**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# Hybrid-DBT: Hardware Accelerated Dynamic Binary Translation

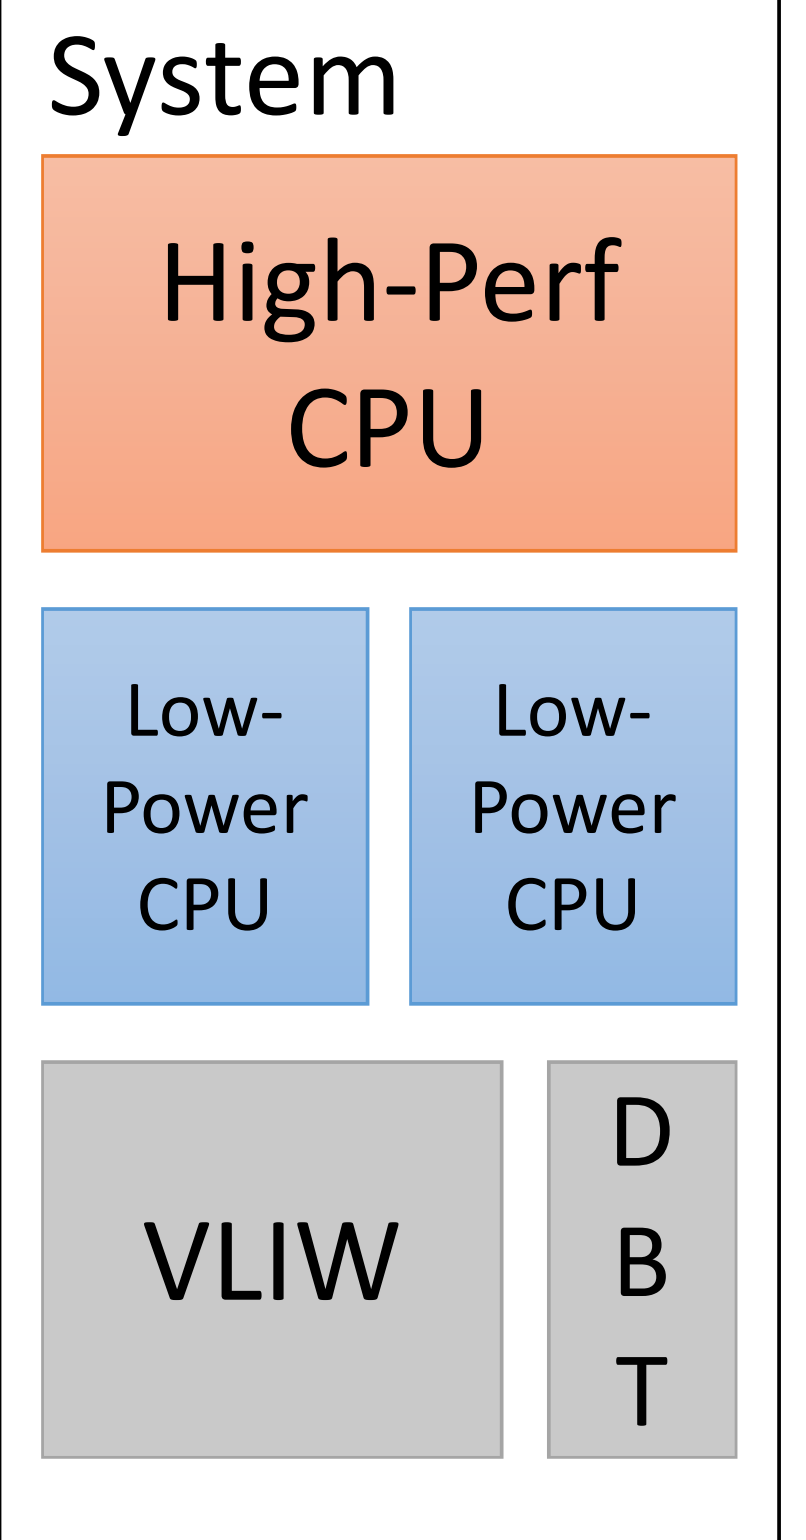

Simon Rokicki, Erven Rohou, Steven Derrien  
Univ Rennes, Inria, CNRS, IRISA

## Context - Heterogeneous Multi-cores

Heterogeneous multi-core systems present key advantages compared to their homogeneous counterparts. They allow a dynamic balancing between performance and energy efficiency. Current implementations are limited to a single ISA to easily migrate tasks from one core to the other.

To further improve the current systems, specialized cores such as VLIWs can be added. To handle the ISA differences between the cores, a layer of Dynamic Binary Translation is associated to the specialized cores. DBT translates the instructions from a given ISA to another one as they are being executed on the target core. To lessen the overheads introduced by the use of DBT, we present Hybrid-DBT: a HW/SW Co-Designed DBT system which uses several hardware accelerators to reduce the costs of DBT [3][4].

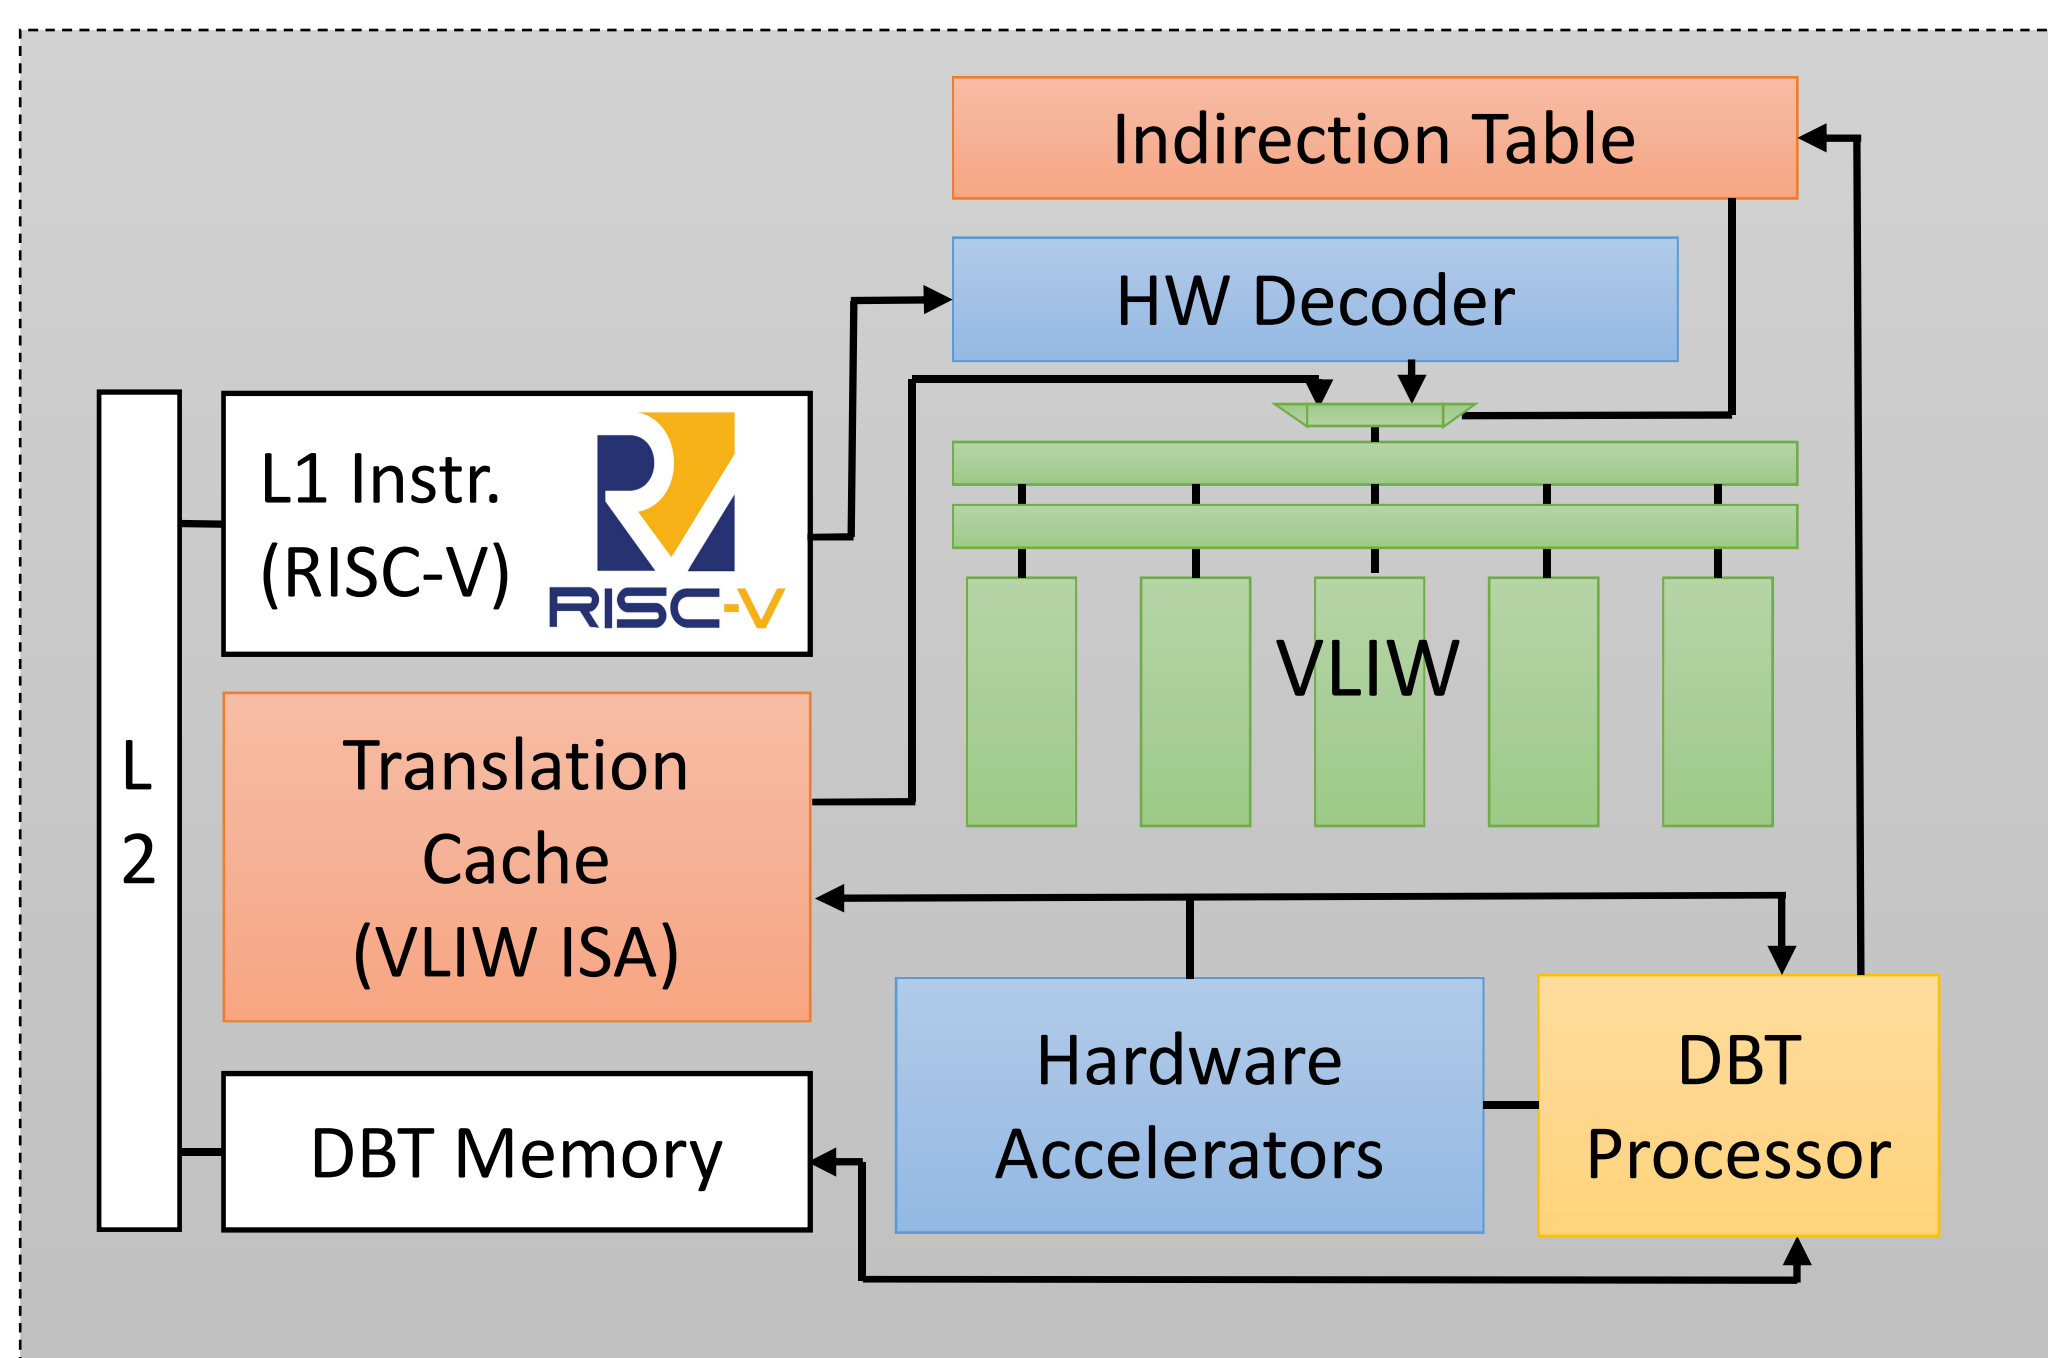

## HW/SW Co-Designed Machines

Previous work on HW/SW Co-Designed Machines:

- Transmeta Crusoe (x86 on VLIW) [1]
- NVidia Denver (Armv8 on VLIW) [2]

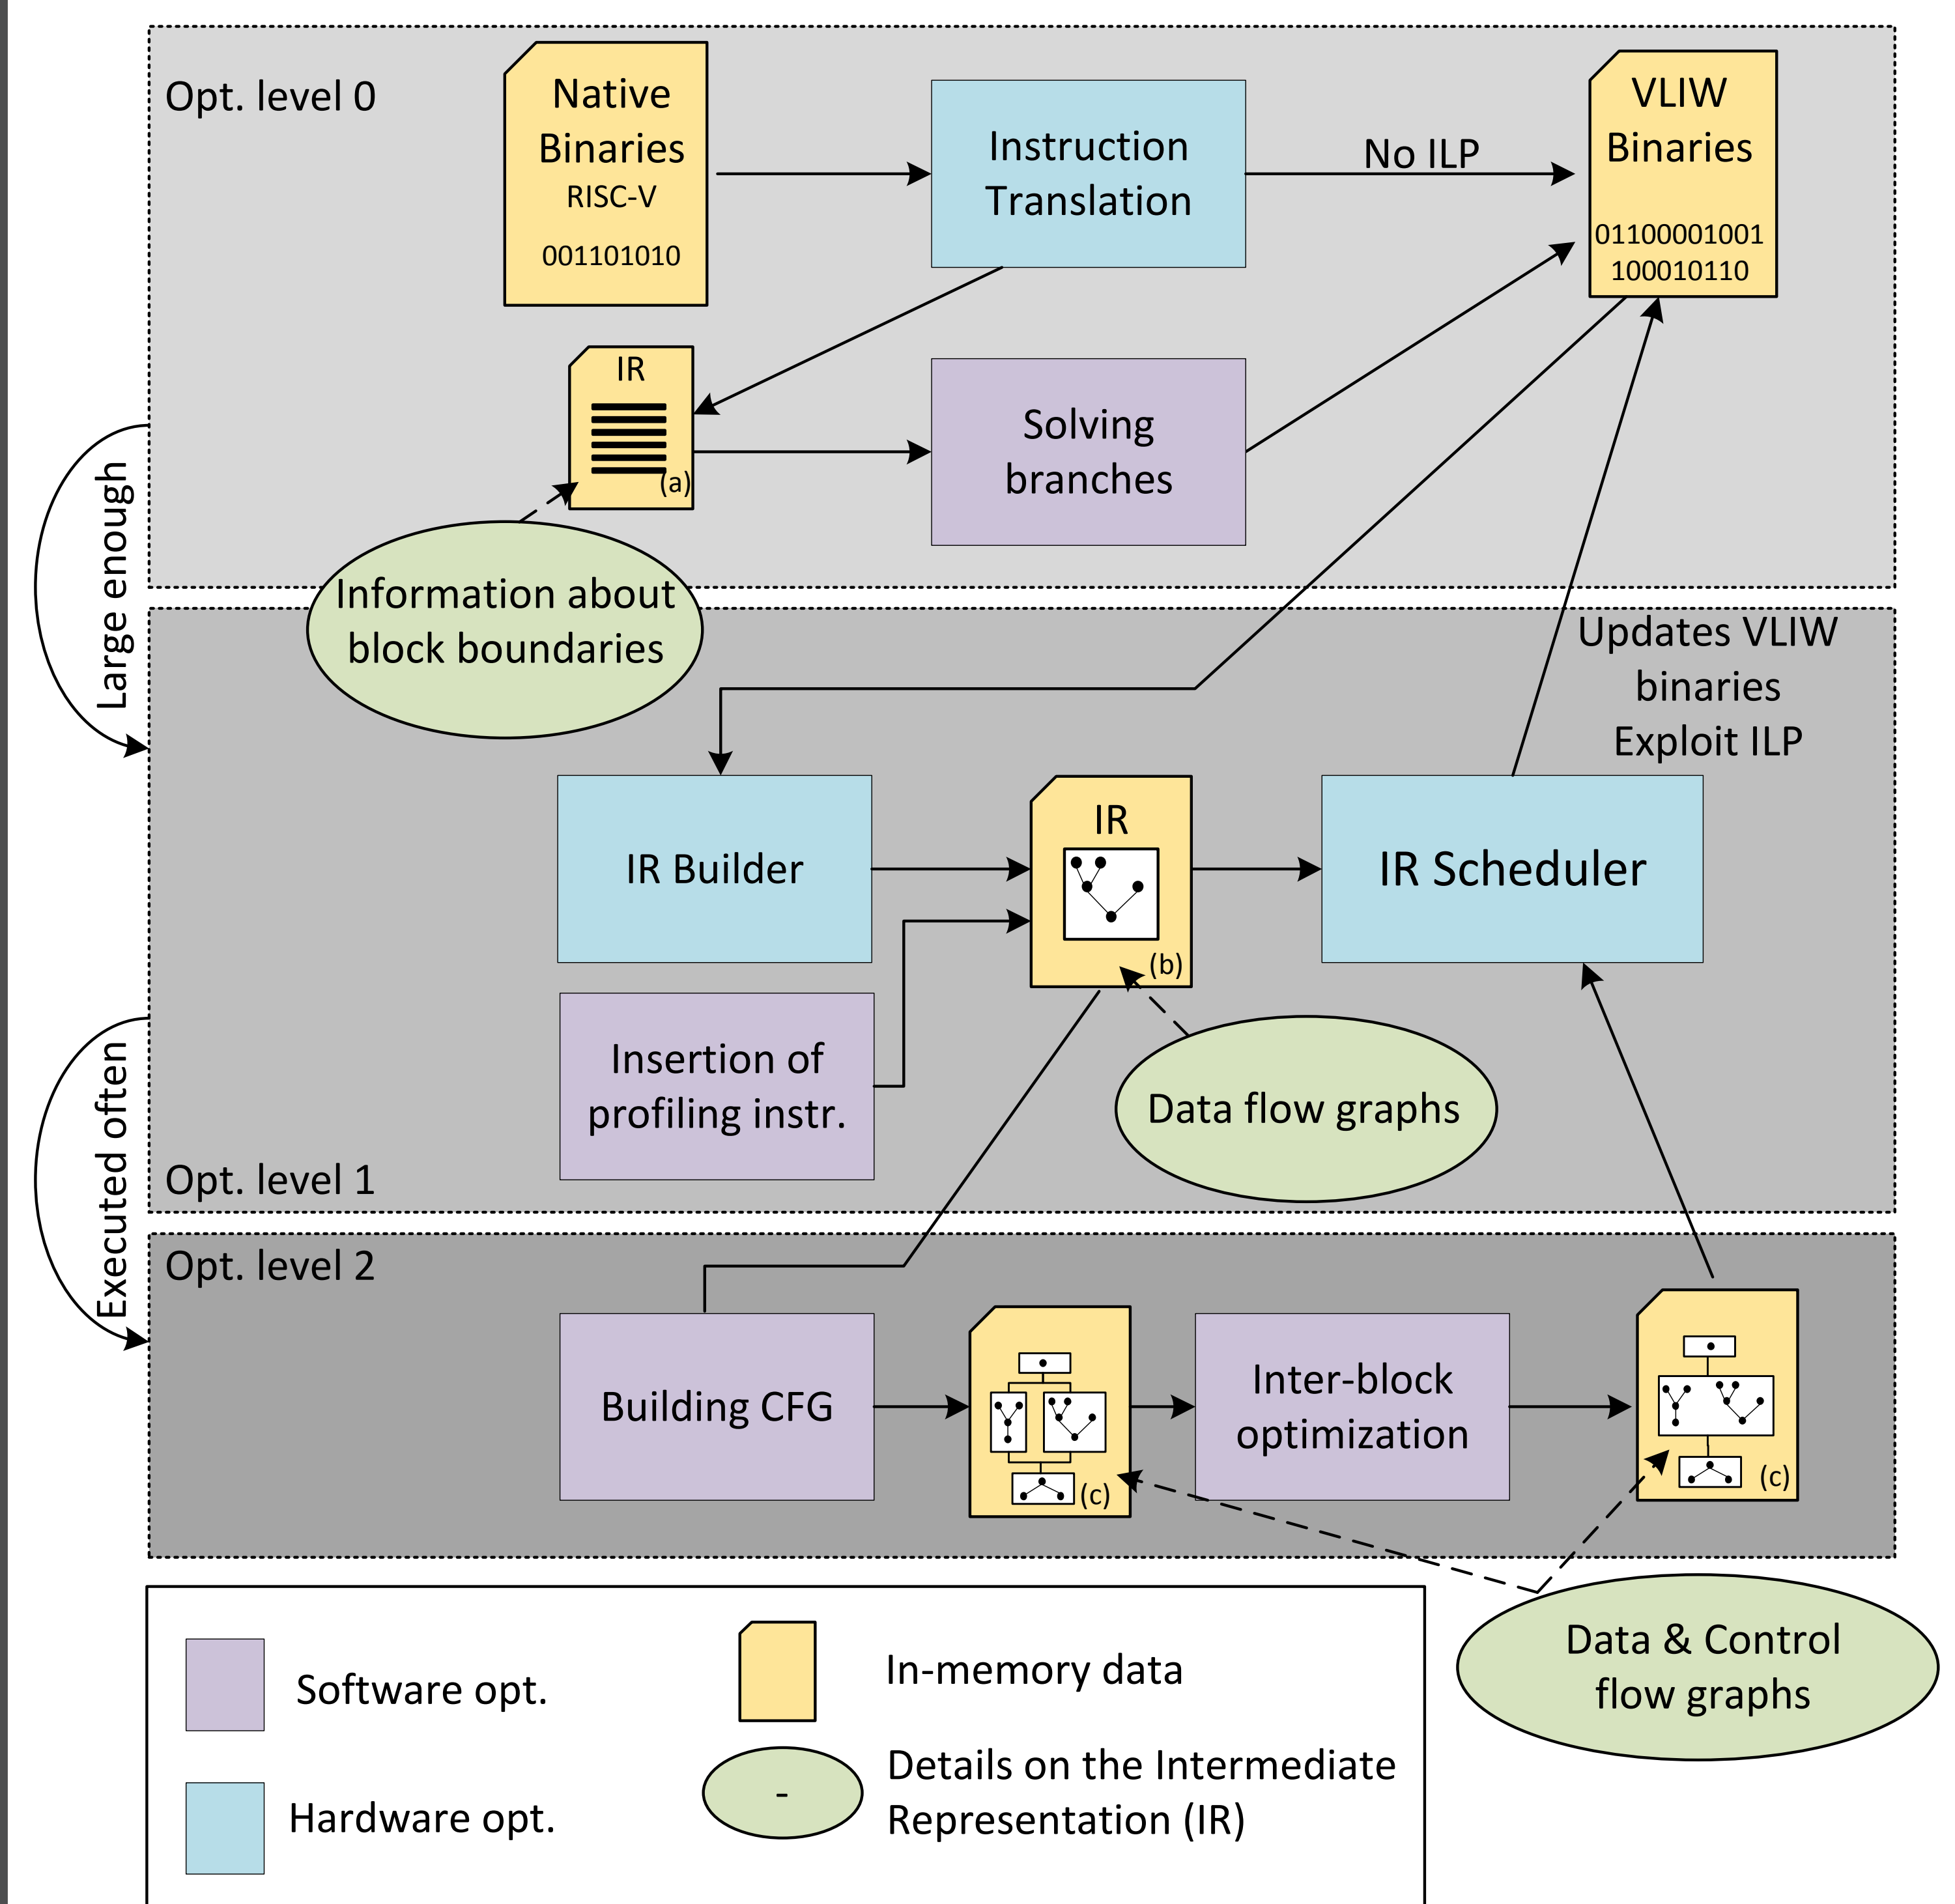

## Overview of Hybrid-DBT

- The **VLIW core** executes applications
- The **L1 Instr.** cache stores RISC-V instructions
- The **HW Decoder** decodes RISC-V into VLIW ISA
- The **DBT Processor** analyses and optimizes RISC-V binaries, using the **HW Accelerators**.
- Those binaries are stored in the **Translation Cache**.

## Translation flow

## Experimental Results
