# Homogenization and localization for a 1-d eigenvalue problem in a periodic medium with an interface 

Grégoire Allaire * Yves Capdeboscq ${ }^{\dagger}$

March 6, 2002

#### Abstract

In one space dimension we address the homogenization of the spectral problem for a singularly perturbed diffusion equation in a periodic medium. Denoting by $\epsilon$ the period, the diffusion coefficient is scaled as $\epsilon^{2}$. The domain is made of two purely periodic media separated by an interface. Depending on the connection between the two cell spectral equations, three different situations arise when $\epsilon$ goes to zero. First, there is a global homogenized problem as in the case without interface. Second, the limit is made of two homogenized problems with a Dirichlet boundary condition on the interface. Third, there is an exponential localization near the interface of the first eigenfunction.

## 1 Introduction

This paper is devoted to the homogenization of the eigenvalue problem for a singularly perturbed diffusion equation in a periodic medium. Although this problem is of interest in higher space dimensions, we restrict ourselves to the one-dimensional case because of the difficulty of the analysis. In particular, one of our key tool is the theory of Hill's ordinary differential equation [Eas73] for which there is no equivalent in higher dimensions. Denoting by $\epsilon$ the period, the diffusion coefficient is assumed to be of the order of $\epsilon^{2}$. Thus, we consider the following model

$$
\left\{\begin{array}{l}
-\epsilon^{2} \frac{d}{d x}\left(a\left(x, \frac{x}{\epsilon}\right) \frac{d}{d x} \phi^{\epsilon}\right)+\Sigma\left(x, \frac{x}{\epsilon}\right) \phi^{\epsilon}=\lambda^{\epsilon} \sigma\left(x, \frac{x}{\epsilon}\right) \phi^{\epsilon} \text { in } \Omega,  \tag{1.1}\\
\phi^{\epsilon}=0 \text { on } \partial \Omega,
\end{array}\right.
$$

where $\lambda^{\epsilon}, \phi^{\epsilon}$ is an eigenvalue and eigenfunction (throughout this paper, the eigenfunctions are normalized by $\left.\left\|\phi^{\epsilon}\right\|_{L^{2}(\Omega)}=1\right)$. In (1.1) the coefficients are periodic of period 1 with respect to the fast variable $x / \epsilon$. The general study of the homogenization of (1.1) is far from being complete. When the coefficients are not rapidly oscillating (i.e., they depend on the slow variable $x$ but not on $x / \epsilon$ ), it is a problem of singular

[^0]perturbation (without homogenization) which is quite well understood now in any space dimension (see, e.g., [Pia98]). When the coefficients are purely periodic functions (i.e., they depend solely on $x / \epsilon$ ), the homogenization of (1.1) (and similar models in higher dimension) has been achieved in [AB99], [AC00], [AM97]. In the case of smooth coefficients with a concentration hypothesis, partial results have recently been obtained in [AP02] (again in any space dimension). Here we focus on the different case (of practical as well as theoretical importance) where the coefficients are discontinuous. More precisely, we focus on the simplest possible model in this context, assuming that the domain is composed of two periodical media separated by an interface.

The domain $\Omega$ is of the form $(-l, L)$, where $l$ and $L$ are strictly positive constants, and we introduce the two sub-domains $\Omega_{1}=(-l, 0)$ and $\Omega_{2}=(0, L)$ separated by an interface located at the point 0 . Denoting by $\chi_{i}(x)$ the characteristic function of $\Omega_{i}$ (satisfying $\chi_{1}+\chi_{2}=1$ and $\chi_{1} \chi_{2}=0$ in $\Omega$ ), the coefficients are assumed to be given as

$$
\left\{\begin{array}{l}
a(x, y)=\chi_{1}(x) a_{1}(y)+\chi_{2}(x) a_{2}(y)  \tag{1.2}\\
\Sigma(x, y)=\chi_{1}(x) \Sigma_{1}(y)+\chi_{2}(x) \Sigma_{2}(y) \\
\sigma(x, y)=\chi_{1}(x) \sigma_{1}(y)+\chi_{2}(x) \sigma_{2}(y)
\end{array}\right.
$$

All functions $a_{1}, a_{2}, \Sigma_{1}, \Sigma_{2}, \sigma_{1}$ and $\sigma_{2}$ are assumed to be measurable, 1-periodic, bounded from above and below by positive constants. Under these assumptions, it is well known that equation (1.1) admits a countable infinite number of non-trivial solutions $\left(\lambda_{m}^{\epsilon}, \phi_{m}^{\epsilon}\right)_{m \geq 1}$. By standard regularity results, each eigenfunction $\phi_{m}^{\epsilon}$ belongs to $H_{0}^{1}(\Omega) \cap C^{0, s}(\Omega)$, with $s>0$, and by the Krein-Rutman theorem the first eigenvalue is simple and the corresponding eigenfunction can be chosen positive. Because of this property, the first eigenpair has a special physical signification, and we are mostly interested in its behavior, although the case of higher level eigenpairs is also treated in some occasions.

The motivation for studying this model comes from several applications. First, it can be seen as a semiclassical limit problem for a Schrödinger-type equation with periodic potential, as well as periodic metric (this is the so-called ground-state asymptotic problem, see, e.g., [KP93], [Pia98]). Second, it plays an important role in the uniform controllability of the wave equation (see, e.g., [CZ]). Third, and this is our main motivation, it is a simple model for computing the power distribution in a nuclear reactor core. This is the so-called criticality problem for the one-group neutron diffusion equation (for more details, we refer to [AC00], [Cap99] and references therein). In all these applications, the assumption of a purely periodic medium (i.e., no dependence on $x$ of the coefficients) is much too strong. On the other hand the coefficients are not smoothly varying but exhibit jumps at material interfaces. This makes model (1.1) with assumptions (1.2) physically relevant.
The limit behavior of (1.1) is mainly governed by the first eigenpair $\left(\psi_{i}, \mu_{i}\right)$ in the unit cell of $\Omega_{i}, i=1,2$, solution of

$$
\left\{\begin{array}{l}
-\frac{d}{d y}\left(a_{i}(y) \frac{d}{d y} \psi_{i}\right)+\Sigma_{i}(y) \psi_{i}=\mu_{i} \sigma_{i}(y) \psi_{i} \quad \text { in }[0,1]  \tag{1.3}\\
y \rightarrow \psi_{i}(y) \quad 1-\text { periodic and positive. }
\end{array}\right.
$$

Before we explain our main results, let us recall what was already proved in [AM97] in the purely periodic case, namely when $a_{1}=a_{2}, \Sigma_{1}=\Sigma_{2}$, and $\sigma_{1}=\sigma_{2}$. Asymptotically, the macroscopic trend of $\phi^{\epsilon}$ is given by an homogeneous eigenvalue problem, whereas its oscillatory behavior is governed by $\psi_{1}\left(\frac{x}{\epsilon}\right)$ (we call this a factorization principle). More precisely, the result of [AM97] is

Theorem 1.1. Assuming that $a_{2}=a_{1}, \Sigma_{2}=\Sigma_{1}$, and $\sigma_{2}=\sigma_{1}$, the m ${ }^{\text {th }}$ eigenpair $\lambda_{m}^{\epsilon}, \phi_{m}^{\epsilon}$ of (1.1) satisfies

$$
\phi_{m}^{\epsilon}(x)=u_{m}^{\epsilon}(x) \psi_{1}\left(\frac{x}{\epsilon}\right) \text { and } \lambda_{m}^{\epsilon}=\mu_{1}+\epsilon^{2} \nu_{m}+o\left(\epsilon^{2}\right)
$$

where, up to a subsequence, the sequence $u_{m}^{\epsilon}$ converges weakly in $H_{0}^{1}(\Omega)$ to $u_{m}$, and $\left(\nu_{m}, u_{m}\right)$ is the $m^{t h}$ eigenvalue and eigenvector for the homogenized problem

$$
\begin{cases}-\bar{D} \frac{d^{2}}{d x^{2}} u_{m}=\nu_{m} \bar{\sigma} u_{m} & \text { in } \Omega  \tag{1.4}\\ u_{m}=0 & \text { on } \partial \Omega\end{cases}
$$

The homogenized coefficients are given by

$$
\begin{equation*}
\bar{D}=\int_{0}^{1} a_{1}(y) \psi_{1}^{2}(y)\left(1+\frac{d \xi}{d y}(y)\right) d y \text { and } \bar{\sigma}=\int_{0}^{1} \sigma_{1}(y) \psi_{1}^{2}(y) d y \tag{1.5}
\end{equation*}
$$

where the function $\xi$ is the solution of

$$
\left\{\begin{array}{l}
-\frac{d}{d y}\left(a_{1}(y) \psi_{1}^{2}(y)\left(\frac{d \xi}{d y}+1\right)\right)=0 \quad \text { in }[0,1]  \tag{1.6}\\
\text { pny } \rightarrow \xi(y) 1-\text { periodic. }
\end{array}\right.
$$

Let us summarize our results in the case of equal first eigenvalue in the cells, $\mu_{1}=\mu_{2}$. In the sequel we choose to normalize the first periodic eigenfunctions as follows

$$
\begin{equation*}
\psi_{1}(0)=\psi_{2}(0)=1 \tag{1.7}
\end{equation*}
$$

We introduce a so-called discontinuity constant $\alpha$ defined by

$$
\begin{equation*}
\alpha=a_{1}(0) \frac{d \psi_{1}}{d y}(0)-a_{2}(0) \frac{d \psi_{2}}{d y}(0) \tag{1.8}
\end{equation*}
$$

Note that $a_{i} \frac{d \psi_{i}}{d y}$ belongs to $H^{1}\left(\Omega_{i}\right)$ which is embedded in $C\left(\bar{\Omega}_{i}\right)$ (in 1-D) and therefore $\alpha$ is well defined as the trace of a continuous function at the origin. Three different situations are possible according to the sign of $\alpha$.

If $\alpha=0$, then the two periodic media are said to be well-connected. In particular, the function equal to $a_{i}\left(d \psi_{i}\right) /(d x)$ in $\Omega_{i}$ is continuous through the interface (as well as $\psi_{i}$ because of the normalization condition (1.7)). Therefore, Theorem 1.1 extends easily to this case, and the discontinuity at the interface is not seen in the limit. Introducing a function $\psi(x / \epsilon)=\chi_{1}(x) \psi_{1}(x / \epsilon)+\chi_{2}(x) \psi_{2}(x / \epsilon)$, the eigenpairs $\left(\lambda_{m}^{\epsilon}, \phi_{m}^{\epsilon}\right)_{m \geq 1}$ satisfy

$$
\begin{equation*}
\lambda_{m}^{\epsilon}=\mu_{1}+\epsilon^{2} \nu_{m}+o\left(\epsilon^{2}\right) \text { and } \phi_{m}^{\epsilon}(x)=u_{m}^{\epsilon}(x) \psi\left(\frac{x}{\epsilon}\right) \tag{1.9}
\end{equation*}
$$

where $u_{m}^{\epsilon}$ converges weakly to $u_{m}$, and $\left(\lambda_{m}, u_{m}\right)_{m \geq 1}$ are the eigenpairs of the homogenized problem (see Theorem 3.1 and Figure 3.1)

$$
\begin{cases}-\frac{d}{d x}\left(\left(\chi_{1}(x) \overline{D_{1}}+\chi_{2}(x) \overline{D_{2}}\right) \frac{d u}{d x}\right)=\nu\left(\chi_{1}(x) \overline{\sigma_{1}}+\chi_{2}(x) \overline{\sigma_{2}}\right) u & \text { in } \Omega \\ u=0 & \text { on } \partial \Omega\end{cases}
$$

If $\alpha>0$, the interface has a repelling effect, and each eigenfunction goes to 0 at the interface. The convergence result (1.9) still holds true, but the homogenized problem has an additional Dirichlet boundary condition at $x=0$. More precisely, the limit homogenized problem is (see Theorem 3.1 and Figure 3.2)

$$
\begin{cases}-\overline{D_{1}} \frac{d^{2}}{d x^{2}} u=\nu \overline{\sigma_{1}} u & \text { in } \Omega_{1} \\ -\overline{D_{2}} \frac{d^{2}}{d x^{2}} u=\nu \overline{\sigma_{2}} u & \text { in } \Omega_{2} \\ u=0 & \text { on } \partial \Omega_{1} \cup \partial \Omega_{2}\end{cases}
$$

If $\alpha<0$, the situation is completely different since the first eigenfunction concentrates exponentially fast at the interface. In this latter case, there is no factorization principle as in Theorem 1.1, but rather a localization principle at the discontinuity (see Theorem 3.5 and Figure 3.3). The first eigenvalue $\lambda_{1}^{\epsilon}$ converges to a limit $0<\lambda_{1}<\mu_{1}=\mu_{2}$, and $0<\lambda_{1}^{\epsilon}-\lambda_{1}<C \exp (-\tau / \epsilon)$, whereas the first normalized eigenvector satisfies

$$
\left\|\frac{d}{d x} \phi_{1}^{\epsilon}(x)-\frac{1}{\sqrt{\epsilon}} \frac{d}{d x}\left(\Psi\left(\frac{x}{\epsilon}\right)\right)\right\|_{L^{2}(\Omega)}+\left\|\phi_{1}^{\epsilon}(x)-\frac{1}{\sqrt{\epsilon}} \Psi\left(\frac{x}{\epsilon}\right)\right\|_{L^{2}(\Omega)} \leq C \exp \left(-\frac{\tau}{\epsilon}\right)
$$

The limit function $\Psi \in H^{1}(\mathbb{R})$ decreases exponentially away from the interface, since it is given by

$$
\Psi(x)= \begin{cases}\psi_{1, \theta_{1}}(x) & \text { for } x<0 \\ \psi_{2, \theta_{2}}(x) & \text { for } x>0\end{cases}
$$

with $\lambda_{1}=\mu_{1}\left(\theta_{1}\right)=\mu_{2}\left(\theta_{2}\right)$, and each of the eigenpairs $\left(\mu_{i}\left(\theta_{i}\right), \psi_{i, \theta_{i}}\right)$ being the first eigencouple of the following spectral cell problem

$$
\left\{\begin{array}{l}
-\frac{d}{d x}\left(a_{i}(x) \frac{d \psi_{i, \theta_{i}}}{d x}\right)+\Sigma_{i}(x) \psi_{i, \theta_{i}}=\mu_{i}\left(\theta_{i}\right) \sigma_{i}(x) \psi_{i, \theta_{i}} \text { in }[0,1]  \tag{1.10}\\
x \rightarrow \psi_{i, \theta_{i}}(x) e^{-\theta_{i} x} \text { 1-periodic. }
\end{array}\right.
$$

The required properties of the $\theta$-parameterized family of spectral cell problems (1.10) are given in section 2.

We now turn to the case $\mu_{1} \neq \mu_{2}$, and with no loss of generality we assume $\mu_{1}>\mu_{2}$. In this case too, the spectral cell problems (1.10) govern the limit behavior of (1.1). We introduce a positive parameter $\theta_{0}>0$, such that $\mu_{1}\left(\theta_{0}\right)=\mu_{2}$, and another discontinuity constant (see Lemma 3.9)

$$
\alpha\left(\theta_{0}\right)=a_{1}(0) \frac{d \psi_{1, \theta_{0}}}{d y}(0)-a_{2}(0) \frac{d \psi_{2}}{d y}(0) .
$$

The sign of this new discontinuity constant determines the asymptotic behavior of (1.1).
If $\alpha\left(\theta_{0}\right)>0$, the eigenfunctions $\phi_{m}^{\epsilon}$ concentrate in the sub-domain $\Omega_{2}$ where the first periodic eigenvalue is the smallest (see Theorem 3.8 in the simpler case when $\alpha \geq 0$, and Theorem 3.11 when $\alpha\left(\theta_{0}\right)>0$ ).

More precisely, the limit of $\phi_{m}^{\epsilon}$ vanishes in the sub-domain $\Omega_{1}$. Introducing the factorization $\phi_{m}^{\epsilon}(x)=$ $u_{m}^{\epsilon}(x) \psi_{2}(x / \epsilon)$ in $\Omega_{2}$, the homogenized problem for the limit of $u_{m}^{\epsilon}$ is simply (see Figure 3.4)

$$
\begin{cases}-\overline{D_{2}} \frac{d^{2}}{d x^{2}} u=\nu \overline{\sigma_{2}} u & \text { in } \Omega_{2}, \\ u=0 & \text { on } \partial \Omega_{2}\end{cases}
$$

The case $\alpha\left(\theta_{0}\right)=0$ corresponds to the limit between localization at the interface and concentration in $\Omega_{2}$. The limit of the eigenfunction $\phi_{m}^{\epsilon}$ still vanishes in $\Omega_{1}$, but in the homogenized problem the Dirichlet boundary condition at $x=0$ is replaced by a Neumann boundary condition (see Theorem 3.12)

$$
\left\{\begin{array}{l}
-\overline{D_{2}} \frac{d^{2}}{d x^{2}} u=\nu \overline{\sigma_{2}} u \quad \text { in } \Omega_{2}, \\
u(L)=0 \text { and } \frac{d u}{d x}(0)=0
\end{array}\right.
$$

Finally, when $\alpha\left(\theta_{0}\right)<0$, a localization phenomenon appears, and the first eigenfunction concentrates exponentially fast at the interface. The result is then similar to the one obtained when $\mu_{1}=\mu_{2}$ and $\alpha<0$ (see Theorem 3.10).

Our main results are stated in section 3 when $\mu_{1}$ is equal or not to $\mu_{2}$. Previously, in section 2 we give a few technical results on the spectral cell problems that are crucial not only for the proof, but also for the statement of our main results. Section 4 contains the proofs when the discontinuity constant is positive, $\alpha \geq 0$, while section 5 focus on the localization phenomena, namely $\alpha<0$ or $\alpha\left(\theta_{0}\right)<0$. Section 6 contains the proofs in the special situation when $\alpha<0$ but no localization occurs $\left(\alpha\left(\theta_{0}\right) \geq 0\right)$, as it can happen when $\mu_{1}$ is not equal to $\mu_{2}$. Section 7 contains the proof of a crucial technical result about the Hill equation in one dimension.

## 2 Cell problems

In order to state precisely our convergence results, the knowledge of the spectral cell problem (1.3) is not enough. As in [Cap98], we need to introduce a parameterized family of spectral cell problems. They are reminiscent of the so-called Bloch wave decomposition (see e.g. [CPV95], [RS78]), but they involve real exponentials instead of complex ones. All the results in this section are proved under the assumption that the periodic coefficients $a_{i}, \Sigma_{i}, \sigma_{i}$ are positive, bounded, measurable functions, except Proposition 2.2 which asks for more smoothness or piecewise constant coefficients.

Lemma 2.1. For each $\theta \in \mathbb{R}$ there exists a unique first eigencouple $\left(\psi_{i, \theta}, \mu_{i}(\theta)\right)$, of the problem

$$
\left\{\begin{array}{l}
-\frac{d}{d x}\left(a_{i}(x) \frac{d \psi_{i, \theta}}{d x}\right)+\Sigma_{i}(x) \psi_{i, \theta}=\mu_{i}(\theta) \sigma_{i}(x) \psi_{i, \theta} \text { in }[0,1],  \tag{2.1}\\
x \rightarrow \psi_{i, \theta}(x) e^{-\theta x} 1-\text { periodic and positive },
\end{array}\right.
$$

which is normalized by

$$
\begin{equation*}
\psi_{i, \theta}(0)=1 \tag{2.2}
\end{equation*}
$$

The map $\theta \rightarrow \mu_{i}(\theta)$ is strictly concave with a maximum at $\theta=0$, and satisfies the following inequalities

$$
c \theta^{2} \leq \mu_{i}(0)-\mu_{i}(\theta) \leq C \theta^{2}
$$

where $C$ and $c$ are positive constants, independent of $\theta$.

A further property of the first eigenfunction $\psi_{i, \theta}$, is given in the next Proposition. Its proof is quite delicate and relies on purely 1-D arguments (we postpone it to section 7). We give two different proofs: first in the case of $C^{2}$ coefficients, which allows to perform a Liouville transformation and to use classical results on the 1-D Hill equation, second in the case of piecewise constant coefficients, which permits to do explicit computations.

Proposition 2.2. Assuming that the coefficients are $C^{2}$ or piecewise constant, for each $\theta \in \mathbb{R}$ the first eigenvector $\psi_{i, \theta}$ of problem (2.1) with the normalization $\psi_{i, \theta}(0)=1$ satisfies

$$
\lim _{\theta \rightarrow-\infty} \frac{d \psi_{i, \theta}}{d x}(0)=-\infty \text { and } \lim _{\theta \rightarrow+\infty} \frac{d \psi_{i, \theta}}{d x}(0)=+\infty
$$

Proof of Lemma 2.1. By introducing the change of variable

$$
\phi_{i, \theta}(x)=\psi_{i, \theta}(x) e^{-\theta x}
$$

equation (2.1) is equivalent to

$$
\left\{\begin{array}{l}
-\frac{d}{d x}\left(a_{i} \frac{d \phi_{i, \theta}}{d x}\right)-\theta\left(\frac{d}{d x}\left(a_{i} \phi_{i, \theta}\right)+a_{i} \frac{d \phi_{i, \theta}}{d x}\right)+\left(\Sigma_{i}-a_{i} \theta^{2}\right) \phi_{i, \theta}=\mu_{i}(\theta) \sigma_{i} \phi_{i, \theta} \text { in [0, 1], }  \tag{2.3}\\
x \rightarrow \phi_{i, \theta}(x) 1 \text {-periodic and positive, }
\end{array}\right.
$$

with the same normalization condition

$$
\phi_{i, \theta}(0)=1
$$

The existence of a unique first positive eigencouple for problem (2.3) is known, see e.g. [GT83, Theorem 8.38], and we have $\phi_{i, \theta} \in H_{\#}^{1}([0,1]) \cap C^{0, s}([0,1])$, with $s>0$. In particular, this imply that $C>\phi_{i, \theta}(x)>$ $c>0$ in $[0,1]$. It is proved in [Cap98] that the function $\theta \rightarrow \mu_{i}(\theta)$ is smooth, strictly concave on all $\mathbb{R}$, and reaches its maximum at $\theta=0$.
To obtain the growth condition on $\mu_{i}(\theta)$, we perform the following change of unknown

$$
u_{\theta}(x)=\frac{\psi_{i, \theta}(x)}{\psi_{i, 0}(x)}
$$

which is licit by virtue of Proposition 4.1. Then, $u_{\theta}$ is solution of the following problem

$$
\left\{\begin{array}{l}
-\frac{d}{d x}\left(b(x) \frac{d u_{\theta}}{d x}\right)=\mu(\theta) s(x) u_{\theta} \text { in }[0,1]  \tag{2.4}\\
x \rightarrow u_{\theta}(x) e^{-\theta x} 1 \text {-periodic }
\end{array}\right.
$$

with $b(x)=a_{i}(x) \psi_{i, 0}^{2}(x), s(x)=\sigma_{i}(x) \psi_{i, 0}^{2}(x)$, and $\mu(\theta)=\mu_{i}(\theta)-\mu_{i}(0)$. These coefficients are bounded, and we can therefore apply Lemma 2.3.

Lemma 2.3. Let $b$ and $s$ be measurable functions on $[0,1]$, bounded above and below by two positive constant $M>m>0$. For each $\theta \in \mathbb{R}$ the first eigenvalue $\mu(\theta)$ of problem (2.4) satisfies

$$
\frac{m}{M} \theta^{2} \leq-\mu(\theta) \leq \frac{M}{m} \theta^{2}
$$

Proof. We already know that $\mu(\theta)<0$ for all $\theta \neq 0$. We can assume that $\theta>0$ since changing the sign of $\theta$ in (2.4) is equivalent to consider its adjoint equation which has the same first eigenvalue. Because we are working in one space dimension, (2.4) can be written as a system of ordinary differential equations. Namely, denoting by $/$ the $x$-derivation,

$$
Y^{\prime}(x)=A(x) Y(x) \text { and } A=\left[\begin{array}{cc}
0 & b^{-1}  \tag{2.5}\\
-\mu(\theta) s & 0
\end{array}\right] \text { and } Y=\binom{Y_{1}=u_{\theta}}{Y_{2}=b u_{\theta}^{\prime}}
$$

By enforcing the normalization $u_{\theta}(0)=Y_{1}(0)=1$, the Krein-Rutman Theorem implies that $Y_{1}$ is positive, and thus $Y_{2}$ is increasing. Since $Y_{2}(n)=e^{n \theta} Y_{2}(0)$, and $\theta>0$, this implies that $Y_{2}(0)>0$, and thus $Y_{2}(x)>0$ for $x \geq 0$. This in turn gives, by the first equation, that $Y_{1}$ is increasing thus $Y_{1} \geq 1$ for $x \geq 0$. Because $Y_{1}$ and $Y_{2}$ are positive functions on $\mathbb{R}^{+}$, we can write

$$
A^{-} Y \leq Y^{\prime} \leq A^{+} Y \text { with } A^{+}=\left[\begin{array}{cc}
0 & m^{-1} \\
-\mu(\theta) M & 0
\end{array}\right], \text { and } A^{-}=\left[\begin{array}{cc}
0 & M^{-1} \\
-\mu(\theta) m & 0
\end{array}\right]
$$

Since the matrices $A^{+}$and $A^{-}$have constant coefficients, it is straightforward to obtain the solutions of the initial value problems

$$
Z^{\prime}=-\left(A^{-}\right)^{T} Z, Z(0)=Z_{0}, \text { and } X^{\prime}=-\left(A^{+}\right)^{T} X, X(0)=X_{0}
$$

In particular, the choice $Z_{0}=X_{0}=\left(1,(-\mu(\theta) m M)^{-1 / 2}\right)$ leads to the positive solutions

$$
Z(x)=Z_{0} \exp \left(-x \sqrt{\frac{-\mu(\theta) m}{M}}\right) \text { and } X(x)=X_{0} \exp \left(-x \sqrt{\frac{-\mu(\theta) M}{m}}\right)
$$

We can compute that $(Y \cdot Z)^{\prime}=Y^{\prime} \cdot Z+Y \cdot Z^{\prime}=\left(Y^{\prime}-A^{-} Y\right) \cdot Z \geq 0$ since $Z$ is positive. Thus $Y \cdot Z \geq Y(0) \cdot Z(0)$ for all $x \geq 0$, and choosing $x=n \in \mathbb{N}$ leads to

$$
Y(n) \cdot Z(n)=\exp \left(n\left(\theta-\sqrt{\frac{(-\mu(\theta)) m}{M}}\right)\right) Y(0) \cdot Z(0) \geq Y(0) \cdot Z(0)
$$

and therefore $\theta \geq \sqrt{\frac{(-\mu(\theta)) m}{M}}$. Similarly, we have $(Y \cdot X)^{\prime}=\left(Y^{\prime}-A^{+} Y\right) \cdot X \leq 0$ since X is positive, which gives in turn for all $n$,

$$
Y(n) \cdot X(n)=\exp \left(n\left(\theta-\sqrt{\frac{(-\mu(\theta)) M}{m}}\right)\right) Y(0) \cdot X(0) \leq Y(0) \cdot X(0)
$$

and therefore $\theta \leq \sqrt{\frac{(-\mu(\theta)) M}{m}}$.

Remark 2.4. Lemma 2.3 can be generalized to higher space dimensions by using the maximum principle. It is proved in [Cap02] that in general $\theta \rightarrow \mu(\theta)$ is a strictly concave function, i.e., that on any bounded subset $K \subset \mathbb{R}^{N}$ (with $N$ the space dimension) the Hessian matrix $H=\left(\frac{\partial^{2} \mu}{\partial \theta_{i} \partial \theta_{j}}\right)_{1 \leq i, j \leq N}$ is negative definite and $H x \cdot x \leq-C(K) x \cdot x$ with $C(K)>0$. The function $\mu(\theta)$ achieves its maximum in 0 and $\lim _{|\theta| \rightarrow \infty} \mu(\theta)=-\infty$.

## 3 Main results

In the spirit of the method of proof of Theorem 1.1 (see [AM97]), we introduce in (1.1) the change of unknown

$$
u^{\epsilon}(x)=\frac{\phi^{\epsilon}(x)}{\psi\left(x, \frac{x}{\epsilon}\right)},
$$

with a function $\psi(x, y)$ defined by

$$
\begin{equation*}
\psi(x, y)=\chi_{1}(x) \psi_{1}(y)+\chi_{2}(x) \psi_{2}(y), \tag{3.1}
\end{equation*}
$$

where ( $\psi_{1}, \mu_{1}$ ) and ( $\psi_{2}, \mu_{2}$ ) are the first eigencouples in each periodic cell of (1.3). By our normalization condition (1.7), the function $\psi(x, x / \epsilon)$ is continuous at the interface $x=0$. On the contrary, the function $a(x, x / \epsilon)(d \psi(x, x / \epsilon)) /(d x)$ is not necessarily continuous and its jump at the interface is measured by the discontinuity constant $\alpha$ introduced in (1.8).
The first result concerns the special case when the first cell eigenvalues of (1.3) are equal, $\mu_{1}=\mu_{2}$, and the discontinuity constant is non-negative, $\alpha \geq 0$. Under these assumptions, we obtain a generalization of Theorem 1.1.
Theorem 3.1. Let $\lambda_{m}^{\epsilon}$ and $\phi_{m}^{\epsilon}$ be the m-th eigenvalue and normalized eigenvectors of (1.1). Assume that the discontinuity constant defined in (1.8) is non negative $\alpha \geq 0$, and that $\mu_{1}=\mu_{2}$. Then

$$
\phi_{m}^{\epsilon}(x)=u_{m}^{\epsilon}(x) \psi\left(x, \frac{x}{\epsilon}\right) \quad \text { and } \quad \lambda_{m}^{\epsilon}=\mu_{1}+\epsilon^{2} \nu_{m}+o\left(\epsilon^{2}\right),
$$

up to a sub-sequence, $u_{m}^{\epsilon}$ converges weakly in $H_{0}^{1}(\Omega)$ towards $u_{m}$, and $\left(\nu_{m}, u_{m}\right)$ is the m-th eigencouple of the homogenized problem, which, if $\alpha=0$, is

$$
\begin{cases}-\frac{d}{d x}\left(\left(\chi_{1}(x) \overline{D_{1}}+\chi_{2}(x) \overline{D_{2}}\right) \frac{d u}{d x}\right)=\nu\left(\chi_{1}(x) \overline{\sigma_{1}}+\chi_{2}(x) \overline{\sigma_{2}}\right) u & \text { in } \Omega,  \tag{3.2}\\ u=0 & \text { on } \partial \Omega,\end{cases}
$$

and, if $\alpha>0$, is

$$
\begin{cases}-\overline{D_{1}} \frac{d^{2}}{d x^{2}} u=\nu \overline{\sigma_{1}} u & \text { in } \Omega_{1},  \tag{3.3}\\ -\overline{D_{2}} \frac{d^{2}}{d x^{2}} u=\nu \overline{\sigma_{2}} u & \text { in } \Omega_{2}, \\ u=0 & \text { on } \partial \Omega_{1} \cup \partial \Omega_{2} .\end{cases}
$$

In both cases, the homogenized coefficients are defined by formula (1.5) for each half domain.

Figure 3.1: First eigenfunction for problem (1.1) in the case of two well-connected media, i.e., $\alpha=0$.

Figure 3.2: First eigenfunction for problem (1.1) in the case of non well-connected media with a positive discontinuity constant $\alpha>0$.

As an illustration of Theorem 3.1, we present some direct computations of the first eigenfunction $\phi_{1}^{\epsilon}$ of problem (1.1). The case $\mu_{1}=\mu_{2}$ and $\alpha=0$ is shown on Figure 3.1. (The domain is composed of an homogeneous medium on the left and an heterogeneous one on the right). The case $\mu_{1}=\mu_{2}$ and $\alpha>0$ is shown on Figure 3.2 (the domain is composed of two heterogeneous media with the same cell coefficients but with a constant phase shift between the right and the left). The data used for the computation is presented in Remark 3.7.
Remark 3.2. Of course, since the homogenized coefficients are constant in each sub-domain we can compute explicitly the eigenvalues of the homogenized problems in Theorem 3.1.

Remark 3.3. There is a simple sufficient condition for having well-connected media, i.e., $\alpha=0$. If all coefficients satisfy a central symmetry condition, i.e., are symmetric with respect to the center of the unit cell $[0,1]$, then it is easy to check that $\psi_{i}$ satisfies a Neumann boundary condition at $x=0$ and $x=1$, and therefore $\alpha=0$. Actually, Theorem 3.1 was already proved by Malige [Mal96] under this assumption. The symmetry was used for the construction of the example shown in Figure 3.1: in $\Omega_{2}$, the periodic coefficients are piecewise constant on $(0.3,0.7)$ and $(0.1,0.3) \cup(0.7,1.0)$; in $\Omega_{1}, a_{1} \equiv 1, \sigma_{1} \equiv 1$ and $\Sigma_{1}=\mu_{2}$.

Remark 3.4. When $\alpha>0$, the homogenized problem is posed on two disjoint sub-domains $\Omega_{1}$ and $\Omega_{2}$. In other words, there are two decoupled homogenized problems. Therefore, there always exist two nonnegative eigenfunctions with disjoint supports, $u_{1}(x)=\sin \left(-\frac{\pi}{l} x\right) \chi_{1}(x)$ corresponding to the eigenvalue $\nu_{1}=\pi^{2} \frac{\bar{D}_{1}}{\bar{\sigma}_{1} l^{2}}$ and $u_{2}(x)=\sin \left(\frac{\pi}{L} x\right) \chi_{2}(x)$ corresponding to the eigenvalue $\nu_{2}=\pi^{2} \frac{\bar{D}_{2}}{\bar{\sigma}_{2} L^{2}}$. If the first eigenvalues in each sub-domain are distinct, e.g., $L^{2} \overline{\sigma_{2}} \overline{D_{1}}>l^{2} \overline{\sigma_{1}} \overline{D_{2}}$, the first factorized eigenfunction $u_{1}^{\epsilon}$ will tend to $u_{2}$, i.e., will concentrate in the sub-domain that has the smallest first eigenvalue and converge to zero in the other one. In the other case where the first eigenvalues in $\Omega_{1}$ and $\Omega_{2}$ are equal, the first eigen-subspace is of dimension 2 , span by $u_{1}$ and $u_{2}$ and the uniqueness of the limit of $\phi_{1}^{\epsilon}$ is lost (on Figure 3.2 the limit seems to be a linear combination of the first eigenfunctions on each sub-domain).

Our second result completes the case $\mu_{1}=\mu_{2}$ when the discontinuity constant is negative, $\alpha<0$. Under these assumptions, we obtain a localization phenomena.

Theorem 3.5. Let $\left(\lambda_{1}^{\epsilon}, \phi_{1}^{\epsilon}\right)$ be the first normalized eigencouple of (1.1). Assume that $\mu_{1}=\mu_{2}$ and $\alpha<0$. Then, there exists a unique $\lambda_{1}>0$ and a unique positive $\Psi(x) \in H^{1}(\mathbb{R})$ such that
$0 \leq \lambda_{1}^{\epsilon}-\lambda_{1} \leq C \exp \left(-\frac{\tau}{\epsilon}\right)$ and $\left\|\frac{d}{d x} \phi_{1}^{\epsilon}(x)-\frac{1}{\sqrt{\epsilon}} \frac{d}{d x}\left(\Psi\left(\frac{x}{\epsilon}\right)\right)\right\|_{L^{2}(\Omega)}+\left\|\phi_{1}^{\epsilon}(x)-\frac{1}{\sqrt{\epsilon}} \Psi\left(\frac{x}{\epsilon}\right)\right\|_{L^{2}(\Omega)} \leq C \exp \left(-\frac{\tau}{\epsilon}\right)$,
where $C$ and $\tau$ are positive constant, independent of $\epsilon$. The limit eigenvalue satisfies $\lambda_{1}<\mu_{1}=\mu_{2}$, and the limit eigenfunction is defined by

$$
\Psi(x)= \begin{cases}\psi_{1, \theta_{1}}(x) & \text { for } x<0 \\ \psi_{2, \theta_{2}}(x) & \text { for } x>0\end{cases}
$$

with $\theta_{1}>0$ and $\theta_{2}<0$ and $\left(\lambda_{1}, \psi_{i, \theta_{i}}\right)$ is the first eigencouple of the cell problem (2.1), i.e.,

$$
\left\{\begin{array}{l}
-\frac{d}{d x}\left(a_{i}(x) \frac{d \psi_{i, \theta_{i}}}{d x}\right)+\Sigma_{i}(x) \psi_{i, \theta_{i}}=\lambda_{1} \sigma_{i}(x) \psi_{i, \theta_{i}} \text { in }[0,1] \\
x \rightarrow \psi_{i, \theta_{i}}(x) e^{-\theta_{i} x} 1-\text { periodic } .
\end{array}\right.
$$

Remark 3.6. Theorem 3.5 is illustrated by Figure 3.3: the first eigenvector of system (1.1) converges exponentially fast towards a localized eigenfunction near the interface between the two domains. Furthermore, the corresponding eigenvalue is smaller than $\mu_{1}=\mu_{2}$, which is the limit obtained in all the other cases. In contrast with Theorem 3.1, no factorization, or limit homogenized problem appear in the wording of Theorem 3.5. The limit eigenfunction $\Psi$ contains both the periodical oscillations and the macroscopic trend.
Remark 3.7. The computations shown on Figure 3.2 and Figure 3.3 were performed with the same two media, but their positions are switched with respect to the interface when passing from one case to the other. We take $-l=L=1$ with 100 periodicity cells, which yields $\epsilon=0.02$. All the more the periodic cell coefficients for the two media are the same up to a phase shift in the unit cell. More precisely, in Figure 3.2 the coefficients are $a_{1}(y)=a(y), a_{2}(y)=a(y+c), \Sigma_{1}(y)=\Sigma(y), \Sigma_{2}(y)=\Sigma(y+c), \sigma_{1}(y)=\sigma(y)$, $\sigma_{2}(y)=\sigma(y+c)$, while in Figure 3.3 they are $a_{1}(y)=a(y+c), a_{2}(y)=a(y), \Sigma_{1}(y)=\Sigma(y+c)$, $\Sigma_{2}(y)=\Sigma(y), \sigma_{1}(y)=\sigma(y+c), \sigma_{2}(y)=\sigma(y)$, where $c=0.6$ is a constant phase shift, and $a, \Sigma$ and $\sigma$ are periodic functions. Each periodicity cell is made of three different media or constituents arranged in

Figure 3.3: First eigenfunction for problem (1.1) in the case of non well-connected media with a negative discontinuity constant $\alpha<0$.
specified order as follows

$$
(a, \Sigma, \sigma)= \begin{cases}\left(a_{I}, \Sigma_{I}, \sigma_{I}\right) & \text { if } 0<y<0.1 \\ \left(a_{I I}, \Sigma_{I I}, \sigma_{I I}\right) & \text { if } 0.1<y<0.5 \\ \left(a_{I I I}, \Sigma_{I I I}, \sigma_{I I I}\right) & \text { if } 0.5<y<0.8 \\ \left(a_{I}, \Sigma_{I}, \sigma_{I}\right) & \text { if } 0.8<y<1\end{cases}
$$

with

$$
\begin{array}{llll}
\text { Constituent } I & a_{I}=0.9666 & \Sigma_{I}=2.1080 & \sigma_{I}=2.8283 \\
\text { Constituent } I I & a_{I I}=2.0086 & \Sigma_{I I}=2.3878 & \sigma_{I I}=2.9451 \\
\text { Constituent III } & a_{I I I}=2.0444 & \Sigma_{I I I}=2.9945 & \sigma_{I I I}=1.1493
\end{array}
$$

Note that, by construction, $\mu_{1}=\mu_{2} \approx 1.3863$. The shape of the first eigenvector $\phi_{1}^{\epsilon}$ on Figure 3.2 (with eigenvalue $\lambda_{1}^{\epsilon} \approx 1.3899$ ), corresponds to what is announced by Theorem 3.1: asymptotically, both media tend to separate when $\alpha>0$. Therefore, by symmetry Figure 3.3 corresponds to a situation where $\alpha<0$ : the first eigenvector concentrates exponentially at the interface between the two media. The numerical calculation confirms that the corresponding eigenvalue ( $\lambda_{1}^{\epsilon} \approx 1.3720$ ) is below that of the periodicity cell. This phenomenon is explained by Lemma 5.4 which gives a necessary and sufficient condition for the existence of a localized eigensolution.

We now turn to the general case $\mu_{1} \neq \mu_{2}$. In the sequel, we shall assume, without loss of generality, that

$$
\mu_{1}>\mu_{2}
$$

If the discontinuity constant is non-negative, i.e., $\alpha \geq 0$, the eigenfunctions concentrate asymptotically in the sub-domain $\Omega_{2}$ where the first periodic eigenvalue is the smallest.

Theorem 3.8. Let $\lambda_{m}^{\epsilon}$ and $\phi_{m}^{\epsilon}$ be the m-th eigenvalue and normalized eigenfunction of (1.1). Assume that $\alpha \geq 0$ and $\mu_{1}>\mu_{2}$. Then,

$$
\phi_{m}^{\epsilon}(x)=u_{m}^{\epsilon}(x) \psi\left(x, \frac{x}{\epsilon}\right) \quad \text { and } \quad \lambda_{m}^{\epsilon}=\mu_{2}+\epsilon^{2} \nu_{m}+o\left(\epsilon^{2}\right)
$$

Figure 3.4: First eigenfunction of (1.1) in the case of two media with $\mu_{1}>\mu_{2}$ and $\alpha=0$.
where, up to a subsequence, $u_{m}^{\epsilon}$ converges weakly in $H_{0}^{1}(\Omega)$ to $u_{m}$, with $u_{m}=0$ in $\Omega_{1}$ and $\left(\nu_{m}, u_{m}\right)$ is the m-th eigenpair of the following homogenized problem

$$
\begin{cases}-\overline{D_{2}} \frac{d^{2}}{d x^{2}} u_{m}=\nu_{m} \overline{\sigma_{2}} u_{m} & \text { in } \Omega_{2},  \tag{3.4}\\ u_{m}=0 & \text { on } \partial \Omega_{2}\end{cases}
$$

and the homogenized coefficients are still given by (1.5).

Figure 3.4 illustrates Theorem 3.8. It displays the first eigenfunction $\phi_{1}^{\epsilon}$ in the case of two media with symmetric periodic structures (so that $\alpha=0$ ), with $\mu_{1} \simeq 1.58$ and $\mu_{2} \simeq 0.43$ and 20 periodic cells on each side of the interface.

When $\mu_{1}>\mu_{2}$, a localization phenomena can also occur. Let us first remark that, as an obvious consequence of Lemma 2.1, we have the following result.

Lemma 3.9. For all $\mu_{1}>\mu_{2}$ there exists a unique $\theta_{0}>0$ such that $\mu_{1}\left(\theta_{0}\right)=\mu_{2}$.

Indeed, Lemma 3.9 is obvious by remarking that $\mu_{1}(\theta)$, defined in Lemma 2.1, is a concave function with quadratic growth at infinity and reaching its maximum at $\theta=0, \mu_{1}(0)=\mu_{1}>\mu_{2}$. The first eigenvectors corresponding to $\mu_{2}$ and $\mu_{1}\left(\theta_{0}\right)$ are denoted by $\psi_{2}$ and $\psi_{1, \theta_{0}}$. They are continuous at the interface, i.e., $\psi_{2}(0)=\psi_{1, \theta_{0}}(0)=1$, and we introduce a new discontinuity constant that will characterize the localization phenomena

$$
\alpha\left(\theta_{0}\right)=a_{1}(0) \frac{d \psi_{1, \theta_{0}}}{d y}(0)-a_{2}(0) \frac{d \psi_{2}}{d y}(0)
$$

Theorem 3.10. Let $\left(\lambda_{1}^{\epsilon}, \phi_{1}^{\epsilon}\right)$ be the first normalized eigencouple of (1.1). Assume that $\alpha\left(\theta_{0}\right)<0$. Then, there exists a unique $\lambda_{1}>0$ and a unique positive $\Psi \in H^{1}(\mathbb{R})$ such that
$0 \leq \lambda_{1}^{\epsilon}-\lambda_{1} \leq C \exp \left(-\frac{\tau}{\epsilon}\right)$ and $\left\|\frac{d}{d x} \phi_{1}^{\epsilon}(x)-\frac{1}{\sqrt{\epsilon}} \frac{d}{d x}\left(\Psi\left(\frac{x}{\epsilon}\right)\right)\right\|_{L^{2}(\Omega)}+\left\|\phi_{1}^{\epsilon}(x)-\frac{1}{\sqrt{\epsilon}} \Psi\left(\frac{x}{\epsilon}\right)\right\|_{L^{2}(\Omega)} \leq C \exp \left(-\frac{\tau}{\epsilon}\right)$,
where $C$ and $\tau$ are positive constant, independent of $\epsilon$. The limit eigenvalue satisfies $\lambda_{1}<\mu_{2}<\mu_{1}$, and the limit eigenfunction is defined by

$$
\Psi(x)= \begin{cases}\psi_{1, \theta_{1}}(x) & \text { for } x<0 \\ \psi_{2, \theta_{2}}(x) & \text { for } x>0\end{cases}
$$

with $\theta_{1}>0$ and $\theta_{2}<0$ and $\left(\lambda_{1}, \psi_{i, \theta_{i}}\right)$ is the first eigencouple of the cell problem (2.1), i.e.,

$$
\left\{\begin{array}{l}
-\frac{d}{d x}\left(a_{i}(x) \frac{d \psi_{i, \theta_{i}}}{d x}\right)+\Sigma_{i}(x) \psi_{i, \theta_{i}}=\lambda_{1} \sigma_{i}(x) \psi_{i, \theta_{i}} \text { in }[0,1] \\
x \rightarrow \psi_{i, \theta_{i}}(x) e^{-\theta_{i} x} 1-\text { periodic } .
\end{array}\right.
$$

Finally, in the remaining case $\alpha<0$ and $\alpha\left(\theta_{0}\right) \geq 0$, there is no localization, and the eigenfunctions still concentrate asymptotically in the sub-domain $\Omega_{2}$ where the first periodic eigenvalue is the smallest. When $\alpha\left(\theta_{0}\right)>0$, the limit problem has Dirichlet boundary conditions. When $\alpha\left(\theta_{0}\right)=0$, the limit problem has a Neumann boundary condition at the interface.

Theorem 3.11. Let $\lambda_{m}^{\epsilon}$ and $\phi_{m}^{\epsilon}$ be the $m$-th eigenvalue and normalized eigenfunction of (1.1). Assume that $\mu_{1}>\mu_{2}, \alpha<0$ and $\alpha\left(\theta_{0}\right)>0$. Then,

$$
\lambda_{m}^{\epsilon}=\mu_{2}+\epsilon^{2} \nu_{m}+o\left(\epsilon^{2}\right), \quad \phi_{m}^{\epsilon}(x) \rightarrow 0 \text { in } L^{2}\left(\Omega_{1}\right) \quad \text { and } \quad \phi_{m}^{\epsilon}(x)=u_{m}^{\epsilon}(x) \psi_{2}\left(\frac{x}{\epsilon}\right)
$$

where, up to a subsequence, $u_{m}^{\epsilon}$ converges weakly in $H^{1}\left(\Omega_{2}\right)$ to $u_{m}$, and $\left(\nu_{m}, u_{m}\right)$ is the m-th eigenpair of the following homogenized problem

$$
\begin{cases}-\overline{D_{2}} \frac{d^{2}}{d x^{2}} u_{m}=\nu_{m} \overline{\sigma_{2}} u_{m} & \text { in } \Omega_{2},  \tag{3.6}\\ u_{m}=0 & \text { on } \partial \Omega_{2}\end{cases}
$$

and the homogenized coefficients are still given by (1.5).
Theorem 3.12. Let $\lambda_{m}^{\epsilon}$ and $\phi_{m}^{\epsilon}$ be the $m$-th eigenvalue and normalized eigenfunction of (1.1). Assume that $\mu_{1}>\mu_{2}, \alpha<0$ and $\alpha\left(\theta_{0}\right)=0$. Then,

$$
\lambda_{m}^{\epsilon}=\mu_{2}+\epsilon^{2} \nu_{m}+o\left(\epsilon^{2}\right), \quad \phi_{m}^{\epsilon}(x) \rightarrow 0 \text { in } L^{2}\left(\Omega_{1}\right) \quad \text { and } \quad \phi_{m}^{\epsilon}(x)=u_{m}^{\epsilon}(x) \psi_{2}\left(\frac{x}{\epsilon}\right)
$$

where, up to a subsequence, $u_{m}^{\epsilon}$ converges weakly in $H^{1}\left(\Omega_{2}\right)$ to $u_{m}$, and $\left(\nu_{m}, u_{m}\right)$ is the m-th eigenpair of the following homogenized problem

$$
\left\{\begin{array}{l}
-\overline{D_{2}} \frac{d^{2}}{d x^{2}} u_{m}=\nu_{m} \overline{\sigma_{2}} u_{m}, \text { in } \Omega_{2},  \tag{3.7}\\
u_{m}(L)=0, \text { and } \frac{d u_{m}}{d x}(0)=0,
\end{array}\right.
$$

and the homogenized coefficients are still given by (1.5).
Remark 3.13. Note that the homogenized problems of Theorems 3.11 and 3.12 (corresponding to $\alpha\left(\theta_{0}\right)>$ 0 and $\alpha\left(\theta_{0}\right)=0$, respectively) are similar except the boundary condition at $x=0$. Then a simple computation shows that the first homogenized eigenvalue $\nu_{1}$ is four times smaller when $\alpha\left(\theta_{0}\right)=0$ than when $\alpha\left(\theta_{0}\right)>0$.

Remark 3.14. At the difference of Theorem 3.8, we do not prove in Theorems 3.11 and 3.12 that the factorized eigensolutions $u_{m}^{\epsilon}$ have bounded gradients in all of $\Omega$, but simply within $\Omega_{2}$. It is therefore difficult (at least for us) to study the possible occurrence of boundary layers in $\Omega_{1}$. In the limit case of Theorem 3.12, because of the homogenized Neumann boundary condition at $x=0$, we expect a nontrivial boundary layer in $\Omega_{1}$.
Remark 3.15. The generalization of the results of this section to higher space dimensions is not obvious for at least two reasons. First, Theorems 3.5 and 3.10 relies on Proposition 2.2 which is proved only in one dimension (by using o.d.e. techniques). Second, even Theorems 3.1 and 3.8 (which do not depend on Proposition 2.2) are not straightforward in higher dimensions because we can not assume a perfect transmission condition (1.7) at the interface. Of course, if it happens by chance that, for a dimension $N>1$, we have

$$
\begin{equation*}
\psi_{1, \theta_{0}}\left(0, y^{\prime}\right)=\psi_{2}\left(0, y^{\prime}\right) \tag{3.8}
\end{equation*}
$$

for almost every $y^{\prime} \in[0,1]^{N-1}$, and

$$
\begin{equation*}
0 \leq \alpha\left(y^{\prime}\right)=a_{1}\left(0, y^{\prime}\right) \frac{d \psi_{1, \theta_{0}}}{d y}\left(0, y^{\prime}\right)-a_{2}\left(0, y^{\prime}\right) \frac{d \psi_{2}}{d y}\left(0, y^{\prime}\right) \leq M<+\infty \tag{3.9}
\end{equation*}
$$

then Theorems 3.1 and 3.8 extend easily since at the interface the problem is essentially one-dimensional (see [Cap99]). Of course, these conditions are very strict and almost never satisfied in practice. In general, we believe that boundary layers at the interface must be taken into account.
Remark 3.16. Throughout this paper we assume that, after rescaling by $\epsilon$, the periodicity on both sides of the interface is exactly one. The fact that the period is the same in $\Omega_{1}$ and $\Omega_{2}$ is not important, and this is purely by convenience that we made this choice. All our results apply if the two periods are different, provided that the discontinuity constants $\alpha$ and $\alpha\left(\theta_{0}\right)$ are properly defined.

## 4 Proofs in the case $\alpha \geq 0$

In order to prove Theorem 3.1 and 3.8 , we first need to justify the factorization $\phi^{\epsilon}(x)=u^{\epsilon}(x) \psi\left(x, \frac{x}{\epsilon}\right)$. This is the goal of the next Proposition which is a generalization of a previous result of [AM97] (see also [AC00]).

Proposition 4.1. Let $\psi(x, y)$ be the function defined by (3.1). Then, the linear operator $T$ defined by

$$
\begin{aligned}
T: H_{0}^{1}(\Omega) & \rightarrow H_{0}^{1}(\Omega) \\
\phi(x) & \rightarrow \frac{\phi(x)}{\psi\left(x, \frac{x}{\epsilon}\right)}
\end{aligned}
$$

is bounded, invertible and bicontinuous.

Proof. Thanks to the normalization condition (1.7) the function $\psi(x, x / \epsilon)$ is continuous on $\mathbb{R}$. By virtue of Lemma 2.1 we know that there exist two positive constants $C>c>0$ such that $C \geq \psi_{1}(y), \psi_{2}(y) \geq c$ for all $y \in[0,1]$, and these bounds also holds for $\psi$. Therefore, for all $\phi \in H_{0}^{1}(\Omega)$, if we define $u=T(\phi)$, we have

$$
\begin{equation*}
C^{-1}\|\phi\|_{L^{2}(\Omega)} \leq\|u\|_{L^{2}(\Omega)} \leq c^{-1}\|\phi\|_{L^{2}(\Omega)} \tag{4.1}
\end{equation*}
$$

and $T$ is an homeomorphism on $L^{2}(\Omega)$. On the other hand,

$$
\begin{align*}
\int_{\Omega} a \frac{d \phi}{d x} \frac{d \phi}{d x} & =\int_{\Omega_{1}} a_{1} \psi_{1}^{2} \frac{d u}{d x} \frac{d u}{d x}+\int_{\Omega_{2}} a_{2} \psi_{2}^{2} \frac{d u}{d x} \frac{d u}{d x} \\
& +\int_{\Omega_{1}} a_{1} \frac{d \psi_{1}}{d x} \frac{d\left(u^{2} \psi_{1}\right)}{d x}+\int_{\Omega_{2}} a_{2} \frac{d \psi_{2}}{d x} \frac{d\left(u^{2} \psi_{2}\right)}{d x} \tag{4.2}
\end{align*}
$$

Equation (1.3) defining $\psi_{1}(x / \epsilon)$ tested against $u^{2}(x) \psi_{1}(x / \epsilon)$ writes

$$
\begin{equation*}
\int_{\Omega_{1}} a_{1} \frac{d \psi_{1}}{d x} \frac{d\left(u^{2} \psi_{1}\right)}{d x}-\frac{1}{\epsilon} a_{1}(0) \frac{d \psi_{1}}{d y}(0) u^{2}(0)=\frac{1}{\epsilon^{2}}\left(\mu_{1} \int_{\Omega_{1}} \sigma_{1} \psi_{1}^{2} u^{2}-\int_{\Omega_{1}} \Sigma_{1} \psi_{1}^{2} u^{2}\right) \tag{4.3}
\end{equation*}
$$

and similarly we have

$$
\begin{equation*}
\int_{\Omega_{2}} a_{2} \frac{d \psi_{2}}{d x} \frac{d\left(u^{2} \psi_{2}\right)}{d x}+\frac{1}{\epsilon} a_{2}(0) \frac{d \psi_{2}}{d y}(0) u^{2}(0)=\frac{1}{\epsilon^{2}}\left(\mu_{2} \int_{\Omega_{2}} \sigma_{2} \psi_{2}^{2} u^{2}-\int_{\Omega_{2}} \Sigma_{2} \psi_{2}^{2} u^{2}\right) \tag{4.4}
\end{equation*}
$$

When we replace (4.3) and (4.4) into (4.2) we obtain

$$
\begin{align*}
\int_{\Omega} a\left(x, \frac{x}{\epsilon}\right) \frac{d \phi}{d x} \frac{d \phi}{d x} d x+\frac{1}{\epsilon^{2}} \int_{\Omega} \Sigma\left(x, \frac{x}{\epsilon}\right) \phi^{2} d x & =\sum_{i=1}^{2} \int_{\Omega_{i}} a_{i}\left(\frac{x}{\epsilon}\right) \psi_{i}^{2}\left(\frac{x}{\epsilon}\right) \frac{d u}{d x} \frac{d u}{d x} d x \\
& +\frac{1}{\epsilon^{2}} \sum_{i=1}^{2} \int_{\Omega_{i}} \mu_{i} \sigma_{i}\left(\frac{x}{\epsilon}\right) \psi_{i}^{2}\left(\frac{x}{\epsilon}\right) u^{2} d x  \tag{4.5}\\
& +\frac{1}{\epsilon} \alpha u^{2}(0)
\end{align*}
$$

Where $\alpha$ is the discontinuity constant given by (1.8). If $\alpha \geq 0$, all the left hand side terms are nonnegative in (4.5). Since $a_{1}, a_{2}, \psi_{1}$ and $\psi_{2}$ are bounded below by positive constants, we can deduce that

$$
\begin{equation*}
\left\|\frac{d u}{d x}\right\|_{L^{2}(\Omega)}^{2}+\|u\|_{L^{2}(\Omega)}^{2} \leq C(\epsilon)\left(\left\|\frac{d \phi}{d x}\right\|_{L^{2}(\Omega)}^{2}+\|\phi\|_{L^{2}(\Omega)}^{2}\right) \tag{4.6}
\end{equation*}
$$

Conversely, we have

$$
\begin{equation*}
0 \leq \alpha u^{2}(0) \leq C \int_{\Omega}\left(\frac{d u}{d x}\right)^{2} d x \tag{4.7}
\end{equation*}
$$

therefore we also obtain from (4.5) that

$$
\begin{equation*}
\left\|\frac{d \phi}{d x}\right\|_{L^{2}(\Omega)}^{2}+\|\phi\|_{L^{2}(\Omega)}^{2} \leq C(\epsilon)\left(\left\|\frac{d u}{d x}\right\|_{L^{2}(\Omega)}^{2}+\|u\|_{L^{2}(\Omega)}^{2}\right) \tag{4.8}
\end{equation*}
$$

and this concludes the proof of the proposition for $\alpha \geq 0$. If $\alpha \leq 0$, note that thanks to the normalization condition (1.7), $u^{2}(0)=\phi^{2}(0)$. Consequently, identity (4.5) is also

$$
\begin{aligned}
\int_{\Omega} a\left(x, \frac{x}{\epsilon}\right)\left(\frac{d \phi}{d x}\right)^{2} d x+\frac{1}{\epsilon^{2}} \int_{\Omega} \Sigma\left(x, \frac{x}{\epsilon}\right) \phi^{2} d x-\frac{1}{\epsilon} \alpha \phi^{2}(0) & =\sum_{i=1}^{2} \int_{\Omega_{i}} a_{i}\left(\frac{x}{\epsilon}\right) \psi_{i}^{2}\left(\frac{x}{\epsilon}\right)\left(\frac{d u}{d x}\right)^{2} d x \\
& +\frac{1}{\epsilon^{2}} \sum_{i=1}^{2} \int_{\Omega_{i}} \mu_{i} \sigma_{i}\left(\frac{x}{\epsilon}\right) \psi_{i}^{2}\left(\frac{x}{\epsilon}\right) u^{2} d x
\end{aligned}
$$

We therefore obtain the same conclusion, reverting the positions of $u$ and $\phi$ in (4.6-4.8).

If we proceed to the change of unknown $u^{\epsilon}=T\left(\phi^{\epsilon}\right)$, problem (1.1) is transformed into a new eigenvalue problem, where the singular perturbation in front of the divergence term has disappeared. Proposition 4.2 gives the form of this new problem after some simple algebra.
Proposition 4.2. Introducing $u^{\epsilon}(x)=\phi^{\epsilon}(x) / \psi\left(x, \frac{x}{\epsilon}\right)$, (1.1) is equivalent to the following eigenvalue problem

$$
\left\{\begin{array}{l}
-\frac{d}{d x}\left(D\left(x, \frac{x}{\epsilon}\right) \frac{d u^{\epsilon}}{d x}\right)+\frac{\mu_{1}-\mu_{2}}{\epsilon^{2}} \chi_{1}(x) B\left(x, \frac{x}{\epsilon}\right) u^{\epsilon}  \tag{4.9}\\
+\epsilon^{-1} \alpha u^{\epsilon}(0) \delta(x)=\nu^{\epsilon} B\left(x, \frac{x}{\epsilon}\right) u^{\epsilon} \quad \text { in } \Omega \\
u^{\epsilon}=0 \text { on } \partial \Omega
\end{array}\right.
$$

where $\delta(x)$ is the Dirac function, the (positive) diffusion coefficient is defined by

$$
D\left(x, \frac{x}{\epsilon}\right)=\chi_{1}(x) \psi_{1}^{2}\left(\frac{x}{\epsilon}\right) a_{1}\left(\frac{x}{\epsilon}\right)+\chi_{2}(x) \psi_{2}^{2}\left(\frac{x}{\epsilon}\right) a_{2}\left(\frac{x}{\epsilon}\right)
$$

the (positive) coefficient $B$ by

$$
B\left(x, \frac{x}{\epsilon}\right)=\chi_{1}(x) \psi_{1}^{2}\left(\frac{x}{\epsilon}\right) \sigma_{1}\left(\frac{x}{\epsilon}\right)+\chi_{2}(x) \psi_{2}^{2}\left(\frac{x}{\epsilon}\right) \sigma_{2}\left(\frac{x}{\epsilon}\right)
$$

and the new eigenvalue by

$$
\nu^{\epsilon}=\frac{\lambda^{\epsilon}-\mu_{2}}{\epsilon^{2}}
$$

Remark 4.3. We proved Proposition 4.1 regardless of the sign of $\alpha$, therefore Proposition 4.2 is also valid when $\alpha<0$. We shall use this equivalent form of (1.1) in Section 6.

Following a strategy already used in [AC00], [AC98], the asymptotic study of the eigenvalue problem (4.9) relies on the detailed homogenization, as $\epsilon$ tend to zero, of the following problem

$$
\left\{\begin{array}{ll}
-\frac{d}{d x}\left(D\left(x, \frac{x}{\epsilon}\right) \frac{d u^{\epsilon}}{d x}\right)+\frac{\mu_{1}-\mu_{2}}{\epsilon^{2}} \chi_{1}(x) B\left(x, \frac{x}{\epsilon}\right) u^{\epsilon}  \tag{4.10}\\
& +\epsilon^{-1} \alpha u^{\epsilon}(0) \delta(x)=f_{\epsilon}
\end{array} \quad \text { in } \Omega\right.
$$

with a right hand side $f_{\epsilon}$ which is a bounded sequence of $L^{2}(\Omega)$, weakly converging to a limit $f \in L^{2}(\Omega)$. We first obtain a priori estimates
Proposition 4.4. If $\alpha \geq 0$, the solution $u^{\epsilon}$ of equation (4.10) satisfies

$$
\begin{equation*}
\left\|u^{\epsilon}\right\|_{H_{0}^{1}(\Omega)}+\frac{\mu_{1}-\mu_{2}}{\epsilon}\left\|u^{\epsilon}\right\|_{L^{2}\left(\Omega_{1}\right)}+\sqrt{\frac{\alpha}{\epsilon}}\left\|u^{\epsilon}(0)\right\| \leq C\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)} \tag{4.11}
\end{equation*}
$$

where $C$ is a constant independent of $\epsilon$. Therefore, up to a subsequence, $u^{\epsilon}$ converges weakly to a limit $u$ in $H_{0}^{1}(\Omega)$. Furthermore,

- if $\mu_{1}>\mu_{2}$, the limit $u$ vanishes in $\Omega_{1}$ and thus belongs to $H_{0}^{1}\left(\Omega_{2}\right)$,
- if $\mu_{1}=\mu_{2}$ and $\alpha>0$, the limit satisfies $u(0)=0$ and thus can be written $u=u_{1}+u_{2}$ with $u_{1} \in H_{0}^{1}\left(\Omega_{1}\right)$ and $u_{2} \in H_{0}^{1}\left(\Omega_{2}\right)$.

Proof. If we test variationally equation (4.10) defining $u^{\epsilon}$ against $u^{\epsilon}$, we obtain

$$
\int_{\Omega} D\left(x, \frac{x}{\epsilon}\right)\left(\frac{d u^{\epsilon}}{d x}\right)^{2} d x+\frac{\mu_{1}-\mu_{2}}{\epsilon^{2}} \int_{\Omega_{1}} B\left(x, \frac{x}{\epsilon}\right)\left(u^{\epsilon}\right)^{2} d x+\frac{1}{\epsilon} \alpha\left(u^{\epsilon}\right)^{2}(0)=\int_{\Omega} f_{\epsilon} u^{\epsilon} d x
$$

Since $D$ and $B$ are bounded below by a positive constant, and since we assume that $\mu_{1} \geq \mu_{2}$ and $\alpha \geq 0$, we obtain

$$
\left\|\frac{d u^{\epsilon}}{d x}\right\|_{L^{2}(\Omega)}^{2}+\frac{\mu_{1}-\mu_{2}}{\epsilon^{2}}\left\|u^{\epsilon}\right\|_{L^{2}\left(\Omega_{1}\right)}^{2}+\frac{\alpha}{\epsilon}\left\|u^{\epsilon}(0)\right\|^{2} \leq C\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}\left\|u^{\epsilon}\right\|_{L^{2}(\Omega)}
$$

which yields the desired result thanks to Poincaré inequality.
Lemma 4.5. Let $S_{\epsilon}$ be the operator defined by

$$
\begin{align*}
S_{\epsilon}: L^{2}(\Omega) & \rightarrow L^{2}(\Omega) \\
f & \rightarrow u^{\epsilon} \text { unique solution in } H_{0}^{1}(\Omega)  \tag{4.12}\\
& \text { of equation (4.10) with r.h.s. } f .
\end{align*}
$$

For all fixed $\epsilon>0, S_{\epsilon}$ is a linear compact operator in $L^{2}(\Omega)$.
This result is a consequence of the a priori estimate (4.11) and of the compact inclusion of $H_{0}^{1}(\Omega)$ in $L^{2}(\Omega)$. We shall show the following result

Proposition 4.6. Let $f_{\epsilon}$ be a weakly converging sequence to a limit fin $L^{2}(\Omega)$. The sequence $u^{\epsilon}=S_{\epsilon}\left(f_{\epsilon}\right)$ weakly converges in $H_{0}^{1}(\Omega)$ towards $u^{0}$ defined by $u^{0}=S(f)$.

1. If $\alpha=0$ and $\mu_{1}=\mu_{2}$ then $S$ is the following compact operator

$$
\begin{aligned}
S: \quad L^{2}(\Omega) & \rightarrow L^{2}(\Omega) \\
f & \rightarrow u \text { unique solution of } \\
& \begin{cases}-\frac{d}{d x}\left(\left(\chi_{1}(x) \overline{D_{1}}+\chi_{2}(x) \overline{D_{2}}\right) \frac{d}{d x} u(x)\right)=f \text { in } \Omega \\
u=0 & \text { on } \\
\partial \Omega\end{cases}
\end{aligned}
$$

where $\overline{D_{1}}$ and $\bar{D}_{2}$ are given by (1.5).
2. If $\alpha \geq 0$ and $\mu_{1}>\mu_{2}$ then $S$ is the following compact operator

$$
\begin{aligned}
S: \quad L^{2}(\Omega) & \rightarrow L^{2}(\Omega) \\
f & \rightarrow u \text { unique solution of } \\
& \begin{cases}-\overline{D_{2}} \frac{d^{2}}{d x^{2}} u(x)=f \text { in } \Omega_{2} \\
u=0 & \text { on } \bar{\Omega} \backslash \Omega_{2}\end{cases}
\end{aligned}
$$

3. If $\alpha>0$ and $\mu_{1}=\mu_{2}$ then $S$ is the following compact operator

$$
\begin{aligned}
S: \quad L^{2}(\Omega) & \rightarrow L^{2}(\Omega) \\
f & \rightarrow u \text { unique solution of } \\
& \left\{\begin{array}{l}
-\overline{D_{1}} \frac{d^{2}}{d x^{2}} u(x)=f \text { in } \Omega_{1} \\
-\overline{D_{2}} \frac{d^{2}}{d x^{2}} u(x)=f \text { in } \Omega_{2} \\
u=0 \quad \text { on } \quad \partial \Omega_{2} \cup \partial \Omega_{2}
\end{array}\right.
\end{aligned}
$$

Proof. The proof is quite standard in homogenization theory. For example, using the notion of two-scale convergence (see [All92], [Ngu89]) it is an easy exercise that we safely leave to the reader (the details can be found in [Cap99] if necessary). Let us simply remark that, if $\mu_{1}=\mu_{2}$ and $\alpha=0$, then the homogenization of (4.10) is completely obvious. If $\mu_{1}=\mu_{2}$ and $\alpha>0$, then the a priori estimates of Proposition 4.4 shows that $u^{\epsilon}(0)$ goes to zero, while, if $\mu_{1}>\mu_{2}$ and $\alpha \geq 0$, they imply that $u^{\epsilon}$ goes to zero in $\Omega_{1}$.

We are now able to conclude the proof of Theorem 3.1 and Theorem 3.8.

Proof of Theorem 3.1 and Theorem 3.8. Let us first remark that Proposition 4.6 imply that the sequence of operators $S_{\epsilon}$, defined by (4.12), uniformly converges to the limit operator $S$. The asymptotic analysis of the eigenvalue problem (4.9) is truly given by that of $T_{\epsilon}$ given by

$$
\begin{array}{ll}
T_{\epsilon}: L^{2}(\Omega) & \rightarrow L^{2}(\Omega) \\
f & \rightarrow S_{\epsilon}\left(B\left(x, \frac{x}{\epsilon}\right) f\right)
\end{array}
$$

The eigenvalues of $T_{\epsilon}$ being the inverse of that of (4.9). Introducing $\bar{\sigma}(x)=\int_{0}^{1} B(x, y) d y$ which is the weak limit of $B\left(x, \frac{x}{\epsilon}\right)$, we define the limit operator $T$ by

$$
\begin{array}{ll}
T: L^{2}(\Omega) & \rightarrow L^{2}(\Omega) \\
f & \rightarrow S(\bar{\sigma} f)
\end{array}
$$

The sequence $T_{\epsilon}$ does not uniformly converge to $T$, but the sequence $T_{\epsilon}$ is nevertheless sequentially compact, in the sense that

$$
\left\{\begin{array}{l}
\forall f \in L^{2}(\Omega) \quad \lim _{\epsilon \rightarrow 0}\left\|T_{\epsilon}(f)-T(f)\right\|_{L^{2}(\Omega)}=0 \\
\text { the set }\left\{T_{\epsilon}(f),\|f\|_{L^{2}(\Omega)} \leq 1, \epsilon \geq 0\right\} \text { is sequentially compact. }
\end{array}\right.
$$

Theorems 3.1 and 3.8 are then consequences of Theorem 4.7 (see also chapter 11 in [JKO95]).
Theorem 4.7. (see e.g. [Ans71], [Cha83]) Let $T_{n}$ be a sequence of compact operators that converges to $T$. Assume that $\left(T_{n}\right)_{n \geq 1}$ is collectively compact and $T$ is compact. Let $\mu \in \mathbb{C}$ be an eigenvalue of $T$, of multiplicity $m$. Let $\Gamma$ be a smooth curve enclosing $\mu$ in the complex plane and leaving outside the rest of the spectrum of $T$. Then, for sufficiently large values of $n, \Gamma$ encloses also exactly $m$ eigenvalues of $T_{n}$ and leaves outside the rest of the spectrum of $T_{n}$.

## 5 Proofs in the case $\alpha\left(\theta_{0}\right)<0$.

The goal of this section is to prove Theorems 3.5 and 3.10. To understand the asymptotic behavior of problem (1.1) when the discontinuity constant $\alpha\left(\theta_{0}\right)$ is negative, we first rescale the equations by introducing the change of variables $y=\frac{x}{\epsilon}$. Then, problem (1.1) is equivalent to

$$
\left\{\begin{array}{l}
-\frac{d}{d y}\left(a(y) \frac{d \varphi^{\epsilon}}{d y}\right)+\Sigma(y) \varphi^{\epsilon}=\lambda^{\epsilon} \sigma(y) \varphi^{\epsilon} \text { in } \Omega_{\epsilon}  \tag{5.1}\\
\varphi^{\epsilon}\left(-\epsilon^{-1} l\right)=\varphi^{\epsilon}\left(\epsilon^{-1} L\right)=0
\end{array}\right.
$$

with $\left.\Omega_{\epsilon}=\right]-\epsilon^{-1} l, \epsilon^{-1} L\left[, \varphi^{\epsilon}(y)=\phi^{\epsilon}\left(\frac{x}{\epsilon}\right)\right.$, and

$$
a(y)(\operatorname{resp} . \Sigma(y), \sigma(y))= \begin{cases}a_{1}(y)\left(\operatorname{resp} . \Sigma_{1}(y), \sigma_{1}(y)\right) & \text { if } y<0 \\ a_{2}(y)\left(\operatorname{resp} . \Sigma_{2}(y), \sigma_{2}(y)\right) & \text { if } y>0\end{cases}
$$

As $\epsilon$ goes to 0 , the domain $\Omega_{\epsilon}$ converges to $\mathbb{R}$, and formally the limit problem of (5.1) is

$$
\left\{\begin{array}{l}
-\frac{d}{d x}\left(a(x) \frac{d \Psi}{d x}\right)+\Sigma(x) \Psi=\lambda \sigma(x) \Psi \text { in } \mathbb{R}  \tag{5.2}\\
\Psi \in H^{1}(\mathbb{R})
\end{array}\right.
$$

We first recall some properties of the spectrum of (5.2). We introduce the Green operator $S$ acting in $L^{2}(\mathbb{R})$ defined by

$$
\begin{align*}
S: L^{2}(\mathbb{R}) & \rightarrow L^{2}(\mathbb{R}) \\
f \rightarrow & u \text { unique solution in } H^{1}(\mathbb{R}) \text { of }  \tag{5.3}\\
& -\frac{d}{d x}\left(a(x) \frac{d u}{d x}\right)+\Sigma(x) u=\sigma(x) f \text { in } \mathbb{R}
\end{align*}
$$

The eigenvalues of $S$ are precisely the inverse of those of (5.2). Nevertheless, to simplify the discussion we shall say that $\lambda$ is an eigenvalue of $S$, or (5.2), if its inverse belongs to the spectrum of $S$.

Proposition 5.1. The operator $S$ is self-adjoint and non-compact. Its spectrum can be decomposed in its discrete and essential part, $\sigma(S)=\sigma_{\text {disc }}(S) \cup \sigma_{\text {ess }}(S)$. The lower bound of the essential spectrum is equal to the smallest cell first eigenvalue in (1.3), namely

$$
\min \sigma_{e s s}(S)=\min \left(\mu_{1}, \mu_{2}\right)
$$

If $(\lambda, \Psi)$ is an eigencouple in the discrete spectrum, then there exist $\theta_{1}>0$ and $\theta_{2}<0$ such that

$$
\Psi(x)= \begin{cases}\psi_{1}(x) & \text { if } x<0 \\ \psi_{2}(x) & \text { if } x>0\end{cases}
$$

and $\left(\lambda, \psi_{i}\right)$ is an eigencouple of

$$
\left\{\begin{array}{l}
-\frac{d}{d x}\left(a_{i}(x) \frac{d \psi_{i}}{d x}\right)+\Sigma_{i}(x) \psi_{i}=\lambda \sigma_{i}(x) \psi_{i} \text { in }[0,1]  \tag{5.4}\\
x \rightarrow \psi_{i}(x) e^{-\theta_{i} x} 1-\text { periodic. }
\end{array}\right.
$$

Remark 5.2. By definition, the discrete spectrum of $S$ is composed of isolated eigenvalues of finite multiplicity, while its essential spectrum is characterized by Weyl criterion, i.e., $\forall \lambda \in \sigma_{e s s}(S)$ there exists a sequence $\left\{u_{n}\right\} \in L^{2}(\mathbb{R})$ such that

$$
\left\{\begin{array}{l}
\left\|u_{n}\right\|_{L^{2}(\mathbb{R})}=1, u_{n} \rightarrow 0 \text { in } L^{2}(\mathbb{R}) \text { weakly } \\
(S-\lambda I d) u_{n} \rightarrow 0 \text { in } L^{2}(\mathbb{R}) \text { strongly. }
\end{array}\right.
$$

Proposition 5.1 tells us in particular that $\sigma_{\text {ess }}(S)$ is not empty and that any discrete eigenvector decays exponentially at infinity. Remark that equation (5.4) is similar to (2.1).

Proof. The study of the spectrum of $S$ is classical. The exponential decay of the discrete eigenfunctions is obtained through Floquet Theory (see, e.g., [MR73], [RS78]). The same tool yields the lower bound of the essential spectrum (see [AC98], [CPV95]). Note that these results are obtained under the mere assumption that the coefficients of equation (5.3) are positive measurable functions (no smoothness is required).

In order to pass to the limit $\epsilon \rightarrow 0$ in (5.1), we also introduce an operator $S_{\epsilon}$ acting in $L^{2}(\mathbb{R})$ defined by

$$
\begin{align*}
S_{\epsilon}: L^{2}(\mathbb{R}) & \rightarrow L^{2}(\mathbb{R}) \\
f & \rightarrow u^{\epsilon} \text { unique solution in } H_{0}^{1}\left(\Omega_{\epsilon}\right) \text { of } \\
& \left\{\begin{array}{l}
-\frac{d}{d x}\left(a(x) \frac{d u^{\epsilon}}{d x}\right)+\Sigma(x) u^{\epsilon}=\sigma(x) f, \text { in } \Omega_{\epsilon} \\
u^{\epsilon}(x)=0 \text { on } \partial \Omega_{\epsilon} .
\end{array}\right. \tag{5.5}
\end{align*}
$$

The operator $S_{\epsilon}$ is compact and its eigenvalues are the inverses of that of (5.1). Unfortunately, the convergence of the sequence $S_{\epsilon}$ to $S$ is not uniform, so that the limit of the spectrum of $S_{\epsilon}$ is not the spectrum of $S$. Nevertheless, this limit can be characterized explicitly and we recall the following result that may be found in [AC98].

Proposition 5.3. For all $f \in L^{2}(\mathbb{R}), S_{\epsilon}(f)$ converges strongly to $S(f)$ in $L^{2}(\mathbb{R})$, and we have

$$
\lim _{\epsilon \rightarrow 0} \sigma\left(S_{\epsilon}\right)=\sigma(S) \cup \sigma_{B L}
$$

Furthermore, the first eigenvalue $\lambda_{1}^{\epsilon}$ converges to a limit $\lambda_{1}$ which does belong to the spectrum of $S$ and is thus the smallest element of $\sigma(S)$. We also have

$$
\begin{equation*}
\min \sigma_{B L}=\min \sigma_{e s s}(S)=\min \left(\mu_{1}, \mu_{2}\right) \tag{5.6}
\end{equation*}
$$

That part of the limit spectrum, denoted by $\sigma_{B L}$, is called the boundary layer spectrum. It can be characterized completely in terms of an equation similar to (5.2) but in the half-line (for details, see [AC98]). We do not dwell on this boundary layer spectrum since we only need to know (5.6) in the sequel.

Lemma 5.4. Let $\theta_{0}$ be defined as in Lemma 3.9, i.e., $\mu_{1}\left(\theta_{0}\right)=\mu_{2}$, and $\psi_{1, \theta_{0}}$ the corresponding eigenvector defined by (2.1). Let $\alpha\left(\theta_{0}\right)$ be defined by

$$
\alpha\left(\theta_{0}\right)=a_{1}(0) \frac{d \psi_{1, \theta_{0}}}{d y}(0)-a_{2}(0) \frac{d \psi_{2}}{d y}(0)
$$

If and only if

$$
\begin{equation*}
\alpha\left(\theta_{0}\right)<0 \tag{5.7}
\end{equation*}
$$

the limit $\lambda_{1}$ of the first eigenvalue $\lambda_{1}^{\epsilon}$ of problem (1.1) satisfies

$$
\lambda_{1}<\min \left(\mu_{1}, \mu_{2}\right)
$$

Remark 5.5. In particular, this Lemma applies when $\mu_{1}=\mu_{2}$, and $\alpha \equiv \alpha\left(\theta_{0}\right)<0$. It implies that, when the discontinuity constant is negative, the limit first eigenvalue cannot be predicted by the homogenized models obtained under strict periodicity assumption on each side of the interface. The proof of Lemma 5.4 relies on Proposition 2.2, that we have not been able to prove in the general case, but under the additional assumption that the coefficients are $C^{2}$, or piecewise constant.

Proof of Lemma 5.4. For all $\theta \in\left[\theta_{0},+\infty\left[\right.\right.$, where $\theta_{0}$ is defined in Lemma 3.9, because of the concavity of $\mu_{1}(\theta)$ and $\mu_{2}(\theta)$, we can associate to each $\theta$ a unique $\theta^{\prime} \leq 0$ such that $\mu_{1}(\theta)=\mu_{2}\left(\theta^{\prime}\right)$ and $\psi_{2, \theta^{\prime}}$ is the first eigenvector defined by

$$
\left\{\begin{array}{l}
-\frac{d}{d x}\left(a_{2}(x) \frac{d \psi_{2, \theta^{\prime}}}{d x}\right)+\Sigma_{2}(x) \psi_{2, \theta^{\prime}}=\mu_{2}\left(\theta^{\prime}\right) \sigma_{2}(x) \psi_{2, \theta^{\prime}} \text { in }[0,1]  \tag{5.8}\\
x \rightarrow \psi_{2, \theta}(x) e^{-\theta^{\prime} x} 1-\text { periodic } \\
\psi_{2, \theta^{\prime}}(0)=1
\end{array}\right.
$$

Note that for $\theta=\theta_{0}$, we have $\theta^{\prime}=0$. The pair $(\lambda, \Psi)$ defined by

$$
\begin{aligned}
& \lambda=\mu_{1}(\theta)=\mu_{2}\left(\theta^{\prime}\right) \\
& \Psi=\psi_{1, \theta} \text { for } x>0 \\
& \Psi=\psi_{2, \theta}, \text { for } x<0
\end{aligned}
$$

is an eigencouple for problem (5.2) if and only if

$$
\begin{equation*}
\alpha(\theta)=a_{1}(0) \frac{d \psi_{1, \theta}}{d x}(0)-a_{2}(0) \frac{d \psi_{2, \theta^{\prime}}}{d x}(0)=0 \tag{5.9}
\end{equation*}
$$

Thanks to Proposition 2.2, we have

$$
\lim _{\theta \rightarrow+\infty} \alpha(\theta)=\lim _{\theta \rightarrow+\infty} a_{1}(0) \frac{d \psi_{1, \theta}}{d x}(0)-\lim _{\theta^{\prime} \rightarrow-\infty} a_{2}(0) \frac{d \psi_{2, \theta^{\prime}}}{d x}(0)=+\infty
$$

Therefore, if we assume $\alpha\left(\theta_{0}\right)<0$ then Equation (5.9) admits a solution, for some $\theta<\theta_{0}$, and $\theta^{\prime}>0$. We have thus obtained a value of $\theta$ such that $\lambda<\min \left(\mu_{1}, \mu_{2}\right)$. Finally, since $\lambda_{1} \leq \lambda$, by virtue of Proposition 5.1, we have $\lambda_{1} \in \sigma_{d i s c}(S)$.
Conversely, if $\lambda_{1}<\min \left(\mu_{1}, \mu_{2}\right)$ we know from Proposition 5.6 that on both sides of the origin the corresponding eigenfunction $\Psi$ has an exponential decay. Then Proposition 5.1 show that it must of the form $\Psi=c \psi_{1, \theta}$ and $\Psi=c \psi_{2, \theta \prime}$ for some $\theta$ and $\theta^{\prime}$ on each half line. Since identity (5.9) is a necessary and sufficient condition for the existence of such a $\Psi$, the proof is complete.

Proof of Theorems 3.5 and 3.10. Thanks to Lemma 5.4 and Proposition 5.1, if condition (5.7) is satisfied then $\lambda_{1}$ is in the discrete spectrum of problem (5.2). Theorems 3.5 and 3.10 are then a consequence of Proposition 5.6. Indeed the eigenfunction $\phi_{1}^{\epsilon}(x)$ in Theorems 3.5 and 3.10 is equal to $\frac{1}{\sqrt{\epsilon}} \varphi_{1}^{\epsilon}\left(\frac{x}{\epsilon}\right)$ where $\varphi_{1}^{\epsilon}$ is the first eigenfunction in Proposition 5.6. Inequality (5.10) then becomes

$$
\epsilon^{2}\left\|\frac{d}{d x} \phi_{1}^{\epsilon}(x)-\frac{1}{\sqrt{\epsilon}} \frac{d}{d x}\left(\Psi\left(\frac{x}{\epsilon}\right)\right)\right\|_{L^{2}(\Omega)}+\left\|\phi_{1}^{\epsilon}(x)-\frac{1}{\sqrt{\epsilon}} \Psi\left(\frac{x}{\epsilon}\right)\right\|_{L^{2}(\Omega)} \leq C \exp \left(-\frac{\tau}{\epsilon}\right)
$$

which in turn imply

$$
\left\|\frac{d}{d x} \phi_{1}^{\epsilon}(x)-\frac{1}{\sqrt{\epsilon}} \frac{d}{d x}\left(\Psi\left(\frac{x}{\epsilon}\right)\right)\right\|_{L^{2}(\Omega)}+\left\|\phi_{1}^{\epsilon}(x)-\frac{1}{\sqrt{\epsilon}} \Psi\left(\frac{x}{\epsilon}\right)\right\|_{L^{2}(\Omega)} \leq C^{\prime} \exp \left(-\frac{\tau^{\prime}}{\epsilon}\right)
$$

for any $\tau^{\prime}<\tau$.
Proposition 5.6. Assume that problem (5.2), or equivalently operator $S$, admits a first positive normalized eigencouple $\left(\lambda_{1}, \Psi\right)$ such that $\lambda_{1}<\min \left(\mu_{1}, \mu_{2}\right)$. Then the first positive normalized eigencouple $\left(\lambda_{1}^{\epsilon}, \varphi_{1}^{\epsilon}\right)$ of (5.1), or of $S_{\epsilon}$, satisfies

$$
\begin{equation*}
0 \leq \lambda_{1}^{\epsilon}-\lambda_{1} \leq C \exp \left(-\frac{\tau}{\epsilon}\right) \text { and }\left\|\frac{d}{d x} \varphi_{1}^{\epsilon}-\frac{d}{d x} \Psi\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}+\left\|\varphi_{1}^{\epsilon}-\Psi\right\|_{L^{2}\left(\Omega_{\epsilon}\right)} \leq C \exp \left(-\frac{\tau}{\epsilon}\right) \tag{5.10}
\end{equation*}
$$

where $C$ and $\tau$ are strictly positive constant independent of $\epsilon$.
Proof. Since we assumed $\lambda_{1}<\min \sigma_{\text {ess }}(S)$, we have

$$
\lambda_{1}=\min _{\substack{\varphi \in H^{1}(\mathbb{R}) \\ \phi \neq 0}} \frac{\int_{\mathbb{R}} a(x)\left|\frac{d}{d x} \varphi\right|^{2} d x+\int_{\mathbb{R}} \Sigma(x) \phi^{2} d x}{\int_{\mathbb{R}} \sigma(x) \varphi^{2} d x},
$$

and this minimum is attained for $\varphi=\Psi$ which belongs to the discrete spectrum of $S$. We also have

$$
\lambda_{1}^{\epsilon}=\min _{\substack{\varphi \in H_{0}^{1}\left(\Omega_{\epsilon}\right) \\ \phi \neq 0}} \frac{\int_{\Omega_{\epsilon}} a(x)\left|\frac{d}{d x} \varphi\right|^{2} d x+\int_{\Omega_{\epsilon}} \Sigma(x) \varphi^{2} d x}{\int_{\Omega_{\epsilon}} \sigma(x) \varphi^{2} d x},
$$

and this implies, by inclusion of spaces that $\lambda_{1} \leq \lambda_{1}^{\epsilon}$. Let $\chi$ be a smooth cut-off function, vanishing outside $\left.\Omega_{\epsilon}=\right]-\frac{l}{\epsilon}, \frac{L}{\epsilon}[$, equal to 1 on $]-\frac{l}{\epsilon}+1, \frac{L}{\epsilon}-1\left[\right.$, such that $0 \leq \chi \leq 1$, and $\frac{d \chi}{d x}$ does not depend on $\epsilon$ (see Figure 5.1). We then have $\chi \Psi \in H_{0}^{1}\left(\Omega_{\epsilon}\right)$, and

$$
\begin{equation*}
\lambda_{1}^{\epsilon} \leq \frac{\int_{\Omega_{\epsilon}} a(x)\left|\frac{d}{d x}(\chi \Psi)\right|^{2} d x+\int_{\Omega_{\epsilon}} \Sigma(x)(\chi \Psi)^{2} d x}{\int_{\Omega_{\epsilon}} \sigma(x)(\chi \Psi)^{2} d x} \tag{5.11}
\end{equation*}
$$

Figure 5.1: Cut-off function $\chi$.

By construction $\frac{d \chi}{d x}$ has its support in $\left[-\frac{l}{\epsilon},-\frac{l}{\epsilon}+1\right] \cup\left[\frac{L}{\epsilon}-1, \frac{L}{\epsilon}\right]$ and inequality (5.11) becomes

$$
\begin{equation*}
\lambda_{1}^{\epsilon} \leq \frac{\int_{\mathbb{R}} a(x)\left|\frac{d}{d x} \Psi\right|^{2} d x+\int_{\mathbb{R}} \Sigma(x) \Psi^{2} d x+R_{1}^{\epsilon}}{\left(1-R_{2}^{\epsilon}\right) \int_{\mathbb{R}} \sigma(x) \Psi^{2} d x} \tag{5.12}
\end{equation*}
$$

with

$$
R_{1}^{\epsilon}=2 \int_{\left[-\frac{l}{\epsilon},-\frac{l}{\epsilon}+1\right] \cup\left[\frac{L}{\epsilon}-1, \frac{L}{\epsilon}\right]} a(x)|\Psi(x)|\left|\frac{d}{d x} \chi\right|\left(\left|\chi \frac{d}{d x} \Psi\right|+\left|\Psi \frac{d}{d x} \chi\right|\right) d x
$$

and

$$
R_{2}^{\epsilon}=\frac{\int_{-\infty}^{-\frac{l}{\epsilon}+1} \sigma(x) \Psi(x)^{2}+\int_{\frac{L}{\epsilon}-1}^{+\infty} \sigma(x) \Psi(x)^{2}}{\int_{\mathbb{R}} \sigma(x) \Psi(x)^{2}}
$$

Thanks to Proposition 5.1, we know that

$$
\sup _{x \in\left(-\infty,-\frac{l}{\epsilon}\right)}|\Psi(x)| \leq C \exp \left(-\theta_{1} \frac{l}{\epsilon}\right), \text { and } \sup _{x \in\left(\frac{L}{\epsilon},+\infty\right)}|\Psi(x)| \leq C \exp \left(\theta_{2} \frac{L}{\epsilon}\right)
$$

with $\theta_{1}>0$ and $\theta_{2}<0$. We can deduce that $R_{1}^{\epsilon} \leq C \exp \left(-\frac{\tau}{\epsilon}\right)$ and $R_{2}^{\epsilon} \leq C \exp \left(-\frac{\tau}{\epsilon}\right)$ with $\tau=$ $\min \left(l\left|\theta_{1}\right|, L\left|\theta_{2}\right|\right)$, and inserting these inequalities in (5.12) we obtain

$$
\begin{equation*}
\lambda_{1}^{\epsilon} \leq \lambda_{1}\left(1+C \exp \left(-\frac{\tau}{\epsilon}\right)\right) \tag{5.13}
\end{equation*}
$$

Let us now show that $\varphi_{1}^{\epsilon}$ converges to $\Psi$. In order to obtain an approximation of $\Psi$ that vanishes on the boundaries of the domain $\Omega_{\epsilon}$, we add to $\Psi$ an affine function which compensates its values at both ends of the domain. We define $\Psi^{\epsilon}(x)=\Psi(x)+\ell^{\epsilon}(x)$ where $\ell^{\epsilon}$ is the affine function such that

$$
\Psi\left(-\frac{l}{\epsilon}\right)+\ell^{\epsilon}\left(-\frac{l}{\epsilon}\right)=0 \text { and } \Psi\left(\frac{L}{\epsilon}\right)+\ell^{\epsilon}\left(\frac{L}{\epsilon}\right)=0 .
$$

By construction, $\Psi^{\epsilon} \in H_{0}^{1}\left(\Omega_{\epsilon}\right)$, and $\Psi^{\epsilon}$ is solution of the same problem than $\varphi_{1}^{\epsilon}$ up to a perturbation $r^{\epsilon}$.

$$
\left\{\begin{array}{l}
\left.-\frac{d}{d x}\left(a(x) \frac{d \Psi^{\epsilon}}{d x}\right)+\Sigma(x) \Psi^{\epsilon}=\lambda_{1}^{\epsilon} \sigma(x) \Psi^{\epsilon}+r^{\epsilon} \text { in }\right]-\frac{l}{\epsilon}, \frac{L}{\epsilon}[  \tag{5.14}\\
\Psi^{\epsilon}\left(-\frac{l}{\epsilon}\right)=\Psi^{\epsilon}\left(\frac{L}{\epsilon}\right)=0
\end{array}\right.
$$

The perturbation is $r^{\epsilon}=\left(\lambda_{1}-\lambda_{1}^{\epsilon}\right) \sigma \Psi^{\epsilon}+\Sigma \ell^{\epsilon}-\lambda_{1} \sigma \ell^{\epsilon}-\frac{d}{d x}\left(a \frac{d \ell^{\epsilon}}{d x}\right) \in H^{-1}\left(\Omega_{\epsilon}\right)$. The coefficients being bounded, we obtain that for all $\phi \in H_{0}^{1}\left(\Omega_{\epsilon}\right)$,

$$
\left|\int_{\Omega_{\epsilon}} r^{\epsilon} \phi\right| \leq C\left(\left|\lambda-\lambda_{1}^{\epsilon}\right|+\sup _{\Omega_{\epsilon}}\left|\ell^{\epsilon}\right|\right)\|\phi\|_{L^{2}\left(\Omega_{\epsilon}\right)}+C\left\|\frac{d \ell^{\epsilon}}{d x}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}\left\|\frac{d \phi}{d x}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)},
$$

where $C$ is a constant which does not depend on $\epsilon$. From the exponential decay of $\Psi$ we deduce that

$$
\begin{equation*}
\sup _{\Omega_{\epsilon}}\left|\ell^{\epsilon}\right| \leq C \exp \left(-\frac{\tau}{\epsilon}\right) \text { and }\left\|\frac{d \ell^{\epsilon}}{d x}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)} \leq C \sqrt{\epsilon} \exp \left(-\frac{\tau}{\epsilon}\right) \tag{5.15}
\end{equation*}
$$

and with the help of estimate (5.13) we obtain

$$
\begin{equation*}
\left|\int_{\Omega_{\epsilon}} r^{\epsilon} \phi\right| \leq C \exp \left(-\frac{\tau}{\epsilon}\right)\left(\|\phi\|_{L^{2}\left(\Omega_{\epsilon}\right)}+\left\|\frac{d \phi}{d x}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}\right) . \tag{5.16}
\end{equation*}
$$

The first eigenvalue $\lambda_{1}^{\epsilon}$ being simple, by a Fredholm alternative we can decompose $\Psi^{\epsilon}$ into a component proportional to $\varphi_{1}^{\epsilon}$ and a component orthogonal to $\varphi_{1}^{\epsilon}$. We write $\Psi^{\epsilon}=\beta_{\epsilon} \phi_{1}^{\epsilon}+g^{\epsilon}$, where $\beta_{\epsilon}$ is a constant, and

$$
\left\|g^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}+\left\|\frac{d g^{\epsilon}}{d x}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)} \leq C_{\epsilon}\left\|r^{\epsilon}\right\|_{H^{-1}\left(\Omega_{\epsilon}\right)}
$$

where $C_{\epsilon}$ is the norm of $\left(S_{\epsilon}{ }^{-1}-\lambda_{1}^{\epsilon} I d\right)^{-1}$, a bounded operator defined on the orthogonal of the line generated by $\varphi_{1}^{\epsilon}$. We have $C_{\epsilon} \leq \frac{C}{\left|\lambda_{1}^{\epsilon}-\lambda_{2}^{\epsilon}\right|}$, where $C$ is a constant independent of $\epsilon$, and $\lambda_{2}^{\epsilon}$ is the next eigenvalue of $S_{\epsilon}$. If we obtain that $\left|\lambda_{1}^{\epsilon}-\lambda_{2}^{\epsilon}\right|>c>0$, with $c$ independent of $\epsilon$, we then deduce, with the help of inequality (5.16)

$$
\begin{equation*}
\left\|g^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}+\left\|\frac{d g^{\epsilon}}{d x}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)} \leq \frac{C}{c} \exp \left(-\frac{\tau}{\epsilon}\right) \tag{5.17}
\end{equation*}
$$

From the decomposition $\Psi^{\epsilon}=\beta_{\epsilon} \varphi_{1}^{\epsilon}+g^{\epsilon}$, we get

$$
\left|\beta_{\epsilon}\right|\left\|\varphi_{1}^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}-\left\|g^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)} \leq\left\|\Psi^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)} \leq\left|\beta_{\epsilon}\right|\left\|\varphi_{1}^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}+\left\|g^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)} .
$$

We have $\left\|\varphi_{1}^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}=1$ and $\|\Psi\|_{L^{2}(\mathbb{R})}=1$ thus

$$
\left|\left\|\Psi^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}-1\right|=\left|\left\|\ell^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}-\|\Psi\|_{L^{2}\left(\mathbb{R} \backslash \Omega_{\epsilon}\right)}\right| \leq\left\|\ell^{\epsilon}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}+\|\Psi\|_{L^{2}\left(\mathbb{R} \backslash \Omega_{\epsilon}\right)} \leq C \frac{1}{\epsilon} \exp \left(-\frac{\tau}{\epsilon}\right)
$$

thanks to estimate (5.15) and the exponential decay of $\Psi$. As a consequence, $\left|\left|\beta_{\epsilon}\right|-1\right| \leq C \frac{1}{\epsilon} \exp \left(-\frac{\tau}{\epsilon}\right)$ and $\Psi^{\epsilon}$ and $\varphi_{1}^{\epsilon}$ being positives, we also have

$$
\begin{equation*}
\left|\beta_{\epsilon}-1\right| \leq C \frac{1}{\epsilon} \exp \left(-\frac{\tau}{\epsilon}\right) \tag{5.18}
\end{equation*}
$$

Finally, if we write $\varphi_{1}^{\epsilon}(x)-\Psi(x)=\left(1-\beta_{\epsilon}\right) \varphi_{1}^{\epsilon}(x)-g^{\epsilon}(x)+\ell^{\epsilon}(x)$ on $\Omega_{\epsilon}$ and using estimates (5.15), (5.17) and (5.18) we obtain

$$
\left\|\frac{d \varphi_{1}^{\epsilon}}{d x}-\frac{d \Psi}{d x}\right\|_{L^{2}\left(\Omega_{\epsilon}\right)}+\left\|\varphi_{1}^{\epsilon}-\Psi\right\|_{L^{2}\left(\Omega_{\epsilon}\right)} \leq C \frac{1}{\epsilon} \exp \left(-\frac{\tau}{\epsilon}\right) \leq C \exp \left(-\frac{\tau^{\prime}}{\epsilon}\right)
$$

and this concludes the proof.
Let us now show that the spectral gap is uniformly bounded, i.e., $0<c<\lambda_{2}^{\epsilon}-\lambda_{1}^{\epsilon}<C$. We know that $\lambda_{2}^{\epsilon}$ converges to a limit $\lambda_{2}$ which either belongs to $\sigma_{B L} \cup \sigma_{e s s}(S)$ or to $\sigma_{d i s c}(S)$. In the latter case, the eigenvalues of the discrete spectrum are isolated so that $0<c<\lambda_{2}-\lambda_{1}<C$. In the former case, we know from (5.6) that $\lambda_{2} \geq \min \left(\mu_{1}, \mu_{2}\right)$ which is strictly larger than $\lambda_{1}$ by assumption, so that again $0<c<\lambda_{2}-\lambda_{1}<C$. This yields the desired result for sufficiently small $\epsilon$.

## 6 Proofs in the case $\alpha<0$ and $\alpha\left(\theta_{0}\right) \geq 0$.

In this section we prove Theorems 3.11 and 3.12 following the strategy used in section 4 for the case $\alpha \geq 0$. According to Proposition 4.2 and Remark 4.3, the original problem (1.1) is equivalent to the factorized problem (4.9) for any value of the discontinuity constant $\alpha$. Introducing, as in Lemma 4.5, an operator $S_{\epsilon}$, the convergence of (4.9) is governed by the homogenization of problem (4.10) with given right hand side. The key element for the proof of Proposition 4.6, and in turn Theorem 3.8, is the a priori estimate given by Proposition 4.4. It does not hold for $\alpha<0$. Nevertheless, the arguments of the proof of Proposition 4.4 yields a similar result that we state in Proposition 6.1 below.
Proposition 6.1. The solution $u^{\epsilon}$ of equation (4.10) satisfies

$$
\begin{equation*}
\left\|u^{\epsilon}\right\|_{H_{0}^{1}(\Omega)}^{2}+\frac{\mu_{1}-\mu_{2}}{\epsilon^{2}}\left\|u^{\epsilon}\right\|_{L^{2}\left(\Omega_{1}\right)}^{2}+\frac{\alpha}{\epsilon}\left|u^{\epsilon}(0)\right|^{2} \leq C\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}\left\|u^{\epsilon}\right\|_{L^{2}(\Omega)} \tag{6.1}
\end{equation*}
$$

where $C$ is a constant independent of $\epsilon$.
Since we assumed $\alpha<0$, (6.1) alone does not furnish sufficient a priori estimates for concluding. Thus, for the proof of Theorems 3.11 and 3.12 we need an additional lemma.
Lemma 6.2. Assume that $\mu_{1}>\mu_{2}, \alpha<0$ and $\alpha\left(\theta_{0}\right)>0$. Then, the solution $u^{\epsilon}$ of equation (4.10) satisfies

$$
\left\|\frac{d u^{\epsilon}}{d x}\right\|_{L^{2}(\Omega)} \leq C\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}, \quad\left\|u^{\epsilon}\right\|_{L^{2}\left(\Omega_{1}\right)} \leq C \epsilon\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}, \text { and }\left|u^{\epsilon}(0)\right| \leq C \sqrt{\epsilon}\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}
$$

Assume that $\mu_{1}>\mu_{2}, \alpha<0$ and $\alpha\left(\theta_{0}\right)=0$. Then, the solution $u^{\epsilon}$ of equation (4.10) satisfies

$$
\left\|\frac{d u^{\epsilon}}{d x}\right\|_{L^{2}\left(\Omega_{2}\right)} \leq C\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}, \quad\left\|u^{\epsilon}\right\|_{L^{2}\left(\Omega_{1}\right)} \leq C \sqrt{\epsilon}\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}, \text { and }\left\|e^{\theta_{0} \frac{x}{\epsilon}} \frac{d v^{\epsilon}}{d x}\right\|_{L^{2}\left(\Omega_{1}\right)} \leq C\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}
$$

where $v^{\epsilon}=u^{\epsilon} \psi_{1}(x, x / \epsilon) / \psi_{1, \theta_{0}}(x, x / \epsilon)$ in $\Omega_{1}$.
Proof of Theorem 3.11. Thanks to the a priori estimate of Lemma 6.2, the case $\mu_{1}>\mu_{2}, \alpha<0$ and $\alpha\left(\theta_{0}\right)>0$ is completely similar to the case $\mu_{1}>\mu_{2}$ and $\alpha \geq 0$, which is already solved in section 4 .

Proof of Theorem 3.12. Let $u^{\epsilon}$ be the solution of (4.10) with right hand side $f_{\epsilon}$ which is a bounded sequence in $L^{2}(\Omega)$. We introduce the function

$$
\begin{equation*}
\psi_{\theta_{0}}(x, y)=\chi_{1}(x) \psi_{1, \theta_{0}}(y)+\chi_{2}(x) \psi_{2}(y) \tag{6.2}
\end{equation*}
$$

and define a new factorization (or change of unknown which is licit by virtue of Proposition 4.1)

$$
v^{\epsilon}(x)=u^{\epsilon}(x) \frac{\psi\left(x, \frac{x}{\epsilon}\right)}{\psi_{\theta_{0}}\left(x, \frac{x}{\epsilon}\right)}
$$

Remark that $v^{\epsilon}=u^{\epsilon}$ in $\Omega_{2}$, and $v^{\epsilon}(0)=u^{\epsilon}(0)$ (because of the normalization condition (2.2)). Testing variationally equation (4.10) against $\frac{\psi_{\theta_{0}}\left(x, \frac{x}{\epsilon}\right)}{\psi\left(x, \frac{x}{\epsilon}\right)} \phi^{\epsilon}(x)$, where $\phi^{\epsilon}$ is a test function in $H_{0}^{1}(\Omega)$, we obtain

$$
\begin{gather*}
\int_{\Omega} D\left(x, \frac{x}{\epsilon}\right) \frac{d u^{\epsilon}}{d x} \frac{d}{d x}\left(\frac{\psi_{\theta_{0}}\left(x, \frac{x}{\epsilon}\right)}{\psi\left(x, \frac{x}{\epsilon}\right)} \phi^{\epsilon}\right) d x+\frac{\mu_{1}-\mu_{2}}{\epsilon^{2}} \int_{\Omega_{1}} B\left(x, \frac{x}{\epsilon}\right) u^{\epsilon}\left(\frac{\psi_{\theta_{0}}\left(x, \frac{x}{\epsilon}\right)}{\psi\left(x, \frac{x}{\epsilon}\right)} \phi^{\epsilon}\right) d x  \tag{6.3}\\
+\frac{1}{\epsilon} \alpha u^{\epsilon}(0) \phi^{\epsilon}(0)=\int_{\Omega} f_{\epsilon}\left(\frac{\psi_{\theta_{0}}\left(x, \frac{x}{\epsilon}\right)}{\psi\left(x, \frac{x}{\epsilon}\right)} \phi^{\epsilon}\right) d x
\end{gather*}
$$

Replacing $u^{\epsilon}$ by $v^{\epsilon}$ in its left hand side, identity (6.3) becomes

$$
\begin{gather*}
\int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \psi_{1}^{2}\left(\frac{x}{\epsilon}\right) \frac{d}{d x}\left(v^{\epsilon} \frac{\left.\psi_{1, \theta_{0}\left(\frac{x}{\epsilon}\right)}^{\psi_{1}\left(\frac{x}{\epsilon}\right)}\right)}{}\right) \frac{d}{d x}\left(\phi^{\epsilon} \frac{\left.\psi_{1, \theta_{0}\left(\frac{x}{\epsilon}\right)}^{\psi_{1}\left(\frac{x}{\epsilon}\right)}\right) d x+\int_{\Omega_{2}} D\left(x, \frac{x}{\epsilon}\right) \frac{d v^{\epsilon}}{d x} \frac{d \phi^{\epsilon}}{d x} d x}{}+\frac{\mu_{1}-\mu_{2}}{\epsilon^{2}} \int_{\Omega_{1}} \sigma_{1}\left(\frac{x}{\epsilon}\right) \psi_{1, \theta_{0}}^{2}\left(\frac{x}{\epsilon}\right) v^{\epsilon} \phi^{\epsilon} d x+\frac{1}{\epsilon} \alpha v^{\epsilon}(0) u^{\epsilon}(0)=\int_{\Omega} \frac{\psi_{1, \theta_{0}}\left(\frac{x}{\epsilon}\right)}{\psi_{1}\left(\frac{x}{\epsilon}\right)} f_{\epsilon} \phi^{\epsilon} d x\right. \tag{6.4}
\end{gather*}
$$

Note that

$$
\begin{aligned}
& \int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \psi_{1}^{2}\left(\frac{x}{\epsilon}\right) \frac{d}{d x}\left(v^{\epsilon} \frac{\psi_{1, \theta_{0}}\left(\frac{x}{\epsilon}\right)}{\psi_{1}\left(\frac{x}{\epsilon}\right)}\right) \frac{d}{d x}\left(\phi^{\epsilon} \frac{\left.\psi_{1, \theta_{0}\left(\frac{x}{\epsilon}\right)}^{\psi_{1}\left(\frac{x}{\epsilon}\right)}\right) d x=\int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \psi_{1, \theta_{0}}^{2}\left(\frac{x}{\epsilon}\right) \frac{d v^{\epsilon}}{d x} \frac{d \phi^{\epsilon}}{d x} d x}{+\int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \frac{d}{d x}\left(\psi_{1, \theta_{0}}\left(\frac{x}{\epsilon}\right)\right) \frac{d}{d x}\left(v^{\epsilon} \phi^{\epsilon} \psi_{1, \theta_{0}}\left(\frac{x}{\epsilon}\right)\right)-\int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \frac{d}{d x}\left(\psi_{1}\left(\frac{x}{\epsilon}\right)\right) \frac{d}{d x}\left(\frac{\left(\psi_{1, \theta_{0}}\left(\frac{x}{\epsilon}\right)\right)^{2}}{\psi_{1}\left(\frac{x}{\epsilon}\right)} v^{\epsilon} \phi^{\epsilon}\right)}\right.
\end{aligned}
$$

and, by integration by parts and definition (2.1) of $\psi_{1, \theta}$, we have

$$
\begin{aligned}
& \int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \frac{d}{d x}\left(\psi_{1, \theta_{0}}\left(\frac{x}{\epsilon}\right)\right) \frac{d}{d x}\left(v^{\epsilon} \phi^{\epsilon} \psi_{1, \theta_{0}}\left(\frac{x}{\epsilon}\right)\right)-\int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \frac{d}{d x}\left(\psi_{1}\left(\frac{x}{\epsilon}\right)\right) \frac{d}{d x}\left(\frac{\psi_{1, \theta_{0}}^{2}\left(\frac{x}{\epsilon}\right)}{\psi_{1}\left(\frac{x}{\epsilon}\right)} v^{\epsilon} \phi^{\epsilon}\right) \\
& =\frac{1}{\epsilon}\left(\alpha\left(\theta_{0}\right)-\alpha\right) v^{\epsilon}(0) \phi^{\epsilon}(0)+\frac{\mu_{2}-\mu_{1}}{\epsilon^{2}} \int_{\Omega_{1}} \sigma_{1}\left(\frac{x}{\epsilon}\right) \psi_{1, \theta_{0}}^{2}\left(\frac{x}{\epsilon}\right) v^{\epsilon} \phi^{\epsilon} .
\end{aligned}
$$

As a consequence, identity (6.4) becomes

$$
\begin{gather*}
\int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \psi_{1, \theta_{0}}^{2}\left(\frac{x}{\epsilon}\right) \frac{d v^{\epsilon}}{d x} \frac{d \phi^{\epsilon}}{d x} d x+\int_{\Omega_{2}} D\left(x, \frac{x}{\epsilon}\right) \frac{d v^{\epsilon}}{d x} \frac{d \phi^{\epsilon}}{d x} d x  \tag{6.5}\\
+\frac{1}{\epsilon} \alpha\left(\theta_{0}\right) v^{\epsilon}(0) \phi^{\epsilon}(0)=\int_{\Omega} \frac{\psi_{1, \theta_{0}\left(\frac{x}{\epsilon}\right)}^{\psi_{1}\left(\frac{x}{\epsilon}\right)} f_{\epsilon} \phi^{\epsilon} d x}{}
\end{gather*}
$$

Since $\alpha\left(\theta_{0}\right)=0$, we have

$$
\int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \psi_{1, \theta_{0}}^{2}\left(\frac{x}{\epsilon}\right) \frac{d v^{\epsilon}}{d x} \frac{d \phi^{\epsilon}}{d x} d x+\int_{\Omega_{2}} D\left(x, \frac{x}{\epsilon}\right) \frac{d v^{\epsilon}}{d x} \frac{d \phi^{\epsilon}}{d x} d x=\int_{\Omega} \frac{\psi_{1, \theta_{0}\left(\frac{x}{\epsilon}\right)}^{\psi_{1}\left(\frac{x}{\epsilon}\right)} f_{\epsilon} \phi^{\epsilon} d x . d x=0 .}{}
$$

Note that for any bounded sequence $\phi^{\epsilon}$ in $W^{1, \infty}(\Omega)$,

$$
\left|\int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \psi_{1, \theta_{0}}^{2}\left(\frac{x}{\epsilon}\right) \frac{d v^{\epsilon}}{d x} \frac{d \phi^{\epsilon}}{d x} d x\right| \leq C\left\|e^{\theta_{0} \frac{x}{\epsilon}} \frac{d v^{\epsilon}}{d x}\right\|_{L^{2}\left(\Omega_{1}\right)}\left\|e^{\theta_{0} \frac{x}{\epsilon}}\right\|_{L^{2}\left(\Omega_{1}\right)} \rightarrow 0
$$

since $\left\|e^{\theta_{0} \frac{x}{\epsilon} \frac{d v^{\epsilon}}{d x}}\right\|_{L^{2}\left(\Omega_{1}\right)}$ is bounded, thanks to Lemma 6.2. Of course $\int_{\Omega_{1}} \frac{\psi_{1, \theta_{0}}\left(\frac{x}{\epsilon}\right)}{\psi_{1}\left(\frac{x}{\epsilon}\right)} f_{\epsilon} \phi^{\epsilon}$ goes to 0 exponentially fast. For such bounded $\phi^{\epsilon},(6.3)$ therefore writes

$$
\begin{equation*}
\int_{\Omega_{2}} D\left(x, \frac{x}{\epsilon}\right) \frac{d u^{\epsilon}}{d x} \frac{d \phi^{\epsilon}}{d x} d x=\int_{\Omega_{2}} f_{\epsilon} \phi^{\epsilon} d x+o(1) \tag{6.6}
\end{equation*}
$$

Since the test functions in the two-scale convergence method are of the type $\phi^{\epsilon}(x)=\phi^{0}(x)+\epsilon \phi^{1}(x, x / \epsilon)$ with smooth functions $\phi^{0}, \phi^{1}$, they are uniformly bounded in $W^{1, \infty}(\Omega)$ and one can use (6.6) to pass to the limit. Classical arguments of homogenization allow to conclude.

Proof of Lemma 6.2. With the choice $\phi^{\epsilon}=v^{\epsilon}$ in (6.5) we obtain

$$
\begin{equation*}
\int_{\Omega_{1}} a_{1}\left(\frac{x}{\epsilon}\right) \psi_{1, \theta_{0}}^{2}\left(\frac{x}{\epsilon}\right)\left(\frac{d v^{\epsilon}}{d x}\right)^{2} d x+\int_{\Omega_{2}} D\left(x, \frac{x}{\epsilon}\right)\left(\frac{d v^{\epsilon}}{d x}\right)^{2} d x+\frac{1}{\epsilon} \alpha\left(\theta_{0}\right)\left(v^{\epsilon}\right)^{2}(0)=\int_{\Omega} f_{\epsilon} u^{\epsilon} d x \tag{6.7}
\end{equation*}
$$

If $\alpha\left(\theta_{0}\right)>0$, this implies that

$$
\begin{equation*}
\left|v^{\epsilon}(0)\right|^{2} \leq C \epsilon\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}\left\|u^{\epsilon}\right\|_{L^{2}(\Omega)} \tag{6.8}
\end{equation*}
$$

Because $u^{\epsilon}(0)=v^{\epsilon}(0)$, plugging (6.8) in (6.1) yields the desired results.
If $\alpha\left(\theta_{0}\right)=0$, identity (6.7) only implies that

$$
\begin{equation*}
\left\|e^{\theta_{0} \frac{x}{\epsilon}} \frac{d v^{\epsilon}}{d x}\right\|_{L^{2}\left(\Omega_{1}\right)}^{2} \leq C\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}\left\|u^{\epsilon}\right\|_{L^{2}(\Omega)}, \text { and }\left\|\frac{d u^{\epsilon}}{d x}\right\|_{L^{2}\left(\Omega_{2}\right)}^{2} \leq C\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}\left\|u^{\epsilon}\right\|_{L^{2}(\Omega)} \tag{6.9}
\end{equation*}
$$

We will next show that

$$
\begin{equation*}
\left\|u^{\epsilon}\right\|_{L^{2}(\Omega)}^{2} \leq C\left(\epsilon\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}^{2}+\left\|u^{\epsilon}\right\|_{L^{2}\left(\Omega_{2}\right)}^{2}\right) \tag{6.10}
\end{equation*}
$$

and, together with (6.9) and Poincaré inequality in $\Omega_{2}$, this yields the desired results.
Note that

$$
u^{\epsilon}(0)^{2} \leq\left|\Omega_{2}\right|^{2} \int_{\Omega_{2}}\left(\frac{d u^{\epsilon}}{d x}\right)^{2} \leq C\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}\left\|u^{\epsilon}\right\|_{L^{2}(\Omega)}
$$

Using this inequality in (6.1) gives

$$
\left\|u^{\epsilon}\right\|_{L^{2}\left(\Omega_{1}\right)}^{2} \leq C \epsilon\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}\left\|u^{\epsilon}\right\|_{L^{2}(\Omega)} \leq C \epsilon\left(\left\|f_{\epsilon}\right\|_{L^{2}(\Omega)}^{2}+\left\|u^{\epsilon}\right\|_{L^{2}(\Omega)}^{2}\right)
$$

which in turn implies (6.10).

## 7 Proof of Proposition 2.2.

### 7.1 The case of $C^{2}$ coefficients.

The first step is similar to the proof of Lemma 2.1, namely we transform (2.1) into (2.4). If we assume that the coefficients $a_{i}, \Sigma_{i}$ and $\sigma_{i}$ are $C^{2}$ periodic functions on $[0,1]$, then the first eigenfunction $\psi_{i, 0}$ is actually two times differentiable, and thus the coefficients $b$ and $s$ of (2.4) are also of class $C^{2}$. Proposition 2.2 is then a consequence of Lemma 7.1.
Lemma 7.1. Let $b$ and $s$ be periodic positive functions on $[0,1]$ such that their second derivative $b^{\prime \prime}$ and $s^{\prime \prime}$ exist and are piecewise continuous. Denote by $M>m>0$ two positive constant which are the upper and lower bounds of $b$ and $s$. For each $\theta \in \mathbb{R}$ the first eigenvector $u_{\theta}$ of problem (2.4) with the normalization $u_{\theta}(0)=1$ satisfies

$$
\begin{equation*}
-C_{1}-\frac{C_{2}}{\sqrt{-\mu(\theta)}}+C_{3} \sqrt{-\mu(\theta)} \leq \frac{\theta}{|\theta|} u_{\theta}^{\prime}(0) \leq C_{3} \sqrt{-\mu(\theta)}+C_{1}+\frac{C_{2}}{\sqrt{-\mu(\theta)}} \tag{7.1}
\end{equation*}
$$

where the positive constants $C_{1}, C_{2}$ and $C_{3}$ depend only on $b$ and $s$.
Proof. The assumed smoothness of $b$ and $s$ enables us to perform a Liouville transformation of problem (2.4). Introducing

$$
\begin{equation*}
t=\frac{1}{\gamma} \int_{0}^{x}\left(\frac{s(z)}{b(z)}\right)^{\frac{1}{2}} d z \gamma=\int_{0}^{1}\left(\frac{s(z)}{b(z)}\right)^{\frac{1}{2}} d z, \quad \text { and } \quad f_{\theta}(t)=(s(x) b(x))^{\frac{1}{4}} u_{\theta}(x) \tag{7.2}
\end{equation*}
$$

the transformed equation is, see [Eas73],

$$
\left\{\begin{array}{l}
\frac{d^{2} f_{\theta}}{d t^{2}}(t)+\left(\gamma^{2} \mu(\theta)+Q(t)\right) f_{\theta}=0 \text { in }[0,1]  \tag{7.3}\\
t \rightarrow f_{\theta}(t) e^{-\theta t} 1-\text { periodic }
\end{array}\right.
$$

with

$$
Q(t)=\gamma^{2} b^{\frac{1}{4}}(x) s^{-\frac{3}{4}}(x) \frac{d}{d x}\left(b(x) \frac{d}{d x}(b(x) s(x))^{-\frac{1}{4}}\right) .
$$

We can assume without loss of generality that $\gamma=1$. The boundary conditions are preserved since this change of variable preserves periodicity. We shall use the fact that $Q$ is a bounded 1-periodic function. It is sufficient to prove (7.1) for $\theta>0$, since in the other case the function $g_{\theta}(t)=f_{\theta}(-t)$ is solution of (7.3), with $\theta>0$, if $Q$ is replaced by $Q(-t)$, which is also a bounded 1-periodic function. By adding a constant to $Q$ (and subtracting it from $\mu(\theta)$ ), we can always assume that $-M<Q(t)<-1$. On the other hand, thanks to Lemma 2.3, for sufficiently large $\theta$ we can also assume that $\mu(\theta)$ translated by the above constant is negative.

Next, we introduce $g_{1}$ and $g_{2}$ as the two fundamental solutions of the Cauchy problem for the ordinary differential equation $\frac{d^{2} g}{d t^{2}}+(\mu(\theta)+Q(t)) g=0$, satisfying

$$
g_{1}(0)=1, g_{1}^{\prime}(0)=0, \operatorname{and} g_{2}(0)=0, g_{2}^{\prime}(0)=1
$$

It is a classical result of Floquet theory that $X_{1}=e^{\theta}$ and $X_{2}=e^{-\theta}$ are the roots of the characteristic equation

$$
X^{2}-\left(g_{1}(1)+g_{2}^{\prime}(1)\right) X+1=0
$$

By linearity, we can write $f_{\theta}(t)=f_{\theta}(0) g_{1}(t)+f_{\theta}^{\prime}(0) g_{2}(t)$. Since $\theta>0, e^{\theta}=\Delta+\left(\Delta^{2}-1\right)^{\frac{1}{2}}$ where $2 \Delta=\left(g_{1}(1)+g_{2}^{\prime}(1)\right)$. Consequently, $\Delta>1$ and

$$
\begin{equation*}
g_{1}(1)+g_{2} \prime(1)=2 \Delta>e^{\theta} \text { and } e^{\theta}>2 \Delta-\frac{1}{\Delta}>2 \Delta-2 e^{-\theta}=g_{1}(1)+g_{2} \prime(1)-2 e^{-\theta} \tag{7.4}
\end{equation*}
$$

From the relation $f_{\theta}(1)=e^{\theta} f_{\theta}(0)$ we deduce that $\frac{f_{\theta}^{\prime}(0)}{f_{\theta}(0)} g_{2}(1)=e^{\theta}-g_{1}(1)$. Using relation (7.4) we have obtained that

$$
\begin{equation*}
g_{2}^{\prime}(1)>\frac{f_{\theta}^{\prime}(0)}{f_{\theta}(0)} g_{2}(1)>g_{2}^{\prime}(1)-2 e^{-\theta} \tag{7.5}
\end{equation*}
$$

Following Picard's iteration method (see e.g. [MW79]), we define recursively a sequence $\left(v_{n}(t)\right)_{n \in \mathbb{N}}$ by

$$
v_{0}(t)=\frac{1}{\omega} \sinh (\omega t) \text { and } v_{n}(t)=-\frac{1}{\omega} \int_{0}^{t} \sinh (\omega(t-\xi)) Q(\xi) v_{n-1}(\xi) d \xi \text { for all } n \geq 1
$$

For $\omega=\sqrt{-\mu(\theta)}$, we find that $g_{2}(x)=\sum_{n=0}^{+\infty} v_{n}(x)$. Since $-\sinh (\omega(t-\xi)) Q(\xi)>0$ for all $0<\xi<t$, and $v_{0}(t)>0$ for all $t>0$, by induction, we can conclude that $W_{n}(x) \geq v_{n}(x) \geq w_{n}(x)$, for all $n \geq 0$ and $x \geq 0$, where $W_{n}$ and $w_{n}$ are two other sequences defined by $W_{0}=v_{0}=w_{0}$, and

$$
W_{n}=\frac{M}{\omega} \int_{0}^{t} \sinh (\omega(t-\xi)) W_{n-1}(\xi) d \xi, w_{n}=\frac{1}{\omega} \int_{0}^{t} \sinh (\omega(t-\xi)) w_{n-1}(\xi) d \xi \text { for } n \geq 1
$$

Note that $W(t)=\sum_{0}^{+\infty} W_{n}(t)\left(\right.$ resp. $\left.w(t)=\sum_{0}^{+\infty} w_{n}(t)\right)$ is a solution of

$$
\frac{d^{2} W}{d t^{2}}+(\mu-M) W=0\left(\operatorname{resp} \cdot \frac{d^{2} w}{d t^{2}}+(\mu-1) w=0\right)
$$

and therefore is given by $W(t)=\sinh (t \sqrt{M-\mu})$ (resp. $w(t)=\sinh (t \sqrt{1-\mu})$ ) and consequently

$$
\begin{equation*}
\sinh (\sqrt{M-\mu})=W(1) \geq g_{2}(1) \geq w(1)=\sinh (\sqrt{1-\mu}) \tag{7.6}
\end{equation*}
$$

Similarly $W_{n}^{\prime}(t) \geq v_{n}^{\prime}(t) \geq w_{n}^{\prime}(t)$, and

$$
\begin{equation*}
\sqrt{M-\mu} \cosh (\sqrt{M-\mu})=W^{\prime}(1) \geq g_{2}^{\prime}(1) \geq w^{\prime}(1)=\sqrt{1-\mu} \cosh (\sqrt{1-\mu}) \tag{7.7}
\end{equation*}
$$

Using inequalities (7.6) and (7.7) in (7.5) yields,

$$
C e^{\frac{M-1}{2 \sqrt{-\mu}}} \sqrt{M-\mu} \geq \frac{f_{\theta}^{\prime}(0)}{f_{\theta}(0)} \geq c \sqrt{1-\mu} e^{-\frac{M-1}{2 \sqrt{-\mu}}}-2 e^{-\theta}
$$

Using the change of variables (7.2), and using the result of Lemma 2.3 to bound $e^{-\theta}$ in terms of $\mu(\theta)$ this inequality concludes the proof.

### 7.2 The case of piecewise constant coefficients.

As in the previous subsection, it is sufficient to consider system (2.4), which is equivalent to (2.1), and to study the case $\theta$ going to $+\infty$. As in Lemma 2.3, we rewrite (2.4) as a first-order system

$$
\left\{\begin{array}{l}
Y^{\prime}(x)=A(x) Y(x) \\
Y(1)=e^{\theta} Y(0)
\end{array}, A=\left[\begin{array}{cc}
0 & b^{-1} \\
-\mu(\theta) s & 0
\end{array}\right], \text { and } Y=\binom{Y_{1}=u_{\theta}}{Y_{2}=b u_{\theta}^{\prime}} .\right.
$$

Here we assume that the coefficients $b, s$ are piecewise constant functions. More precisely, there exists a number $N$, a family of points $\left(x_{i}\right)_{0 \leq i \leq N}$ satisfying $x_{0}=0<x_{i-1}<x_{i}<x_{i+1}<x_{N}=1$ for $2 \leq i \leq N-2$, and positive values $\left(b_{i}\right)_{1 \leq i \leq N}$ and $\left(s_{i}\right)_{1 \leq i \leq N}$ such that

$$
b(x)=b_{i} \text { and } s(x)=s_{i} \text { for } x \in\left(x_{i-1}, x_{i}\right), 1 \leq i \leq N .
$$

The goal is to prove that $Y_{2}(0)$ grows linearly as $\theta$ goes to $+\infty$, which in turn proves Proposition 2.2, since

$$
\frac{d \psi_{i, \theta}}{d x}(0)=b^{-1}(0) Y_{2}(0)+\frac{d \psi_{i, 0}}{d x}(0)
$$

By Lemma 2.3 we already know that $\mu(\theta)<0$ for $\theta \neq 0$ and has quadratic growth at infinity. A straightforward computation yields for any $x \in\left(x_{i-1}, x_{i}\right)$

$$
Y(x)=M_{i}(\theta, x) Y\left(x_{i-1}\right), \quad M_{i}(\theta, x)=\left[\begin{array}{cc}
\cosh \varphi_{i}(x) & \frac{1}{\sqrt{-\mu(\theta) b_{i} s_{i}}} \sinh \varphi_{i}(x)  \tag{7.8}\\
\sqrt{-\mu(\theta) b_{i} s_{i}} \sinh \varphi_{i}(x) & \cosh \varphi_{i}(x)
\end{array}\right],
$$

with $\varphi_{i}(x)=\sqrt{\frac{-\mu(\theta) s_{i}}{b_{i}}}\left(x-x_{i-1}\right)$. Thus

$$
Y(1)=M(\theta) Y(0)=e^{\theta} Y(0), \text { with } M(\theta)=\prod_{i=1}^{N} M_{i}\left(\theta, x_{i}\right) .
$$

Each matrix $M_{i}(\theta, x)$ has its determinant equal to 1 , as well as $M(\theta)$. Thus the two eigenvalues of $M(\theta)$ are $e^{\theta}$ and $e^{-\theta}$. Let us compare these exact eigenvalues with those of the leading order term of $M(\theta)$ as $\theta$ goes to $+\infty$. Introducing $D(\theta)=\operatorname{diag}(\sqrt{-\mu(\theta)}, 1)$, we have

$$
M_{i}\left(\theta, x_{i}\right)=e^{\varphi_{i}\left(x_{i}\right)} D(\theta)^{-1} M_{i}^{0} D(\theta)\left(1+O\left(e^{-\alpha \theta}\right)\right), \text { with } M_{i}^{0}=\frac{1}{2}\left[\begin{array}{cc}
1 & \frac{1}{\sqrt{b_{i} s_{i}}} \\
\sqrt{b_{i} s_{i}} & 1
\end{array}\right]
$$

and $\alpha=\min _{1 \leq i \leq N}\left(2\left(x_{i}-x_{i-1}\right) \sqrt{\frac{s_{i} M}{b_{i} M}}\right)>0$. Therefore, noticing that $\sum_{i=1}^{N} \varphi_{i}\left(x_{i}\right)=C \sqrt{-\mu(\theta)}$ where $C>0$ does not depend on $\theta$, we obtain

$$
M(\theta)=e^{C \sqrt{-\mu(\theta)}} D(\theta)^{-1} M^{0} D(\theta)\left(1+O\left(e^{-\alpha \theta}\right)\right), \text { with } M^{0}=\prod_{i=1}^{N} M_{i}^{0} .
$$

Up to a small remainder, the eigenvalues of $M(\theta)$ are thus equal to those of $M^{0}$ times the multiplicative factor $\exp (C \sqrt{-\mu(\theta)})$. Since $M^{0}$ does not depend on $\theta$, this proves that $\mu(\theta)=-c \theta^{2}+o(1)$ for some positive constant $c>0$. On the other hand, the eigenvectors of $M(\theta)$ are equal to $D(\theta)^{-1}$ times those of $M^{0}$ (up to a small remainder). Choosing the normalization $Y_{1}(0)=1$, this yields that $Y_{2}(0)=c^{\prime} \theta+o(1)$ for some constant $c^{\prime}$, which is positive as already remarked in the proof of Lemma 2.3.
Note Added in Proof. After submission of this paper for publication, we found an alternative proof of Lemma 5.4, which do not rely on Proposition 2.2. This enables us to prove Theorem 3.5 and Theorem 3.10 assuming only that the periodic coefficients are positive, bounded, measurable functions. This proof will be presented in a future work in collaboration with A. Piatnitski.
