# Thermal flows in fractured porous media 

Isabelle Gruais and Dan Poliševski

#### Abstract

We consider the thermal flow problem occuring in a fractured porous medium. The incompressible filtration flow in the porous matrix and the viscous flow in the fractures obey the Boussinesq approximation of the Darcy-Forchheimer law and respectively, the Stokes system. They are coupled by the Saffman's variant of the Beavers-Joseph condition. Existence and uniqueness properties are presented. In the $\varepsilon$-periodic framework, the two-scale homogenized system which governs the asymptotic behaviour (when $\varepsilon \rightarrow 0$ ) is found.

Mathematics Subject Classification (2010). 35B27; 76M50; 76Rxx; 74F10; 74Q05.
Keywords. fractured porous media, $\varepsilon$-domes, two-scale homogenized system, Darcy-Forchheimer law, Boussinesq approximation, Beavers-Joseph condition.

## 1. Introduction

Among the issues raised by the heat and mass transfer in fractured porous media, the requirement for further construction and characterization of macroscopic models is of special interest. It is a difficult task because the two components have highly constrasting behaviours. The models of flows through fractured porous media (see [5], [6], [12], [27] and [29]) are usually obtained by asymptotic methods, from the alteration of a homogeneous porous medium by a distribution of microscopic fractures/fissures. In this context, the periodic homogenization, based on the assumption of the $\varepsilon$ periodicity of the structure properties, is an important modelling tool for a fractured porous media process. Although it looks like an idealistic assumption, it usually authorizes a rigorous approach, yielding many of the properties which must be taken into account at macroscopic level.

We consider that the heat and mass transfer takes place in a periodically structured domain consisting of two interwoven regions, separated by an interface. It was not until the non-connectedness assumption could be dropped out that the homogenization of phenomena in fractured media could be studied rigorously (see [2], [25] and [26]). As the process at the microscopic scale takes place under the assumption of $\varepsilon$-periodicity, the study of its asymptotic behaviour (when $\varepsilon \rightarrow 0$ ) is amenable to the procedures of the homogenization theory. We improve the properties of the $\varepsilon$-periodic biphasic structure introduced in [26], by attaching the so-called $\varepsilon$-domes. They are placed in the last entire $\varepsilon$-cells contained in the domain, near its boundary, and they complete the $\varepsilon$-periodic interface such that it can be as smooth as it is needed, all the properties of [26] remaining valid.

The first region, the only one reaching the boundary of the domain, represents a connected porous matrix, where, disregarding its pore scale, we consider the movement of an incompressible average filtration fluid governed by the Boussinesq approximation of the Darcy-Forchheimer system. The linear Darcy's law relating the flow and the pressure gradient in the porous surrounding matrix relies on the assumption of laminar flow (see [31]). Unfortunately, this assumption does not hold when high imposed pressure gradients and resistance from fracture walls lead to reduced flow rates compared to the linear Darcy relation. The standard extended model involves a Forchheimer correction term (see [13]) which introduces a non-linear coupling between pressure gradient and flow rates. This Forchheimer term was proved to be valid at higher Reynolds number by Muskat (see [23]).

The second region, representing the fractures which are not necessarily connected, is saturated by an incompressible viscous fluid governed by the Boussinesq approximation of the Stokes system.

These two flows are coupled on the interface by the Saffman's variant [28] of the Beavers-Joseph condition [7], [19] which was confirmed by [18] as the limit of a homogenization process. Besides the
continuity of the normal component of the velocity, it imposes the proportionality of the tangential velocity with the tangential component of the viscous stress on the fluid-side of the interface.

The tensors of thermal diffusion of the two phases are $\varepsilon$-periodic and not necessarily equal. On the interface, the heat flux is continuous and proportional with the temperature jump. This firstorder jump condition presents an heat transfer coefficient which is also assumed $\varepsilon$-periodic. Finally, a temperature distribution is imposed on the boundary of the domain.

We prove the existence and uniqueness properties of the velocity, pressure and temperature distribution, solutions of the corresponding thermal flow boundary problem. An $L^{\infty}$-estimate of the temperature, uniform with respect to $\varepsilon$, is also presented.

As the Forchheimer effect vanishes with the small period of the distribution shrinking to zero, we study the asymptotic behaviour of the flow when the Rayleigh number is of unity order, the permeability of the porous blocks of unity order and the Beavers-Joseph transfer coefficient of $\varepsilon$-order, balancing the measure of the interface. Using the techniques of the two-scale convergence theory (see [4], [9] and [24]), we find the two-scale system verified by the limits of the $\varepsilon$-solutions and the local problems which allow us to define the effective coefficients of the leading homogenized system.

The paper is organized as follows.
In Section 2 we present our fractured porous medium, the $\varepsilon$-periodic structure provided with the useful $\varepsilon$-domes. The direct form of the thermal flow problem is introduced.

In Section 3 we prove the existence and uniqueness properties. The weak solutions of our nonlinear problem are found by means of the Browder-Minty and Schauder fixed-point theorems. The primary estimates are also obtained.

Section 4 is devoted to the homogenization in the case when the Forchheimer effect is vanishing. We present the a priori estimates which serve as departure point for adapting the compacity results of the two-scale convergence theory (see [4], [22] and [24]). Using the techniques of the two-scale convergence theory (see [4], [9] and [24]), we obtain the so-called two-scale homogenized problem and the solutions of the local problems which allow us to define the effective coefficients of the homogenized system and eliminate some of the oscillating unknowns. In the case of non-oscillating permeability tensor, we present an interesting macroscopic problem, governing all the leading non-oscillating unknowns.

At the end, there is added an Appendix A, where we prove a usefull inequality that was already used in some particular cases (see [14] and [30]).

## 2. The fractured structure and the governing system

Let $\Omega$ be an open connected bounded set in $\mathbb{R}^{N}, N \in\{2,3\}$, a manifold of class $\mathrm{C}^{2}$ composed of a finite number of connected components, locally located on one side of the boundary $\partial \Omega$ with $\nu$ its outward normal.

We describe now the geometric structure of our fractured porous medium, similar to that introduced in [17].

Let $E$ be the rhombic polyhedron obtained by affixing square pyramids of $1 / 2$ height on each face of the cube $Y=]-1 / 2,1 / 2\left[{ }^{N}\right.$, that is

$$
\begin{equation*}
E=\operatorname{int}\left(\operatorname{Conv}\left(\bar{Y} \cup\left\{ \pm e_{i}, i=1,2, \ldots, N\right\}\right)\right), \tag{2.1}
\end{equation*}
$$

where $e_{i}$ are the unit vectors of the canonical basis in $\mathbb{R}^{N}$.
For $D \subset \subset E$, an open set of class $\mathrm{C}^{2}$, we assume that $Y_{f}:=Y \cap D$ has the property

$$
\begin{equation*}
\bar{Y}_{f} \cap \Sigma^{ \pm i} \subset \subset \Sigma^{ \pm i}, \quad \forall i \in\{1,2, \ldots, N\} \tag{2.2}
\end{equation*}
$$

where $\Sigma^{ \pm i}=\left\{y \in \partial Y: y_{i}= \pm 1 / 2\right\}$.
For every $i \in\{1,2, \ldots, N\}$ we define the corresponding two domes of $Y_{f}$ by

$$
\begin{equation*}
D_{i}^{+}=\left(Y+e_{i}\right) \cap D \quad \text { and } \quad D_{i}^{-}=\left(Y-e_{i}\right) \cap D . \tag{2.3}
\end{equation*}
$$

Denoting $Y_{s}:=Y \backslash \bar{Y}_{f}$, we assume that the reunion in $\mathbb{R}^{N}$ of all the $\bar{Y}_{s}$ parts, denoted by $\mathbb{R}_{s}^{N}$, has a $\mathrm{C}^{2}$ boundary; $\mathbb{R}_{f}^{N}$ is similarly defined. The characteristic functions of $Y_{s}$ and $Y_{f}$ are denoted by $\chi_{s}$ and $\chi_{f}$, respectively; we also assume $\left.m:=\left|Y_{f}\right| \in\right] 0,1[$.

Without loss of the generality, we set the origin of the coordinate system in such a way that there exists $r>0$ with the property $B(0, r) \subseteq \mathbb{R}_{s}^{N}$.

For any $\varepsilon \in] 0,1[$ we denote

$$
\begin{gather*}
\mathbb{Z}_{\varepsilon}=\left\{k \in \mathbb{Z}^{N}: \varepsilon k+\varepsilon Y \subseteq \Omega\right\},  \tag{2.4}\\
\mathbb{I}_{\varepsilon}=\left\{k \in \mathbb{Z}_{\varepsilon}: \varepsilon k \pm \varepsilon e_{i}+\varepsilon Y \subseteq \Omega, \forall i \in\{1,2, \ldots, N\}\right\},  \tag{2.5}\\
\Omega_{\varepsilon f}^{\square}=\cup_{k \in \mathbb{I}_{\varepsilon}}\left(\varepsilon k+\varepsilon Y_{f}\right) . \tag{2.6}
\end{gather*}
$$

For any $k \in \mathbb{Z}_{\varepsilon} \backslash \mathbb{I}_{\varepsilon}$, denoting by

$$
\begin{equation*}
\mathbb{J}_{\varepsilon k}^{ \pm}=\left\{i \in\{1,2, \ldots, N\}, \quad\left(\varepsilon k+\varepsilon \bar{D}_{i}^{ \pm}\right) \cap \overline{\Omega_{\varepsilon f}^{\square}} \neq \emptyset\right\}, \tag{2.7}
\end{equation*}
$$

we define the $\varepsilon$-domes which have to be attached to $\Omega_{\varepsilon f}^{\square}$ in order to regularize the interface between the free fluid saturating the fractures and the filtration fluid saturating the porous matrix, by

$$
\begin{equation*}
D_{\varepsilon k}=\left(\cup_{i \in \mathbb{J}_{\varepsilon k}^{+}}\left(\varepsilon k+\varepsilon D_{i}^{+}\right)\right) \cup\left(\cup_{i \in \mathrm{~J}_{\varepsilon k}^{-}}\left(\varepsilon k+\varepsilon D_{i}^{-}\right)\right) . \tag{2.8}
\end{equation*}
$$

We consider that the free fluid takes place in

$$
\begin{equation*}
\Omega_{\varepsilon f}=\operatorname{int}\left(\left(\cup_{k \in \mathbb{I}_{\varepsilon}}\left(\varepsilon k+\varepsilon \bar{Y}_{f}\right)\right) \cup\left(\cup_{k \in \mathbb{Z}_{\varepsilon} \backslash \mathbb{I}_{\varepsilon}} D_{\varepsilon k}\right)\right) . \tag{2.9}
\end{equation*}
$$

Consequently, the porous matrix and the interface between the two components are defined by:

$$
\begin{gather*}
\Omega_{\varepsilon s}=\Omega \backslash \bar{\Omega}_{\varepsilon f}  \tag{2.10}\\
\Gamma_{\varepsilon}=\partial \Omega_{\varepsilon f} \cap \partial \Omega_{\varepsilon s}=\partial \Omega_{\varepsilon f} \tag{2.11}
\end{gather*}
$$

We assume that $\Omega_{\varepsilon s}$ is connected and that for every $\varepsilon>0$, there exist $k_{\varepsilon} \in \mathbb{N}, k_{\varepsilon} \geq 1$, such that

$$
\begin{equation*}
\Omega_{\varepsilon f}=\cup_{k=1}^{k_{\varepsilon}} \Omega_{\varepsilon f}^{k} \tag{2.12}
\end{equation*}
$$

where every $\Omega_{\varepsilon f}^{k}$ is a connected subdomain of $\Omega_{\varepsilon f}$ with $\operatorname{dist}\left(\Omega_{\varepsilon f}^{i}, \Omega_{\varepsilon f}^{j}\right)>0$ if $i \neq j$. The characteristic functions of $\Omega_{\varepsilon s}$ and $\Omega_{\varepsilon f}$ are denoted by $\chi_{\varepsilon s}$ and $\chi_{\varepsilon f}$, respectively.

Denoting $\Gamma_{\varepsilon}^{k}=\partial \Omega_{\varepsilon f}^{k}$, it follows that

$$
\begin{equation*}
\Gamma_{\varepsilon}=\cup_{k=1}^{k_{\varepsilon}} \Gamma_{\varepsilon}^{k} \tag{2.13}
\end{equation*}
$$

Denoting by $\Gamma=\partial Y_{f} \cap \partial Y_{s} \subseteq \partial D$, by $n$ the normal on $\partial D$ (inward to D ) and by $n^{\varepsilon}$ the normal on $\Gamma_{\varepsilon}$ (outward to $\Omega_{\varepsilon s}$ ), we have

$$
\begin{equation*}
n^{\varepsilon}(x)=n(x / \varepsilon), \text { for any } x \in(\varepsilon k+\varepsilon \Gamma) \text { with } k \in \mathbb{I}_{\varepsilon} \tag{2.14}
\end{equation*}
$$

where the Y-periodic prolongation of $\left.n\right|_{\Gamma}$ is still denoted by $n$.
The class of the connections between $\Omega_{\varepsilon f}^{\square}$ and the corresponding $\varepsilon$-domes is similar to that between $Y_{f}$ and its domes, that is the class of D . This is an important advantage of the structures with $\varepsilon$-domes: the class of $\Gamma_{\varepsilon}$ is given by D and by the reunion of all the $\bar{Y}_{s}$ parts in $\mathbb{R}^{N}$, which can be assumed as smooth as it is needed. There is also an important feature of our periodic structure, provided with $\varepsilon$-domes. As the $(\varepsilon k+\varepsilon Y)$-cells containing $\varepsilon$-domes are of at most $\left(4^{N}-2\right)$ types and the distance between $\Gamma_{\varepsilon}$ and $\partial \Omega$ is greater than $\varepsilon / 2$, they do not affect the results obtained for the classical $\varepsilon$-periodic structures. The present structure preserves many specific properties (see [8], [12], [16], [17], [26]).

Now we can present the thermal flow problem which corresponds to our framework. If ( $u^{\varepsilon s}, p^{\varepsilon s}, \theta^{\varepsilon s}$ ) and $\left(u^{\varepsilon f}, p^{\varepsilon f}, \theta^{\varepsilon f}\right)$ stand for the velocities, pressures and temperatures associated to the corresponding phase of our structure, then they verify the following system:

$$
\begin{gather*}
\operatorname{div} u^{\varepsilon s}=0 \quad \text { in } \quad \Omega_{\varepsilon s}, \quad \operatorname{div} u^{\varepsilon f}=0 \quad \text { in } \quad \Omega_{\varepsilon f}, \quad u^{\varepsilon s} \cdot n^{\varepsilon}=u^{\varepsilon f} \cdot n^{\varepsilon} \quad \text { on } \quad \Gamma_{\varepsilon},  \tag{2.15}\\
\nabla p^{\varepsilon s}+\left(1+d_{\varepsilon}\left|u^{\varepsilon s}\right|_{A^{\varepsilon}}^{r-2}\right) A^{\varepsilon} u^{\varepsilon s}+\alpha_{\varepsilon} \theta^{\varepsilon s} g=0, \quad\left|u^{\varepsilon s}\right|_{A^{\varepsilon}}=\left(A_{i j}^{\varepsilon} u_{i}^{s s} u_{j}^{\varepsilon s}\right)^{1 / 2} \quad \text { in } \Omega_{\varepsilon s}, \tag{2.16}
\end{gather*}
$$

$$
\begin{gather*}
-\operatorname{div} \Sigma^{\varepsilon i}+\alpha_{\varepsilon} \theta^{\varepsilon f} g_{i}=0 \quad \text { in } \quad \Omega_{\varepsilon f}, \quad \forall i \in\{1,2, \cdots, N\},  \tag{2.17}\\
\Sigma_{j}^{\varepsilon i}=-p^{\varepsilon f} \delta_{i j}+e_{i j}\left(u^{\varepsilon f}\right), \quad e_{i j}\left(u^{\varepsilon f}\right)=\frac{1}{2}\left(\frac{\partial u_{i}^{\varepsilon f}}{\partial x_{j}}+\frac{\partial u_{j}^{\varepsilon f}}{\partial x_{i}}\right) \text { in } \Omega_{\varepsilon f},  \tag{2.18}\\
p^{\varepsilon s} n_{i}^{\varepsilon}+\Sigma^{\varepsilon i} n^{\varepsilon}+\varepsilon \beta_{\varepsilon}\left(u_{i}^{\varepsilon f}-\left(u^{\varepsilon f} \cdot n^{\varepsilon}\right) n_{i}^{\varepsilon}\right)=0 \quad \text { on } \quad \Gamma_{\varepsilon}, \quad \forall i \in\{1,2, \cdots, N\},  \tag{2.19}\\
u^{\varepsilon f} \nabla \theta^{\varepsilon f}-\operatorname{div}\left(B^{\varepsilon f} \nabla \theta^{\varepsilon f}\right)=Q^{f} \quad \text { in } \Omega_{\varepsilon f},  \tag{2.20}\\
u^{\varepsilon s} \nabla \theta^{\varepsilon s}-\operatorname{div}\left(B^{\varepsilon s} \nabla \theta^{\varepsilon s}\right)=Q^{s} \quad \text { in } \Omega_{\varepsilon s},  \tag{2.21}\\
B_{i j}^{\varepsilon f} \frac{\partial \theta^{\varepsilon f}}{\partial x_{j}} n_{i}^{\varepsilon}=B_{i j}^{\varepsilon s} \frac{\partial \theta^{\varepsilon s}}{\partial x_{j}} n_{i}^{\varepsilon}, \quad \theta^{\varepsilon s}=\theta^{\varepsilon f} \quad \text { on } \Gamma_{\varepsilon}  \tag{2.22}\\
u^{\varepsilon s} \cdot \nu=0 \quad \text { on } \partial \Omega, \quad \nu \text { the outward normal, }  \tag{2.23}\\
\theta^{\varepsilon}=\tau \quad \text { on } \partial \Omega, \tag{2.24}
\end{gather*}
$$

where $\tau \in H^{1}(\Omega) \cap L^{\infty}(\Omega)$ has the property that $\exists \tau_{0}>0$ for which

$$
\begin{equation*}
\left.|\tau| \leq \tau_{0} \text { on } \partial \Omega \text { in the sense of } H^{1}(\Omega) \text { (see }[20]\right) \tag{2.25}
\end{equation*}
$$

The symmetric permeability tensor $A^{\varepsilon} \in L^{\infty}(\Omega)^{N \times N}$, the Beavers-Joseph coefficient $\beta_{\varepsilon} \in C^{1}(\Omega)$ and the symmetric conductivities $B^{\varepsilon f}, B^{\varepsilon s} \in L^{\infty}(\Omega)^{N \times N}$ are given with the property that there exist $b_{2}$ and $b_{1}>0, b_{1}<b_{2}$, independent of $\varepsilon$, such that for any $\varepsilon>0$ we have

$$
\begin{gather*}
\left|A^{\varepsilon}\right|_{L^{\infty}(\Omega)} \leq b_{2}, \quad\left|B^{\varepsilon s}\right|_{L^{\infty}(\Omega)} \leq b_{2}, \quad\left|B^{\varepsilon f}\right|_{L^{\infty}(\Omega)} \leq b_{2}, \quad \text { a.e. in } \Omega,  \tag{2.26}\\
\beta_{\varepsilon} \geq b_{1}, \quad A_{i j}^{\varepsilon} \xi_{i} \xi_{j} \geq b_{1} \xi_{i} \xi_{i}, \quad B_{i j}^{\varepsilon s} \xi_{i} \xi_{j} \geq b_{1} \xi_{i} \xi_{i}, \quad B_{i j}^{\varepsilon f} \xi_{i} \xi_{j} \geq b_{1} \xi_{i} \xi_{i}, \quad \forall \xi \in \mathbb{R}^{N}, \quad \text { a.e. in } \Omega .
\end{gather*}
$$

The rest of the data are the Forchheimer coefficient $d_{\varepsilon}>0$, the Rayleigh number $\alpha_{\varepsilon}>0$, the exterior forces $g \in L^{2}(\Omega)^{N}$, the heat sources $Q^{f}, Q^{s} \in L^{2}(\Omega)$ and the Forchheimer exponent $r \in \mathbb{R}$ with the property:

$$
\begin{equation*}
r \geq 2 \quad \text { if } \quad N=2 \quad \text { and } \quad 3 \leq r<6 \quad \text { if } \quad N=3 . \tag{2.28}
\end{equation*}
$$

## 3. Existence and estimates of the weak solutions

We present in this section the existence and uniqueness properties of the weak solutions of the convection problem (2.15) - (2.24), together with an $L^{\infty}$-estimate of the temperature.

Let us introduce the following spaces:

$$
\begin{align*}
& H=\left\{v \in H(\operatorname{div}, \Omega), \quad v \in L^{r}(\Omega), \quad v_{\nu}=0 \quad \text { on } \quad \partial \Omega\right\},  \tag{3.1}\\
& V=\{v \in H, \quad \operatorname{div} v=0 \quad \text { in } \Omega\},  \tag{3.2}\\
& H_{\varepsilon}=\left\{v \in H,\left.\quad v\right|_{\Omega_{\varepsilon f}} \in H^{1}\left(\Omega_{\varepsilon f}\right)^{N}\right\},  \tag{3.3}\\
& V_{\varepsilon}=\left\{v \in H_{\varepsilon}, \quad \operatorname{div} v=0 \quad \text { in } \Omega\right\},  \tag{3.4}\\
& L_{0}^{2}(\Omega)=\left\{p \in L^{2}(\Omega), \quad \int_{\Omega} p=0\right\}, \tag{3.5}
\end{align*}
$$

where $v_{\nu}$ stands for the normal trace on $\partial \Omega$.
For any $v \in H_{\varepsilon}$ we denote the normal trace on $\Gamma_{\varepsilon}$ in $H(\operatorname{div}, \Omega)$ by $v_{n^{\varepsilon}}$ and the trace on $\Gamma_{\varepsilon}$ in $H^{1}\left(\Omega_{\varepsilon f}\right)$ by $\gamma_{\varepsilon f} v$. As $\Gamma_{\varepsilon}$ is of class $C^{2}$, let us remark that

$$
\begin{equation*}
v_{n^{\varepsilon}}=\left(\gamma_{\varepsilon f} v\right) n^{\varepsilon} \in H^{1 / 2}\left(\Gamma_{\varepsilon}\right) . \tag{3.6}
\end{equation*}
$$

Denoting

$$
\begin{equation*}
v_{t^{\varepsilon}}=\gamma_{\varepsilon f} v-\left(v_{n^{\varepsilon}}\right) n^{\varepsilon} \in H^{1 / 2}\left(\Gamma_{\varepsilon}\right)^{N}, \tag{3.7}
\end{equation*}
$$

we have also

$$
\begin{equation*}
\left(\gamma_{\varepsilon f} v\right)^{2}=\left(v_{n^{\varepsilon}}\right)^{2}+\left(v_{t^{\varepsilon}}\right)^{2} \quad \text { a.e. on } \quad \Gamma_{\varepsilon} . \tag{3.8}
\end{equation*}
$$

We see now that $H$ and $H_{\varepsilon}$, endowed with the norms

$$
\begin{equation*}
|v|_{H}=|v|_{L^{r}(\Omega)}+|\operatorname{div} v|_{L^{2}(\Omega)}, \tag{3.9}
\end{equation*}
$$

$$
\begin{equation*}
|v|_{H_{\varepsilon}}=|v|_{L^{r}\left(\Omega_{\varepsilon s}\right)}+|\operatorname{div} v|_{L^{2}\left(\Omega_{\varepsilon s}\right)}+|e(v)|_{L^{2}\left(\Omega_{\varepsilon f}\right)}+\varepsilon^{1 / 2}\left|v_{t^{\varepsilon}}\right|_{\Gamma_{\varepsilon}}, \tag{3.10}
\end{equation*}
$$

are Banach spaces. Moreover, by rescaling the corresponding inequalities in $Y$, we obtain

$$
\begin{align*}
& |v|_{L^{2}\left(\Omega_{\varepsilon f}\right)} \leq C\left(\varepsilon|\nabla v|_{L^{2}\left(\Omega_{\varepsilon f}\right)}+\varepsilon^{1 / 2}\left|\gamma_{\varepsilon f} v\right|_{L^{2}\left(\Gamma_{\varepsilon}\right)}\right),  \tag{3.11}\\
& \varepsilon^{1 / 2}\left|v_{n^{\varepsilon}}\right|_{L^{2}\left(\Gamma_{\varepsilon}\right)} \leq C\left(|v|_{L^{2}\left(\Omega_{\varepsilon s}\right)}+\varepsilon|\operatorname{div} v|_{L^{2}\left(\Omega_{\varepsilon s}\right)}\right), \tag{3.12}
\end{align*}
$$

and consequently

$$
\begin{equation*}
|v|_{L^{2}\left(\Omega_{\varepsilon f}\right)} \leq C\left(|v|_{L^{2}\left(\Omega_{\varepsilon s}\right)}+\varepsilon|\operatorname{div} v|_{L^{2}\left(\Omega_{\varepsilon s}\right)}+\varepsilon|e(v)|_{L^{2}\left(\Omega_{\varepsilon f}\right)}+\varepsilon^{1 / 2}\left|v_{t^{\varepsilon}}\right|_{L^{2}\left(\Gamma_{\varepsilon}\right)}\right) . \tag{3.13}
\end{equation*}
$$

A useful property of the present structure is the existence of a bounded extension operator similar to that introduced in [1], [3], [8] and [10] in the case of isolated fractures.

Theorem 3.1. There exists an extension operator $P_{\varepsilon}: H^{1}\left(\Omega_{\varepsilon f}\right) \rightarrow H^{1}(\Omega)$ such that

$$
\begin{gather*}
P_{\varepsilon} u=u \quad \text { in } \quad \Omega_{\varepsilon f}  \tag{3.14}\\
\left|e\left(P_{\varepsilon} u\right)\right|_{L^{2}(\Omega)} \leq C|e(u)|_{L^{2}\left(\Omega_{\varepsilon f}\right)}, \quad \forall u \in H^{1}\left(\Omega_{\varepsilon f}\right) \tag{3.15}
\end{gather*}
$$

where $C$ is independent of $\varepsilon$.
A straightforward consequence, via the corresponding Korn inequality, is
Lemma 3.2. There exists some constant $C>0$, independent of $\varepsilon$, such that

$$
\begin{equation*}
|u|_{H^{1}\left(\Omega_{\varepsilon f}\right)} \leq C|u|_{H_{\varepsilon}}, \quad \forall u \in H_{\varepsilon} \tag{3.16}
\end{equation*}
$$

Denoting $T^{\varepsilon}=\theta^{\varepsilon}-\tau$ in (2.15)-(2.24), we are led to the following variational problem:
To find $\left(u^{\varepsilon}, T^{\varepsilon}\right) \in V_{\varepsilon} \times H_{0}^{1}(\Omega)$ which verifies

$$
\begin{gather*}
\int_{\Omega_{\varepsilon s}}\left(1+d_{\varepsilon}\left|u^{\varepsilon}\right|_{A^{\varepsilon}}^{r-2}\right) A^{\varepsilon} u^{\varepsilon} v+\int_{\Omega_{\varepsilon f}} e_{i j}\left(u^{\varepsilon}\right) e_{i j}(v)+\varepsilon \beta_{\varepsilon} \int_{\Gamma_{\varepsilon}} u_{t_{\varepsilon}}^{\varepsilon} v+\alpha_{\varepsilon} \int_{\Omega}\left(T^{\varepsilon}+\tau\right) g v=0, \quad \forall v \in V_{\varepsilon},  \tag{3.17}\\
\int_{\Omega} B^{\varepsilon} \nabla T^{\varepsilon} \nabla S+\int_{\Omega} u^{\varepsilon} S \nabla T^{\varepsilon}=\int_{\Omega} Q S-\int_{\Omega} u^{\varepsilon} S \nabla \tau-\int_{\Omega} B^{\varepsilon} \nabla \tau \nabla S, \quad \forall S \in H_{0}^{1}(\Omega), \tag{3.18}
\end{gather*}
$$

where we denoted

$$
B^{\varepsilon}=\left\{\begin{array}{lll}
B^{\varepsilon s} & \text { in } & \Omega_{\varepsilon s},  \tag{3.19}\\
B^{\varepsilon f} & \text { in } & \Omega_{\varepsilon f}
\end{array} \quad \text { and } \quad Q=\left\{\begin{array}{lll}
Q^{s} & \text { in } & \Omega_{\varepsilon s}, \\
Q^{f} & \text { in } & \Omega_{\varepsilon f} .
\end{array}\right.\right.
$$

Theorem 3.3. There exists a solution of the problem (3.17)-(3.18). Any solution ( $u^{\varepsilon}, T^{\varepsilon}$ ) of (3.17)(3.18) has the property that $T^{\varepsilon} \in L^{\infty}(\Omega)$ and that for some $c>0$, independent of $\varepsilon$, we have

$$
\begin{gather*}
\left|\nabla T^{\varepsilon}\right|_{L^{2}(\Omega)}+\left|T^{\varepsilon}+\tau\right|_{L^{\infty}(\Omega)} \leq c  \tag{3.20}\\
\left|u^{\varepsilon}\right|_{L^{2}(\Omega)}+\left|u^{\varepsilon}\right|_{H^{1}\left(\Omega_{\varepsilon f}\right)}+\varepsilon^{1 / 2}\left|u_{t^{\varepsilon}}^{\varepsilon}\right|_{L^{2}\left(\Gamma_{\varepsilon}\right)} \leq c \alpha_{\varepsilon}  \tag{3.21}\\
\left|u^{\varepsilon}\right|_{L^{r}\left(\Omega_{\varepsilon s}\right)} \leq c \alpha_{\varepsilon}^{2 / r} d_{\varepsilon}^{-1 / r} \tag{3.22}
\end{gather*}
$$

Proof. By splitting the system according to the two distinct types of nonlinearities involved, we expect to complete the proof by the Schauder fixed-point theorem.
For $w \in V_{\varepsilon}$, we define $T_{w} \in H_{0}^{1}(\Omega)$ to be the unique solution of the problem:

$$
\begin{equation*}
\int_{\Omega} B^{\varepsilon} \nabla T_{w} \nabla S+\int_{\Omega} w S \nabla T_{w}=\int_{\Omega} Q S-\int_{\Omega} w S \nabla \tau-\int_{\Omega} B^{\varepsilon} \nabla \tau \nabla S, \quad \forall S \in H_{0}^{1}(\Omega) \tag{3.23}
\end{equation*}
$$

First, let us examine the continuity of the convective term.

$$
\begin{equation*}
\left|\int_{\Omega} w S \nabla T_{w}\right| \leq|w|_{L^{r}(\Omega)}\left|T_{w}\right|_{L^{2 r /(r-2)}(\Omega)}|S|_{H_{0}^{1}(\Omega)} . \tag{3.24}
\end{equation*}
$$

As $r \geq N$, that is $2 r /(r-2) \leq 2 N /(N-2)$, and using the corresponding Sobolev inequality, we get

$$
\begin{equation*}
\left|T_{w}\right|_{L^{2 r /(r-2)}(\Omega)} \leq c\left|T_{w}\right|_{H_{0}^{1}(\Omega)} . \tag{3.25}
\end{equation*}
$$

Also, as $r \in \mathbb{R}$ and $r<6$ if $N=3$, we have

$$
\begin{equation*}
|w|_{L^{r}\left(\Omega_{\varepsilon f}\right)} \leq c|w|_{H^{1}\left(\Omega_{\varepsilon f}\right)} \tag{3.26}
\end{equation*}
$$

and together with (3.25), we finally obtain

$$
\begin{equation*}
\left|\int_{\Omega} w S \nabla T_{w}\right| \leq|w|_{H_{\varepsilon}}\left|T_{w}\right|_{H_{0}^{1}(\Omega)}|S|_{H_{0}^{1}(\Omega)} \tag{3.27}
\end{equation*}
$$

Then, the existence and uniqueness results follow straightly from the Lax-Milgram Theorem.
Moreover, acting like in Theorem 3.9 (see [11] and [17]), we prove that $T_{w} \in L^{\infty}(\Omega)$ and there exists $c>0$ (independent of $\varepsilon$ ) such that (3.18) is satisfied. Setting $S=T_{w}$ in (3.23), we obtain

$$
\begin{equation*}
\left|\nabla T_{w}\right|_{L^{2}(\Omega)} \leq c\left(|Q|_{L^{2}(\Omega)}+|\nabla \tau|_{L^{2}(\Omega)}+\left(|Q|_{L^{2}(\Omega)}+\tau_{0}\right)|w|_{L^{2}(\Omega)}\right) \tag{3.28}
\end{equation*}
$$

where $c>0$ is independent of $\varepsilon$.
Also, we define $F(w) \in V_{\varepsilon}$ as the unique solution of the problem:

$$
\begin{align*}
\int_{\Omega_{\varepsilon s}}\left(1+d_{\varepsilon}|F(w)|_{A^{\varepsilon}}^{r-2}\right) A^{\varepsilon} F(w) v+\int_{\Omega_{\varepsilon f}} e_{i j}(F(w)) e_{i j}(v)+\varepsilon \beta_{\varepsilon} \int_{\Gamma_{\varepsilon}} F(w)_{t_{\varepsilon}} v & = \\
& =-\alpha_{\varepsilon} \int_{\Omega}\left(T_{w}+\tau\right) g v, \quad \forall v \in V_{\varepsilon} \tag{3.29}
\end{align*}
$$

The existence and the uniqueness can be proved by the Browder-Minty Theorem (see [32]) applied to the strictly monotone function (see Corollary A. 3 in the Appendices) $G_{\varepsilon}: V_{\varepsilon} \rightarrow V_{\varepsilon}^{\prime}$ defined by

$$
\begin{equation*}
\left\langle G_{\varepsilon} u, v\right\rangle_{V_{\varepsilon}, V_{\varepsilon}^{\prime}}=\int_{\Omega_{\varepsilon s}}\left(1+d_{\varepsilon}|u|_{A^{\varepsilon}}^{r-2}\right) A^{\varepsilon} u v+\int_{\Omega_{\varepsilon f}} e_{i j}(u) e_{i j}(v)+\varepsilon \beta_{\varepsilon} \int_{\Gamma_{\varepsilon}} u_{t_{\varepsilon}} v \tag{3.30}
\end{equation*}
$$

which is also bounded and hemicontinuous. As $r \geq 2$ and as for any $u \in H_{\varepsilon}$ we have

$$
\begin{equation*}
\left\langle G_{\varepsilon} u, u\right\rangle_{V_{\varepsilon}, V_{\varepsilon}^{\prime}} \geq c_{\varepsilon}\left(|u|_{L^{r}\left(\Omega_{\varepsilon s}\right)}^{r}+|e(u)|_{L^{2}\left(\Omega_{\varepsilon f}\right)}^{2}+\left|u_{t^{\varepsilon}}\right|_{L^{2}\left(\Gamma_{\varepsilon}\right)}^{2}\right) \tag{3.31}
\end{equation*}
$$

for some $c_{\varepsilon}>0$ independent of $u$, the coerciveness of $G_{\varepsilon}$ follows.
Next, we estimate the range of $F(w)$ with respect to $w \in V_{\varepsilon}$. Setting $v=F(w)$ in (3.29) and calling (3.18) we get for some $c>0$ independent of $\varepsilon$

$$
\begin{align*}
d_{\varepsilon}|F(w)|_{L^{r}\left(\Omega_{\varepsilon s}\right)}^{r}+|F(w)|_{L^{2}\left(\Omega_{\varepsilon s}\right)}^{2}+|e(F(w))|_{L^{2}\left(\Omega_{\varepsilon f}\right)}^{2} & +\varepsilon\left|F(w)_{t_{\varepsilon}}\right|_{L^{2}\left(\Gamma_{\varepsilon}\right)}^{2} \leq \\
& \leq c \alpha_{\varepsilon}\left(\tau_{0}+|Q|_{L^{2}(\Omega)}\right)|F(w)|_{L^{2}(\Omega)} \tag{3.32}
\end{align*}
$$

Using (3.13) we finally obtain:

$$
\begin{gather*}
|F(w)|_{L^{2}\left(\Omega_{\varepsilon s}\right)}+|e(F(w))|_{L^{2}\left(\Omega_{\varepsilon f}\right)}+\varepsilon^{1 / 2}\left|F(w)_{t_{\varepsilon}}\right|_{L^{2}\left(\Gamma_{\varepsilon}\right)} \leq c \alpha_{\varepsilon}\left(\tau_{0}+|Q|_{L^{2}(\Omega)}\right)  \tag{3.33}\\
|F(w)|_{L^{r}\left(\Omega_{\varepsilon s}\right)} \leq c \alpha_{\varepsilon}^{2 / r}\left(\tau_{0}+|Q|_{L^{2}(\Omega)}\right)^{2 / r} d_{\varepsilon}^{-1 / r} \tag{3.34}
\end{gather*}
$$

that is, there exists $c_{F}>0$ independent of $\varepsilon$ such that

$$
\begin{equation*}
|F(w)|_{H_{\varepsilon}} \leq c_{F}\left(\alpha_{\varepsilon}+\alpha_{\varepsilon}^{2 / r} d_{\varepsilon}^{-1 / r}\right) \tag{3.35}
\end{equation*}
$$

Thus we have defined a mapping $w \in M_{\varepsilon} \mapsto F(w) \in M_{\varepsilon}$, where

$$
\begin{equation*}
M_{\varepsilon}=\left\{v \in V_{\varepsilon}, \quad|v|_{H_{\varepsilon}} \leq c_{F}\left(\alpha_{\varepsilon}+\alpha_{\varepsilon}^{2 / r} d_{\varepsilon}^{-1 / r}\right)\right\} \tag{3.36}
\end{equation*}
$$

We check now that $F$ is compact. Let $\left(w_{k}\right)_{k \in \mathbb{N}}$ be bounded in $V_{\varepsilon}$; then, using (3.28) and (3.13), we see that $\left(\nabla T_{w_{k}}\right)_{k \in \mathbb{N}}$ is bounded in $L^{2}(\Omega)$. As $H_{0}^{1}(\Omega)$ is compactly included in $L^{2}(\Omega)$, we find that there exists a subsequence $\left(T_{w_{k^{\prime}}}\right)_{k^{\prime} \in \mathbb{N}}$ which is a Cauchy sequence in $L^{2}(\Omega)$. Using the strict monotony of $G_{\varepsilon}$, it follows from (3.29) that $\left(F\left(w_{k^{\prime}}\right)\right)_{k^{\prime} \in \mathbb{N}}$ is a Cauchy sequence in $V_{\varepsilon}$.
We see that the Schauder fixed-point theorem can be applied. Thus we obtain an element $u \in V_{\varepsilon}$ such that $u=F(u)$ and obviously $\left(u, T_{u}\right) \in V_{\varepsilon} \times H_{0}^{1}(\Omega)$ is a solution of the problem (3.17)-3.18).
The rest of the proof is straightforward.
Remark 3.4. Problem (3.17)-(3.18) has a unique solution only if we assume the Rayleigh number $\alpha_{\varepsilon}>0$ to be small enough.

We proceed by recovering the pressure which was hidden by the (3.17)-(3.18) formulation. Let us introduce the spaces

$$
\begin{equation*}
\mathcal{V}\left(\Omega_{\varepsilon h}\right)=\left\{v \in \mathcal{D}\left(\Omega_{\varepsilon h}\right)^{N}, \operatorname{div} v=0 \text { in } \Omega_{\varepsilon h}\right\}, \quad h=s \text { or } f \tag{3.37}
\end{equation*}
$$

$$
\begin{equation*}
L_{\varepsilon}=\left\{q \in L_{0}^{2}(\Omega),\left.q\right|_{\Omega_{\varepsilon s}} \in W^{1, r^{\prime}}\left(\Omega_{\varepsilon s}\right)\right\}, \quad \frac{1}{r^{\prime}}+\frac{1}{r}=1 \tag{3.38}
\end{equation*}
$$

Remark 3.5. $W^{1, r^{\prime}}\left(\Omega_{\varepsilon s}\right) \subset L^{2}\left(\Omega_{\varepsilon s}\right)$.
Theorem 3.6. Let $\left.\left(u^{\varepsilon}, T^{\varepsilon}\right) \in V_{\varepsilon} \times H_{0}^{1}(\Omega)\right)$ be a solution of (3.17)-(3.18). Then there exists $p^{\varepsilon} \in L_{\varepsilon}$ such that

$$
\begin{gather*}
\int_{\Omega_{\varepsilon s}}\left(1+d_{\varepsilon}\left|u^{\varepsilon}\right|_{A^{\varepsilon}}^{r-2}\right) A^{\varepsilon} u^{\varepsilon} v+\int_{\Omega_{\varepsilon f}} e_{i j}\left(u^{\varepsilon}\right) e_{i j}(v)+\varepsilon \beta_{\varepsilon} \int_{\Gamma_{\varepsilon}} u_{t_{\varepsilon}}^{\varepsilon} v+\alpha_{\varepsilon} \int_{\Omega}\left(T^{\varepsilon}+\tau\right) g v= \\
=\int_{\Omega} p^{\varepsilon} \operatorname{div} v, \quad \forall v \in H_{\varepsilon} \tag{3.39}
\end{gather*}
$$

Moreover, there exists $c>0$ independent of $\varepsilon$ such that

$$
\begin{equation*}
\left|p^{\varepsilon}\right|_{L^{2}(\Omega)} \leq c\left(d_{\varepsilon}^{1 / r} \alpha_{\varepsilon}^{2 / r^{\prime}}+\alpha_{\varepsilon}+\alpha_{\varepsilon} \beta_{\varepsilon}\right) \quad \text { and } \quad\left|\nabla p^{\varepsilon}\right|_{L^{r^{\prime}}\left(\Omega_{\varepsilon s}\right)} \leq c\left(\alpha_{\varepsilon}+\alpha_{\varepsilon}^{2 / r^{\prime}} d_{\varepsilon}^{1 / r^{\prime}}\right) \tag{3.40}
\end{equation*}
$$

Proof. For some $w \in \mathcal{V}\left(\Omega_{\varepsilon s}\right)$, we set in (3.17)

$$
v=\left\{\begin{array}{lll}
0 & \text { in } & \Omega_{\varepsilon f}  \tag{3.41}\\
w & \text { in } & \Omega_{\varepsilon s}
\end{array} .\right.
$$

Applying the corresponding version of the De Rham theorem we find that $\exists p^{\varepsilon s} \in W^{1, r^{\prime}}\left(\Omega_{\varepsilon s}\right)$, unique up to an additive constant, such that

$$
\begin{equation*}
-\nabla p^{\varepsilon s}=\left(1+d_{\varepsilon}\left|u^{\varepsilon s}\right|_{A \varepsilon}^{r-2}\right) A^{\varepsilon} u^{\varepsilon s}+\alpha_{\varepsilon}\left(T^{\varepsilon}+\tau\right) g \quad \text { in } \quad L^{r^{\prime}}\left(\Omega_{\varepsilon s}\right) . \tag{3.42}
\end{equation*}
$$

The corresponding Green formula follows:

$$
\begin{equation*}
\int_{\Omega_{\varepsilon s}}\left(1+d_{\varepsilon}\left|u^{\varepsilon}\right|_{A^{\varepsilon}}^{r-2}\right) A^{\varepsilon} u^{\varepsilon} v+\alpha_{\varepsilon} \int_{\Omega_{\varepsilon s}}\left(T^{\varepsilon}+\tau\right) g v=\int_{\Omega_{\varepsilon s}} p^{\varepsilon s} \operatorname{div} v+\int_{\Gamma_{\varepsilon}} p^{\varepsilon s} v_{n^{\varepsilon}}, \quad \forall v \in H_{\varepsilon} . \tag{3.43}
\end{equation*}
$$

Next, let $w \in \mathcal{V}\left(\Omega_{\varepsilon f}\right)$ and set in (3.17)

$$
v=\left\{\begin{array}{lll}
0 & \text { in } & \Omega_{\varepsilon s}  \tag{3.44}\\
w & \text { in } & \Omega_{\varepsilon f}
\end{array} .\right.
$$

Using again De Rham theorem, we find that $\exists p^{\varepsilon f} \in L^{2}\left(\Omega_{\varepsilon f}\right)$, unique up to additive constants corresponding to each connected component of $\Omega_{\varepsilon f}$, and such that

$$
\begin{equation*}
-\frac{\partial p^{\varepsilon f}}{\partial x_{i}}=\alpha_{\varepsilon}\left(T^{\varepsilon}+\tau\right) g_{i}-\frac{\partial e_{i j}\left(u^{\varepsilon}\right)}{\partial x_{j}} \quad \text { in } \quad H^{-1}\left(\Omega_{\varepsilon f}\right) . \tag{3.45}
\end{equation*}
$$

Defining $\Sigma^{\varepsilon i} \in L^{2}\left(\Omega_{\varepsilon f}\right)^{N}$ by

$$
\begin{equation*}
\Sigma_{j}^{\varepsilon i}=-p^{\varepsilon f} \delta_{i j}+e_{i j}\left(u^{\varepsilon}\right) \tag{3.46}
\end{equation*}
$$

we see that $\operatorname{div}\left(\Sigma^{\varepsilon i}\right)=\alpha_{\varepsilon}\left(T^{\varepsilon}+\tau\right) g_{i} \in L^{2}\left(\Omega_{\varepsilon f}\right)$ and the Green formula follows:

$$
\begin{equation*}
\int_{\Omega_{\varepsilon f}} e_{i j}\left(u^{\varepsilon}\right) e_{i j}(v)+\alpha_{\varepsilon} \int_{\Omega_{\varepsilon f}}\left(T^{\varepsilon}+\tau\right) g v=\int_{\Omega_{\varepsilon f}} p^{\varepsilon f} \operatorname{div} v+\left\langle\Sigma_{n^{\varepsilon}}^{\varepsilon i}, v_{i}\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}, \quad \forall v \in H_{\varepsilon} \tag{3.47}
\end{equation*}
$$

From (3.43) and (3.47) we deduce that

$$
\begin{equation*}
\left\langle\Sigma_{n^{\varepsilon}}^{\varepsilon i}, v_{i}\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}+\int_{\Gamma_{\varepsilon}} p^{\varepsilon s} v_{n^{\varepsilon}}+\varepsilon \beta_{\varepsilon} \int_{\Gamma_{\varepsilon}} u_{t^{\varepsilon}}^{\varepsilon} v=0, \quad \forall v \in V_{\varepsilon} \tag{3.48}
\end{equation*}
$$

We shall prove now that for a certain choice of the free constants, (3.48) holds for any $v \in H_{\varepsilon}$.
As $\Omega_{f}^{\varepsilon}$ is of class $C^{2}$, we can introduce $\Sigma_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon} \in H^{-1 / 2}\left(\Gamma_{\varepsilon}\right)$ by

$$
\begin{equation*}
\left\langle\Sigma_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon}, u\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}=\left\langle\Sigma_{n^{\varepsilon}}^{\varepsilon i}, u n_{i}^{\varepsilon}\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}, \quad \forall u \in H^{1 / 2}\left(\Gamma_{\varepsilon}\right) \tag{3.49}
\end{equation*}
$$

Also, for $k \in\left\{1,2, \cdots, k_{\varepsilon}\right\}$, we define $Q_{\varepsilon}^{k}: H^{1 / 2}\left(\Gamma_{\varepsilon}^{k}\right) \rightarrow H^{1 / 2}\left(\Gamma_{\varepsilon}\right)$ as the natural extension with zero:

$$
Q_{\varepsilon}^{k} w(x)=\left\{\begin{array}{cl}
w(x), & x \in \Gamma_{\varepsilon}^{k}  \tag{3.50}\\
0, & x \in \Gamma_{\varepsilon}^{i}, \quad i \neq k .
\end{array}\right.
$$

First, let $w \in H^{1 / 2}\left(\Gamma_{\varepsilon}\right)^{N}$; we set in (3.48) $v \in V_{\varepsilon}$ with the properties

$$
\begin{equation*}
v=0 \quad \text { in } \quad \Omega_{\varepsilon s} \quad \text { and } \quad v=w-w_{n \varepsilon} n^{\varepsilon} \quad \text { on } \quad \Gamma_{\varepsilon} . \tag{3.51}
\end{equation*}
$$

Thus we obtain

$$
\begin{equation*}
\left\langle\Sigma_{n^{\varepsilon}}^{\varepsilon i}, w_{i}\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}-\left\langle\sum_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon}, w_{n^{\varepsilon}}\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}+\varepsilon \beta_{\varepsilon} \int_{\Gamma_{\varepsilon}} u_{t^{\varepsilon}}^{\varepsilon} w=0, \quad \forall w \in V_{\varepsilon} \tag{3.52}
\end{equation*}
$$

Next, let $w \in H^{1 / 2}\left(\Gamma_{\varepsilon}^{k}\right)$ with $\int_{\Gamma_{\varepsilon}^{k}} w=0$; obviously, there exists $v \in V_{\varepsilon}$ such that $v=w n^{\varepsilon}$ on $\Gamma_{\varepsilon}^{k}$ and $v=0$ in $\Omega \backslash \Omega_{\varepsilon}^{k}$. By setting such a $v$ in (3.48) we get

$$
\begin{equation*}
\left\langle\sum_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon k}, w\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}^{k}\right)}+\int_{\Gamma_{\varepsilon}^{k}} p^{\varepsilon s} w=0 \tag{3.53}
\end{equation*}
$$

where $\Sigma_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon k} \in H^{-1 / 2}\left(\Gamma_{\varepsilon}^{k}\right)$ is defined by

$$
\begin{equation*}
\left\langle\Sigma_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon k}, v\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}^{k}\right)}=\left\langle\Sigma_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon}, Q_{\varepsilon}^{k} v\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}, \quad \forall v \in H^{1 / 2}\left(\Gamma_{\varepsilon}^{k}\right) \tag{3.54}
\end{equation*}
$$

Classic manipulations of (3.53) yield

$$
\begin{equation*}
\Sigma_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon k}+p^{\varepsilon s}=\frac{1}{\left|\Gamma_{\varepsilon}^{k}\right|}\left(\left\langle\Sigma_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon}, Q_{\varepsilon}^{k} 1\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}+\int_{\Gamma_{\varepsilon}^{k}} p^{\varepsilon s}\right) \quad \text { in } \quad H^{-1 / 2}\left(\Gamma_{\varepsilon}^{k}\right) \tag{3.55}
\end{equation*}
$$

Choosing the free constants of $p^{\varepsilon f}$ and $p^{\varepsilon s}$ such that

$$
\begin{gather*}
\left\langle\Sigma_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon}, Q_{\varepsilon}^{k} 1\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}+\int_{\Gamma_{\varepsilon}^{k}} p^{\varepsilon s}=0, \quad \forall k \in\left\{1,2, \cdots, k_{\varepsilon}\right\}  \tag{3.56}\\
\int_{\Omega_{\varepsilon f}} p^{\varepsilon f}+\int_{\Omega_{\varepsilon s}} p^{\varepsilon s}=0 \tag{3.57}
\end{gather*}
$$

we find that

$$
\begin{gather*}
\left\langle\sum_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon}, w_{n^{\varepsilon}}\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}=\sum_{k=1}^{k_{\varepsilon}}\left\langle\sum_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon}, Q_{\varepsilon}^{k}\left(\left.w_{n^{\varepsilon}}\right|_{\Gamma_{\varepsilon}^{k}}\right)\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}\right)}= \\
=\sum_{k=1}^{k_{\varepsilon}}\left\langle\sum_{n^{\varepsilon} n^{\varepsilon}}^{\varepsilon k},\left.w_{n^{\varepsilon}}\right|_{\Gamma_{\varepsilon}^{k}}\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}^{k}\right)}=-\sum_{k=1}^{k_{\varepsilon}}\left\langle p^{\varepsilon s},\left.w_{n^{\varepsilon}}\right|_{\Gamma_{\varepsilon}^{k}}\right\rangle_{H^{-1 / 2}, H^{1 / 2}\left(\Gamma_{\varepsilon}^{k}\right)}= \\
=-\sum_{k=1}^{k_{\varepsilon}} \int_{\Gamma_{\varepsilon}^{k}} p^{\varepsilon s}\left(\left.w_{n^{\varepsilon}}\right|_{\Gamma_{\varepsilon}^{k}}\right)=-\int_{\Gamma_{\varepsilon}} p^{\varepsilon s} w_{n^{\varepsilon}}, \quad \forall w \in H_{\varepsilon} \tag{3.58}
\end{gather*}
$$

and hence (3.48) holds for any $v \in H_{\varepsilon}$.
Also, by adding (3.43) and (3.47), it follows that $p^{\varepsilon} \in L^{\varepsilon}$, defined by

$$
p^{\varepsilon}=\left\{\begin{array}{lll}
p^{\varepsilon f} & \text { in } & \Omega_{\varepsilon f}  \tag{3.59}\\
p^{\varepsilon s} & \text { in } & \Omega_{\varepsilon s}
\end{array}\right.
$$

satisfies (3.39).
Finally, as $p^{\varepsilon} \in L^{\varepsilon}$, there exists $v^{\varepsilon} \in H_{\varepsilon}$ such that

$$
\begin{align*}
\operatorname{div} v^{\varepsilon} & =p^{\varepsilon} \quad \text { in } \quad \Omega  \tag{3.60}\\
\left|v^{\varepsilon}\right|_{H_{\varepsilon}} & \leq C\left|p^{\varepsilon}\right|_{L^{2}(\Omega)} \tag{3.61}
\end{align*}
$$

with $C>0$ independent of $\varepsilon$. The estimate (3.40) is obtained by using (3.18)-(3.22) and (3.61) in a straightforward manner.

## 4. Homogenizing the case of negligeable Forchheimer effect

In this section we shall study the asymptotic behaviour (when $\varepsilon \rightarrow 0$ ) of $\left(u^{\varepsilon}, T^{\varepsilon}, T^{\varepsilon}\right) \in V_{\varepsilon} \times L_{\varepsilon} \times H_{0}^{1}(\Omega)$ verifying (3.18) and (3.39), as the Forchheimer efect is vanishing, that is,

$$
\begin{equation*}
d_{\varepsilon} \rightarrow 0 \tag{4.1}
\end{equation*}
$$

In the framework of the homogenization procedure, we assume that there exist $A \in L^{\infty}\left(\Omega, L_{\mathrm{per}}^{\infty}(Y)\right)^{N \times N}$, $\beta \in C_{\mathrm{per}}^{1}(Y), B^{f}$ and $B^{s} \in L_{\mathrm{per}}^{\infty}(Y)^{N \times N}$ such that

$$
\begin{equation*}
\beta^{\varepsilon}(x)=\beta\left(\frac{x}{\varepsilon}\right), A^{\varepsilon}(x)=A\left(x, \frac{x}{\varepsilon}\right), B^{\varepsilon s}(x)=B^{s}\left(\frac{x}{\varepsilon}\right) \text { and } B^{\varepsilon f}(x)=B^{f}\left(\frac{x}{\varepsilon}\right) \text { for a.a. } x \in \Omega, \tag{4.2}
\end{equation*}
$$

$\beta \geq b_{1}, \quad A \xi_{i} \xi_{j} \geq b_{1} \xi_{i} \xi_{i}, \quad B^{f} \xi_{i} \xi_{j} \geq b_{1} \xi_{i} \xi_{i}, \quad$ and $\quad B^{s} \xi_{i} \xi_{j} \geq b_{1} \xi_{i} \xi_{i}, \quad \forall \xi \in \mathbb{R}^{N}$, a.e. in $\Omega \times Y$. Also, there exists $\alpha>0$ such that

$$
\begin{equation*}
\alpha_{\varepsilon} \rightarrow \alpha \text { when } \quad \varepsilon \rightarrow 0 \tag{4.4}
\end{equation*}
$$

Under these conditions, the estimates (3.20)-(3.22), (3.40) and the relation (3.42) yield

$$
\begin{gather*}
\left|u^{\varepsilon}\right|_{L^{r}\left(\Omega_{\varepsilon s}\right)} \leq C d_{\varepsilon}^{-1 / r},  \tag{4.5}\\
\left|u^{\varepsilon}\right|_{L^{2}(\Omega)}+\left|\nabla u^{\varepsilon}\right|_{L^{2}\left(\Omega_{\varepsilon f}\right)}+\varepsilon\left|u_{t^{\varepsilon}}^{\varepsilon}\right|_{L^{2}\left(\Gamma_{\varepsilon}\right)} \leq C,  \tag{4.6}\\
\left|\nabla T^{\varepsilon}\right|_{L^{2}(\Omega)}+\left|T^{\varepsilon}\right|_{L^{\infty}(\Omega)} \leq C,  \tag{4.7}\\
\left|p^{\varepsilon}\right|_{L^{2}(\Omega)}+\left|\nabla p^{\varepsilon}\right|_{L^{r^{\prime}}\left(\Omega_{\varepsilon s}\right)} \leq C, \tag{4.8}
\end{gather*}
$$

for some $C>0$ independent of $\varepsilon$.
From (4.5) we obtain immediately

$$
\begin{equation*}
\int_{\Omega_{\varepsilon s}} d_{\varepsilon}\left|u^{\varepsilon}\right|^{r-2} A^{\varepsilon} u^{\varepsilon} v \rightarrow 0, \quad \forall v \in H_{\varepsilon} \tag{4.9}
\end{equation*}
$$

that is, the Forchheimer term has no macroscopic influence in this case.
For any $h \in\{s, f\}$ and for any function $\varphi$ defined on $\Omega \times Y$, let us introduce the following notations.

$$
\begin{gather*}
H_{\mathrm{per}}(\operatorname{div}, Y)=\left\{\varphi \in H_{\mathrm{loc}}\left(\operatorname{div}, \mathbb{R}^{N}\right), \varphi \text { is } Y \text {-periodic }\right\},  \tag{4.10}\\
V_{\mathrm{per}}(\operatorname{div}, Y)=\left\{\varphi \in H_{\mathrm{per}}(\operatorname{div}, Y), \operatorname{div}_{y} \varphi=0 \text { in } Y\right\}  \tag{4.11}\\
\varphi^{h}=\left.\varphi\right|_{\Omega \times Y_{h}}, \quad \tilde{\varphi}^{h}=\frac{1}{\left|Y_{h}\right|} \int_{Y_{h}} \varphi(\cdot, y) d y, \quad h \in\{s, f\},  \tag{4.12}\\
\tilde{\varphi}=\int_{Y} \varphi(\cdot, y) d y, \quad \text { that is } \tilde{\varphi}=(1-m) \tilde{\varphi}^{s}+m \tilde{\varphi}^{f}  \tag{4.13}\\
H_{\mathrm{per}}^{1}\left(Y_{h}\right)=\left\{\varphi \in H_{\mathrm{loc}}^{1}\left(\mathbb{R}_{h}^{N}\right), \varphi \text { is } Y \text {-periodic }\right\}  \tag{4.14}\\
\tilde{H}_{\mathrm{per}}^{1}\left(Y_{h}\right)=\left\{\varphi \in H_{\mathrm{per}}^{1}\left(Y_{h}\right), \quad \tilde{\varphi}=0\right\} \tag{4.15}
\end{gather*}
$$

Also, for any sequence $\left(\varphi^{\varepsilon}\right)_{\varepsilon}$, bounded in $L^{p}(\Omega \times Y), 1<p<\infty$, we denote

$$
\varphi^{\varepsilon} \stackrel{p}{\rightarrow} \varphi
$$

when $\varphi^{\varepsilon}$ is two-scale convergent to $\varphi \in L^{p}(\Omega \times Y)$ in the sense of [22] and as usual

$$
\left.\begin{array}{lll}
H_{0}(\operatorname{div}, \Omega)=\{v \in H(\operatorname{div}, \Omega), & v_{\nu}=0 \quad \text { on } \quad \partial \Omega
\end{array}\right\}, ~ 子 \begin{array}{ll} 
\\
V_{0}(\operatorname{div}, \Omega)=\left\{v \in H_{0}(\operatorname{div}, \Omega),\right. & \operatorname{div} v=0 \quad \text { in } \quad \Omega \tag{4.17}
\end{array} .
$$

From (4.6), it follows that $\exists u \in L^{2}(\Omega \times Y)^{N}$ such that, on some subsequence

$$
\begin{array}{r}
u^{\varepsilon} \stackrel{2}{\rightharpoonup} u \\
u^{\varepsilon} \rightharpoonup \int_{Y} u(\cdot, y) d y \in V_{0}(\text { div }, \Omega) \quad \text { weakly in } \quad L^{2}(\Omega)^{N} \tag{4.19}
\end{array}
$$

Also, we see that $\left(\chi_{\varepsilon s} u^{\varepsilon}\right)_{\varepsilon},\left(\chi_{\varepsilon f} u^{\varepsilon}\right)_{\varepsilon}$ and $\left(\chi_{\varepsilon f} \frac{\partial u^{\varepsilon}}{\partial x_{i}}\right)_{\varepsilon}$ are bounded in $\left(L^{2}(\Omega)\right)^{N}, \forall i \in\{1,2, \cdots, N\}$. This situation was already studied in [15] and we recall the results proved there.

Theorem 4.1. There exist $u \in L^{2}\left(\Omega, V_{\mathrm{per}}(\operatorname{div}, Y)\right)$ and $w \in L^{2}\left(\Omega,\left(H_{\mathrm{per}}^{1}\left(Y_{f}\right) / \mathbb{R}\right)^{N}\right)$ such that the following convergences hold on some subsequence:

$$
\begin{align*}
u^{\varepsilon} \stackrel{2}{\rightharpoonup} u,  \tag{4.20}\\
\chi_{\varepsilon f} \nabla u_{i}^{\varepsilon} \stackrel{2}{\longrightarrow} \chi_{f}\left(\nabla u_{i}^{f}+\nabla_{y} w_{i}\right), \quad \forall i \in\{1,2, \cdots, N\} . \tag{4.21}
\end{align*}
$$

Moreover, we have

$$
\begin{gather*}
u^{f}=\tilde{u}^{f} \in H_{0}^{1}(\Omega)  \tag{4.22}\\
\tilde{u} \in V_{0}(\operatorname{div}, \Omega)  \tag{4.23}\\
\operatorname{div}_{y} w+\operatorname{div} u^{f}=0 \quad \text { in } \Omega \times Y_{f} . \tag{4.24}
\end{gather*}
$$

Concerning the temperature behaviour, from (4.7), and using the compacity result of [4], we get
Theorem 4.2. There exist $T \in H_{0}^{1}(\Omega)$ and $R \in L^{2}\left(\Omega, H_{\mathrm{per}}^{1}(Y) / \mathbb{R}\right)$ such that

$$
\begin{gather*}
T^{\varepsilon} \stackrel{2}{\rightharpoonup} T  \tag{4.25}\\
\frac{\partial T^{\varepsilon}}{\partial x_{i}} \stackrel{2}{\rightharpoonup}\left(\frac{\partial T}{\partial x_{i}}+\frac{\partial R}{\partial y_{i}}\right), \quad \forall i \in\{1,2, \cdots, N\} . \tag{4.26}
\end{gather*}
$$

Moreover, $T \in L^{\infty}(\Omega)$ and we have

$$
\begin{equation*}
T^{\varepsilon} \rightharpoonup T \quad \text { weakly in } \quad H_{0}^{1}(\Omega) \quad \text { and weakly star in } \quad L^{\infty}(\Omega) . \tag{4.27}
\end{equation*}
$$

Theorem 4.3. There exists $p \in L_{0}^{2}(\Omega \times Y)$ with $p^{s}=\tilde{p}^{s} \in W^{1, r^{\prime}}(\Omega)$, such that on some subsequence we have

$$
\begin{equation*}
p^{\varepsilon} \stackrel{2}{\rightharpoonup} p . \tag{4.28}
\end{equation*}
$$

Proof. Calling (4.8), the compacity result of [4] implies the existence of some $p \in L_{0}^{2}(\Omega \times Y)$ such that (4.28) holds on some subsequence.

By rescaling the corresponding Rellich-Kondrachov inequality in $Y_{s}$, we have

$$
\begin{equation*}
|q|_{L^{r}\left(\Omega_{\varepsilon s}\right)} \leq C \varepsilon|q|_{W_{0}^{1, r}\left(\Omega_{\varepsilon s}\right)}, \quad \forall q \in W_{0}^{1, r}\left(\Omega_{\varepsilon s}\right) . \tag{4.29}
\end{equation*}
$$

Thus, taking (3.42) into account, we obtain

$$
\begin{equation*}
\left|\left\langle\nabla p^{\varepsilon s}, q\right\rangle_{W^{-1, r^{\prime}}, W_{0}^{1, r}\left(\Omega_{\varepsilon s}\right)}\right|=\left|\int_{\Omega_{\varepsilon s}} q \nabla p^{\varepsilon s}\right| \leq|q|_{L^{r}\left(\Omega_{\varepsilon s}\right)}\left|\nabla p^{\varepsilon s}\right|_{L^{r^{\prime}}\left(\Omega_{\varepsilon s}\right)} \leq C \varepsilon|q|_{W_{0}^{1, r}\left(\Omega_{\varepsilon s}\right)}, \tag{4.30}
\end{equation*}
$$

that is,

$$
\begin{equation*}
\left|\nabla p^{\varepsilon s}\right|_{W^{-1, r^{\prime}}\left(\Omega_{\varepsilon s}\right)} \leq C \varepsilon \tag{4.31}
\end{equation*}
$$

Then, using the extension operator of Lipton-Avellaneda ([21]), $Q_{\varepsilon s} \in \mathcal{L}\left(L^{2}\left(\Omega_{\varepsilon s}\right), L^{2}(\Omega)\right)$ defined by

$$
Q_{\varepsilon s} \pi=\left\{\begin{array}{lll}
\pi(x) & \text { in } \Omega_{\varepsilon s},  \tag{4.32}\\
\frac{1}{\varepsilon\left|Y_{s}\right|} \int_{\varepsilon k+\varepsilon Y_{s}} \pi(y) d y & \text { in } & \Omega_{\varepsilon f},
\end{array}\right.
$$

Theorem 3.2 of [26] implies that there exists $q^{s} \in L^{2}(\Omega)$ such that

$$
\begin{gather*}
Q_{\varepsilon s} p^{\varepsilon s} \rightarrow q^{s} \quad \text { in } \quad L^{2}(\Omega)  \tag{4.33}\\
\chi_{\varepsilon s} p^{\varepsilon s} \stackrel{2}{\sim} \chi_{s}(y) q^{s}(x) \quad \text { in } \quad L^{2}(\Omega \times Y) . \tag{4.34}
\end{gather*}
$$

Passing the equality

$$
\begin{equation*}
\chi_{\varepsilon s} Q_{\varepsilon s} p^{\varepsilon s}=\chi_{\varepsilon s} p^{\varepsilon} \quad \text { in } \quad L^{2}(\Omega), \tag{4.35}
\end{equation*}
$$

at the two-scale limit, we obtain

$$
\begin{equation*}
\chi_{s}(y) q^{s}(x)=\chi_{s}(y) p(x, y) \quad \text { for a.a. }(x, y) \in \Omega \times Y \tag{4.36}
\end{equation*}
$$

that is, $\tilde{p}^{s}=p^{s} \in L^{2}(\Omega)$.
Moreover, (3.20)-(3.21) of [26] reads:

$$
\begin{gather*}
Q_{\varepsilon s} p^{\varepsilon s} \rightarrow p^{s} \quad \text { in } \quad L^{r}(\Omega) / \mathbb{R},  \tag{4.37}\\
\nabla\left(Q_{\varepsilon s} p^{\varepsilon s}\right) \rightarrow \nabla p^{s} \quad \text { in } \quad W^{-1, r^{\prime}}(\Omega) . \tag{4.38}
\end{gather*}
$$

Noticing that

$$
\begin{equation*}
\left|\nabla\left(Q_{\varepsilon s} p^{\varepsilon s}\right)\right|_{L^{r^{\prime}}(\Omega)}+\left|\nabla p^{\varepsilon s}\right|_{L^{r^{\prime}}(\Omega)} \leq C, \tag{4.39}
\end{equation*}
$$

we infer that (4.38) implies

$$
\begin{equation*}
\nabla\left(Q_{\varepsilon s} p^{\varepsilon s}\right) \rightarrow \nabla p^{s} \quad \text { in } \quad L^{r^{\prime}}(\Omega) \tag{4.40}
\end{equation*}
$$

that is, $\tilde{p}^{s}=p^{s} \in W^{1, r^{\prime}}(\Omega)$.
Now, we can present the so-called two-scale homogenized problem, verified by the limits given by Theorems $4.1-4.3$. We find this problem to be well-posed at least for $\alpha$ sufficiently small. Hence, the asymptotic behaviour of $u^{\varepsilon}, T^{\varepsilon}$ and $p^{\varepsilon}$ is completely described by the solutions of this problem, via (4.20)-(4.21), (4.25)-(4.27) and (4.28).

Denoting

$$
\begin{align*}
& H(\Omega \times Y)=\left\{u \in L^{2}(\Omega \times Y), \operatorname{div}_{y} u=0 \text { in } \Omega \times Y, u^{f}=\tilde{u}^{f} \in H_{0}^{1}(\Omega)^{N}, \tilde{u} \in H_{0}(\operatorname{div}, \Omega)\right\},  \tag{4.41}\\
& V(\Omega \times Y)=\{u \in H(\Omega \times Y), \operatorname{div} \tilde{u}=0 \text { in } \Omega\}, \tag{4.42}
\end{align*}
$$

we see that

$$
\begin{equation*}
X=H(\Omega \times Y) \times L^{2}\left(\Omega, \tilde{H}_{\mathrm{per}}^{1}\left(Y_{f}\right)^{N}\right) \tag{4.43}
\end{equation*}
$$

is a Hilbert space endowed with the scalar product

$$
\begin{equation*}
((u, w),(\varphi, \psi))_{X}=\int_{\Omega \times Y_{s}} u \cdot \varphi+\int_{\Omega} \operatorname{div} \tilde{u} \operatorname{div} \tilde{\varphi}+\int_{\Omega \times Y_{f}}\left(e(u)+e_{y}(w)\right)\left(e(\varphi)+e_{y}(\psi)\right) . \tag{4.44}
\end{equation*}
$$

We also have to introduce the following spaces

$$
\begin{gathered}
M=\left\{q \in L_{0}^{2}(\Omega \times Y), \quad q^{s}=\tilde{q}^{s} \in H^{1}(\Omega)\right\}, \\
X_{0}=\left\{(u, w) \in X, \operatorname{div} \tilde{u}=0 \text { in } \Omega, \operatorname{div}_{y} w+\operatorname{div} u u^{f}=0 \text { in } \Omega \times Y_{f}\right\} .
\end{gathered}
$$

Theorem 4.4. $(u, w) \in X_{0},(T, R) \in H_{0}^{1}(\Omega) \times H_{\mathrm{per}}^{1}(Y) / \mathbb{R}$ and $p \in M$, the limits of the convergences (4.20)-(4.21), (4.25)-(4.27) and (4.28), verify the following system:

$$
\begin{gather*}
\int_{\Omega \times Y} B\left(\nabla(T+\tau)+\nabla_{y} R\right)\left(\nabla \Phi+\nabla_{y} \Psi\right)+\int_{\Omega} \tilde{u} \Phi \nabla(T+\tau)=\int_{\Omega} \tilde{Q} \Phi, \forall(\Phi, \Psi) \in H_{0}^{1}(\Omega) \times H_{\mathrm{per}}^{1}(Y) / \mathbb{R} .  \tag{4.45}\\
\int_{\Omega \times Y_{s}} A u \varphi+\int_{\Omega \times Y_{f}}\left(e(u)+e_{y}(w)\right)\left(e(\varphi)+e_{y}(\psi)\right)+\int_{\Omega \times \Gamma} \beta\left(u^{f}-u_{n}^{f} n\right) \varphi+\alpha \int_{\Omega}(T+\tau) g \tilde{\varphi}= \\
=\int_{\Omega} p^{s} \operatorname{div} \tilde{\varphi}+\int_{\Omega \times Y_{f}}\left(p^{f}-p^{s}\right)\left(\operatorname{div} \varphi+\operatorname{div}_{y} \psi\right), \quad \forall(\varphi, \psi) \in X . \tag{4.46}
\end{gather*}
$$

Proof. First, for some $\Phi \in \mathcal{D}(\Omega)$ and $\Psi \in \mathcal{D}\left(\Omega, C_{\mathrm{per}}^{\infty}(Y)\right)$, we set $S=\Phi+\varepsilon \Psi^{\varepsilon}$ in (3.18), where $\Psi^{\varepsilon}(x)=\Psi(x, x / \varepsilon)$ for a.a. $x \in \Omega$. Using (4.20)-(4.21) and (4.25)-(4.27) we easily obtain (4.45), even the convergence of the convective term, as

$$
\begin{equation*}
\int_{\Omega} u^{\varepsilon} \Phi \nabla T^{\varepsilon}=-\int_{\Omega} T^{\varepsilon} u^{\varepsilon} \nabla \Phi \quad \text { and } \quad u^{\varepsilon} \rightharpoonup \tilde{u} \quad \text { weakly in } \quad L^{2}(\Omega) . \tag{4.47}
\end{equation*}
$$

Next, let $\varphi \in \mathcal{D}\left(\Omega, C_{\mathrm{per}}^{\infty}(Y)\right)^{N}$ and $\psi \in \mathcal{D}\left(\Omega, C_{\mathrm{per}}^{\infty}\left(Y_{f}\right)\right)^{N}$ such that $(\varphi, \psi) \in X$. Let $\hat{\psi}$ a prolongation of $\psi$ to $\mathcal{D}\left(\Omega, \tilde{H}_{\mathrm{per}}(\operatorname{div}, Y)\right)$, which can be done, for instance, by considering a certain Neumann problem in $Y_{s}$. Denoting, as usual, $\varphi^{\varepsilon}(x)=\varphi\left(x, \frac{x}{\varepsilon}\right)$ and $\psi^{\varepsilon}(x)=\hat{\psi}\left(x, \frac{x}{\varepsilon}\right)$, we can set $v(x)=\varphi^{\varepsilon}(x)+\varepsilon \psi^{\varepsilon}(x)$ in (3.39). Passing to the limit with $\varepsilon \rightarrow 0$ and using the two-scale convergences of Theorems 4.1-4.3, we obtain:

$$
\begin{gathered}
\int_{\Omega} p^{\varepsilon} \operatorname{div}\left(\varphi^{\varepsilon}+\varepsilon \psi^{\varepsilon}\right)=\int_{\Omega_{\varepsilon f}} p^{\varepsilon}\left(\left(\operatorname{div}_{x} \varphi\right)^{\varepsilon}+\left(\operatorname{div}_{y} \psi\right)^{\varepsilon}+\varepsilon\left(\operatorname{div}_{x} \psi\right)^{\varepsilon}\right)+ \\
+\int_{\Omega_{\varepsilon s}} p^{\varepsilon}\left(\left(\operatorname{div}_{x} \varphi\right)^{\varepsilon}+\left(\operatorname{div}_{y} \hat{\psi}\right)^{\varepsilon}+\varepsilon\left(\operatorname{div}_{x} \psi\right)^{\varepsilon}\right) \rightarrow \int_{\Omega \times Y_{f}} p^{f}\left(\operatorname{div}_{x} \varphi+\operatorname{div}_{y} \psi\right)+\int_{\Omega \times Y_{s}} p^{s}\left(\operatorname{div}_{x} \varphi+\operatorname{div}_{y} \hat{\psi}\right) .
\end{gathered}
$$

As $p \in M$, we have also

$$
\int_{\Omega \times Y_{s}} p^{s} \operatorname{div}_{y} \hat{\psi}=-\int_{\Omega \times \Gamma} p^{s} \psi_{n}=-\int_{\Omega \times Y_{f}} p^{s} \operatorname{div}_{y} \psi
$$

and the convergence of the right-hand side term of (3.39) is proved. All the other convergences are straightforward, except that on $\Omega \times \Gamma_{\varepsilon}$, which is similar to that in [17].

The system (4.45)-(4.46) will provide all the local solutions of our problem, allowing us to successively eliminate some of the rapidly oscillating unknowns from the governing system.

First, denoting

$$
\begin{align*}
V_{f} & =\left\{\varphi \in\left(H_{\mathrm{per}}^{1}\left(Y_{f}\right) / \mathbb{R}\right)^{N}, \operatorname{div}_{y} \varphi=0\right\},  \tag{4.48}\\
K_{f} & =\left\{\varphi \in\left(H_{\mathrm{per}}^{1}\left(Y_{f}\right) / \mathbb{R}\right)^{N}, \operatorname{div}_{y} \varphi=-1\right\}, \tag{4.49}
\end{align*}
$$

for any $k, h \in\{1,2, \cdots, N\}$ we define $R^{k} \in H_{\text {per }}^{1}(Y) / \mathbb{R},\left(W^{k h}, q^{k h}\right) \in V_{f} \times L_{0}^{2}\left(Y_{f}\right)$ and $W \in K_{f}$ as the unique solutions of the following three problems:

$$
\begin{equation*}
\int_{Y} B \nabla\left(y_{k}+R^{k}\right) \nabla \psi=0, \quad \forall \psi \in H_{\mathrm{per}}^{1}(Y) / \mathbb{R}, \tag{4.50}
\end{equation*}
$$

where $B=\left\{\begin{array}{lll}B^{s} & \text { in } & Y_{s}, \\ B^{f} & \text { in } & Y_{f},\end{array}\right.$

$$
\left\{\begin{array}{l}
\int_{Y_{f}}\left(\delta_{i k} \delta_{j h}+e_{y, i j}\left(W^{k h}\right)\right) e_{y, i j}(\psi)=\int_{Y_{f}} q^{k h} \operatorname{div}_{y} \psi, \quad \forall \psi \in\left(H_{\mathrm{per}}^{1}\left(Y_{f}\right) / \mathbb{R}\right)^{N}, \\
\int_{Y_{f}} q \operatorname{div}_{y}\left(W^{h k}\right)=0,  \tag{4.52}\\
\int_{Y_{f}} e_{y}(W) e_{y}(\psi)=0, \quad \forall \psi \in L_{f}^{2}\left(Y_{f}\right),
\end{array}\right.
$$

The existence and uniqueness results for (4.50) and (4.51) are obtained by the Lax-Milgram Theorem. Regarding (4.52), we notice that $W$ is the projection of 0 on the closed convex $K_{f} \neq \emptyset$ in $\left(H_{\text {per }}^{1}\left(Y_{f}\right) / \mathbb{R}\right)^{N}$.

Setting $\Phi=0$ in (4.45) and $\varphi=0$ in (4.46), we find that $R, w$ and $p^{f}$ have closed expressions with respect to $u^{f}, T$ and $p^{s}$ :

$$
\begin{gather*}
R(x, y)=R^{i}(y) \frac{\partial T}{\partial x_{i}}(x),  \tag{4.53}\\
w(x, y)=W^{i j}(y) e_{i j}\left(u^{f}\right)(x)+W(y) \operatorname{div}\left(u^{f}\right)(x),  \tag{4.54}\\
p^{f}(x, y)=p^{s}(x)+q^{i j}(y) e_{i j}\left(u^{f}\right)(x), \quad \text { for a.a. }(x, y) \in \Omega \times Y . \tag{4.55}
\end{gather*}
$$

Using (4.53)-(4.55), we elimitate $R, w$ and $p^{f}$ by an appropriate choice of test functions, respectively

$$
\Psi=R^{i} \frac{\partial \Phi}{\partial x_{i}} \text { in (4.45) and } \psi=W^{i j} e_{i j}(\varphi) \text { in (4.46). }
$$

Thus we find the system which determines the leading limits of our homogenisation process.
Theorem 4.5. If $u \in V(\Omega \times Y), T \in H_{0}^{1}(\Omega)$ and $p \in M$ are the limits given by Theorems 4.1, 4.2 and 4.3 , then they verify the following system:

$$
\begin{gather*}
\int_{\Omega \times Y} B^{H} \nabla(T+\tau) \nabla \Phi+\int_{\Omega} \tilde{u} \Phi \nabla(T+\tau)=\int_{\Omega} \tilde{Q} \Phi, \quad \forall \Phi \in H_{0}^{1}(\Omega)  \tag{4.56}\\
\int_{\Omega \times Y_{s}} A u^{s} \varphi^{s}+m \mu_{i j k h}^{H} \int_{\Omega} e_{i j}\left(u^{f}\right) e_{k h}\left(\varphi^{f}\right)+m \beta_{i j}^{H} \int_{\Omega} u_{i}^{f} \varphi_{j}^{f}+\alpha \int_{\Omega}(T+\tau) g \tilde{\varphi}= \\
=\int_{\Omega} p^{s} \operatorname{div} \tilde{\varphi}, \quad \forall \varphi \in H(\Omega \times Y), \tag{4.57}
\end{gather*}
$$

where the so-called effective coefficients which appear in (4.56)-(4.57) are given by

$$
\begin{equation*}
B_{i j}^{H}=\int_{Y} B_{k h}\left(\delta_{i k}+\frac{\partial R^{k}}{\partial y_{i}}\right)\left(\delta_{j h}+\frac{\partial R^{h}}{\partial y_{j}}\right), \tag{4.58}
\end{equation*}
$$

$$
\begin{gather*}
\mu_{i j k h}^{H}=\frac{1}{\left|Y_{f}\right|} \int_{Y_{f}}\left(\left(\delta_{\ell k} \delta_{m h}+e_{y, \ell m}\left(W^{k h}\right)\right)\left(\delta_{\ell i} \delta_{m j}+e_{y, \ell m}\left(W^{i j}\right)\right)+e_{y}(W) e_{y}(W) \delta_{i k} \delta_{j h}\right),  \tag{4.59}\\
\beta_{i j}^{H}=\frac{1}{\left|Y_{f}\right|} \int_{\Gamma} \beta(y)\left(\delta_{i j}-\nu_{i}(y) \nu_{j}(y)\right) d \sigma_{y} . \tag{4.60}
\end{gather*}
$$

Remark 4.6. The tensors $B^{H}$ and $\mu^{H}$ are positive-definite and have the usual symmetry properties $B_{i j}^{H}=B_{j i}^{H}$ and $\mu_{i j k h}^{H}=\mu_{k h i j}^{H}=\mu_{j i k h}^{H} ; \beta^{H}$ is also symmetric and has the property:

$$
\begin{equation*}
\beta_{i j}^{H} \int_{\Omega} \varphi_{i} \varphi_{j}=\int_{\Omega \times \Gamma} \beta\left(\gamma \varphi-\left(\gamma_{\nu} \varphi\right) \nu\right)^{2} \geq 0, \quad \forall \varphi \in H_{0}^{1}(\Omega)^{N} . \tag{4.61}
\end{equation*}
$$

Remark 4.7. In the case when $A$ is independent of $y$, that is $A \in L^{\infty}(\Omega)^{N \times N}$, we can go further. The system (4.56)-(4.57) yields:

$$
\begin{equation*}
u_{i}^{s}=u_{i}^{f}-\left(\frac{1}{\left|Y_{s}\right|} \int_{Y_{s}} U_{i}^{k}(y)\right)\left(A_{k j} u_{j}^{f}+\alpha(T+\tau) g_{i}+\frac{\partial p^{s}}{\partial x_{k}}\right) \quad \text { in } \quad L^{2}\left(\Omega \times Y_{s}\right), \tag{4.62}
\end{equation*}
$$

where $U^{k} \in H_{0}\left(\operatorname{div}, Y_{s}\right)$ is the unique solution of

$$
\begin{equation*}
\int_{Y_{s}} A U^{k} \Theta=\int_{Y_{s}} \Theta_{k}, \quad \forall \Theta \in H_{0}\left(\operatorname{div}, Y_{s}\right) . \tag{4.63}
\end{equation*}
$$

Noticing that $\left(\frac{1}{\left|Y_{s}\right|} \int_{Y_{s}} U_{i}^{k}(y)\right)$ are the elements of a symmetric and positive-definite matrix, we define its inverse by $A^{H}$. Thus, redenoting $\theta=T+\tau$, we find that

$$
\left(\tilde{u}^{s}, u^{f}, p^{s}, \theta\right) \in H_{0}(\operatorname{div}, \Omega) \times H_{0}^{1}(\Omega) \times W^{1, r^{\prime}}(\Omega) / \mathbb{R} \times H^{1}(\Omega) \text { is weak solution of the system }
$$

$$
\begin{align*}
& (1-m) \operatorname{div} \tilde{u}^{s}+m \operatorname{div} u^{f}=0 \quad \text { in } \Omega  \tag{4.64}\\
& \nabla p^{s}+A^{H} \tilde{u}^{s}+\alpha \theta g=\left(A^{H}-A\right) u^{f} \quad \text { in } \Omega,  \tag{4.65}\\
& \nabla p^{s}-\operatorname{div}\left(\mu^{H} e\left(u^{f}\right)\right)+\alpha \theta g=-\beta^{H} u^{f} \quad \text { in } \Omega,  \tag{4.66}\\
& -\operatorname{div}\left(B^{H} \nabla \theta\right)+\tilde{u} \nabla \theta=(1-m) Q^{s}+m Q^{f} \quad \text { in } \Omega .  \tag{4.67}\\
& \theta=\tau \quad \text { on } \quad \partial \Omega . \tag{4.68}
\end{align*}
$$

This is a model of two coupled thermal flows, neither of them being incompressible. The terms of the right-hand sides of (4.65) and (4.66) come from the Beavers-Joseph and the incompressible transfer conditions on the vanished interface.

## Appendices

## A. A result of strict monotonicity

We present here the inequality claimed in the proof of Theorem 3.3.
Theorem A.1. Let $(\cdot, \cdot)_{V}$ be an inner product on a vector space $V$ over $\mathbb{R}$ and let $|\cdot|_{V}$ be the associated norm. Then, for every $p \geq 2$, it holds:

$$
\begin{equation*}
|u+v|_{V}^{p} \leq\left(|2 u|_{V}^{p-2} u+|2 v|_{V}^{p-2} v, u+v\right)_{V}, \quad \forall u, v \in V . \tag{A.1}
\end{equation*}
$$

Proof. The cases when $p=2$ or $u=0$ or $v=0$ are obvious. Then, let $p>2, u \neq 0, v \neq 0$; denoting $|u|_{V}=a>0,|v|_{V}=b>0$ and $|u+v|_{V}=t$ and defining $f:[0,+\infty) \rightarrow \mathbb{R}$ by:

$$
\begin{equation*}
f(t)=t^{p}-2^{p-3}\left(a^{p-2}+b^{p-2}\right) t^{2}-2^{p-3}\left(a^{p-2}-b^{p-2}\right)\left(a^{2}-b^{2}\right) \tag{A.2}
\end{equation*}
$$

we see that (A.1) is equivalent to:

$$
\begin{equation*}
f(t) \leq 0, \quad \forall t \in[|a-b|, a+b] . \tag{A.3}
\end{equation*}
$$

As $f$ is decreasing on $\left[0, t_{0}\right]$ and increasing on $\left[t_{0},+\infty[\right.$ where

$$
\begin{equation*}
t_{0}=2\left(\frac{a^{p-2}+b^{p-2}}{p}\right)^{\frac{1}{p-2}} \tag{A.4}
\end{equation*}
$$

the proof is completed by the following two inequalities:

$$
\begin{gather*}
f(0)=-2^{p-3}\left(a^{p-2}-b^{p-2}\right)\left(a^{2}-b^{2}\right) \leq 0  \tag{A.5}\\
f(a+b)=2^{p}\left(\frac{a+b}{2}\right)\left(\left(\frac{(a+b)}{2}\right)^{p-1}-\frac{a^{p-1}+b^{p-1}}{2}\right) \leq 0 \tag{A.6}
\end{gather*}
$$

which holds for any $a, b>0$ as $p>2$.
When $A=I$, the following results have been already proved in $\mathbb{R}^{2}($ see $[14])$ and in $\mathbb{R}^{N}($ see $[30])$.
Corollary A.2. Let $A$ be a positive-definite matrix on $\mathbb{R}^{N}, N \geq 1$, and $p \geq 2$. Denoting by $(x, y)_{A}=$ $\left(y^{T} A x\right)^{1 / 2}, \forall x, y \in \mathbb{R}^{N}$, and by $|\cdot|_{A}$ the associated norm, we have

$$
\begin{equation*}
|x-y|_{A}^{p} \leq 2^{p-2}(x-y)^{T}\left(|x|_{A}^{p-2} A x-|y|_{A}^{p-2} A y\right), \quad \forall x, y \in \mathbb{R}^{N} \tag{A.7}
\end{equation*}
$$

Corollary A.3. Let $A \in L^{\infty}(\Omega)$ be symmetric with the property that $\exists \alpha>0$ such that

$$
\begin{equation*}
A_{i j}(x) \xi_{i} \xi_{j} \geq \alpha|\xi|^{2}, \quad \forall \xi \in \mathbb{R}^{N}, \quad \text { for a.e. } \quad x \in \Omega \tag{A.8}
\end{equation*}
$$

with $\Omega$ a bounded domain in $\mathbb{R}^{N}, N \geq 1$. Then, there exists $m>0$ such that for any $p \geq 2$ it holds:

$$
\begin{equation*}
\int_{\Omega}\left(|u|_{A}^{p-2} A u-|v|_{A}^{p-2} A v, u-v\right) d x \geq m \int_{\Omega}|u-v|^{p} d x \tag{A.9}
\end{equation*}
$$

where $(\cdot, \cdot)$ denotes the Euclidean inner product on $\mathbb{R}^{N}$.

## Acknowledgment

This work has been accomplished during the visit of D. Poliševski at the I.R.M.A.R.'s Department of Mechanics (University of Rennes 1), whose support is gratefully acknowledged. The authors also acknowledge partial support from the International Network GDRI ECO-Math.
