_d$ possible
monomials of $x$ with degree inferior to $d$, $A : \mathbb{R}^{d_x} \times \mathbb{R}^{d_y} \rightarrow \mathbb{R}^{d_x \times d_x}$, $B : \mathbb{R}^{d_y} \times \mathbb{R}^{d_x} \rightarrow \mathbb{R}^{d_y}$ and $C : \mathbb{R}^{d_y} \rightarrow \mathbb{R}^{d_y \times k_d}$ matrices depending on $u$. For any $i$ in $\{1, \cdots, d_y\}$, a transformation $T_{\lambda,i}$ of the form
\[
T_{\lambda,i}(x,t) = M_{\lambda,i}(t)P_d(x)
\]
with $M_{\lambda,i} : \mathbb{R} \rightarrow \mathbb{R}^{1 \times k_d}$, verifies
\[
\frac{\partial T_{\lambda,i}}{\partial x}(x,t)f(x,u) + \frac{\partial T_{\lambda,i}}{\partial t}(x,t) = M_{\lambda,i}(t)\frac{\partial P_d}{\partial x}(x)(A(u,y)x + B(u,y)) + \dot{M}_{\lambda,i}(t)P_d(x) .
\]
But there exists a matrix of coefficients $D : \mathbb{R}^{d_x} \times \mathbb{R}^{d_y} \rightarrow \mathbb{R}^{k_d}$
such that
\[
\frac{\partial P_d}{\partial x}(x)(A(u,y)x + B(u,y)) = D(u,y)P_d(x)
\]
so that we get
\[
\frac{\partial T_{\lambda,i}}{\partial x}(x,t)f(x,u) + \frac{\partial T_{\lambda,i}}{\partial t}(x,t) = \left( M_{\lambda,i}(t)D(u,y) + \dot{M}_{\lambda,i}(t) \right)P_d(x) .
\]
It follows that by choosing the coefficients $M_{\lambda,i}$ as solutions of the filters
\[
\dot{M}_{\lambda,i}(t) + \lambda M_{\lambda,i}(t) = -M_{\lambda,i}(t)D(u(t),y) + C_i(u(t)) ,
\]
$T_{\lambda,i}$ is solution to the PDE (9) with $\mathcal{X} = \mathbb{R}^{d_x}$.

A practical example of this kind of systems is a Permanent
Magnet Synchronous Motor (PMSM), which can be modeled
by
\[
\dot{x} = u(t) - Ri(t) , \quad y = |x - Li(t)|^2 - \Phi^2 = 0
\]
where $x$ is in $\mathbb{R}^2$, the voltages $u$ and currents $i$ are time varying
exogenous signals taking value in $U = \mathbb{R}^2$, the resistance $R$,
impedance $L$ and flux $\Phi$ are known scalar parameters and
the measurement $y$ is constantly zero. Applying the method
presented above and removing the unnecessary terms, we find
that we can choose $T_{\lambda}$ of the form ($d_y = 1$)
\[
T_{\lambda}(x,t) = |x|^2 + a_{\lambda}(t)\top x + b_{\lambda}(t)
\]
with the dynamics of $a_{\lambda}$ and $b_{\lambda}$ given by
\[
\dot{a}_{\lambda} = -\lambda a_{\lambda} - 2u(t) - Ri(t)) + 2Li(t)
\]
\[
\dot{b}_{\lambda} = -\lambda b_{\lambda} - a_{\lambda}\top (u(t) - Ri(t)) + L^2|i(t)|^2 - \Phi^2
\]
Once this solution has been found, an observability analysis
must be carried out to know the number of eigenvalues $\lambda$
which are necessary to ensure the injectivity of the transformation.
This is developed in [17].

Note that for this particular system, a classical gradient ob-
server of smaller dimension exists ([21], [22]). The Luemberger
observer that we would obtain here offers the advantage of
depending only on filtered versions of $u$ and $i$, which can be
useful in presence of significant noise. On the other hand, no
high gain design would have been possible for this system
without computing the derivatives of $i$, which is not desirable
in practice.
B. A time-varying transformation for an autonomous system

It was observed in [23, Section 8.4] that it is sometimes useful to allow the transformation to be time-varying even for an autonomous system. Only results concerning stationary transformations were available at the time, so that the framework of dynamic extensions had to be used. This is no longer necessary thanks to Theorems 2 and 3. Indeed, consider for instance the system

\[
\begin{align*}
\dot{x}_1 &= x_2^3 \\
\dot{x}_2 &= -x_1 ,
\end{align*}
\]

which admits bounded trajectories (the quantity \(x_2^2 + x_2^4\) is constant). This system is weakly differentially observable of order 2 on \(\mathbb{R}^2\) since \(x \mapsto H_2(x) = (x_1, x_2^3)\) is injective on \(\mathbb{R}^2\). It is thus a fortiori instantaneously backward-distinguishable and [13, Theorem 3] holds. Applying Luenberger's methodology to this system would thus bring us to look for a stationary transformation \(T_\lambda\) into

\[
\dot{\xi}_\lambda = -\lambda \xi_\lambda + x_1 ,
\]

for which a possible solution is

\[
T_\lambda(x) = \int_{-\infty}^{0} e^{\lambda \tau} Y(x; \tau) \, d\tau .
\]

Although the injectivity of \(T = (T_{\lambda_1}, T_{\lambda_2}, T_{\lambda_3})\) is satisfied for a generic choice of \((\lambda_1, \lambda_2, \lambda_3)\) in \(\{\lambda \in \mathbb{C} : \Re(\lambda) > 0\}\) according to [13, Theorem 3], it is difficult to compute \(T\) numerically and as far as we are concerned, we are not able to find an explicit expression.

Instead, it may be easier to look for a time-varying transformation and apply either Theorem 2 or 3. According to Lemma 1, such a transformation exists whatever the chosen set \(\mathcal{X}\) of interest and given the structure of the dynamics, one can try to look for it in the form

\[
T_\lambda(x, t) = a_\lambda(t)x_2^3 + b_\lambda(t)x_2^2 + c_\lambda(t)x_2 + d_\lambda(t)x_1 + e_\lambda(t) .
\]

It verifies the dynamics (16) if for instance

\[
\begin{align*}
\dot{a}_\lambda(t) &= -\lambda a_\lambda(t) + d_\lambda(t) \\
\dot{b}_\lambda(t) &= -\lambda b_\lambda(t) + 3a_\lambda(t)y \\
\dot{c}_\lambda(t) &= -\lambda c_\lambda(t) + 2b_\lambda(t)y \\
\dot{d}_\lambda(t) &= -\lambda d_\lambda(t) + 1 \\
\dot{e}_\lambda(t) &= -\lambda e_\lambda(t) + c_\lambda(t)y .
\end{align*}
\]

Using Remark 6 and applying Theorem 3, we know that, by initializing the filters \(a_\lambda, b_\lambda, c_\lambda, d_\lambda\) and \(e_\lambda\) at 0 at time 0, \(x \mapsto (T_{\lambda_1}(x, t), T_{\lambda_2}(x, t), T_{\lambda_3}(x, t))\) is injective on \(\mathbb{R}^2\) for \(t > 0\) and for a generic choice of \((\lambda_1, \lambda_2, \lambda_3)\) in \(\{\lambda \in \mathbb{C} : \Re(\lambda) > 0\}\).

To reduce the dimension of the filters, we can take \(d_\lambda(t) = \frac{1}{\lambda}\) and \(a_\lambda(t) = \frac{1}{\lambda^3}\). In that case Theorem 3 cannot be properly applied because \(T_\lambda\) is not \(T^0\). However, we have found at least in simulations that injectivity is preserved after a certain time as shown in Figure 1.

![Graph](image)

**Remark 7.** In those examples, the time dependence of \(T\) comes through filters \(a_\lambda, \ldots, e_\lambda\), that take into account the input and output signals. Therefore, \(T\) could also be seen as a stationary transformation \(T(x, a_\lambda, \ldots, e_\lambda)\) if the filters’ states were added to the system and observer states.

IV. STATIONARY TRANSFORMATION

We have just seen that a time-varying transformation could be used for an autonomous system. We investigate here the converse, i.e. if a stationary transformation can be used for
Consider a control-affine single-output system
\[
\dot{x} = f(x) + g(x)u, \quad y = h(x) \in \mathbb{R}.
\] (18)

We will use the following two notions of observability:

Definition 1 (Differential observability of the drift system). The drift system of system (18) is said weakly differentially observable of order \( m \) on an open subset \( S \) of \( \mathbb{R}^{d_x} \) if the function
\[
H_m = (h(x), L_f h(x), \ldots, L_f^{m-1} h(x))
\]
is injective on \( S \). If it is also an immersion, we say strongly differentially observable of order \( m \).

Definition 2 (Instantaneous uniform observability). System (18) is instantaneously uniformly observable on an open subset \( S \) of \( \mathbb{R}^{d_x} \) if, for any pair \((x_a, x_b)\) in \( S^2 \) with \( x_a \neq x_b \), any strictly positive number \( \bar{T} \), and any function \( u \) defined on \([0, \bar{T}]\), there exists a time \( t < \bar{T} \) such that \( h(X_u(x_a, t)) \neq h(X_u(x_b, t)) \) and \( (X_u(x_a, s), X_u(x_b, s)) \) in \( S^2 \) for all \( s \leq t \).

In the high gain framework, we know from [5], [6] that when system (18) is uniformly instantaneously observable and its drift dynamics are differentially observable of order \( d_x \), it is possible to keep the stationary transformation associated to the drift autonomous system, because the additional terms resulting from the presence of inputs are triangular and do not prevent the convergence of the observer. It turns out that, inspired from [1, Theorem 5], an equivalent result exists in the Luenberger framework.

Example 1. Consider the bioreactor model used in [6]
\[
\begin{align*}
\dot{x}_1 &= \mu(x_1, x_2) x_1 - u x_1, \\
\dot{x}_2 &= -a_3 \mu(x_1, x_2) x_1 - u x_2 + ua_4, \\
y &= x_1
\end{align*}
\] (22)

where \( x_1 \) (resp the substrate) in a tank of constant volume, \( u \) is bounded positive input and the growth rate is given by the "Contois" model
\[
\mu(x_1, x_2) = \frac{a_1 x_2}{a_2 x_1 + x_2}
\]
with $a_i$ positive constants. This system is uniformly instantaneously observable on the set

\[ S = \{(x_1, x_2) \in \mathbb{R}^2 : x_1 > 0, x_2 > 0 \} \]

which is invariant by the dynamics (22). Besides, it is straightforward to check that the drift system is strongly differentially observable of order 2 on $S$. Note finally that the input $u$ being bounded, the trajectories are bounded and all the assumptions of Theorem 4 are satisfied.

Let us look for a transformation $T$ solution to the PDE (19) associated to the drift system. We first note that the quantity $z = a_3 x_1 + x_2$ is constant along the drift dynamics and to facilitate the computations, we look for $T$ as a function of $(x_1, z)$ instead of $(x_1, x_2)$, namely we solve:

\[ \frac{\partial T_\lambda}{\partial x_1}(x_1, z) \mu(x_1, z - a_3 x_1) x_1 = -k \lambda T_\lambda(x_1, z) + x_1 \]

Integrating with respect to $x_1$, we find that a possible solution is:

\[ T_\lambda(x_1, z) = \frac{1}{a_1} \int_0^{x_1} \left( \frac{z - a_3 x_1}{z - a_3 s} \right)^{\frac{k \lambda + 3}{a_3}} \left( \frac{s}{x_1} \right)^{\frac{k \lambda}{a_1}} \left( \frac{a_2}{z - a_3 s} + 1 \right) ds \]

By taking

\[ T(x_1, x_2) = \left( T_{\lambda_1}(x_1, a_3 x_1 + x_2), T_{\lambda_2}(x_1, a_3 x_1 + x_2) \right) \]

with $\lambda_1$ and $\lambda_2$ two distinct strictly positive numbers, we thus obtain a solution to PDE (19) on $S$.

For $k$ sufficiently large, we know from Theorem 4 that there exists at least one solution of (19) which is a diffeomorphism and we assume the same property holds for this particular solution. Assuming also that $\xi$ remains in $T(\mathcal{X})$ as in [6], the observer writes

\[ \dot{\xi} = kA \xi + B y + \frac{dT}{dx}(\hat{x}) g(\hat{x}) u, \quad \hat{x} = T^{-1}(\xi) \]

which may be realized in the $x$-coordinates as

\[ \dot{\hat{x}} = f(\hat{x}) + g(\hat{x}) u + \left( \frac{dT}{dx}(\hat{x}) \right)^{-1} (y - \hat{x}_1). \quad (23) \]

The results of a simulation with the same system parameters as in [6] are presented on Figure 2.

V. Conclusion

We have shown how a Luenberger methodology can be applied to nonlinear controlled systems. It is based on the resolution of a time-varying PDE, the solutions of which exist under very mild assumptions, transform the system into a linear asymptotically stable one, and become injective after a certain time if

- either the function made of the output and a certain number of its derivatives is Lipschitz-injective: this is verified when the system is strongly differentially observable and the trajectories are bounded,
- or the system is backward-distinguishable (uniformly in time), but in this case, injectivity is ensured for "almost all" choice of a diagonal complex matrix $A$ (of sufficiently large dimension) in the sense of the Lebesgue measure in $\mathbb{C}$.

Although solutions to the PDE are guaranteed to exist, they may be difficult to compute. We have shown on practical examples how this can be done by a priori guessing their "structure". The advantage with respect to a more straightforward high gain design is however that the transformation does not depend on the derivatives of the input which thus need not be computed.

Also, it is interesting to remember that exactly as in the high gain paradigm, for uniformly instantaneously observable control-affine systems, we may use the stationary transformation associated to the autonomous drift system when it is strongly differentially observable of order $d_x$. The result does not stand for higher orders of differential observability, since it relies on the existence of Lipschitz functions $g_i$ such that $g_i(H_i(x)) = L_y L_i^{-1}(x)$, and it is shown in [18] that the Lipschitzness is lost when the drift system is differentially observable of higher order.

A perspective of this work could be to study the impact of the noise in a Luenberger design and in particular see if it
is possible to optimize the choice of the eigenvalues of the Hurwitz matrix $A$ in order to limit its effect.

**APPENDIX A**

**PROOF OF THEOREM 4**

Let $\mathcal{X}'$ and $\mathcal{X}''$ be open sets such that

$$c_1(\mathcal{X}) \subset \mathcal{X}' \subset c_1(\mathcal{X}'') \subset \mathcal{X}'' \subset c_1(\mathcal{X}'') \subset \mathcal{S}.$$ **Consider the function $T : \mathbb{R}^{d_x} \to \mathbb{R}^{d_x}$ defined by**

$$T(x) = \int_{-\infty}^{0} e^{-kA\tau} B h(\hat{X}(x, \tau)) d\tau$$

where $\hat{X}(x, \tau)$ denotes the value at time $\tau$ of the solution initialized at $x$ at time $0$ of the modified autonomous drift system

$$\dot{x} = \chi(x)f(x),$$

for any $C^\infty$ function $\chi : \mathbb{R}^{d_x} \to \mathbb{R}$ satisfying

$$\chi(x) = \begin{cases} 1 & \text{if } x \in c_1(\mathcal{X}') \\ 0 & \text{if } x \notin \mathcal{X}'' \end{cases}$$

**According to [25, Proposition 3.3], there exists $k_0$ such that for all $k \geq k_0$, $T$ is $C^1$ and verifies PDE (19). Now let us prove that it is injective on $c_1(\mathcal{X}')$ for $k$ sufficiently large.** The drift system being strongly differentially observable of order $d_x$, the function

$$H_{d_x}(x) = (h(x), L_f h(x), \ldots, L_{d_x}^{d_x}(x))$$

is an injective immersion on $c_1(\mathcal{X}')$ and by [25, Lemma 3.2], there exists $L_H > 0$ such that for all $(x_a, x_b)^T \in c_1(\mathcal{X}')^2$,

$$|H_{d_x}(x_a) - H_{d_x}(x_b)| \leq L_H |x_a - x_b|.$$ **Besides, since $\chi f = f$ on $c_1(\mathcal{X}')$, after several integrations by parts (by integrating $e^{-kA\tau}$ and differentiating $h(\hat{X}(x, \tau))$ with respect to $\tau$, and using that $A$ is Hurwitz and $\mathcal{X}''$ bounded for the limit $\tau \to -\infty$), we obtain for all $x \in c_1(\mathcal{X}')$**

$$T(x) = A^{-d_x} \mathcal{C} \left( -kH_{d_x}(x) + \frac{1}{k^{d_x}} R(x) \right)$$

where $K = \text{diag} \left( \frac{1}{k}, \ldots, \frac{1}{k^{d_x}} \right)$, $\mathcal{C}$ is the invertible controllability matrix

$$\mathcal{C} = [A^{d_x-1} B \ldots AB B],$$

and $R$ the remainder

$$R(x) = \mathcal{C}^{-1} \int_{-\infty}^{0} e^{-kA\tau} B L_f^{d_x}(\hat{X}(x, \tau)) d\tau.$$ **This latter integral makes sense on $c_1(\mathcal{X}')$ because :**

- $A$ being diagonal and denoting $a = \min_i |\lambda_i| > 0$, for all $\tau \in (-\infty, 0]$, 

$$|e^{-kA\tau}| \leq e^{ka\tau}.$$ - By definition of the function $\chi$, for all $x \in c_1(\mathcal{X}')$, $\hat{X}(x, \tau)$ is in $c_1(\mathcal{X}')$ for all $\tau$, i.e. $\tau \mapsto L_f^{d_x}(\hat{X}(x, \tau))$ is bounded.

So now taking $(x_a, x_b)$ in $c_1(\mathcal{X}')^2$, and considering the difference $|T(x_a) - T(x_b)|$, from (24), we obtain

$$|T(x_a) - T(x_b)| \geq \frac{|A^{-d_x} \mathcal{C}|}{k^{d_x}} \left( |H_{d_x}(x_a) - H_{d_x}(x_b)| \right),$$

and if $R$ is Lipschitz with Lipschitz constant $L_R$, we get

$$|T(x_a) - T(x_b)| \geq \frac{|A^{-d_x} \mathcal{C}|}{k^{d_x}} (L_H - L_R) |x_a - x_b|.$$ **In order to deduce the injectivity of $T$, we also need $L_R < L_H$ and we are going to prove that this is true for $k$ sufficiently large. To compute $L_R$, let us find a bound of $|\frac{\partial R}{\partial x}(x)|$. By defining**

$$c_0 = \max_{x \in c_1(\mathcal{X}')} \left| B \frac{\partial L_f^{d_x} h}{\partial x}(x) \right|, \quad \rho_1 = \max_{x \in c_1(\mathcal{X}')} \left| \frac{\partial f}{\partial x}(x) \right|,$$

we have for all $\tau$ in $(-\infty, 0]$ and all $x \in c_1(\mathcal{X}')$,

$$\left| B \frac{\partial L_f^{d_x} h}{\partial x}(\hat{X}(x, \tau)) \right| \leq c_0 \text{ and }$$

$$\left| \frac{\partial \hat{X}}{\partial x}(x, \tau) \right| \leq e^{-\rho_1 \tau}.$$ **We conclude that for $k > \frac{\rho_1}{a}$, $R$ is $C^1$ and there exists a positive constant $c_1$ such that for all $x \in c_1(\mathcal{X}')$,**

$$\left| \frac{\partial R}{\partial x}(x) \right| \leq |\mathcal{C}^{-1}| \int_{-\infty}^{0} \left| e^{-kA\tau} \right| \left| B \frac{\partial L_f^{d_x} h}{\partial x}(\hat{X}(x, \tau)) \right| \left| \frac{\partial \hat{X}}{\partial x}(x, \tau) \right| d\tau \leq \frac{c_0}{k^{d_x} a - \rho_1},$$

We finally obtain

$$|T(x_a) - T(x_b)| \geq L_T |x_a - x_b| \quad \forall (x_a, x_b) \in c_1(\mathcal{X}')^2$$

where

$$L_T = \frac{|A^{-d_x} \mathcal{C}|}{k^{d_x}} \left( L_H - \frac{c_1}{k^{d_x} a - \rho_1} \right),$$

and $T$ is injective on $c_1(\mathcal{X}')$ if $k \geq \bar{k}_1$ with

$$\bar{k}_1 = \max \left\{ \bar{k}_0, \frac{c_1 + \rho_1 L_H}{a L_H} \right\}.$$ **Moreover, taking $x$ in $\mathcal{X}'$, any $v$ in $\mathbb{R}^{m'}$ and $h$ sufficiently small for $x + hv$ to be in $\mathcal{X}'$, it follows from (26) that**

$$\left| T(x + hv) - T(x) \right| \geq \frac{L_T |v|}{h},$$

and making $h$ tend to zero, we get

$$\left| \frac{\partial T}{\partial x}(x)v \right| \geq L_T |v|$$

and $T$ is full-rank on $\mathcal{X}'$. So $T$ is a diffeomorphism on $\mathcal{X}'$ for $k \geq \bar{k}_1$.

---

11This proof is similar to that of [13, Theorem 4].

12Because $\psi(\tau) = \frac{\partial X}{\partial x}(x, \tau)$ follows the ODE $\frac{d}{d\tau}(\tau) = \frac{\partial f}{\partial x}(X(x, \tau)) \psi(\tau)$, and $\psi(0) = I$. 
Now, let us show that system (21) is an observer for system (18). Suppose for the time being that we have shown that there exists a strictly positive number $a$ such that for any $k \geq k_1$, there exists a function $\bar{\psi}$ such that (20) holds and
\[
|\bar{\psi}(\hat{\xi}) - \bar{\psi}(\xi)| \leq a|\hat{\xi} - \xi| \quad \forall (\hat{\xi}, \xi) \in (\mathbb{R}^d)^2 .
\] (27)
Take $u$ in $U$, $x_0$ in $\mathcal{K}_0 \subset \mathbb{R}^d$, and consider the solution $X(x_0; t; u)$ of system (18) and any corresponding solution $\hat{X}(\hat{x}_0; t; u, y_0)$ of system (21). Since $X(x_0; t; u)$ remains in $\mathcal{A}$ by assumption, the error $e(t) = \hat{X}(\hat{x}_0; t; u, y_0) - T(X(x_0; t; u))$ verifies
\[
\dot{e} = kAe + \left(\bar{\psi}(\hat{X}(\hat{x}_0; t; u, y_0)) - \bar{\psi}(T(X(x_0; t; u)))\right)u
\]
and thus
\[
e^{-\rho_1 t} - 2(k\alpha + \alpha \pi)e^{-\rho_1 t} .
\]
Defining $\bar{k}_2 = \max\{k_1, \alpha \pi\}$, we conclude that $e$ asymptotically converges to 0 if $k \geq k_2$. Note for this conclusion to hold, it is crucial to have a independent from $k$. Now, consider an open set $\mathcal{A}'$ such that $c_1(\mathcal{A}) \subset \mathcal{A} \subset \mathcal{A}'$. Since $T(X(x_0; t; u))$ remains in $\mathcal{A}'$, and $c_1(T(X(x_0; t; u)))$ is contained in the open set $\mathcal{A}$, there exists a time $T$ such that for all $t \geq T$, $\hat{X}(\hat{x}_0; t; u)$ is in $\mathcal{A}$. $T = T' > 1$ is determined by the compact set $c_1(T(X(x_0; t; u)))$ and thus Lipschitz on that set. It follows that $\hat{X}(x_0; \hat{x}_0; t; u) = T(\hat{X}(\hat{x}_0; t; u))$ converges to $X(x_0; t; u)$.

It remains to show the existence of the functions $\bar{\psi}$. Since system (18) is uniformly instantaneously observable and its drift system is strongly differentially observable of order $d_x$ on $S$, we know since [5] that for all $i$ in $\{1, \ldots, d_x\}$, there exists a Lipschitz function $g_i$ such that
\[
L_i^i h(x) = g_i(h(x), \ldots, L_i^i h(x)) \ \forall x \in c_1(\mathcal{A}) .
\] (28)
Consider the function
\[
\varphi(x) = \frac{\partial T}{\partial x}(x)g(x) = A^{-d_x}g(x)
\]
\[
= A^{-d_x}g(x) + \frac{1}{k_2} \left(\frac{\partial H_{d_x}}{\partial x}(x)g(x) + \frac{1}{k_2} \frac{\partial R}{\partial x}(x)g(x)\right) .
\]
Let us first study $\varphi_H$. Notice that the $i$th-component of $\varphi_H$ is $\varphi_{H,i} = \frac{1}{k_2}L_i^i h(x)$ and according to (28), there exists $L_i$ such that for all $(x, \hat{x})$ in $c_1(\mathcal{A})^2$
\[
|\varphi_{H,i}(\hat{x}) - \varphi_{H,i}(x)| \leq L_i \sum_{j=1}^{d_x} \left|L_j^i(\hat{x}) - L_j^i(x)\right|
\]
and thus $L$ such that for all $(x, \hat{x})$ in $c_1(\mathcal{A})^2$
\[
|\varphi_H(\hat{x}) - \varphi_H(x)| \leq L|KH_{d_x}(\hat{x}) - KH_{d_x}(x)| .
\]
But using (24), we get
\[
|KH_{d_x}(\hat{x}) - KH_{d_x}(x)| \leq |A^{d_x}g^{-1}| |T(\hat{x}) - T(x)|
\]
\[
+ \frac{1}{k_2} |R(\hat{x}) - R(x)| .
\]
We have seen that for all $(x, \hat{x})$ in $c_1(\mathcal{A})^2$
\[
|R(\hat{x}) - R(x)| \leq \frac{c_1}{k_2 - \rho_1} |\hat{x} - x|
\]
and according to (26),
\[
\frac{1}{k_2} |\partial f(\hat{x}) - \partial f(x)| \leq \frac{c_1}{L_H - \frac{c_1}{k_2 - \rho_1}} |A^{d_x}g^{-1}| |T(\hat{x}) - T(x)| .
\]
We finally obtain, for any $(x, \hat{x})$ in $c_1(\mathcal{A})^2$ and for any $k \geq k_1$,
\[
|\varphi_H(\hat{x}) - \varphi_H(x)| \leq \frac{L|A^{d_x}g^{-1}|}{1 + \frac{c_1}{L_H - \frac{c_1}{k_2 - \rho_1}}} (T(\hat{x}) - T(x))
\]
\[
\leq \frac{L|A^{d_x}g^{-1}|}{1 + \frac{c_1}{L_H - \frac{c_1}{k_2 - \rho_1}}} (T(\hat{x}) - T(x)) .
\]
Let us now study the term $\varphi_R(x)$. For $(x, \hat{x})$ in $c_1(\mathcal{A})^2$
\[
\varphi_R(x) = \frac{1}{k_2} \int_{-\infty}^{0} e^{-k_2 \tau} B(x, \hat{x}, \tau) + D_2(x, \hat{x}, \tau) + D_3(x, \hat{x}, \tau) d\tau
\]
where
\[
D_1(x, \hat{x}, \tau) = \left( \frac{\partial L^d h}{\partial x}(X(x, \tau)) - \frac{\partial L^d h}{\partial x}(\hat{X}(\hat{x}, \tau)) \right) \frac{\partial X}{\partial x}(\hat{x}, \tau) g(x)
\]
\[
D_2(x, \hat{x}, \tau) = \left( \frac{\partial L^d h}{\partial x}(X(x, \tau)) - \frac{\partial X}{\partial x}(\hat{x}, \tau) \right) g(x)
\]
\[
D_3(x, \hat{x}, \tau) = \frac{\partial L^d h}{\partial x}(X(x, \tau)) \frac{\partial X}{\partial x}(\hat{x}, \tau) g(x) - g(x)
\]
Assuming that $L^d h$ is $C^2$ and $g$ is $C^1$, it follows from (25) and the fact that $\hat{X}(x, \tau) = X(x, \tau)$ in the compact set $c_1(\mathcal{X}')$ for all $\tau$ in $(-\infty, 0]$, that for all $(x, \hat{x})$ in $c_1(\mathcal{A})^2$ and for all $\tau$ in $(-\infty, 0]$, we have
\[
\left|D_1(x, \hat{x}, \tau)\right| \leq c_2 e^{-2\rho_1 \tau} |x - \hat{x}|
\]
\[
\left|D_2(x, \hat{x}, \tau)\right| \leq c_3 e^{-\rho_1 \tau} |x - \hat{x}|
\]
As for $D_2$, posing $\varphi(\tau) = \frac{\partial X}{\partial x}(\hat{x}, \tau) - \frac{\partial X}{\partial x}(x, \tau)$, and differentiating $\varphi$ with respect to time, we get
\[
\varphi(0) = 0
\]
\[
\varphi'(\tau) = \frac{\partial f}{\partial x}(\hat{X}(\hat{x}, \tau)) \varphi(\tau)
\]
\[
+ \left( \frac{\partial X}{\partial x}(\hat{x}, \tau) - \frac{\partial X}{\partial x}(x, \tau) \right) \frac{\partial X}{\partial x}(x, \tau) .
\] (29)
Since for all $\tau$ in $(-\infty, 0]$ and for all $(x, \hat{x})$ in $c_1(\mathcal{A})^2$,
\[
\left|\frac{\partial f}{\partial x}(\hat{X}(\hat{x}, \tau)) \varphi(\tau)\right| \leq \rho_1 , \quad \left|\frac{\partial X}{\partial x}(x, \tau)\right| \leq e^{-\rho_1 \tau}
\]
and
\[
\left|\frac{\partial f}{\partial x}(\hat{X}(\hat{x}, \tau)) \varphi(\tau)\right| \leq c_4 e^{-\rho_1 \tau} |x - \hat{x}| ,
\]
we obtain by solving (29) in negative time and taking the norm
\[ |D^2(\hat{x}, x, \tau)| \leq (c_5e^{-\rho_1\tau} + c_6e^{-2\rho_1\tau}) |x - \hat{x}| \leq c_7 e^{-\rho_1\tau} + c_6e^{-2\rho_1\tau} |x - \hat{x}| \]
for all \( \tau \) in \(( -\infty, 0]\) and all \((x, \hat{x})\) in \(c\ell(X)^2\). Therefore, for all \( k \geq k_1\),
\[ |\varphi(x) - \varphi(\hat{x})| \leq \frac{1}{k_{a-c}} \varphi_{\ell}(x) \leq \frac{c_8}{k_{a-c} - \rho_1} |x - \hat{x}| \leq \frac{c_8}{k_{a-c} - \rho_1} [T(x) - T(\hat{x})] \leq \frac{c_8}{L_{\varphi}(\hat{\ell}_{1}(a - \rho_1))} [T(x) - T(\hat{x})]. \]

Finally, there exists a constant \( a \) such that for all \( k \geq k_1 \), and for all \((x, \hat{x})\) in \(c\ell(X)^2\),
\[ |\varphi(x) - \varphi(\hat{x})| \leq a [T(x) - T(\hat{x})]. \tag{30} \]

Consider now the function
\[ \varphi(\xi) = \varphi(T^{-1}(\xi)) \]
defined on \(T(X')\). According to (30), \( \varphi \) is Lipschitz on \(T(X')\), and with Kirszbraun-Valentine Theorem \([26], [27] \), it admits a Lipschitz extension on \(R^d\) with same Lipschitz constant \( a \), i.e. such that (20) and (27) hold. This concludes the proof.
