HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Gas Hydrates, Fluid Venting and Slope Stability on the Upper Amazon Deep-Sea Fan

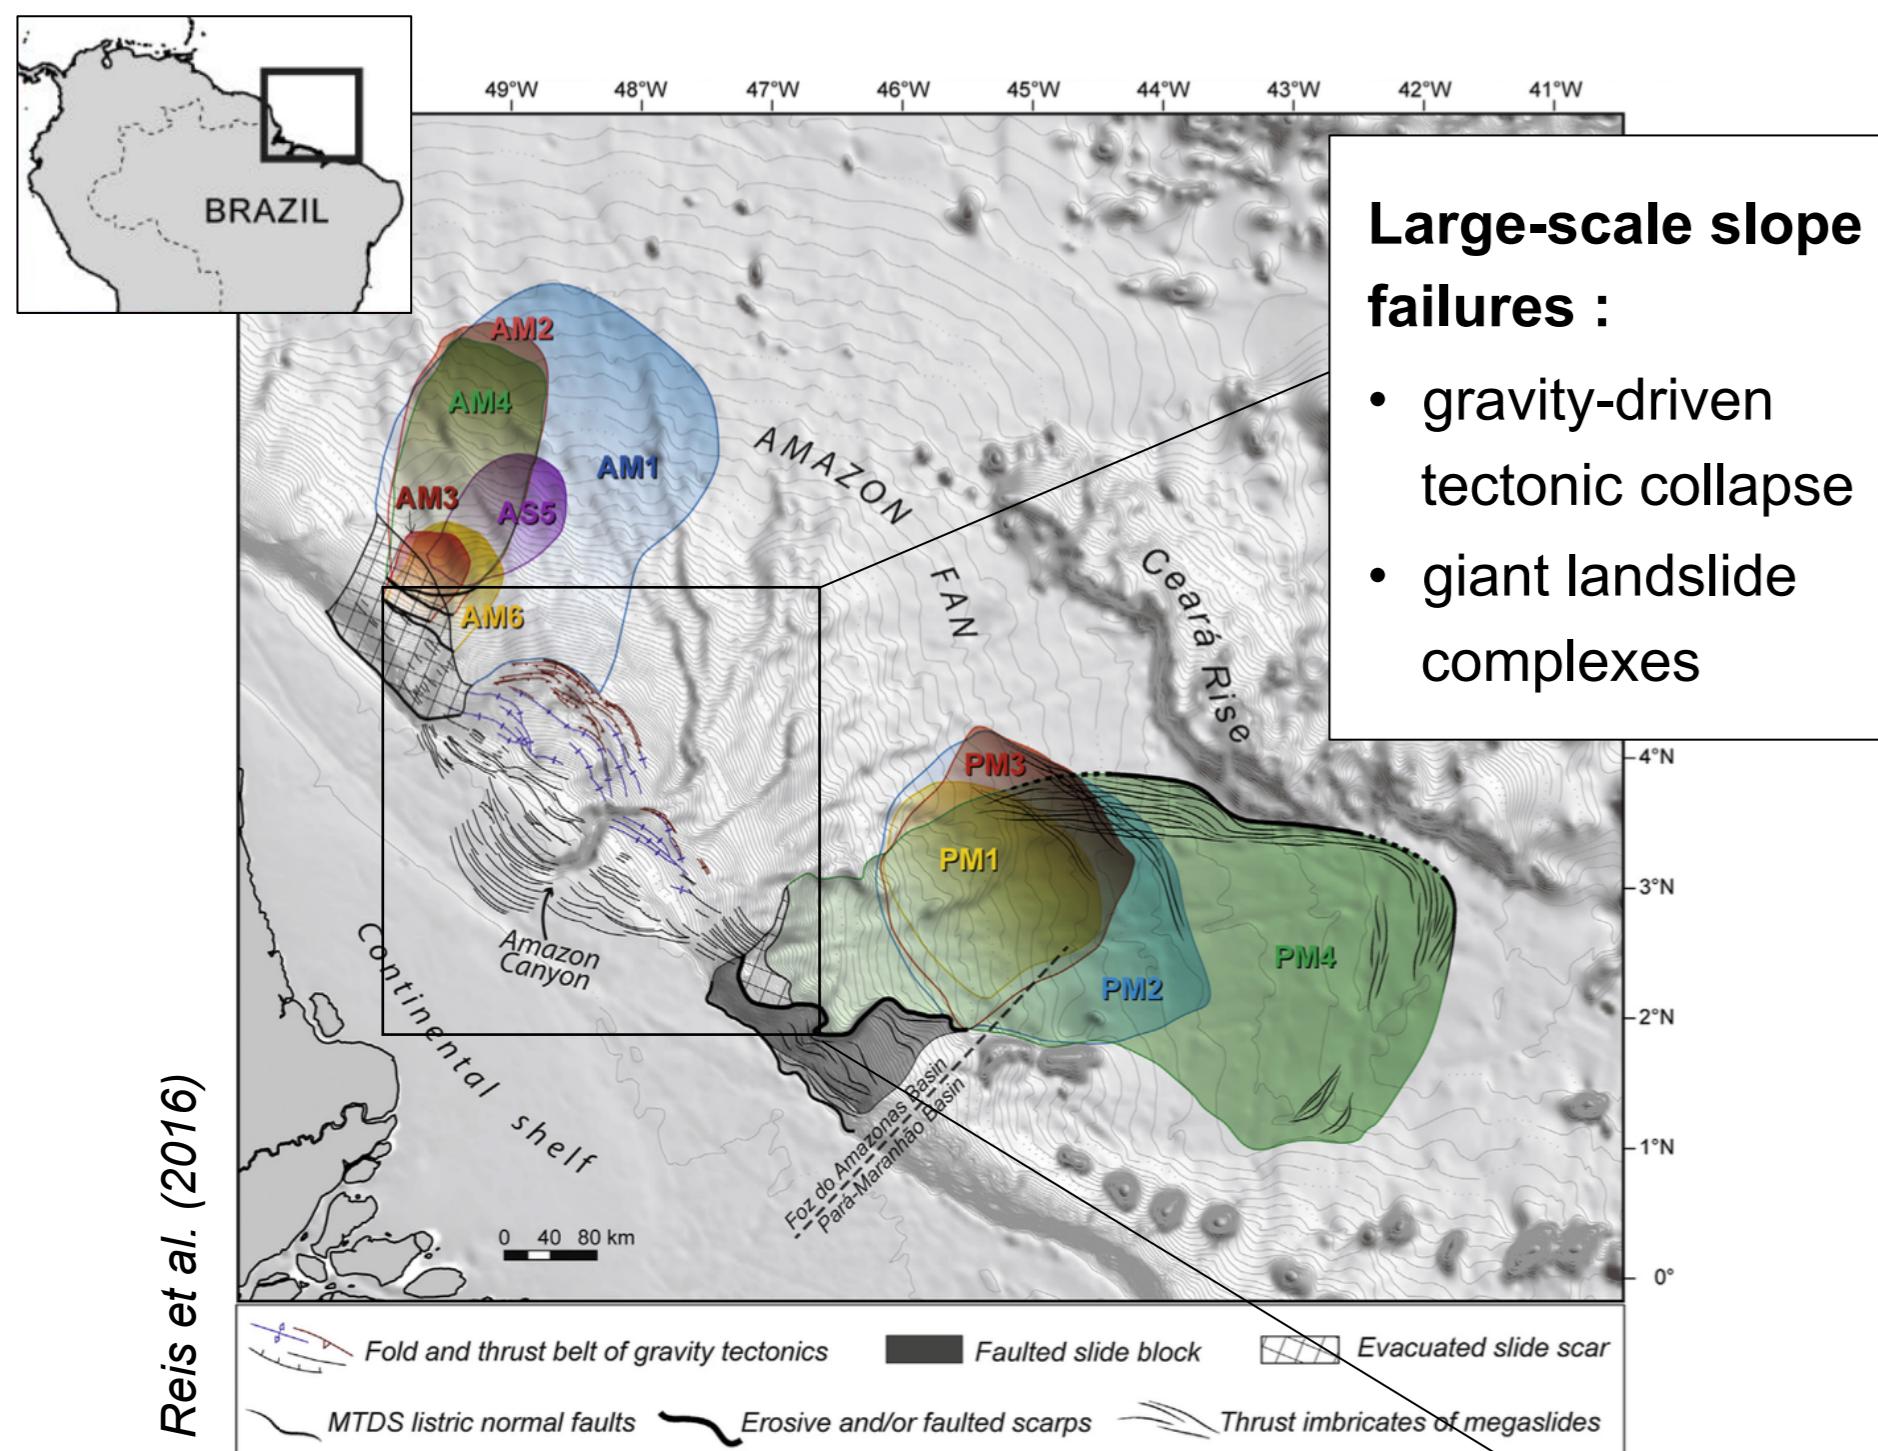

Praeg D (daniel.praeg@geoazur.unice.fr)¹⁻³; Silva C¹; Reis AT⁴; Ketzer JM⁵; Migeon S³; Unnithan V⁶; Perovano R⁴; Cruz A⁷; Gorini C⁷

1. Amazon fan & slope instabilities

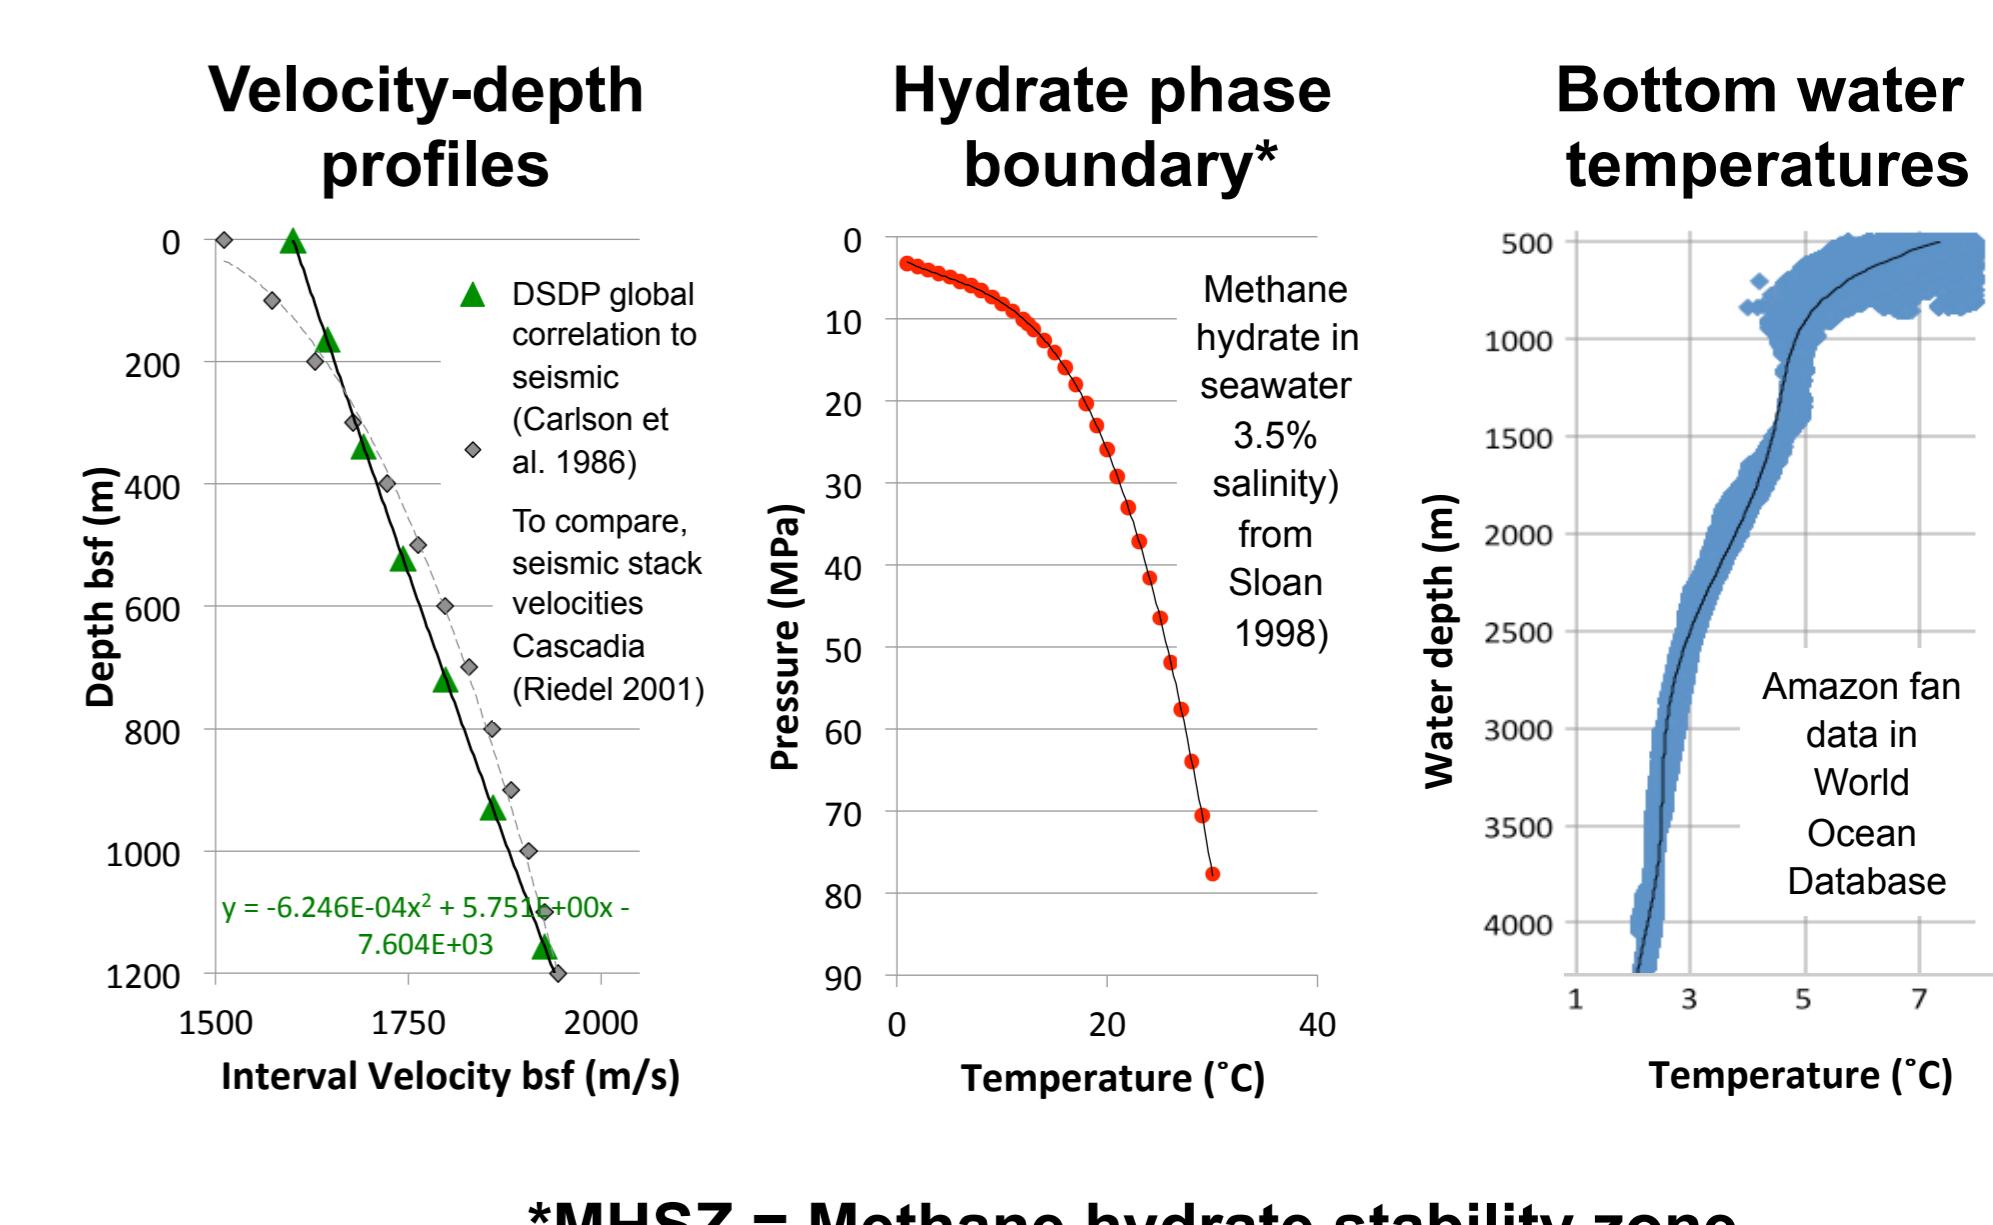

2. Mapping bottom simulating reflections (BSRs)

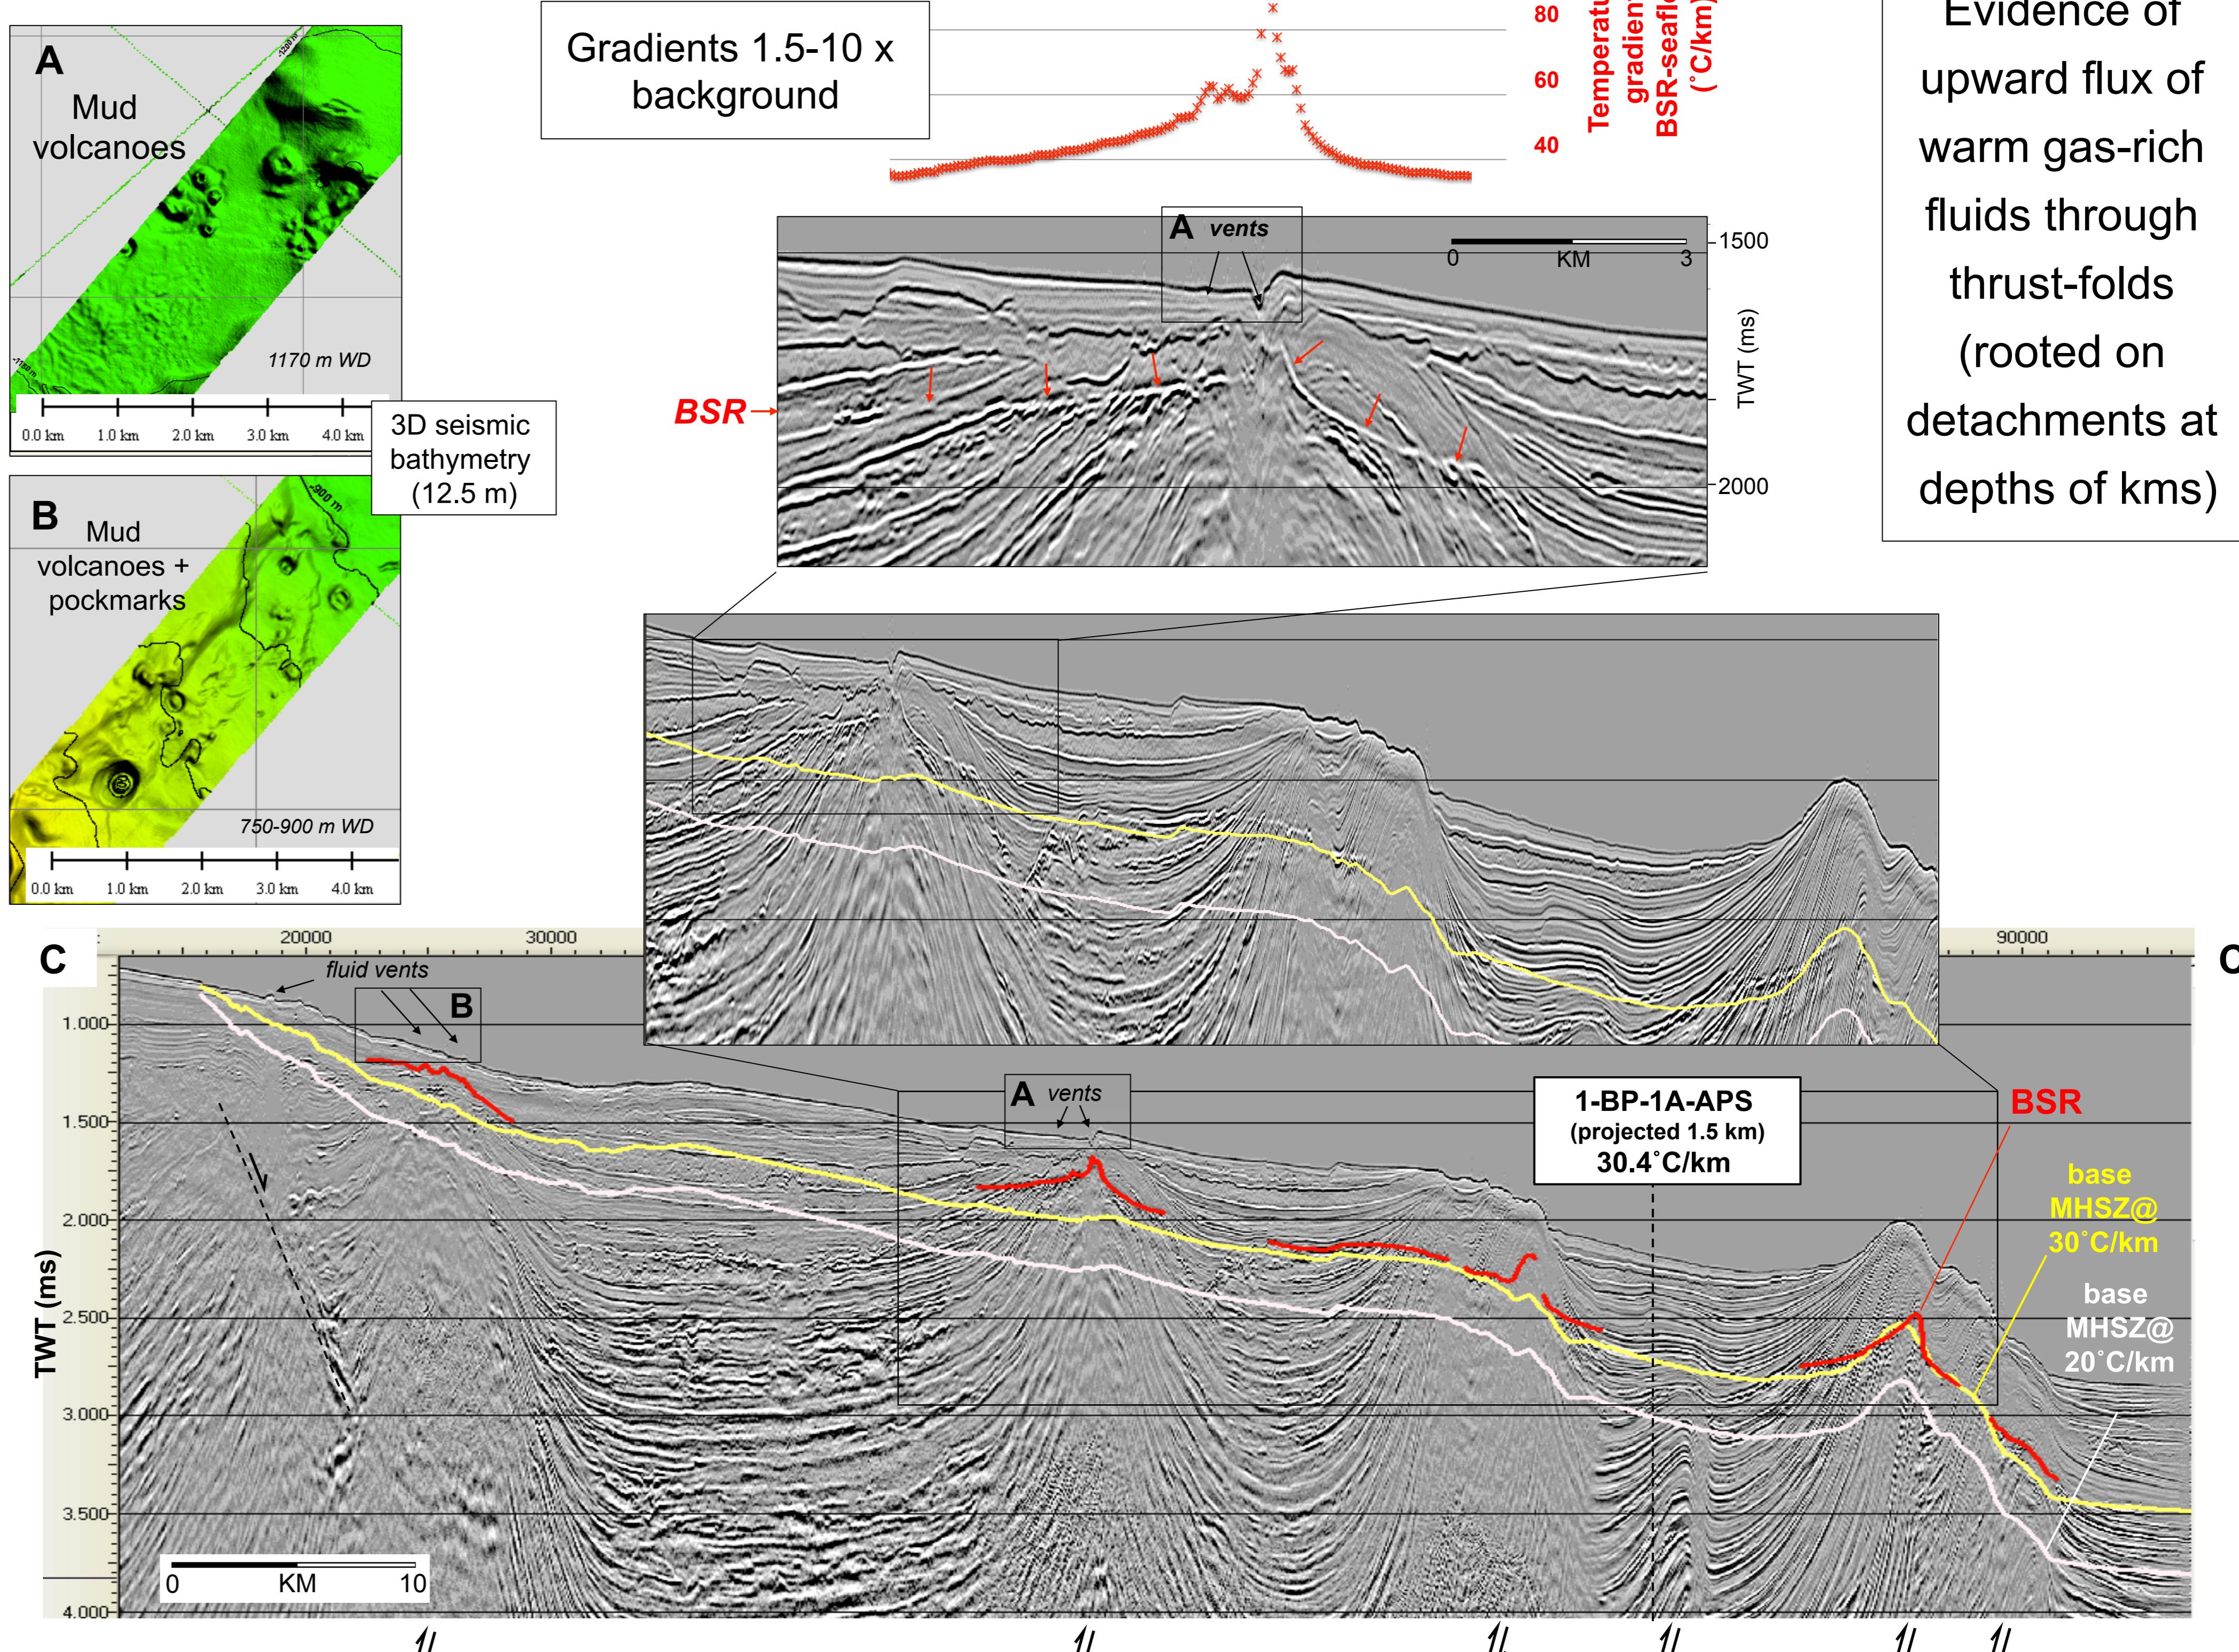

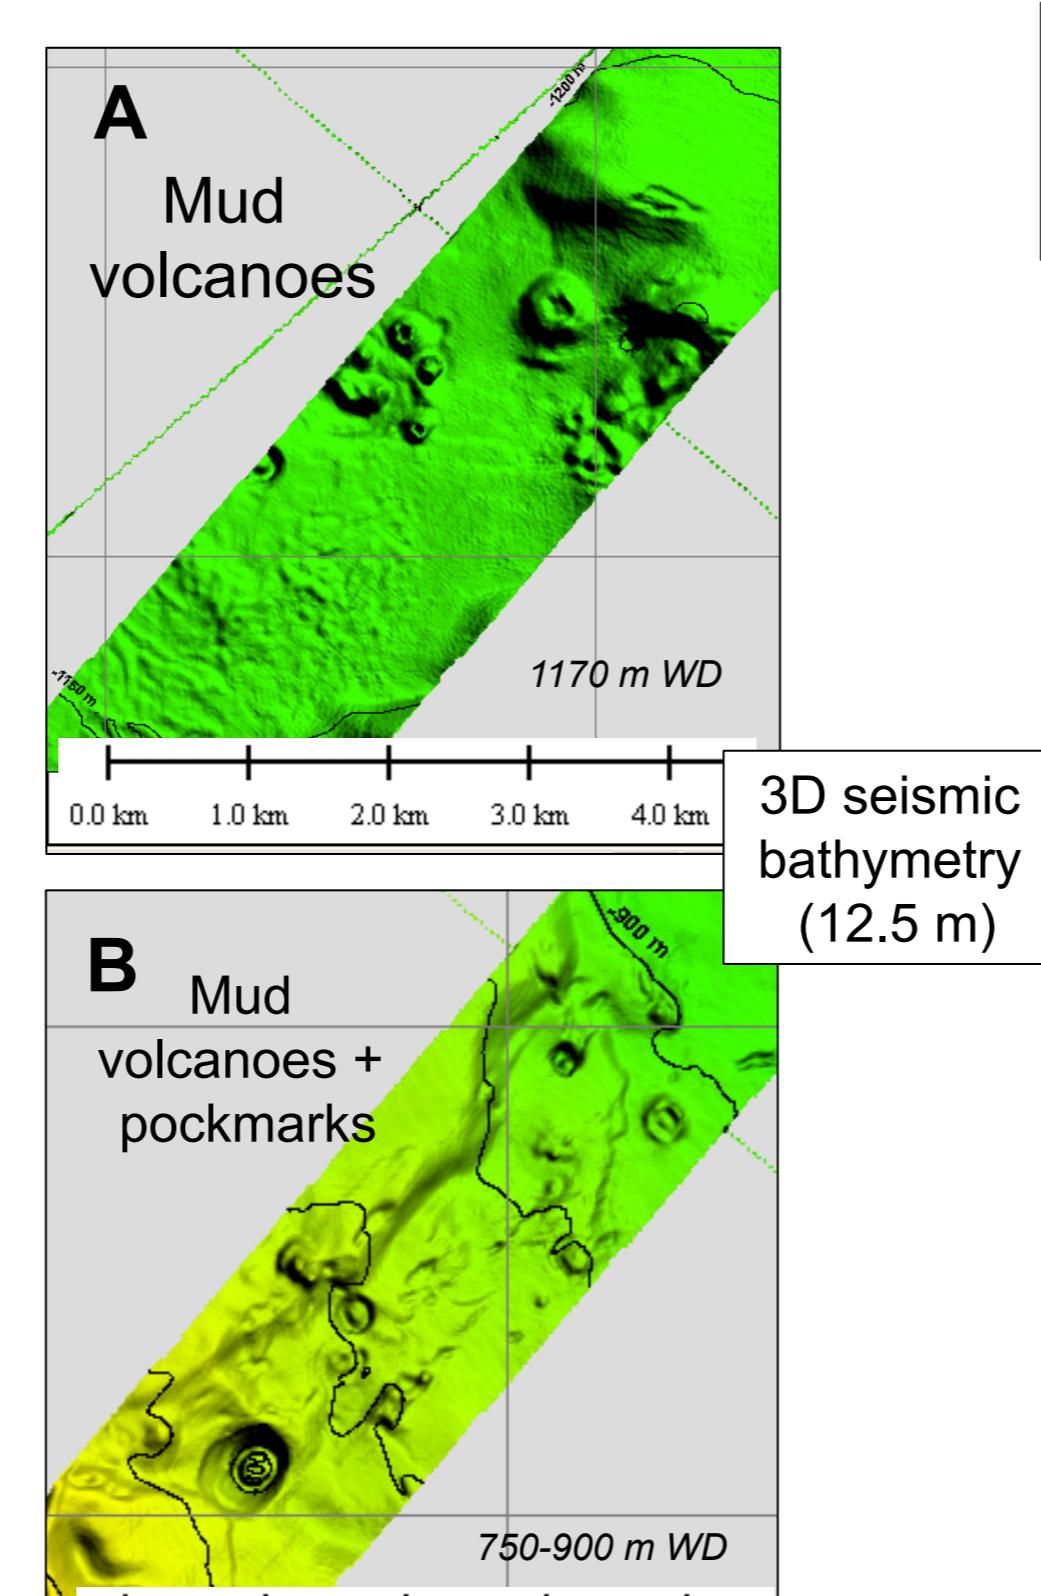

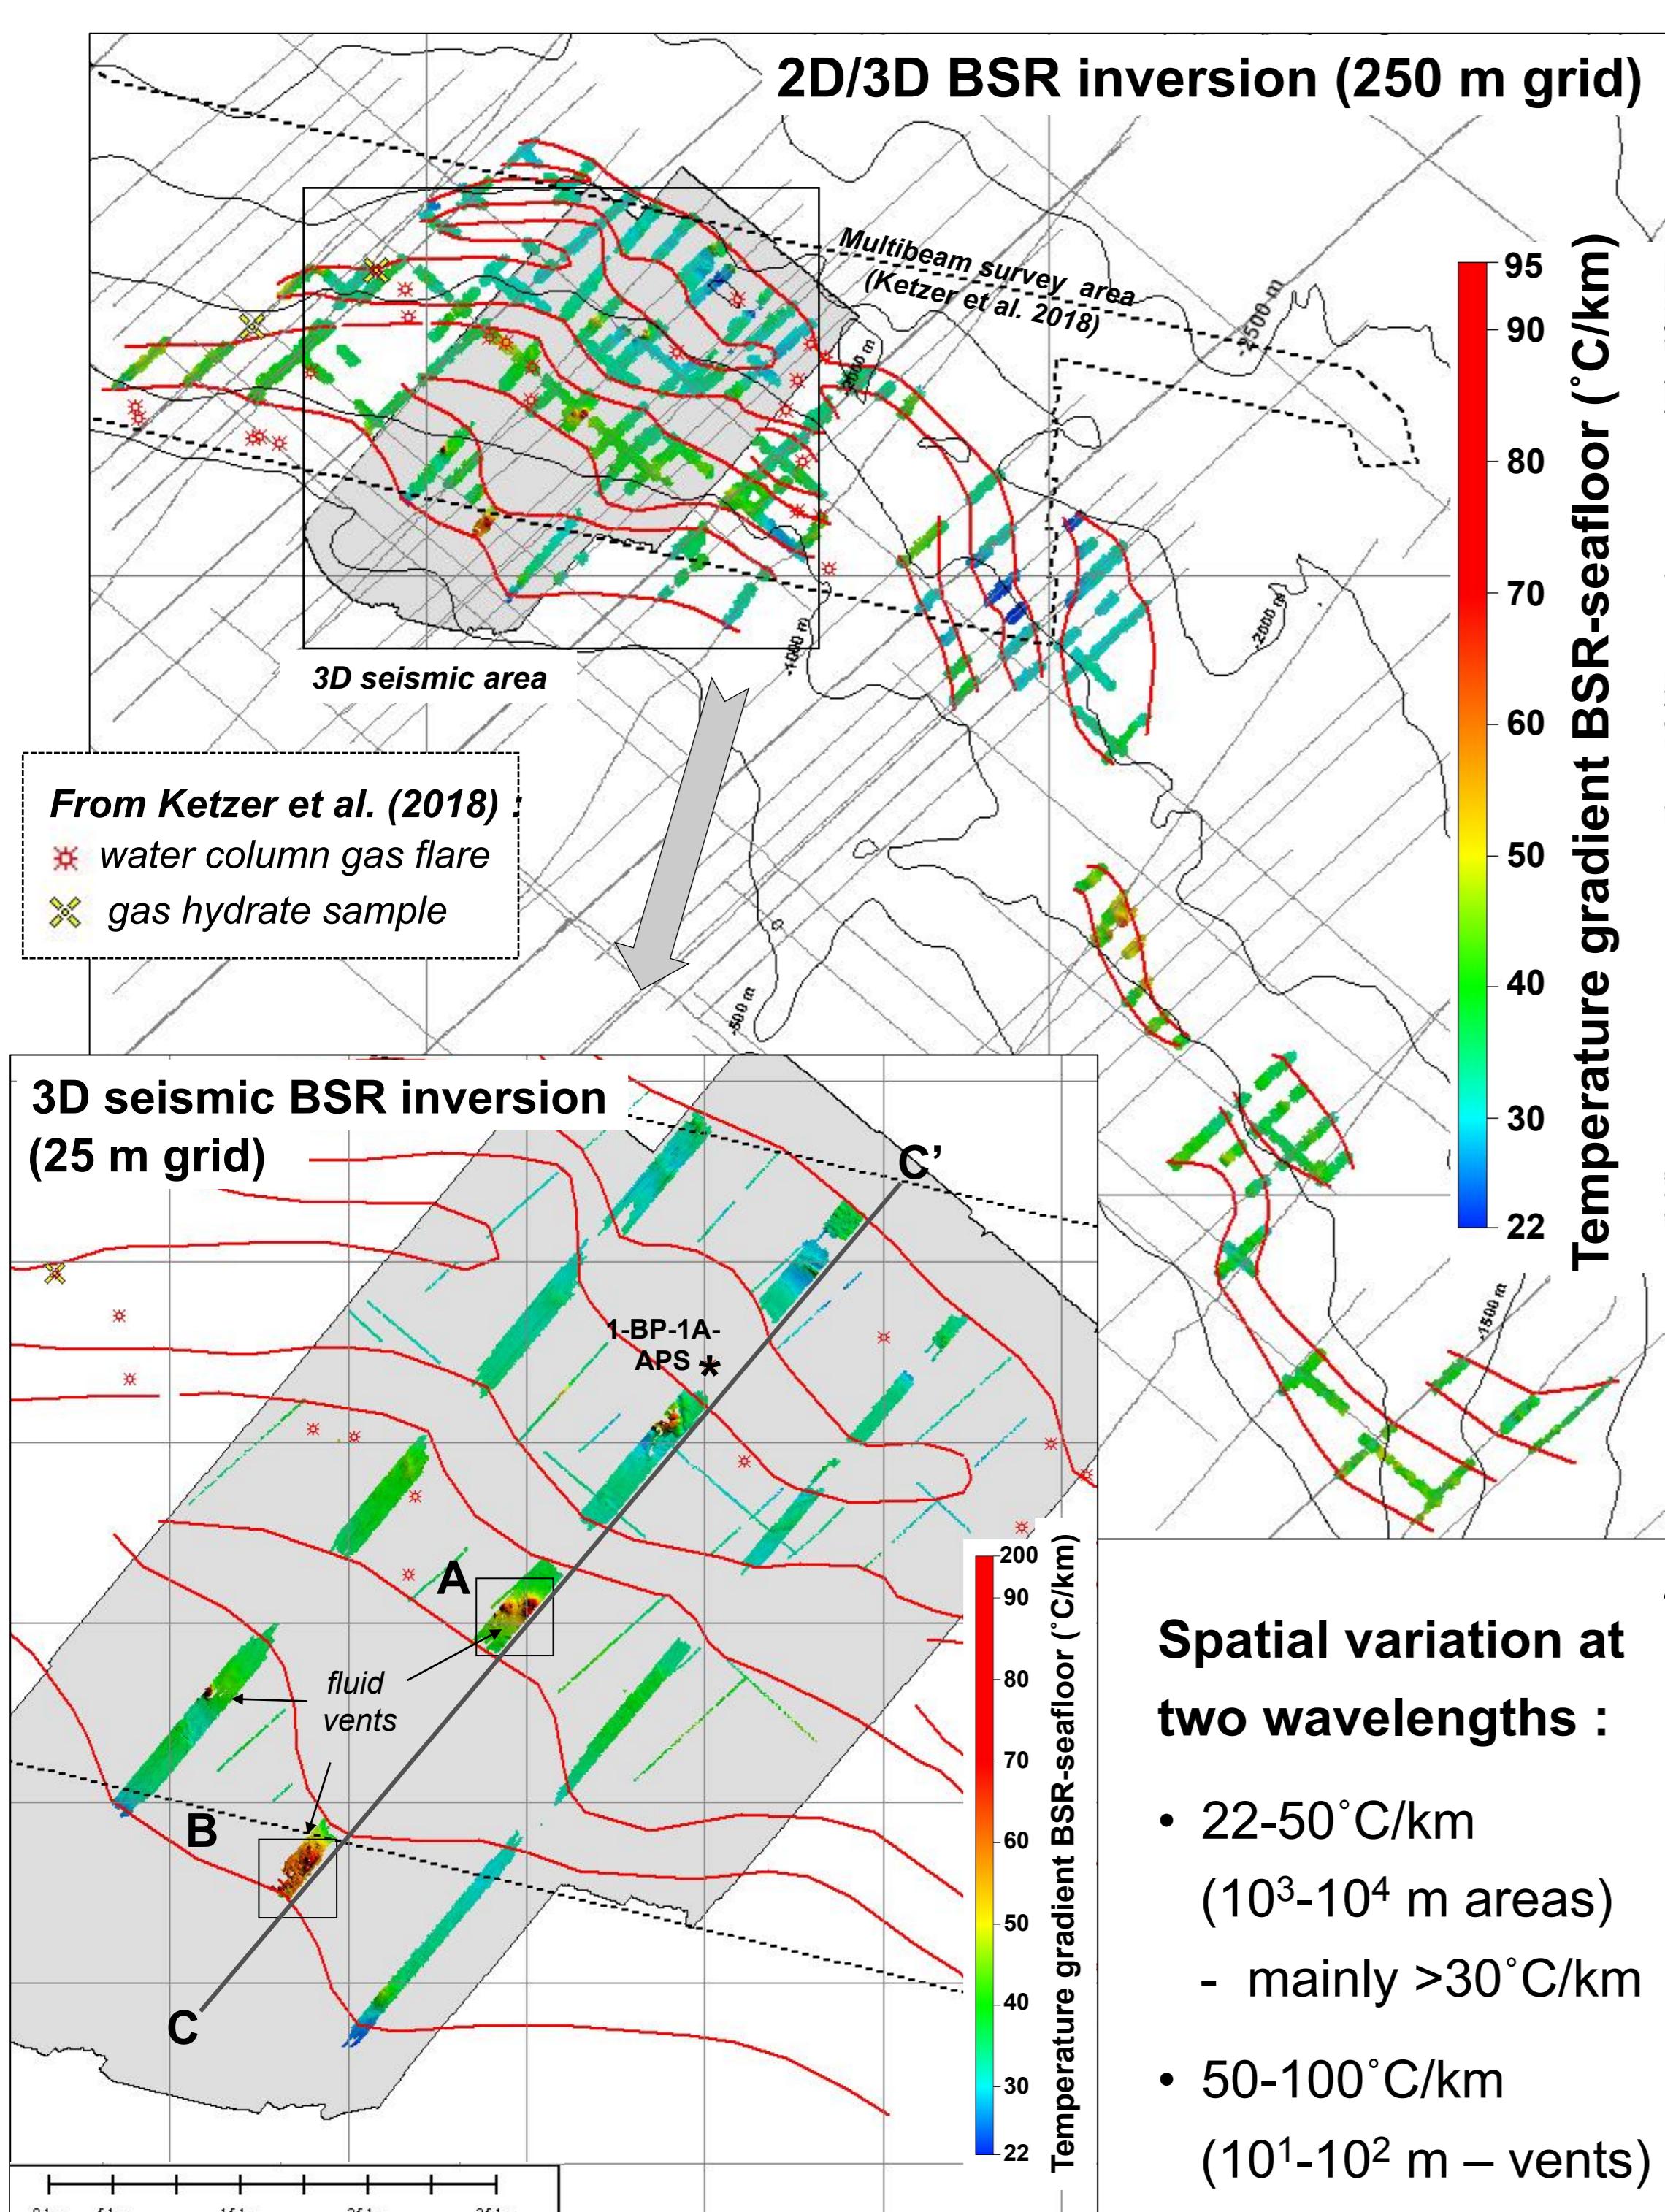

3. BSR depth inversion to temperatures

Inversion method (after Riedel et al. 2010)

- BSR TWT → depth (velocity profile from Carlson et al. 1986)
- Depth of BSR → hydrostatic pressure
- Pressure at BSR → temperature at phase boundary (MHSZ*)
- Bottom water temperatures (WOD) → geothermal gradients

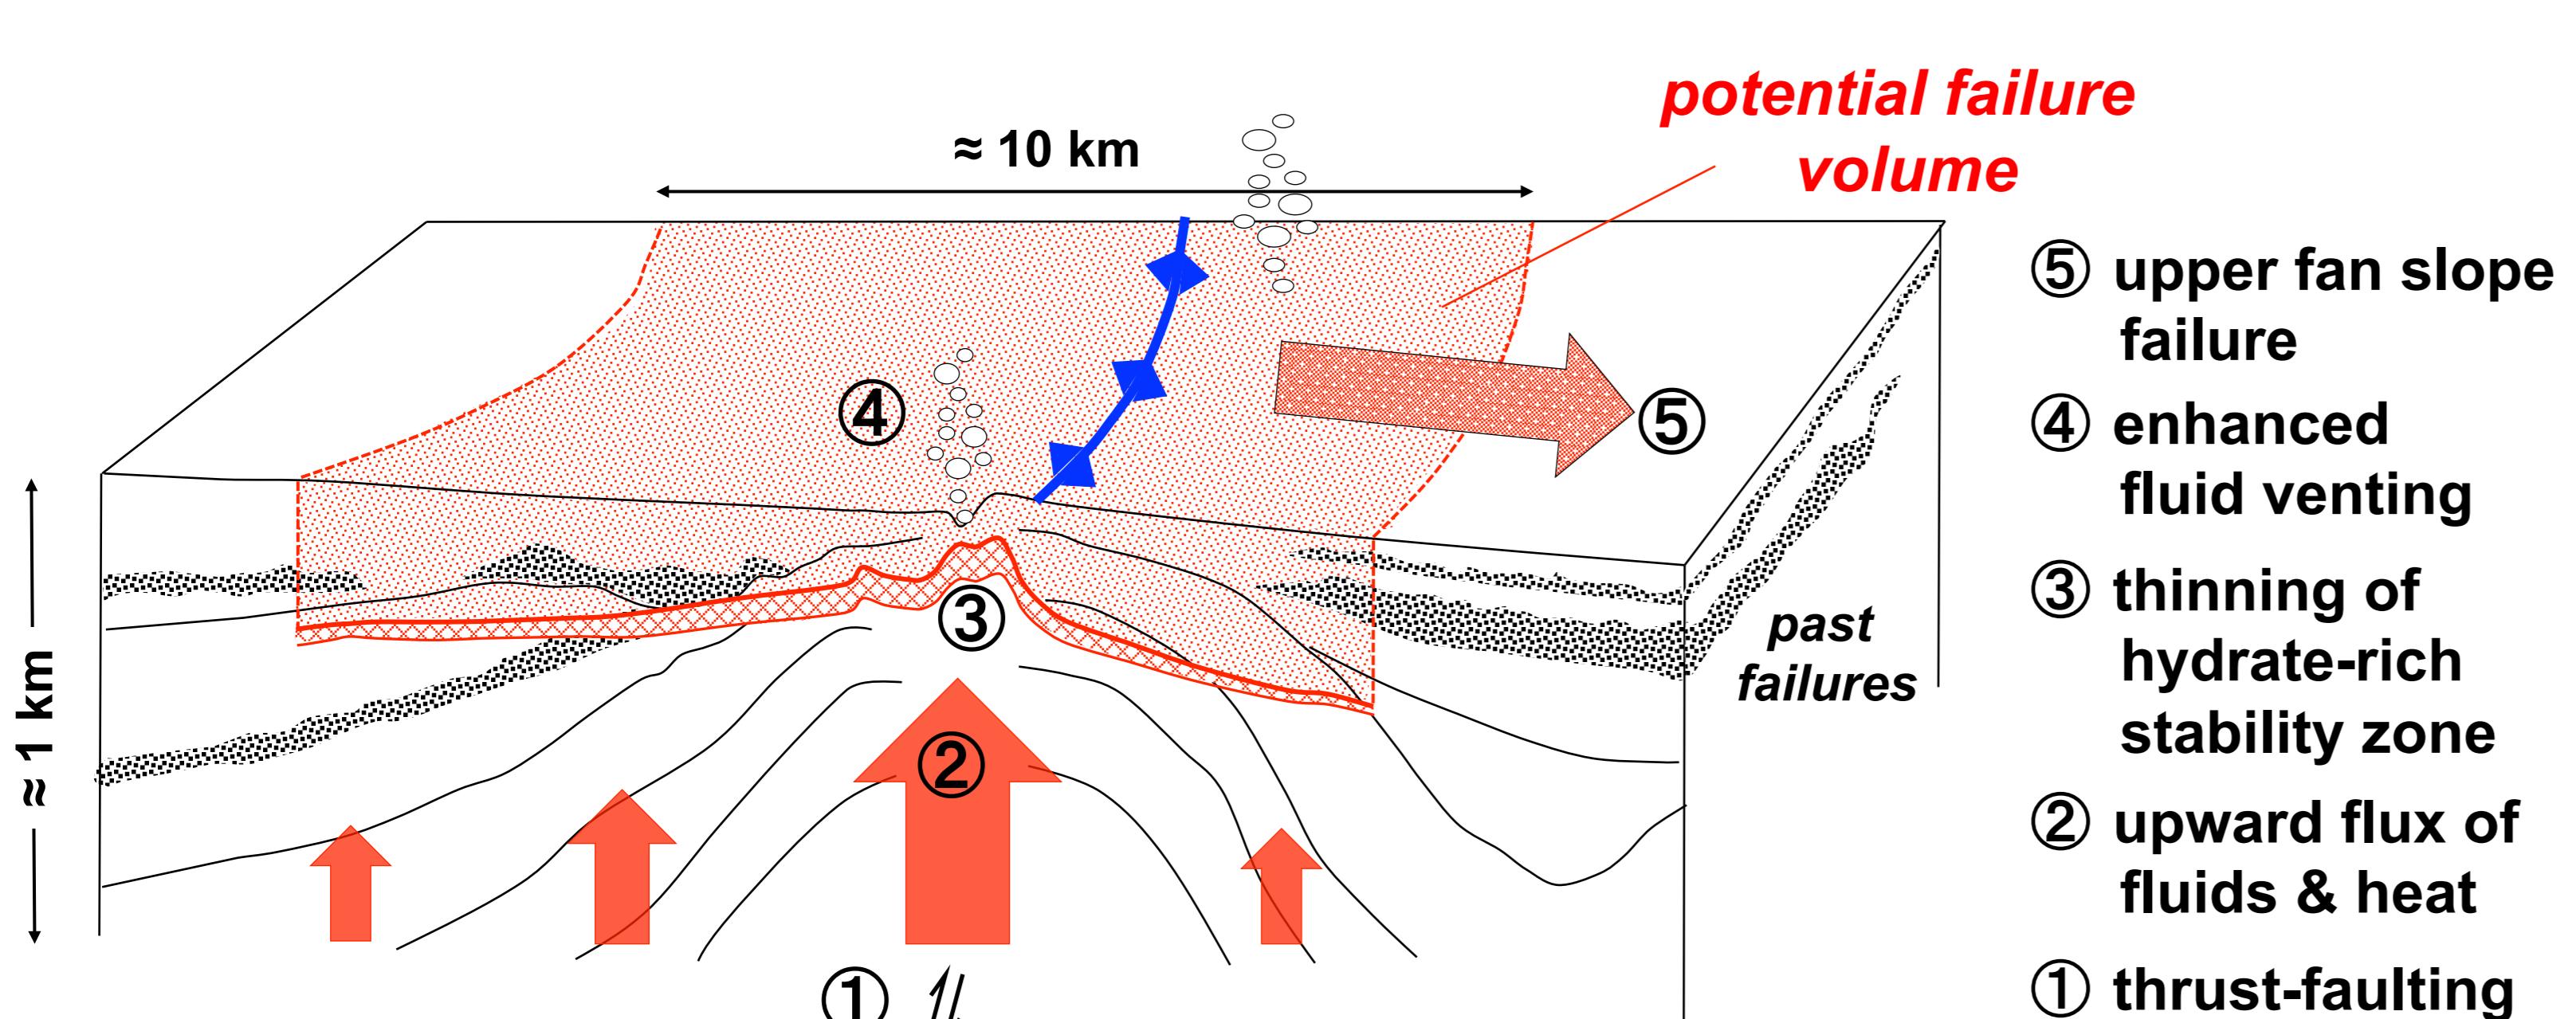

4. BSR patches → spatially variable temperature gradients + seafloor fluid vents

5. Bottom-up gas hydrate & slope dynamics

- Changes in upward flux of fluid (heat) will modify gas hydrate stability from below
- Increased flux during thrust episodes will thin hydrate-rich zone over wide areas
- Reduced sediment strength at base of stability zone may trigger large landslides

6. Conclusions

- Elongate BSR patches on the upper Amazon fan linked to upward flux of gas-rich fluids through thrust-folds recording collapse above deep detachments
- Tectonically-driven changes in fluid flux will thin gas hydrate-rich zones from below and may trigger recurrent giant slope failures from the upper fan
- Bottom-up mechanism independent of climate-driven changes in hydrate stability
