# A multilevel synergy Thompson sampling hyper-heuristic for solving Max-SAT

Mourad Lassouaoui<sup>a,∗</sup>, Dalila Boughaci<sup>a</sup> and Belaid Benhamou<sup>b</sup> <sup>a</sup>*LRIA, USTHB, BP 32 El-ALIA Beb-Ezzouar, Algiers, Algeria* <sup>b</sup>*LIS, AIX-Marseille University, Marseille Cedex, France*

Abstract. Hyper-heuristics are high-level methods, used to solve various optimization problems. Some of them are capable of learning and adapting their behavior throughout the solving process. Selection hyper-heuristics evaluate low-level heuristics and determine which of them to be applied at a given point in the search process. However, it has been shown that the additive learning process becomes inefficient in hard problems where the probability of fitness improvement is less than  $\frac{1}{2}$ . Other alternative learning mechanisms have been proposed however they don't take into account the synergy between the low-level heuristics. Moreover they haven't been tested on large NP-hard problems. In this work, we propose a new hyper-heuristic which we called *the Multilevel Synergy Thompson Sampling Hyper-Heuristic*. The proposed method includes both the probabilistic learning mechanism and the multilevel paradigm. The latter refers to the process of creating hierarchically smaller sub-problems from large problem instances. The proposed hyper-heuristic is applied on very large industrial Max-SAT instances from the latest Max-SAT competition. The numerical results are promising and demonstrate the benefits of our method. The proposed method outperforms the other four types of hyper-heuristics: Random, Choice Function, Stochastic Choice Function and the simple Thompson Sampling Hyper-Heuristics.

Keywords: Selection hyper-heuristic, Max-SAT, Thompson sampling, choice-function, random, multilevel paradigm

#### 1. Introduction

<sup>2</sup> In practice, several real world optimization prob- lems are difficult to solve and most of them are "NP- hard". Due to their exponential nature, exact algo-<sup>5</sup> rithms fail to solve them efficiently. In this case, an- other category of methods is used: inexact algorithms which include heuristics, metaheuristics and hyper- heuristics. Hyper-heuristics are problem independent high level methods that create a collaboration between different search methods in order to fill the weaknesses of each other. The term hyper-heuristic was first intro-duced by Cowling et al. [1].

<sup>13</sup> Given a set of low-level heuristics, a selection hyper-<sup>14</sup> heuristic tries to predict which heuristic is the most <sup>15</sup> suitable to apply at a given point during the search

<sup>∗</sup>Corresponding author: Mourad Lassouaoui, LRIA, USTHB, BP 32 El-ALIA Beb-Ezzouar, Algiers 16111, Algeria. E-mail: lassouaoui.mourad@gmail.com.

process. Reinforcement learning is a general machine 16 learning technique based on a system of reward and 17 punishment. A reinforcement learning algorithm learns 18 by interacting with its environment and aims to max-<br>19 imize its reward and to minimize its penalty by per-<br>20 forming correctly.

A reinforcement learning hyper-heuristic needs to  $_{22}$ gather information about the performances of lowlevel heuristics to learn their behavior then to predict  $_{24}$ which one will be the most efficient in the next itera- $\frac{1}{25}$ tion. The most common hyper-heuristics use simple re- 26 inforcement learning mechanisms such as random gra- $\frac{27}{27}$ dient, greedy, and most importantly, the additive rein-<br>28 forcement learning mechanism such as the well-known 29 choice function.

An additive learning hyper-heuristic, attributes  $a_{31}$ weight to each low-level heuristic, then increases the  $\frac{32}{2}$ weight of the selected heuristic if its application led to  $\frac{33}{2}$ an improvement in the candidate solution with respect  $34$ to a given fitness function, or decreases the weight 35  otherwise. Recently, authors in [2] have presented the first theoretical study evaluating the performance of the reinforcement learning mechanisms and compared them to a uniform random selection hyper-heuristic. This study has shown the limits of the additive rein- forcement learning mechanism, then proposed to use 42 Thompson sampling mechanism as an alternative.

<sup>43</sup> In this paper, we discuss how the Thompson sam-<sup>44</sup> pling mechanism do not take into account the syn- ergy between the low-level heuristics, which is an im- portant feature of any hyper-heuristics. On the other 47 hand, we are interested in solving very large indus- trial instances from the latest Max-SAT competition. 49 We propose then, an algorithm that integrates the mul- tilevel paradigm with an adaptive learning selection 51 hyper-heuristic which we called the multilevel Synergy Thompson Sampling Hyper-Heuristic. The multilevel paradigm is an interesting technique that has been used to deal with large instances of different problems. It involves recursive coarsening to create a hierarchy of approximations to the original problem. In the case of Max-SAT, the coarsening phase consists in merging variables together into clusters to create smaller sam- ples from the original instance for each level. At the coarsest level, an initial solution is computed, and then iteratively refined at each level, coarsest to finest, using a search algorithm [3].

<sup>63</sup> In the rest of the paper, we summarize in Section 2, the maximum satisfiability problem (Max-SAT), the hyper-heuristics, the proposition of Alanazi [2] regard- ing the limits of additive learning hyper-heuristics, the 67 simple Thompson Sampling Hyper-Heuristic and the multilevel paradigm. In Section 3 we explain the com- ponents of our approach. Section 4 exposes and dis- cusses the experimental results. Finally, we conclude the work in Section 5 and give some research perspec-<sup>72</sup> tives.

#### $73\quad$  2. State of the art

 The maximum satisfiability problem (Max-SAT) has a central importance in various areas of computer sci- ence, including theoretical computer science, artificial intelligence, optimization, hardware design and verifi-<sup>78</sup> cation.

An instance of the satisfiability problem (SAT) is a propositional formula in a conjunctive normal form (CNF). Given a set of  $N$  Boolean variables, A CNF formula  $F$  is the conjunction of  $M$  clauses. Each clause is a disjunction of  $r$  literals representing its length. A literal is a Boolean variable that occurs in its positive or negative form.

$$
F = \bigwedge_{i=1}^{M} C_i \text{ where } C_i = \bigvee_{i=1}^{r} l_j, l_j = \left\{ \begin{array}{l} x_j \\ \neg x_j, j = 1..N \end{array} \right\}
$$

The SAT problem is to decide whether an assign- $\frac{1}{80}$ ment of truth values to the N variables, such that all the  $\begin{array}{c} 81 \end{array}$ clauses of F are simultaneously satisfied exists or not.  $\begin{array}{c} 82 \end{array}$ It is known in complexity theory that SAT is the canon- 83 ical NP-complete problem [4]. The maximum satis-<br>satisfiability problem (Max-SAT) is an optimization vari-<br>s5 ant of SAT. It requires a variable truth assignment that  $86$ maximizes the number of satisfied clauses of  $F$ . It has  $\qquad$ been proven to be a NP-hard problem, even when each  $\begin{array}{c} 88 \end{array}$ clause has no more than two literals, while SAT with  $\frac{1}{89}$ two literals per clause can be solved in polynomial 90 time. Various exact and non-exact methods have been <sub>91</sub> developed to address the Max-SAT problem.  $|_{2}$ 

Because of their exponential complexity, the ex-<br>s act methods can be applied only on small instances. 94 Among the well-known methods for SAT, the method 95 SATO [5], the solver Satz [6], the method Chaff  $[7]$  96 that are all SAT solvers based on the Davis Putnam 97 method [8]. There are also exact methods such as  $\frac{98}{2}$ the Branch and Bound algorithms [9,10], the Max-  $99$ Solver [11], and the method MiniMaxSat [12] that are  $\frac{1}{100}$ used to solve the optimization variant Max-SAT  $\vert$  101

On the other hand, approximation methods (or non- $\frac{1}{102}$ exact methods) make a local exploration in the search 103 space. They can tackle large Max-SAT instances and 104 could find good solutions in a reasonable time. Among 105 them, we can find the local search and metaheuristic  $_{106}$ methods such as: the CCLS: an efficient local search 107 algorithm [13], the GSAT procedure [14], the sim- $\frac{108}{108}$ ulated annealing [15], the WALKSAT method  $[16]$ , 109 the scatter search algorithm  $[17]$ , the genetic algo- $\vert$  110 rithm  $[17–19]$ , the GASAT algorithm  $[20]$ , the nov- $\vert$  111 elty method [21], the adaptnovelty method [22], the  $_{112}$ guided local search method [23], the tabu search 113 algorithm  $[24,25]$ , the G2wSAT method  $[26]$ , the 114 memetic algorithm  $[27,28]$ , and the variable neighbor- $\frac{1}{115}$ hood search (VNS) based Genetic algorithm [29].  $\vert$  116

A hyper-heuristic can be viewed as a non-exact  $117$ method that makes several metaheuristics and/or spe-<br>118 cific heuristic algorithms interact with each other. To  $119$ our knowledge, hyper-heuristics have not been tested 120 on the large industrial Max-SAT instances. 121

<sup>79</sup> *2.1. Max-SAT*

#### <sup>122</sup> *2.2. Hyper-heuristics*

 A hyper-heuristic is a problem independent search method and a learning mechanism for selecting or 125 generating heuristics to solve computational search problems [30]. During the search process, the hyper-127 heuristic selects the (meta) heuristic that should be ap- plied to improve the fitness function and avoid local optima. These (meta) heuristics are called low-level heuristics. In other words, hyper-heuristics perform the 131 search over the space of the low-level heuristics, and not directly on the problem search space [30–32].

<sup>133</sup> Hyper-heuristics have been used in many optimiza- tion problems, such as, the frequency assignment prob- lem in cellular networks [33,34], the winner deter- mination problem [35], the problem of examination timetabling problem [32,36–41], the planning prob- $\lim$  lem [1], the flow shop problem [42] and so on.

#### <sup>139</sup> *2.2.1. Classification of hyper-heuristics*

 Hyper-heuristics can be classified using several cri- teria describing the nature of the hyper-heuristic, the nature of the low-level heuristics and the use or not of a learning mechanism.

 *Selective or generative hyper-heuristics.* Generative hyper-heuristics combine several components to gen- erate themselves the low-level heuristics. The most known generative techniques are based on genetic pro- gramming [43–46]. Selective hyper-heuristics aim to choose the right (meta) heuristics to be executed in the search process. The set of low-level heuristics should include methods with different strategies that allow a better exploration of the problem search space. Selec- tive hyper-heuristics attempt to combine these methods to compensate the weaknesses of some heuristics by the strength of some other one's [47,48].

 *Constructive or perturbative low-level heuristics.* A constructive low-level heuristic starts with an empty solution and tries to complete it at each step. On the other hand, a perturbative low-level heuristic starts with a complete initial solution and tries to find better ones by improving it during the search process.

 *Hyper-heuristics with or without a learning mecha- nism.* Hyper-heuristics that do not use learning mecha- nism can be random or exhaustive [30]. In this case the selection mechanism does not benefit from the feed- back that can be collected during the search phase. To improve the performances of hyper-heuristics, two types of learning mechanisms can be used: on-line or off-line learning. In the on-line case, the hyperheuristic uses feedback information to learn while 170 solving the problem. In the off-line learning case, it  $_{171}$ trains first to get information from the considered prob- 172 lem (under resolution) that could be used to solve un- $\frac{1}{173}$ seen instances of the problem.

For example, we can cite the work given in  $[42]$   $\frac{175}{175}$ which is based on a multi-agent system where a hyper-<br>176 heuristic agent manages the low-level heuristic agents 177 by using a reinforcement learning mechanism. The <sup>178</sup> system was applied on the flow shop problem. In [49],  $\frac{179}{179}$ authors propose a method based on Q-learning to automatically design the high-level heuristic of a hyper-<br>181 heuristic model. In [50], a deterministic learning selec- $\frac{1}{182}$ tion strategy based on the Multi-Armed Bandit prob- 183 lem is used. It has been implemented using the HyFlex  $_{184}$ framework.

In our work, we are interested in selective-pertur-<br>186 bative hyper-heuristics with an on-line learning mech-<br>187 anism. <sup>188</sup>

#### 2.2.2. The architecture of a selective-perturbative | 189 *hyper-heuristic* 190

A selective hyper-heuristic is composed of two mod-<br>191 ules: a selection module and a move acceptance mod-<br>192 ule. The selection module chooses which low-level 193 heuristic will be called in the next iteration. Such selection could be done randomly or by using a learning  $_{195}$ mechanism. The acceptance module decides whether 196 the current solution will be accepted or not. This de- $\vert$  197 cision can be deterministic (all moves will be  $ac$ <sup>198</sup> cepted [1], only improvement moves are accepted  $[35]$  199 51]) or non-deterministic (Monte Carlo move accep-<br>200 tance [36] simulated annealing [52], ... ). For more  $20$ details about the selection strategies and move accep-<br>202 tance module, the reader could refer to [30].  $\qquad \qquad | \qquad \qquad |$ 

The hyper-heuristic process works as follows: given 204 an instance of a problem, the selection module picks an  $\qquad$  205 adequate low-level heuristic according to a given strat-<br>206 egy at each iteration. Then, the acceptance module de $\vert$  207 cides whether to accept or reject the solution returned 208 by the low-level heuristic. The process continues until the termination criterion is met. The hyper-heuristic  $_{210}$ process is depicted in Fig. 1. One of the well-known  $_{211}$ selection strategies is the Choice-Function method. 212

#### 2.3. The choice function selection strategy and  $\frac{1}{213}$

The Choice function is a score based selection strat-<br>214 egy that uses on-line learning to decide which lowlevel heuristic to be called for the next execution. It  $_{216}$ measures the effectiveness of the low-level heuristics  $_{217}$

 based on their performances. It assigns a weight to each low-level heuristic according to three parameters, which are: the CPU time consumed by a heuristic dur- ing the search process, the quality of the solution and the elapsed time since the heuristic has been called. The modified score based choice-function is described in [53] as follows:

Candidate

solution

 $S_{0}$ 

 $T/(1)$ 

Selection Low-leve

**heuristics Module** 

$$
\forall i, g_1(h_i) = \sum_n \phi^{n-1} \frac{I_n(h_i)}{T_n(h_i)}
$$
  

$$
\forall i, g_2(h_{ID}, h_i) = \sum_n \phi^{n-1} \frac{I_n(h_{ID}, h_i)}{T_n(h_{ID}, h_i)}
$$
  

$$
\forall i, g_3(h_i) = \text{elanged Time}(h_i)
$$
  

$$
\forall i, score(h_i) = \phi g_1(h_i) + \phi g_2(h_{ID}, h_i)
$$
  

$$
+ \delta g_3(h_i)
$$

where  $h_i$  is a low-level heuristic and  $h_{ID}$  is the last low-level heuristic recently launched.  $I_n(h_i)$  (respectively,  $I_n(h_{ID}, h_i)$ ) represents the change in the evaluation function after the  $n<sup>th</sup>$  execution of the heuristic  $h_i$  (respectively,  $n^{\text{th}}$  execution of the heuristic  $h_i$  after  $h_{ID}$ ).  $T_n(h_i)$  (respectively,  $T_n(h_{ID}, h_i)$ ) represents the execution time of the heuristic  $h_i$  after his  $n^{\text{th}}$  call (respectively, the execution time of the  $n<sup>th</sup>$  call of  $h<sub>i</sub>$ following  $h_{ID}$ ). The value of  $\phi$  depends on the performances of the low-level heuristics during the search process. If there is an improvement, then  $\phi$  receives it's maximum value (0.99), otherwise, it takes the maximum between  $\phi$  – 0.01 and 0.01.  $\delta$  is closely related to  $\phi$ , its value is defined by the following equation:

$$
\phi_t = \begin{cases} 0.99 & \text{if improvement} \\ \max\{\phi_{t-1} - 0.01, 0.01\} & \text{otherwise} \end{cases}
$$
  
and  $\delta_t = 1 - \phi_t$ .

 $h_1$ 

#### 2.4. Additive reinforcement learning hyper-heuristics | 226 *behavior and Thompson sampling* 227

The reinforcement learning mechanisms iteratively 228 choose the appropriate heuristic by trial and error inter-<br>229 actions with the search space. Each low-level heuris- <sup>230</sup> tic is associated with a weight, initially the same. The 231 adaptation module, determine how the weights should 232 be updated. The additive weights adaptation scheme 233 is the most frequently used one. If the selected low- $\begin{vmatrix} 234 & 234 \\ 234 & 234 \end{vmatrix}$ level heuristic improves the solution, its weight is in-<br>235 creased by a certain value; otherwise, the weight is de- 236 creased. An example is the choice-function mechanism <sup>237</sup> described above. Among recent works using choice 238 function mechanism we can cite:  $[54]$  where a choice  $_{239}$ function hyper-heuristic has been applied on the allo-<br>240 cation of maintenance tasks problem in Danish rail-<br>
<sub>241</sub> ways. In [55,56] an artificial bee colony algorithm is  $_{242}$ combined with a modified choice function for the trav-<br>243 eling salesman problem. In [57] a hyper-heuristic with  $_{244}$ a parameter free choice function strategy has been ap- <sup>245</sup> plied on pairwise test generation. In [58] a modified <sup>246</sup> choice function heuristic selection strategy has been <sub>247</sub> proposed for the multidimensional knapsack problem. <sub>248</sub> In [59], a Choice Function-based Constructive Hyper- 249 Heuristic is used for generating personalized healthy 250 menu recommendations.

 $_{252}$  In [2], the limitations of learning in additive rein- forcement learning hyper-heuristics are shown. They have proven theoretically that if the success probabilties of the low-level heuristics are less than  $\frac{1}{2}$ , then these hyper-heuristics will have the same performance as a simple random mechanism. In their experimen- tal analysis, an additive learning mechanism on the HyFlex framework has been implemented then applied on the bin-packing problem and the permutation flow- shop problem. The results show that the estimated suc- cess probabilities of the low-level heuristics are in fact much smaller than a half, and consequently, both the additive reinforcement learning hyper-heuristic and the simple random hyper-heuristic have asymptotically the <sup>266</sup> same behavior. This shows that additive reinforcement learning mechanisms are not necessarily capable of distinguishing between the performances of the heuris- tics, in other words, they don't adapt themselves to cope with the dynamic change in the success probabil-ities of low-level heuristics.

<sup>272</sup> Since the additive learning mechanism is not effi-<sup>273</sup> cient in these cases, [60] propose using a probabilistic 274 selection approach called Thompson sampling.

#### <sup>275</sup> *2.5. The Thompson sampling hyper-heuristic*

<sup>276</sup> In 1933, Thompson introduced a reinforcement <sub>277</sub> learning mechanism for the multi-armed bandit prob-<sup>278</sup> lem referred to as Thompson sampling [61].

 Despite the fact that it was absent from the arti- ficial intelligence literature, recently it has attracted considerable interest. Several studies have empiri- cally demonstrated the efficiency of Thompson sam- pling [62–65]. It has also been successfully applied to several real-world problems [66–68].

 As shown in Algorithm 1, Thompson sampling is a reinforcement learning mechanism that uses prob- abilities to predict the most suitable heuristic to be called. It also uses a sliding time window to adapt its behavior according to recent observations about the performance of the low-level heuristics. This enables to discard past and potentially irrelevant observations. In this case, the low-level heuristics are divided into two sets: MU (mutation heuristics) and LS (simple lo- cal search heuristics). The hyper-heuristic chooses a heuristic from the MU set then chooses a heuristic from LS set at each iteration. To each low-level heuristic  $\frac{1}{297}$  *i*, we attribute a beta distribution with two parameters <sup>298</sup>  $\alpha_i^{(t)}$  and  $\beta_i^{(t)}$  which represent the number of successes and failures observed within a time window at the  $t^{\text{th}}$ 299 iteration. These parameters are initialized to one and

### Algorithm 1 The thompson sampling hyper-heuristic.

**Require:** a Max-SAT instance, a set  $H$  of  $m$  low-level heuristics (a subset " $MU$ " of mutational heuristics and another subset " $LS$ of local search heuristics), the maxiter parameter, the sliding window  $w \in \mathbb{N}$ .

Ensure: a solution S.

- 20: end if
- 21: if  $t \geq w$  then
- 22:  $-\forall i \in [m]$  if at iteration  $(t w)$ ,  $h_i$  has been called then improved the solution, then  $\alpha_i^{(t+1)} := \alpha_i^{(t+1)} - 1$
- 23:  $-\forall i \in [m]$  if at iteration  $(t w)$ ,  $h_i$  has been called then not improved the solution, then  $\beta_i{}^{(t+1)} := \beta_i{}^{(t+1)} - 1$
- 24: **end if**<br>25: //the ac
- //the acceptance method.
- 26: if  $(f(S'') \geq f(S))$  then
- 27:  $S := S''$ ;  $F := F''$ ;  $28$ : end if
- 29: end while
- 30: return the best solution found.

updated during the search process. In the case of suc- $\int$  301 cess, meaning the low-level heuristic has improved the <sub>302</sub> best solution found with respect to the objective func-<br>303 tion,  $\alpha_i^{(t)}$  is incremented,  $\bar{\beta}_i^{(t)}$  is incremented other-<br>304 wise. In order to select the next low-level heuristic to 305 be called, a random variable  $U_i^{(t)}$  called utility score 306 is drawn from the beta distribution of each low-level 307 heuristic. The one with the maximum utility score is  $\frac{1}{308}$ then selected. The hyper-heuristic only keeps the ob-<br>solservations about the low-level heuristics in the last  $w_3$ <sup>310</sup> iterations.

The Thompson Sampling Hyper-Heuristic focuses 312 on choosing, at each iteration, the low-level heuristic 313

Fig. 2. The multilevel process.

<sup>314</sup> that will potentially improve the candidate solution, 315 without taking into account the synergy between the 316 low-level heuristics. We mentioned earlier that hyper-317 heuristics attempt to compensate the weaknesses of 318 some low-level heuristics by the strength of the others. 319 But, the Thompson Sampling Hyper-Heuristic fails to <sup>320</sup> do that. We propose, in this paper, a new approach that 321 adds the synergy aspect to the Thompson Sampling. <sup>322</sup> It also combines the hyper-heuristic with the multi-<sup>323</sup> level paradigm in order to deal with large Max-SAT <sup>324</sup> instances.

#### <sup>325</sup> *2.6. The multilevel paradigm*

<sup>326</sup> The multilevel paradigm is inspired from the multi- grid methods used in physics since the 1970's to solve differential equations. This method has been ap- plied essentially on the graph partitioning problem (GPP) [69,70]. This method has proven to be very ef- ficient and has replaced the spectral methods used in GPP in 1990's. In early 2000, Chris Walshaw used the multilevel paradigm on other combinatorial optimiza- tion problems such as the traveling salesman problem (TSP) [71], the graph coloring problem (GCP) [72], the vehicles routing problem (VRP) [73], or the clustering 337 problem [74]. It has also been used to solve the SAT 338 problem [75] then the Max-SAT problem [51,76,77]. The multilevel paradigm goes through three phases, as shown in Fig. 2.

<sup>341</sup> *2.6.1. The coarsening phase*

 $342$  In this step, a hierarchical sequence of progressively 343 smaller problems  $P_0, P_1, P_2, \ldots, P_L$  is defined, where 344  $P_i$  is a coarser approximation of  $P_{i-1}$ . Thus, the original problem is successively shrunk until the size of 345 the smallest problem falls below a certain coarsen-<br>346 ing threshold. There is no general coarsening strat- <sup>347</sup> egy; it depends mainly on the nature of the problem. <sub>348</sub> For example, in the graph partitioning problem, most 349 of the proposed multilevel methods use a progressive 350 and uniform reduction. It is generally based on merg- 351 ing groups of variables into one cluster for the next 352 level. The coarsening phase seems to hold three prin- <sup>353</sup> ciples  $[3]$ :

- $-$  A solution (even if it is not the optimal one) found  $355$ in any of the coarsened spaces could simply be 356 extended through all the problem levels to form a 357 solution of the original problem. This requirement  $358$ ensures that the coarsening is truly filtering the  $_{359}$ solution space. 360
- The number of levels in the coarsening phase does  $\frac{361}{861}$ not need to be determined beforehand, however 362 the coarsening should cease when any further it-<br>363 eration would render the initialization degenerate. <sub>364</sub>
- Any solution in a coarsened space should have the  $\frac{365}{100}$ same cost with respect to the objective function as  $366$ its extension to the original space. This principal 367 ensures that the coarsening algorithm samples the  $_{368}$ solution space without altering it. In this case we  $\frac{369}{869}$ say that the coarsening is exact.  $\vert$  370

#### **2.6.2.** The initialization phase  $\begin{array}{|c|c|c|c|c|c|} \hline \text{371} & \text{372} \hline \end{array}$

The initial phase is very simple. It produces an initial  $372$ solution of  $P_L$  (the problem at the coarsest level). This  $\frac{373}{2}$ could be done using a simple random assignment or a  $374$ specific heuristic. 375

## <sup>376</sup> *2.6.3. The extension and refinement phase*

377 This phase is an iterated combination of two steps:

- <sup>378</sup> *The extension step:* The extension algorithm is the <sup>379</sup> unversed process of the coarsening algorithm. It <sup>380</sup> extends the solution found at the previous level <sup>381</sup> to give an initial solution to the problem at the 382 current level.
- <sup>383</sup> *The refinement step:* builds a better solution from <sup>384</sup> the initial one at each level. It can be a simple <sup>385</sup> local search or a more sophisticated heuristic or <sup>386</sup> metaheuristic. In this paper, we have used a hyper-<sup>387</sup> heuristic.

#### 388 3. The multilevel synergy thompson sampling <sup>389</sup> hyper-heuristic

 In the following, we introduce our method called 391 the Multilevel Synergy Thompson Sampling Hyper- Heuristic (ML-SyTS-HH). We first describe the mul- tilevel (ML) framework. Then we detail the Synergy Thompson Sampling Hyper-Heuristic (SyTS-HH) 395 components.

<sup>397</sup> The multilevel framework has four basic compo-<sup>398</sup> nents described as follows:

<sup>399</sup> *3.1.1. The coarsening process*

<sup>400</sup> In the coarsening phase, the algorithm reduces <sup>401</sup> the problem size recursively until reaching a desired <sup>402</sup> threshold. In the case of a SAT problem instance, the algorithm merges pairs of variables chosen randomly to create what we call clusters, which reduces the size of the problem by half at each iteration, as illustrated 405 in Fig. 3. In this case, the complexity of the coarsening algorithm is  $\log_2 N$ , N being the number of variables. These clusters are then used to define a coarser and 408 smaller sample of the problem in the next iteration as shown in Fig. 4. The remaining variables that have not been merged are simply copied to the next level. Merg- 411 ing more than two variables at once, results in a too fast coarsening and lower quality samples. This coarsening 413 technique is exact: indeed, at any stage after initializa-<br>414 tion the current solution could simply be extended to form a legitimate solution of the original problem, with the same cost (see the extension and refinement phase of Fig. 7).

#### *3.1.2. The initialization process*

The search process starts by computing an initial so- $\frac{420}{420}$ lution at the coarsest level. The truth/false values will 421 be assigned randomly to the clusters. As a cluster rep-  $422$ resents one variable, to compute the cost of a solution,  $423$ all the variables that compose the cluster will be as- $\begin{vmatrix} 424 & 424 \\ 424 & 424 \end{vmatrix}$ signed the same value.  $\frac{1}{425}$ 

#### *3.1.3. The extension process*

When going from one level to another, the exten- $427$ sion strategy should guarantee that the number of sat- $428$ isfied clauses by the solution will remain the same be- $\frac{429}{ }$ fore and after the extension. The extension algorithm  $_{430}$ being the reverse procedure of the coarsening, it splits  $431$ 

<sup>396</sup> *3.1. The multilevel framework*

Fig. 5. Illustration of the initialization phase.

<sup>432</sup> up each cluster into the clusters that compose it and <sup>433</sup> assigns them the same value as the original cluster.

#### <sup>434</sup> *3.1.4. The refinement process*

435 At each generated level, after the extension process, the refinement algorithm is applied to search the best solution for the problem sample corresponding to the current level. In this paper, we have used the Synergy Thompson Sampling that we describe later (for the refinement). In the coarse levels, the hyper-heuristic works on smaller and easier versions of the initial prob- lems until reaching level 0. We had to make a few ad- justments to the hyper-heuristic to make it deal with the clusters directly instead of the variables. Algo-<sup>445</sup> rithm 2 shows how *SyTS-HH* is integrated in the mul- tilevel framework. The main benefit of the multilevel <sup>447</sup> paradigm is that, when going through the lower levels, it guides the search to a very promising area. When the original level (level 0) is reached, the initial solution is one of very good quality. In this case, in order to keep this advantage, the intensification/diversification mechanisms are managed by the low-level heuristics.

#### Algorithm 2 The ML-SyTS-HH.

#### *3.2. The components of the SyTS-HH*  $_{453}$

The proposed hyper-heuristic uses the method of *so*- 454 *lution acceptance* based on the *all moves acceptance*strategy. In the following we explain how a solution is represented, how the fitness is calculated, then discuss the low-level heuristics that we use and finally describe the Synergy Thompson Sampling process.

#### *3.2.1. The solution representation*

A solution is represented as a vector X with size n. Each element  $X_i$  receives the value 0 (False) or 1 462 (True). X represents an assignment of truth values to the *n* Boolean variables of the Max-SAT instance.  $\Big|$ 

#### *3.2.2. The objective function*  $\left| \right|$  465

The quality of a solution (fitness) is measured by using an objective function. In the Max-SAT problem, it consists in maximizing the number of satisfied clauses of the considered instance. The goal of a search method 469 is to find an assignment to the variables that maximizes the number of satisfied clauses. Given a solution  $X$ ,  $\frac{471}{471}$ the objective function f that we want to maximize is expressed as follows: <sup>473</sup>

$$
f(X) = \sum_{i=0}^{n} C_i
$$
, Where the clause  

$$
C_i = \begin{cases} 1 \text{ when } C_i \text{ is satisfied} \\ 0 \text{ otherwise.} \end{cases}
$$

#### 3.2.3. The low-level heuristics for Max-SAT  $\vert$ <sup>474</sup>

Six perturbative low-level heuristics are used in this 475 paper. We have chosen some of the best state of the art  $476$ Max-SAT search methods. After each execution, the  $_{477}$ selected low-level heuristic returns the solution found 478 to the hyper-heuristic. We give in the following a con- $\begin{vmatrix} 479 \end{vmatrix}$ cise description of each of the considered low-level <sup>480</sup> heuristics.

 $\blacksquare$  *The heuristic*  $h_1$ : GSAT [14].

This method chooses to flip the variable with the 483 highest net gain (the number of satisfied clauses 484 minus the number of unsatisfied clauses if the 485 variable will be flipped). In the case of having  $486$ many variables with the highest net gain, we  $487$ choose one randomly.

 $-$  *The heuristic*  $h_2$ : HSAT [78]. This algorithm is similar to GSAT. However, in  $490$ the case of having many variables with the high- <sup>491</sup> est net gain, we choose the oldest one (the variable's age represents the number of iterations 493 spent since the last time it was flipped). 494

Fig. 7. The extension and refinement phase.

 $_{495}$  – *The heuristic*  $h_3$ *:* SLS [17]

<sup>496</sup> it is the stochastic local search method, which 497 explores the neighborhood of a candidate solu- $\frac{498}{498}$  tion with three strategies managed by two walking 499 | probabilities.

 $\begin{bmatrix} 500 \\ -7he \; heuristic \; h_4 \end{bmatrix}$  WalkSat [16]

501 It's an algorithm that starts by choosing randomly an unsatisfied clause. If there is a variable with negative gain equals 0 in the selected clause, then this variable is flipped. The negative gain of a variable is the number of clauses that will be bro- $\frac{1}{506}$  ken if the variable is flipped. It means that the said clause can be satisfied without breaking another clause. If no such variable exists, then depend- ing on the walk probability, the variable with the minimum negative gain is selected or a variable is  $\frac{1}{511}$  simply picked randomly from this clause.

 $\frac{1}{512}$  – *The heuristic h<sub>5</sub>:* Novelty [21]

 In Novelty, after choosing a broken clause, the variable to be flipped is selected as follow. If the variable with the highest net gain does not have the minimum age among the other variables 517 within the selected clause, it is always selected

Otherwise, it is only selected with the probability  $\frac{518}{2}$  $1 - p$ , else the variable with the next lower net  $519$ gain is selected. 520

*The heuristic*  $h_6$ : VNS [79] 521

The variable neighborhood search (VNS) is a 522 metaheuristic that explores several neighborhoods 523 for better diversification, and uses a local search 524 for the intensification. The VNS starts by defining  $525$ a set of neighborhood structures  $N_1, N_2, \ldots, N_k$  526 that will be explored during the search. Starting 527 with an initial solution, VNS calls a local search 528 method to explore the first neighborhood  $N_1$  of  $_{529}$ the said solution. If the solution is improved, then  $\frac{1}{530}$ the same neighborhood is further explored with 531 the local search method, otherwise, VNS switches 532 to the next neighborhood  $N_2$ , and so on. In VNS,  $\frac{1}{2}$  533 a solution is only accepted if there is an improve-<br>
<sub>534</sub> ment in the fitness function.

#### *3.2.4. The synergy thompson sampling* 536 *hyper-heuristic* 537

The SyTS-HH has a probabilistic learning approach 538 to handle the set of perturbative heuristics described 539

 above, to solve the considered Max-SAT problem. It uses the historical performances of the low-level heuristics to update its learning mechanism based on the Beta probability law. The Beta probability law is usually used to model the uncertainty about the prob- ability of success of an experiment. It is a continuous  $_{546}$  probability distribution defined on the interval  $[0, 1]$ ,  $_{547}$  and has two positive parameters  $\alpha$  and  $\beta$  that control the shape of the distribution. For example, to predict the success of an experiment, we sample a random variable x from it's beta distribution where the parame- $\frac{1}{551}$  ter  $\alpha$  represents the number of successes from previous experiments and  $\beta$  represents the number of failures. In this case, the Beta distribution is used to understand the 554 synergy between two low-level heuristics i and j, by learning the behavior of the sequence within a certain window throughout the execution. In order to do that,  $\frac{1}{557}$  to each combination of heuristics  $(i, j)$ , we will assign <sup>558</sup> a beta distribution Beta $(\alpha_{ij}^{(t)}, \beta_{ij}^{(t)})$ . At iteration (*t*), the  $\alpha_{ij}^{(t)}$  parameter is increased in the case of success. Oth- $\text{e}^{\text{2}}$  erwise, the  $\beta_{ij}^{(t)}$  parameter is increased. By success we mean an improvement of the fitness function after the execution of the sequence heuristic *i* then heuristic *i*. By doing that, the beta distribution will capture (approximately) the behavior of the sequence  $(i, j)$ . In this case, knowing that in the current iteration the heuristic  $\frac{1}{666}$  i was called, we can predict the success of the heuris- $\frac{1}{567}$  tic j by sampling a random variable from the distribu- $\frac{1}{568}$  tion called the utility score  $U_{ij}$ . We can say that the utility score represents the potential score of success of the sequence  $(i, j)$ , when the heuristic i was pre- $\frac{1}{571}$  viously called. The couples  $(\alpha_{ij}, \beta_{ij})$  are stored in a  $\mu$ <sub>572</sub> matrix ( $L^*L$ ), where L is the number of the low-level heuristics. In our case, we do not need to split the low- level heuristics into two sets as it has been done in al- gorithm 1, since we will be using well known state of the art Max-SAT metaheuristics instead of simple mu-<sub>577</sub> tation and local search methods.

 As shown in Algorithm 3, first, a heuristic i is cho- sen randomly. Then, to select the low-level heuristic that will be used in the next execution, utility scores 581 are sampled from the beta distributions of  $(i, j)$ ,  $\forall$  $\mathbf{582}$   $j \in [1, L]$ . The heuristic j with the maximum util- ity score is then selected. After the call of heuristic j, <sup>584</sup> the  $\alpha_{ij}^{(t+1)}$  and  $\beta_{ij}^{(t+1)}$  are updated: when the selected heuristic improves the quality of the candidate solu- tion, the Alpha of its associated Beta distribution is increased, otherwise, the Beta parameter is increased. After that, the heuristic *i* becomes the heuristic *i* of the next iteration and so on. This allows to implicitly 590 aim for the best sequence of all the low-level heuristics

at each stage of the search. In our case, the *all moves*  $\begin{bmatrix} 591 \end{bmatrix}$ *acceptance strategy* is used. The Thompson sampling 592 mechanisms are used with a *sliding time-window* to 593 only keep recent and potentially relevant observations  $\begin{bmatrix} 594 \end{bmatrix}$ about the behaviors of the low-level heuristics. The 595 sliding time-window has a size w iterations and respects the First in/First out principle. The size w is a  $\frac{1}{597}$ parameter of the algorithm and it should be tuned cor-<br>sse rectly. If w is too large it may include irrelevant information, however if it is too small, the observations  $\begin{bmatrix} 600 \\ 600 \end{bmatrix}$ kept may not be sufficient to capture the behavior of  $\sim$ the low-level heuristics. In the algorithm, at each iter $\frac{1}{100}$  602 ation, the beta distributions changes need to be kept in  $\sim$  603 order to update the beta distributions when it is sliding. 604

#### Algorithm 3 The SyTS-HH.

**Require:** a Max-SAT instance, a set  $H$  of  $m$  low-level heuristics the *maxiter* parameter, the sliding window  $w \in \mathbb{N}$ .

- **Ensure:** a solution  $S$
- 1: Generate an initial random solution  $S$  having a quality  $F$ .
- 2:  $t := 0$ :
- 3:  $\forall i, j \in [m]$ , set the parameters  $\alpha_{ij}^{(0)} := 1$ , and  $\beta_{ij}^{(0)} := 1$
- 4:  $\forall i, j \in [m]$ , let  $U_{ij}^{(0)}$  the utility score of the sequence of the low-level heuristics  $i, j$
- 5:  $h_i$ := a random low-level heuristic from H<br>6: Apply the heuristic  $h_i$  on S and undate t
- Apply the heuristic  $h_i$  on S, and update the candidate solution  $(S')$  with quality  $(F')$ .
- 7: while  $(t <$  maxiter) do
- 8: *//heuristic selection Method*
- 9:  $\forall j \in [m]$ , Sample  $U_{ij}^{(t)}$  from Beta $(\alpha_{ij}^{(t)}, \beta_{ij}^{(t)})$
- 10:  $h_j :=$  a low-level heuristic with the maximum utility score  $U_{ij}^{(t)}$
- 11: Apply the heuristic  $h_j$  on  $S'$  to obtain new solution  $S''$  with a quality  $F''$
- 12: if  $F'' > F$  then
- 13:  $\alpha_{ij}^{(t+1)} := \alpha_{ij}^{(t)} + 1$
- 14: else
- $15:$  $\beta_{ij}^{(t+1)} := \beta_{ij}^{(t)} + 1$
- 16: end if
- 17: if  $t \geqslant w$  then
- 18:  $-\forall j \in [m]$  if at iteration  $(t w)$ ,  $h_j$  has been called after the heuristic  $h_i$  and improved the solution, then  $\alpha_{ij}^{(t+1)} := \alpha_{ij}^{(t+1)} - 1$
- 19:  $-\forall i \in [m]$  if at iteration  $(t w)$ ,  $h_i$  has been called after the heuristic  $h_i$  and not improved the solution, then  $\beta_{ij}^{(t+1)} := \beta_{ij}^{(t+1)} - 1$

```
20: end if
```
- 21: *//the acceptance method: All moves accepted.*<br>  $22 \cdot S := S' \cdot F := F' \cdot S' := S'' \cdot F' := F'' \cdot$
- 22:  $S := S'$ ;  $F := F'$ ;  $S' := S''$ ;  $F' := F''$ ;
- 23: if  $(F'' \geq F_{best})$  then
- 24:  $S_{best} := S''; F_{best} := F'';$
- 25: end if
- 26:  $i := j$
- 27: end while

#### 605 4. The experiments

<sup>606</sup> All experiments were run on an Intel Core (TM) i7 <sup>607</sup> 2 GHz with 8 GB of RAM under Linux operating sys- $\epsilon_{008}$  tem. The source code is written in the C language. <sup>609</sup> We have implemented five variants of the hyper-610 heuristics for the Max-SAT problem corresponding to <sup>611</sup> five different selection strategies:  $\epsilon_{612}$  – *Random (R-HH):* corresponding to the simple <sup>613</sup> random strategy. <sup>614</sup> – *Choice-function (CF-HH):* corresponding to the <sup>615</sup> choice function described above. <sup>616</sup> – *Stochastic choice-function (SCF-HH):* is a com-<sup>617</sup> bination between the random strategy and the <sup>618</sup> choice function strategy [35,80]. <sup>619</sup> – *Tompson Sampling (TS-HH):* corresponding to <sup>620</sup> the original method described above. <sup>621</sup> – *Synergy Thompson Sampling (SyTS-HH):* corre- $622$  sponding to our method. <sup>623</sup> Due to the non-deterministic nature of the proposed  $624$  methods, 10 runs have been considered for each in-625 stance and for each method. Also, an empirical study <sup>626</sup> has been conducted to fix the parameters values. The  $627$  coarsening phase of the multilevel paradigm will stop <sup>628</sup> when reaching a level with *500* clusters.  $629$  – For the TS-HH and the SyTS-HH there is only <sup>630</sup> one parameter which is the size of the sliding win-<sup>631</sup> dow *w*. It has been fixed to *30*.  $\epsilon_{632}$  – For the CF-HH, there are two parameters:  $\phi$  starts <sup>633</sup> with the value *0.99*, and it changes according to the search performance, whilst  $\delta$ , its value de-635 pends on  $\phi$ , as described in Section 2.3.

 $\epsilon_{36}$  – For the SCF-HH, in addition to the  $\phi$  and  $\delta$  pa- $\epsilon_{37}$  rameters, it has also a walk probability  $(wp)$  that  $638$  is fixed to 0.3.

639 There are other parameters which concerns the low-<sup>640</sup> level heuristics:

 $_{641}$  – *Walksat*: The walk probability  $W = 0.3$ ,

- *SLS*: The walk probabilities of the low-level 642 heuristic  $SLS$  are: *WALK1* = 0.3 and *WALK2* = 0.6, 643
- *VNS*: The number of neighborhoods k is fixed to  $\frac{644}{644}$  $10,$  645
- *Novelty*: The walk probability  $W = 0.4$ .

#### *4.1. The obtained results* 647

In the following, we give the numerical results found  $648$ by the implemented methods.  $\begin{array}{c|c}\n\hline\n\end{array}$ 

#### *4.1.1. TS-HH VS ML-TS-HH* 650

The effectiveness of the multilevel paradigm has 651 been proven several times as previously discussed in 652 Section 2.6. To further investigate the impact of the  $_{653}$ multilevel paradigm, we have selected The TS-HH and 654 we have chosen the largest ten instances from the Max- 655 SAT competition industrial benchmarks. The results  $656$ in Table 1 indicate that the ML-TS-HH is more ro- $\vert$  657 bust than the simple TS-HH. The results reported in  $658$ Table 1 represent the number of not satisfied clauses. 659 From Fig. 8, we can see that the larger the instance,  $\frac{660}{660}$ the bigger the difference. This can be explained by the  $\begin{bmatrix} 661 \end{bmatrix}$ fact that the multilevel approach successively approx- $\begin{bmatrix} 662 \end{bmatrix}$ imates the problem with smaller, and hence easier to  $\frac{663}{663}$ solve, versions. The coarsening algorithm filters the so- $\frac{664}{664}$ lution space by placing restrictions on solutions which  $\frac{665}{665}$ the refinement algorithm can visit. Flipping the value  $\begin{bmatrix} 666 \end{bmatrix}$ of one cluster in a coarsened space is equivalent to  $667$ changing the values of several variables in the origi- 668 nal solution space. This allows exploring efficiently the  $\frac{669}{669}$ search space with a good balance between diversifica- 670 tion, by visiting different regions, and intensification,  $\frac{671}{2}$ by exploiting the solutions from previous levels in or- $\frac{672}{672}$ der to reach better solutions. When reaching the level  $\sigma$ <sup>33</sup> 0 (the original instance), the search starts with an ini- $\frac{674}{674}$ tial solution of a good quality, which usually helps the  $675$ search method to get closer to the global optimum.  $\Box$  676

Galley Proof 4/04/2019; 14:29 File: idt-1-idt180036.tex; BOKCTP/xhs p. 13

Fig. 9. Box-plot of the four methods on Max-SAT 2016 benchmarks.

#### <sup>677</sup> *4.1.2. Comparison between the five hyper-heuristics*

<sup>678</sup> Since we are interested in very large industrial Max-679 SAT benchmarks, we applied the multilevel paradigm on all of them to boost the search. The obtained re- sults on the industrial benchmarks are given in Tables 2 and 3, where the best results obtained for each instance are in bold font. Once again, the results are expressed by the number of the remaining unsatisfied clauses. To better expose the results, Table 4 gives some statisti- cal measures calculated from the percentages of sat- isfaction of clauses (number of satisfied clauses/total number of clauses in the instance). For each method, we give the minimum (*Min*), the maximum (*Max*), the average (*Mean*), the midway (*Median*), the first quar- tile (*1st Qu*) and the third quartile (*3rd Qu*). Also, the box-plot diagram is given in Fig. 9 to better visualize the distribution of values of the rate of satisfied clauses given by the different considered methods.

 $\epsilon_{95}$  As shown in the box-plot depicted in Fig. 9, we 696 can clearly see that the ML-CF-HH is almost similar (slightly better) than the ML-R-HH. This indicates that the additive learning mechanism of the choice func- tion stagnates especially when approaching the global optima, and thus the probability of improving a can- didate solution becomes low. However we can see a serious improvement concerning the ML-SCF-HH. This can be explained by the fact that the randomness helps changing the values of the additive weights of the choice function, in a way that improves its perfor- mance. This conclusion is further confirmed when see-ing the results of the ML-TS-HH.

 The ML-TS-HH performed better than the ML-CF- HH. This shows that the probabilistic selection strategy outperforms the additive learning mechanism. However, the ML-SCF-HH is better than the ML-TS-HH.

We can say in this case, that the stochastic mech- $\frac{1}{712}$ anism really improves the additive learning selection  $_{713}$ strategy, that takes into account the synergy between  $_{714}$ the low-level heuristics. On the other hand the Thomp- 715 son sampling selection method is based on the individ-<br>  $\frac{716}{6}$ ual performances of the low-level heuristics.  $\frac{1}{717}$ 

Finally, the experimental results indicate that the 718  $ML-SyTS-HH$  is the most robust among all five exper- $\vert$  719 imented hyper-heuristics. In our opinion, this is mainly  $\tau$ due to the fact of having an adaptive probabilistic se- $\begin{vmatrix} 721 \end{vmatrix}$ lection strategy and on the other hand to the fact of  $\frac{722}{2}$ taking into account the synergy between the low-level 723 heuristics. This confirms the fact that cooperation can  $_{724}$ allow the weaknesses of one low-level heuristic to be  $\frac{725}{6}$ compensated by the strengths of another.

#### *4.2. ANOVA statistical analysis*  $\begin{array}{ccc} 727 & 727 \end{array}$

To show statistically the significance of our results,  $\frac{728}{20}$ we used the ANOVA (Analysis of variance) statistical  $_{729}$ tool. Table 5 presents the results of the ten ANOVA 730 tests where the column *df* represents the degree of free-  $\frac{731}{2}$ dom, the column *SS* represents the Sum of squares, the  $_{732}$ column *MS* represents the mean square, the F-value 733 represents the F-statistic, and the  $P$ -value in bold font  $_{734}$ expresses the interpretation and result analysis. The  $P-$  735 value is lower than  $0.05$  in all of the ten tests. This  $736$ indicates that the values produced by the five meth- 737 ods are highly significantly different one from another. 738 This means that our proposed hyper heuristic is statis-<br>  $738$ tically better than the other methods and confirms the  $_{740}$ conclusions drawn from Table 4.  $\frac{1}{741}$ 

#### 5. Conclusion  $\frac{1}{742}$

In this paper, we proposed a new hyper-heuristic  $743$ that combines the multilevel paradigm and a modi- <sup>744</sup> fied Thompson Sampling selection strategy that takes  $_{745}$ into account the synergy between the different lowlevel heuristics. This method is called the Multilevel  $_{747}$ Synergy Thompson Sampling Hyper-Heuristic (ML- 748  $SyTS-HH$ ) and it has been applied to solve the Max- $\vert$  749 SAT problem. The set of perturbative low-level heuris-<br>  $750$ tics used in this work, contains some of the best state-<br>  $\frac{751}{751}$ of-the-art Max-Sat heuristics such as: GSAT, Walksat,  $_{752}$ HSAT, SLS, VNS and Novelty methods.

The work presented in [2] has shown the limitations  $\frac{754}{754}$ of the additive learning mechanism such as choice 755 function, especially when the probability of success is  $756$ less than  $\frac{1}{2}$ . The Thompson Sampling Hyper-Heuristic  $\frac{757}{757}$ has been proposed as an alternative and has been tested  $758$ 

 on personnel Scheduling, Permutation Flow-shop, and the Traveling Salesman problem. Thompson Sampling Hyper-Heuristic assesses the individual performances of the low-level heuristics and tries to learn it by using the beta probability distribution and it's two shaping parameters Alpha and Beta. The Alpha parameter rep- resents the number of successes and the Beta parame- ter represents the number of failures. The kept values of alpha and beta are within a certain sliding window that insures keeping only relevant information with re- spect to the current phase of the search. However, this selection strategy does not take into consideration the synergy between the low-level heuristics. Since dif- ferent low-level heuristics have different strengths and weaknesses, we believe that cooperation can allow the weaknesses of one low-level heuristic to be compen-sated by the strengths of another.

 On the other hand we integrated in the proposed 777 method the multilevel paradigm that has shown its effi- ciency when dealing with large instances of a problem. It coarsens the initial instance into smaller ones that are generally easier to solve. This is done by putting variables into clusters, then using the solution of the current level as an initial solution to the next level. At any level, the current solution can be extended to the original problem instance.

 For the experimental study, we implemented the proposed method and four other hyper-heuristics that are the Random Hyper-Heuristic, the Choice Func- tion Hyper-Heuristic, the Stochastic Choice Function Hyper-Heuristic and the original Thompson Sampling Hyper-Heuristic. All of these methods have been com- bined with the Multilevel framework, and have been evaluated on very large instances representing the in- dustrial benchmarks of the latest Max-sat competi- tions. The obtained results show that the new proposed method outperforms all other experimented hyper-heuristics.

 In the future, we will try other coarsening meth- ods that will merge the variables in a more intelligent way by taking into account the instance structure. We will also focus on finding other probabilistic learning 801 mechanisms that will take into account other feedback information and that will capture better the low-level heuristics behaviors.
