Abstract

Domain ontologies are pivotal for Semantic Web applications. The richness of an ontology goes in hand with its usefulness and efficiency. Unfortunately, manually enriching an ontology is very time-consuming. In this paper, we propose to enrich an ontology automatically by obtaining logical expressions of concepts. We present NALDO, a novel approach that provides an OWL DL (Web Ontology Language Description Logics) expression of a concept from two inputs: (1) the natural language definition of the concept and (2) an ontology describing the domain of this concept. NALDO uses as much as possible entities provided by the domain ontology, however it can suggest, when needed, new entities. The expressiveness of expressions provided by NALDO covers value and cardinality restrictions, subsumption and equivalence. We evaluate our approach against the definitions and the corresponding ontologies of the BEAUFORD benchmark. Our results show that NALDO is able to perform the correct identification of formal entities with an F1-measure up to 0.79.

Keywords: Ontologies, Natural language definitions, Ontology enrichment, OWL DL, Semantic web

1. Introduction

The usefulness of domain ontologies in various fields is well established. Indeed, they are a pivotal piece when dealing with heterogeneity or complex semantic issues [1, 2, 3, 4]. Building ontologies is a difficult and time-consuming task. It usually requires to combine the knowledge of domain experts with the skills of ontology engineers into a single effort. We believe that this bottleneck currently constitutes a real obstacle for the adoption of semantic technologies into practice. In order to solve this problem, it is worth considering to apply automated techniques to build ontology resources from existing data or at least to assist ontology engineers and domain expert by semi-automatic ways.

Therefore, numerous ontology learning tools have been developed aiming at the automatic or semi-automatic construction of ontologies from structured or unstructured sources. The current state of the art approaches are able to generate lightweight ontology such as [5] and [6]. Some other works are able to generate more expressive ontologies from existing knowledge base (KB) like in [7] and [8], or from natural language definitions like in [9] or [10]. We also have approaches that are able to generate ontologies from sentences written in a given controlled natural language. Among all these approaches only the works described in [7] and [8] propose *formal definition for existing concepts*. Indeed, having a formal definition for concepts in a given ontology facilitates consistency checking and the automatic evaluation of individuals in a KB with regards to that given ontology. However the work in [7] and [8] rely on existing KB having many instances. We argue that, for many domains, it is not guaranteed to have such KB. Approaches like [5] and [6] generate lightweight ontologies, so the inference capabilities of these ontologies are limited. Other approaches, like [9] and [10], do not enhance an *existing ontology* which means that they produce entities in an uncontrolled manner and are not able to find equivalent concepts expressed using different phrasings.

In this work, we propose NALDO, an approach to automatically formalize natural language (NL) definitions of concepts of existing ontologies. We thus

enrich these ontologies using the formal definitions that we obtain. For a given ontology, the formal definitions from NALDO reuse foremost the entities found in that ontology, thus NALDO limits the uncontrolled creation of new entities. For instance, in the domain circumscribed by the *Vertebrate Skeletal Anatomy Ontology* (VSAO)¹, NALDO converts the NL definition \mathcal{S}_1 “A cell space is an anatomical space that is part of a healthy cell” into the expression (using entities of VSAO):

$$\text{CellSpace} \sqsubseteq \text{AnatomicalSpace} \sqcap \exists \text{partOf.Cell}$$

NALDO is consequently an approach that helps ontology engineers and domain
 30 experts to enrich their current ontologies with expressive definitions of the concepts of these ontologies, and in practice there are many lightweight ontologies for which a set of acknowledged NL definitions exist. It is the case of OBO foundry set of ontologies (<http://www.obofoundry.org/>) and BioPortal ontologies (<http://bioportal.bioontology.org/>).

35 *1.1. Issues related with the automatic formalization of natural language definitions*

Getting automatically *a correct expression* from a given natural language (NL) definition, towards a domain ontology, requires to deal with many issues. By correct expression, we mean an expression which is accepted by domain
 40 experts without any change on the expression. We list the main issues to tackle in order to solve the automatic formalization of NL definitions problem. We illustrate each issue with several examples.

1.1.1. (\mathcal{F}_1) Identification of single definitions in a multiple definition sentence

In practice, a sentence may contain more than one definition. So, when one
 45 wants to enrich automatically an ontology using definitions in texts, a first challenge is to identify automatically these definitions. For instance, the sentence

¹<http://svn.code.sf.net/p/phenoscape/code/tags/vocab-releases/VSAO/vsao.owl>

“An american pizza is a pizza which has toppings of tomato and a lujuhman pizza is a pizza made with lamb” contains two distinct definitions: (1) “An american pizza is a pizza which has toppings of tomato” and (2) “A lujuhman
50 pizza is a pizza made with lamb”

1.1.2. (\mathcal{F}_2) Identification of the defined concept and its definition

A same definition can have multiple wordings. The challenge here is to identify the concept that is defined and the phrases that give the definition itself. For example, all the following sentences define the term *cell space*.

- 55 • A **cell space** is an anatomical space that is part of a healthy cell.
- An anatomical space that is part of a healthy cell is a **cell space**.
- If an anatomical space is part of a healthy cell then it is a **cell space**.

1.1.3. (\mathcal{F}_3)-(\mathcal{F}_4) Entity linking

The formalization task requires to provide a formal expression of concepts
60 using entities provided in the domain ontology. Hence, a challenge consists of linking the terms of the definition with the corresponding entities in the ontology. This linking can be

(\mathcal{F}_3) ”Basic”, which means that there are some similarities between the surface form of the term of the definition and the one of the ontology’s
65 entity. For example, when the definition “An american pizza is a pizza which has toppings of tomato” is formalized, against the pizza ontology, as $\text{AmericanPizza} \sqsubseteq \text{Pizza} \sqcap \exists \text{hasTopping.TomatoTopping}$, we consider the linking of “tomato” to TomatoTopping as ”basic”. Formally, basic linking can be defined as: Given a string s , an ontology \mathcal{O} , identify entity
70 $e \in \mathcal{O}$ so that s refers to e . In this task, s and labels of e share common stems² (considering also synonyms).

²Stem is the root or main part of a word, to which inflections or formative elements are added.

(\mathcal{F}_4) "Strong", to denote linkings where there is no similarity between the term of the definition and its formal correspondence in the ontology.

75 When the definition "A *lujuhman pizza is a pizza made with lamb*" is formalized, towards the pizza ontology, as `LujuhmanPizza` \sqsubseteq `Pizza` \sqcap \exists `hasTopping.MeatTopping`, we consider that the resolution of "made" as `hasTopping` and "lamb" as `MeatTopping`³ are both "strong". Formally, strong linking can be defined as: Given a string s , an ontology \mathcal{O} , identify

80 entity $e' \in \mathcal{O}$ so that s refers to a hypothetical entity e , not found in \mathcal{O} , but semantically related to e' .

1.1.4. (\mathcal{F}_5) Pruning

When we transform an NL definition of a concept into a formal expression,

85 some terms of the definition remain unused. So, the formalization prunes these terms. Domain experts, who validate the formalization, assume that those terms are meaningless for this definition. For example, when the definition "A *cell space is an anatomical space that is part of a healthy cell*" is formalized as `CellSpace` \sqsubseteq `AnatomicalSpace` \sqcap \exists `partOf.Cell`, the term "healthy" is

90 pruned. Formally, pruning can be defined as: Given a string s , an ontology \mathcal{O} , discard the words in s so that the intended matching of s to entity e is done correctly.

1.2. Contributions

NALDO presents the following innovative features:

- 95 • It is an approach to support ontology engineers in the creation of new OWL DL assertions, by suggesting automatically a formal expression of ontology's concepts using their NL definitions

³There is not any term which directly refers to "lamb" in the pizza ontology. Thus, since lamb is known as a kind of meat, it is formalized as `MeatTopping`

- It provides the OWL DL expression of a definition towards a given domain ontology
- 100 • It is domain-independent: we make no assumption on the domain ontology
- It deals with the issues (\mathcal{F}_3) and (\mathcal{F}_5). We do not focus on issue (\mathcal{F}_1) because, usually, definitions are found as isolated sentences (in dictionaries, or in ontologies as value of `skos:definition`, `rdfs:comment` properties⁴, etc.). Similarly, since the defined concepts in definitions are generally
105 the starting phrases of definitions, we do not focus on (\mathcal{F}_2). (\mathcal{F}_4) is out of scope of this paper. However, we deem important to state all the issues (\mathcal{F}_1) - (\mathcal{F}_5) the community faces when dealing with the automatic formalization of natural language definitions.

The remainder of this paper is organized as follows. First, we present a
110 section devoted to related works (Sect. 2). Next we present our seven-step approach (Sect. 3.1 - 3.3). Then, we bring in our test material and results we obtain when evaluating our approach (Sect. 4). In the light of these results we discuss the strengths of our algorithm and envision possible improvements (Sect. 4.4). Finally, we make a comparison with similar approaches found within
115 current literature (Sect. 5). We end the paper with conclusion and perspectives (Sect. 6).

2. Related Work

Ontologies support many tasks in the field of Semantic Web. Consequently, there is a real interest in developing methods to enrich existing ones or to build
120 new ones from available unstructured data.

Contributing to the achievement of this goal, Wächter and colleagues [5] propose a method to build automatically hierarchies from texts. They have a

⁴Prefixes `skos` stands for <http://www.w3.org/2004/02/skos/core#> and `rdfs` for and <http://www.w3.org/2000/01/rdf-schema#>

three-step approach: first, terms are identified within text sources, next, definition of these terms are generated (through a web search) and finally, exploiting
125 the “*is a*” pattern they suggest a hierarchical relation between terms. Still
aiming to identify relations between concepts, we have the interesting research
work of Tastsaronis et al. [6]. They propose to identify the predicate of a given
ontology, which links two terms - labelled with the URIs of the concepts they
refer to. The recent research work of Louge et al. [11] fulfills a similar goal
130 by building a taxonomy from services’ short descriptions, but a taxonomy is a
lightweight ontology and is not expressive enough.

Another way to achieve the goal of adding more information to existing
ontologies or knowledge bases (KBs) is to assign formal expressions to concepts.
Hence, through reasoning, new pieces of information could be inferred. We find
135 in the literature several research works aiming to provide expressions of concepts.
In [7, 12] and [8], Bühmann, Lehman and colleagues try to get such expressions
by *studying* the characteristics of concepts’ instances in KBs automatically.

However all the works above-mentioned are far from our goal: NALDO ad-
dresses the problem of formalizations of given NL definition towards an existing
140 domain ontology.

An excellent system which helps users to obtain formal expression from
definitions is the Atempo Controlled English (ACE) [13]. However the input
definitions of the ACE are not actually in NL. Indeed, ACE needs the user to
write the definitions in a given format, so that the system can translate them
145 automatically and without errors in OWL. For example, the definition we took
here to illustrate our approach, “*A cell space is an anatomical space that is part
of a healthy cell*”, must be rewritten as *A cell-space is an anatomical-space that
is part-of a cell*. We see that users have to use *hyphen* to indicate multi-word
entities and that they should manually prune “meaningless” terms like “*healthy*”
150 that appear in the NL definition.

Lexo [9] is another interesting approach which is close to NALDO when
considering goals and inputs. Lexo is a heuristic-based tool that aims to obtain
concepts’ expressions from their definitions. Lexo provides the expression of con-

cept from their definition but that expression is not aligned with any ontology.
155 Hence, all its entities are new and still ambiguous. In addition, Lexo proposes a
non-contextual formalization of meaningless NL predicates. For instance, when
an auxiliary stands by itself as a predicate in an NL phrase, Lexo always assumes
that this auxiliary denotes the same formal predicate, independently of the NL
phrase or the given definition. Such assumption is too restrictive in practice.
160 Finally, Lexo provides an *unduly* formalization of phrases. Indeed, Lexo formal-
izes a phrase considering each token of this phrase individually. For example,
when following the transformation rules of Lexo, the phrase “red onion topping”
in a definition will be turned into ‘:Red \sqcap :Onion \sqcap :Topping’, which does not
consider that this phrase may refer to a single concept. When referring to the
165 PIZZA ontology in this case, this phrase could refer to :RedOnionTopping.

The approach of De Azevedo et al. [10] is similar to Lexo. On the contrary
of Lexo, [10] uses reasoning to ensure the consistency of their expressions and to
provide other expressions which can be semantically derived from the main ex-
pression, i.e. directly obtained from the definition. Such as Lexo, [10] builds DL
170 ALC expressions from scratch, without trying to reuse entities from a domain
ontology.

All these differences, regarding inputs (i.e. definitions and corresponding
domain ontology), and goal (i.e. formalize the definitions w.r.t a corresponding
domain ontology) do not allow us to make a quantitative comparison with all
175 those existing works. However, we provide a detail comparison of NALDO
with Lexo and the work of De Azevedo et al. [10] in section 5. We recall
that NALDO is an approach whose goal is to support ontology building by
suggesting automatically a formal expression of ontology concepts based on
their NL definition. The main advantage of NALDO is that it foremost reuses
180 the ontology entities in the expression that it provides.

Now that we have described state of the art research works, we present the
steps of NALDO.

3. The NALDO approach

Fig. 1 gives an overview of the main steps of NALDO which are then detailed
 185 in sections 3.1 to 3.3. A demo is available at <http://tinyurl.com/j6vfuj5>.
 The NALDO approach is composed of the following steps: 1) Splitting, 2) Lem-
 matisation + Syntactic Pruning, 3) Semantic Pruning, 4) Concepts Identifica-
 tion, 5) Template Identification, 6) Property Identification and finally 7) Re-
 combination. Steps 1 to 3 reuse existing tools, whereas steps 4 to 7 comprise
 190 our contributions.

Figure 1: Steps of NALDO

3.1. Splitting

Splitting is the first step of the processing of a NL definition (see step 1
 Fig. 1). The aim of this task is to identify all the pieces of information within
 the definition \mathcal{S}_j . Each chunk is intended to be *informative* and *atomic*. The
 195 informativeness means that a chunk delivers a piece of information on a given
 subject. We take advantage of the suitable task called Open Information Ex-
 traction (OIE) for this splitting. An OIE-tool generally provides each piece of
 information in form of a triple $\langle \text{subject, predicate, object} \rangle$ [14], [15]. In addition,
 atomicity guarantees that each triple is small enough so that we cannot extract
 200 any other piece of information from it.

In this work, we have chosen the system called CSD-IE⁵ of Bast and Hauss-
 mann [15] to perform OIE. First, let us mention that to the best of our knowl-

⁵<http://ad-wiki.informatik.uni-freiburg.de/research/Projects/CSDIE>

edge, **ClausIE** [14] and **CSD-IE** are the most efficient OIE-tools. Secondly, characteristics of **CSD-IE** in comparison with **ClausIE** make the former more suitable
 205 for us than the latter, because it presents the following aspects:

- **Minimality**, i.e. *atomicity* mentioned above, and **coverage**, which means that there is a concern to use each word from the original sentence at least once in any resulting triple.
- **N-uples**. Instead of presenting an assertion in the form of a triple,
 210 **CSD-IE** can provide *n-uples* also called *tuples* i.e. $\langle \text{subject, predicate, phrase}_1, \text{phrase}_2, \dots \rangle$. For instance, in addition to the triple $\tau_0 = \langle \text{A cell space, is, an anatomical space} \rangle$, **CSD-IE** returns this other tuple $\langle \text{an anatomical space, is, part, of a healthy cell} \rangle$ from the sentence \mathcal{S}_1 . From this tuple, we can obtain:
 1. A single triple, for instance
 - $\tau_1 = \langle \text{an anatomical space, is, part of a healthy cell} \rangle$ or
 - $\tau_a = \langle \text{an anatomical space, is part, of a healthy cell} \rangle$
 2. Or a set of triples, for example
 - $\tau_\alpha = \langle \text{an anatomical space, is, part} \rangle$ and $\tau_\beta = \langle \text{part, of, a healthy cell} \rangle$

220 Tuples allow us to consider different levels of granularity for triples. Hence, the possible cuttings of \mathcal{S}_1 are ' τ_0 and τ_1 ', ' τ_0 and τ_a ', and ' τ_0 and τ_α and τ_β '.

3.2. Rewriting a Triple as an OWL DL Statement

The goal of this task is to write each triple τ_i , made of chunks in NL, as an OWL DL statement. The formal expression we obtain denotes a relation between two
 225 concepts w.r.t to a given domain ontology \mathcal{O} , *if possible*. We denote respectively $?C_s$ and $?C_o$ the concepts or individuals that stand in the position of the *subject* and the *object* within the formal expression. In practice, this task consists in instantiating one of the templates presented in Table 1.

To achieve this goal, we proceed in four steps: (i) The lemmatisation and
 230 the syntactic pruning of the triple, (ii) the semantic pruning, (iii) instantiation

Names	Expressions
Subsumption	$?C_s \sqsubseteq ?C_o$
Equivalence	$?C_s \equiv ?C_o$
Existential restriction	$?C_s \sqsubseteq \exists ?property.?C_o$
Universal restriction	$?C_s \sqsubseteq \forall ?property.?C_o$
HasValue restriction	$?C_s \sqsubseteq \exists ?property.?C_o$, where $?C_o$ is an individual
MinCardinality Restriction	$?C_s \sqsubseteq \geq ?n ?property.?C_o$
MaxCardinality Restriction	$?C_s \sqsubseteq \leq ?n ?property.?C_o$
Cardinality Restriction	$?C_s \sqsubseteq = ?n ?property.?C_o$

Table 1: Templates of atomic OWL DL restrictions (variables are preceded by ’?’)

of $?C_s$ and $?C_o$, (iv) identification of the corresponding template and (v) instantiation of the variable $?property$. These steps are numbered 2 to 6 in Fig. 1.

3.2.1. Lemmatisation and Syntactic Pruning

235 The goal of this step is to have canonical forms of the tokens (i.e. lexical units) within the triples, and to remove from the triples all the stop words. At this stage, lemmatisation and syntactic pruning are carried out for each component (i.e subject, predicate and object) of τ_i .

3.2.2. Semantic Pruning

240 Between the tokens remaining in τ_i after the syntactic pruning, we can still have some noise. Indeed, we consider that tokens (at this stage) in τ_i which stems are not shared with those of the labels of domain entities, even when considering their synonyms⁶, are useless for the linking of \mathcal{O} and τ_i . Using this pruning prevents the overloading of the triple, with a token that will not
245 match any token of the labels of entities in \mathcal{O} . Table 2 gives the results for lemmatisation, syntactic and semantic prunings of our running example. We notice that, the semantic pruning removes the token “*healthy*” from all the triples where this token is found. So, the word “*healthy*” will not cause any

⁶We use the paraphrases database PPDB of Pavlick et al. [16] to identify synonyms.

NL Phrases	Triples	Lemma + Syn. Pruning	Semantic Pruning
A cell space	τ_0	cell space	cell space
is	$\tau_0, \tau_1, \tau_\alpha$	-	-
an anatomical space	$\tau_0, \tau_1, \tau_\alpha, \tau_\alpha$	anatomical space	anatomical space
part of a healthy cell	τ_1	part healthy cell	part cell
is part	τ_a	part	part
of a healthy cell	τ_a	healthy cell	cell
part	τ_α, τ_β	part	part
of	τ_β	-	-
a healthy cell	τ_β	healthy cell	cell

Table 2: Some examples of lemmatisation, syntactic and semantic pruning.

distortion when we will look for the entities, of the domain ontology, that match
250 the NL phrases of the triples.

3.2.3. Concepts Identification

Concepts identification is the 4th step of Fig. 1. In our approach, we upper-
most identify concepts instead of properties. Indeed, there are too many ways
to assert the same thing about a given resource (e.g: “*an anatomical space is*
255 *part of/is a region of/composes a healthy cell*”). Moreover, some predi-
cates/verbs are useless for property identification (e.g: be, have, of, from, etc.).
Also, at this stage we deal with an atomic triple and its structure already sug-
gests a group of words to bind $?C_s$ and another one for $?C_o$. NALDO relies on
the algorithm 1 to bind $?C_o$ and $?C_s$.

260 Algorithm 1 works as follows:

- To instantiate $?C_s$ (resp. $?C_o$), we use the subject (resp. the object) part
of τ_i (Line 1).
- For the subject and object of τ_i (*after their syntactic and semantic prun-*
ings - lines 1 and 2), NALDO identifies the entity within \mathcal{O} with the
265 highest matching score (loop on lines 3-8).

Algorithm 1: Binding of $?C_s$ for the triple τ_i and score computation

```

Input :  $\tau_i, \mathcal{O}$ 
Output:  $?C_s, \text{scoreCs}$ 

1 subjectSynP  $\leftarrow$  lemmatisationAndSynPruning ( $\tau_i$ .subject);
2 subjectSemP  $\leftarrow$  SemanticPruning (subjectSynP); scoreCs  $\leftarrow$  0.0;
3 for each uri in  $\mathcal{O}$ .classesAndIndividuals do
4   | for each label in uri.altLabels do
5   |   | temp  $\leftarrow$  Similarity (label, subjectSemP);
6   |   | if temp > scoreCs then  $?C_s \leftarrow$  uri; scoreCs  $\leftarrow$  temp;
7   |   | end
8   | end
9 if scoreCs <  $\sigma_c$  then
10  |  $?C_s \leftarrow$  newUri (subjectSynP); nbOfTokens  $\leftarrow$  subjectSynP.nbOfTokens;
11  | scoreCs  $\leftarrow$   $\mu_c / (\text{nbOfTokens} + \max(0, \text{nbOfTokens} - \mathcal{O}.\text{nbOfTokensClass}))$ ;
12 end

```

- The string similarity function used here (Line 5) is the average of the *jaccard_2 similarity*⁷ [17] and the *cosine similarity* [19]. This matching score allows taking into account a similarity at word-level, with the cosine, and at the character level, with the *jaccard_2 similarity*.
- 270 • When the similarity score is under a certain threshold σ_c (line 9), a new entity (line 10) having a new score (line 11) is created. This new score, capped to a value μ_c , decreases with the number of tokens of the label of the new entity and the average number of tokens of labels in \mathcal{O} (variable name *nbOfTokensClass*). Tab 4 shows result for our running example.

275 **3.2.4. Template Identification**

The templates we have to deal with are built around a given set of operators ($\sqsubseteq, \equiv, \forall, \exists$, etc.). To identify the correct template of τ_i means to find out in

⁷*jaccard_2 similarity* [17] is an adaptation of the *jaccard similarity* [18]: *jaccard* computes the similarity between two bags of words, where *jaccard_2* considers each word in the bags as a set of two-characters words.

List of keywords	Corresponding template	Symbol
is a, is an, are a	Subsumption	\sqsubseteq
is any, are any, are all	Equivalence	\equiv
at least n , greater than n	MaxCardinality Restriction	$\leq n$
at most n , less than n	MinCardinality Restriction	$\geq n$
with n , exactly n , uniquely n	Cardinality Restriction	$= n$
only, uniquely, exclusively	Universal Restriction	\forall

Table 3: Some examples of phrases for template identification ($n = \text{digits}$)

	NL Subject \rightarrow Formal Entity/Score	NL Object \rightarrow Formal Entity/Score	Sym.
τ_0	cell space \rightarrow CellSpace/1.0	anatomical space \rightarrow AnatomicalSpace/1.0	\sqsubseteq
τ_1	anatomical space \rightarrow AnatomicalSpace/1.0	part cell \rightarrow new:PartHealthyCell/0.3	\exists
τ_a	anatomical space \rightarrow AnatomicalSpace/1.0	cell \rightarrow Cell/1.0	\exists
τ_α	anatomical space \rightarrow AnatomicalSpace/1.0	part \rightarrow new:Part/0.5	\exists
τ_β	part \rightarrow new:Part/0.5	cell \rightarrow Cell/1.0	\exists

Table 4: Concepts, matching scores and templates' symbols for our triples. The prefix **new**: indicates new entities (not found in \mathcal{O})

the text of τ_i any word or group of words that could lead to one of the operators we just listed.

280 This identification process takes advantage of a list of predefined phrases as illustrate in Table 3. Practically, we first verify if $?C_o$ is an *individual*. If yes, we are facing a HasValue restriction. If not, we find, in the *order* exposed in Table 3, which phrases the triple τ_i (without any processing) matches. The existential restriction \exists is the default template because it states that there exists a link
285 between two entities. Table 4 presents in its last column the template for our example.

3.2.5. Properties Identification

Now that we have possible concepts $?C_o$ and $?C_s$, we need to provide the *property* that supports the relation between them. Let us note that this step
290 is useless when we already know that we are facing a classic subsumption or
an equivalence. We obtain the list of properties that can link $?C_s$ and $?C_o$ by
executing the following query displayed in listing 1:

```
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#> 1
PREFIX owl: <http://www.w3.org/2002/07/owl#> 2
PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#> 3
SELECT DISTINCT ?p WHERE { 4
  {{?hierarchySubj owl:onProperty ?p. 5
   :Cs rdfs:subClassOf* ?hierarchySubj.} 6
  UNION 7
  {{:Cs rdfs:subClassOf* ?DomainP. ?p rdfs:domain ?DomainP}}. 8
  {{?r2 owl:onProperty ?p. ?r2 ?prop ?hierarchyObj. 9
   :Co rdfs:subClassOf* ?hierarchyObj. 10
  FILTER(!(?prop = rdf:type) && !(?prop = owl:onProperty))} 11
  UNION 12
  {{:Co rdfs:subClassOf* ?RangeP. ?p rdfs:range ?RangeP}}} 13
```

Listing 1: Query for property identification

This query of listing 1 allows NALDO to select a property $?p$ if:

- $?C_s$ is included in the domain of $?p$ (line 8) *or* $?C_s$ is included in an
310 `owl:Restriction` built on top of $?p$ (lines 5-6) *and*
- $?C_o$ is included in a class targeted by a `owl:Restriction` built on top of
 $?p$ (lines 10-12) *or* $?C_o$ is included in the range of $?p$ (line 13).

Then we have to rank this list of properties according to the tokens of τ_i .
This ranking is similar to the one performed to bind concepts. Algorithm 2
315 details the binding of the *property* for τ_i . In this algorithm, when the property
of the triple has only meaningless tokens (usually auxiliaries or prepositions),
its matching score depends on the tokens of the τ_i and the (potential) additional
tokens from labels of $?C_s$ and $?C_o$ (line 8 in the algorithm).

Algorithm 2: Binding of $?property$ for the triple τ_i and score computation

```
Input :  $\tau_i, \mathcal{O}, ?C_s, ?C_o$ 
Output:  $?property, scoreP$ 

1 tripleUsefulTokens  $\leftarrow$  lemmatisationAndSynPruning ( $\tau_i$ );
2 tripleUsefulTokens.add ( $?C_s$ .label); tripleUsefulTokens.add ( $?C_o$ .label);
3 predicate  $\leftarrow$  lemmatisationAndSynPruning ( $\tau_i$ .predicate);
4 properties  $\leftarrow$  compatibleProps ( $?C_s, ?C_o$ ); scoreP  $\leftarrow$  0.0;
5 if predicate = "" then
6   for each property in properties do
7     for each label in property.altLabels do
8       temp  $\leftarrow$  cosineSimilarity (label, tripleUsefulTokens);
9       if temp > scoreP then  $?property \leftarrow$  property; scoreP  $\leftarrow$  temp;
10    end
11  end
12 else
13   for each property in properties do
14     for each label in property.altLabels do
15       temp  $\leftarrow$  NgramSimilarity (label, predicate, 2);
16       if temp > scoreP then  $?property \leftarrow$  property; scoreP  $\leftarrow$  temp;
17     end
18   end
19 end
20 if scoreP <  $\sigma_p$  then
21    $?property \leftarrow$  newUri (predicate); nbOfTokens  $\leftarrow$  predicate.nbOfTokens;
22   scoreP  $\leftarrow$   $\mu_p / (\text{nbOfTokens} + \max(0, \text{nbOfTokens} - \mathcal{O}.\text{nbOfTokensProps}))$ ;
23 end
```

The splitting of \mathcal{S} provides a collection of sets of triples. Each set of triple is a
 320 candidate to the formalization of the definition. To choose the most suitable set
 of triples, NALDO ranks this collection. To perform this ranking, we assign a
 score to each formal triple. This score depends on **ScoreCs**, **ScoreCo** obtained
 from algorithm 1 and **ScoreP** from algorithm 2 (we consider that triples denoting
 subsumption or equivalence, have property score of 1.0). The score of a cutting
 325 is the *average* of the score of its triples.

Having a single set of formal triples, we need to put them together to obtain
 a formal expression for the input definition. For our running example, the
 properties and the final scores of triples are presented in Table 5. We recall that
 we have three possible cuttings: ' τ_0 and τ_1 ' (score = **2.325**), ' τ_0 and τ_a ' (score
 330 = **2.825**), and ' τ_0 and τ_α and τ_β ' (score = **2.33**). In the light of these scores,
 we will use τ_0 and τ_a for the final expression of \mathcal{S}_1 .

Triples	Formal expression	Scores
τ_0	CellSpace \sqsubseteq AnatomicalSpace	1.0 + 1.0 + 1.0 = 3.0
τ_1	AnatomicalSpace \sqsubseteq \exists hasPart.new:PartHealthyCell	1.0+0.35+0.3 = 1.65
τ_a	AnatomicalSpace \sqsubseteq \exists partOf.Cell	1.0+0.65+1.0 = 2.65
τ_α	AnatomicalSpace \sqsubseteq \exists partOf.new:Part	1.0+0.35+0.5 = 1.85
τ_β	new:Part \sqsubseteq \exists partOf.Cell	0.5+0.65+1.0 = 2.15

Table 5: Properties and final scores, after running algorithms 1 and 2, for τ_0 , τ_1 , τ_a , τ_α and τ_β (with $(\sigma_c, \mu_c, \sigma_p, \mu_p) = (0.40, 0.35, 0.35, 0.30)$)

3.3. Recombination

Recombination is the 7th (Fig. 1) and final step of the formalization process.
 Its aim is to combine a set of formal triples to obtain a single expression. Besides
 335 the triples to be combined, we compute the structure Σ_j that gives information
 on the manner these triples are linked. To perform this merging, we rely on two

main functions that we call *factorization* and *refinement*. They both take as input two triples ($\tau_i = (C_s^i \mathbf{rel}_i C_o^i)$ and $\tau_j = (C_s^j \mathbf{rel}_j C_o^j)$), an operator (**and** or **or**) and return a new triple that is a merging of the input triples. To be
340 coherent with the possible formal expression of a triple, **rel**_{*i*} and **rel**_{*j*} can only be subsumption, equivalence or the body of a restriction. We detail factorization and refinement in the following subsections.

3.3.1. Factorization

We perform this operation when $C_s^i = C_s^j = C_s$. The two triples thus
345 make assertions about the same subject. The resulting triple regroups these two assertions into a single one about C_s . Equations (1) - (8) below ($*$ denotes **and** or **or**) provide all the possible results of factorisation. We make use of lower case for presentation purposes.

$$(c_s \sqsubseteq c_o^i) * (c_s \equiv | \sqsubseteq c_o^j) \rightarrow c_s \sqsubseteq (c_o^i * c_o^j) \quad (1)$$

$$(c_s \equiv c_o^i) * (c_s \equiv c_o^j) \rightarrow c_s \equiv (c_o^i * c_o^j) \quad (2)$$

$$(c_s \equiv | \sqsubseteq c_o^i) * (c_s \sqsubseteq c_o^j) \rightarrow c_s \equiv (c_o^i * c_o^j) \quad (3)$$

$$(c_s \sqsubseteq c_o^i) * (c_s r_j c_o^j) \rightarrow c_s \sqsubseteq (c_o^i * r_j c_o^j) \quad (4)$$

$$(c_s \equiv c_o^i) * (c_s \sqsubseteq r_j c_o^j) \rightarrow c_s \sqsubseteq (c_o^i * r_j c_o^j) \quad (5)$$

$$(c_s \sqsubseteq r_i c_o^i) * (c_s \sqsubseteq c_o^j) \rightarrow c_s \sqsubseteq (r_i c_o^i * c_o^j) \quad (6)$$

$$(c_s \sqsubseteq r_i c_o^i) * (c_s \equiv c_o^j) \rightarrow c_s \sqsubseteq (r_i c_o^i * c_o^j) \quad (7)$$

$$(c_s \sqsubseteq r_i c_o^i) * (c_s \sqsubseteq r_j c_o^j) \rightarrow c_s \sqsubseteq (r_i c_o^i * r_j c_o^j) \quad (8)$$

$(C_s \sqsubseteq r_i C_o^i)$ (in equation (8)) means members of the class C_s are also mem-
350 bers (subsumption) of the anonymous class $r_i C_o^i$. Likewise, $(C_s \sqsubseteq r_j C_o^j)$ means $C_s \sqsubseteq (r_j C_o^j)$. Thus, the first member of (8) means $(C_s \sqsubseteq r_i C_o^i)$ **and**|**or** $(C_s \sqsubseteq r_j C_o^j)$. We can conclude that C_s subsumes the combination (**and** or **or**) of $r_i C_o^i$ and $r_j C_o^j$. Moreover, when we have to put together subsumption and equivalence, we decide to choose subsumption, since equivalence includes subsumption.

355 *3.3.2. Refinement*

In this work, to refine a concept is to add a precision to make it a more specific concept. We perform refinement when $C_o^i = C_s^j$. Hence, it means that a precision is made about C_o^i in the second triple τ_j . All the possible scenarios of refinement are solved through equations (9) - (16) below. Let us note that using
 360 the connector **and** is the only way to handle the piece of information brought by τ_j (one cannot provide further information on an entity using **or**).

$$(c_s \sqsubseteq c_o^i) \sqcap (c_o^i \sqsubseteq | \equiv c_o^j) \rightarrow c_s \sqsubseteq (c_o^i \sqcap c_o^j) \quad (9)$$

$$(c_s \equiv c_o^i) \sqcap (c_o^i \equiv c_o^j) \rightarrow c_s \equiv (c_o^i \sqcap c_o^j) \quad (10)$$

$$(c_s \equiv | \sqsubseteq c_o^i) \sqcap (c_o^i \sqsubseteq c_o^j) \rightarrow c_s \sqsubseteq (c_o^i \sqcap c_o^j) \quad (11)$$

$$(c_s \sqsubseteq c_o^i) \sqcap (c_o^i \sqsubseteq r_j c_o^j) \rightarrow c_s \sqsubseteq (c_o^i \sqcap r_j c_o^j) \quad (12)$$

$$(c_s \equiv c_o^i) \sqcap (c_o^i \sqsubseteq r_j c_o^j) \rightarrow c_s \equiv (c_o^i \sqcap r_j c_o^j) \quad (13)$$

$$(c_s \sqsubseteq r_i c_o^i) \sqcap (c_o^i \sqsubseteq c_o^j) \rightarrow c_s \sqsubseteq (r_i(c_o^i \sqcap c_o^j)) \quad (14)$$

$$(c_s \sqsubseteq r_i c_o^i) \sqcap (c_o^i \equiv c_o^j) \rightarrow c_s \sqsubseteq (r_i(c_o^i \sqcap c_o^j)) \quad (15)$$

$$(c_s \sqsubseteq r_i c_o^i) \sqcap (c_o^i \sqsubseteq r_j c_o^j) \rightarrow c_s \sqsubseteq (r_i(c_o^i \sqcap r_j c_o^j)) \quad (16)$$

To evaluate the simplification of a complex expression, we use the *recursive factorisation algorithm* proposed in [20, p. 13].

For our running example, the expression to recombine is ' τ_0 and τ_a ' i.e.:

365 $(\text{CellSpace} \sqsubseteq \text{AnatomicalSpace}) \sqcap (\text{AnatomicalSpace} \sqsubseteq \exists \text{partOf.Cell})$

This expression strictly follows the refinement equation 12. We thus obtain

$$\text{CellSpace} \sqsubseteq (\text{AnatomicalSpace} \sqcap \exists \text{partOf.Cell}).$$

We provide this running example with details at <http://tinyurl.com/>

370 [h7vgo3r](http://tinyurl.com/h7vgo3r).

4. Evaluation

4.1. Benchmark and Metrics

We evaluate NALDO against the BEAUFORD benchmark [21]. BEAUFORD is a benchmark dedicated to the formalization of definitions. It provides

375 a list of features for a formalization approach, a dataset and a set of metrics for
the current task.

- BEAUFORD provides a corpus made of three domain ontologies (VSAO, the
Semantic Sensor Network Ontology (SSN) and the pizza ontology (PIZZA))
and 25 definitions for each of these domains. Knowing that a definition
380 can be formalized in many ways, BEAUFORD provides a set of possible
formalizations for each definition. For the current evaluation, considering
the goal of NALDO, we consider only the formalizations that give priority
to entities found in the ontologies⁸.
- Finally, BEAUFORD proposes three metrics to evaluate formalization of
385 definitions: *precision*, *recall* and *confidence*. Basically, within BEAU-
FORD, precision denotes the ratio of formal entities correctly identified,
recall quantifies the number of NL phrases within the definition that are
correctly formalized and the confidence is the ratio of definitions of the
corpus that are correctly formalized in all points. [21] provides additional
390 information and illustrations about these metrics.

4.2. Evaluation Results

A demo of NALDO is accessible at <http://tinyurl.com/j6vfuj5>. NALDO is
written in Java and uses the Stanford suite⁹ for natural language processing
tasks.

395 For each of the three domain ontologies of the BEAUFORD corpus, we have
computed precision, recall and F1-measure. These metrics are function of the
values of the parameters σ_c , μ_c , σ_p and μ_p (Fig. 2-4). These parameters serve
to control the quality of the matching between terms of the NL definitions and
labels of ontologies' entities (algorithms 1 and 2). Accordingly, an interpretation

⁸Indeed some formalizations encourage the use of new entities to express a definition. See
[21, Sect. 5.2 and 5.3] for details.

⁹<https://nlp.stanford.edu/software/>

400 of Fig. 2-4 gives us the highest values for parameters σ_c , μ_c , σ_p and μ_p to use in concepts and properties identification. We consider:

- $\sigma_c > \mu_c$ and $\sigma_p > \mu_p$. For the creation of a new class, the string matching score must be under σ_c . Since we want to discourage the creation of new entities, we find suitable to top the score of a new class to a value μ_c that is less than σ_c . The same explanation holds for σ_p and μ_p .
- $\mu_c = \sigma_c - 0.05$ and $\mu_p = \sigma_p - 0.05$. Since we cannot evaluate NALDO for all the possible values of our four parameters, these equations help us to reduce the number of tests to carry on. Hence, precision, recall and F1 are computed only as function of σ_c and σ_p and their values represented using a 3D diagram (Fig. 2 - 4). In these diagrams, the color varies from the lowest to the highest values on the z-axis, respectively from *blue*, then *yellow*, then *orange* and finally *red*.

Figure 2: Precision, Recall and F1-Measure for the VSAO domain.

Figure 3: Precision, Recall and F1-Measure for the PIZZA domain.

Finally, for each domain ontology, for the 4-uple $(\sigma_c, \mu_c, \sigma_p, \mu_p)$ for which the F1-measure is the highest, we have computed confidence, i.e., the number of definitions that have the formal expression correct [21]. Table 6 presents these

Figure 4: Precision, Recall and F1-Measure for the SSN domain.

results. It is useless to find confidence for every 4-uples $(\sigma_c, \mu_c, \sigma_p, \mu_p)$, because a low F1 means a misidentification of several formal entities and thus incorrect final expressions.

420 For each of the 75 definitions of the BEAUFORD dataset, the detailed results are available at <http://tinyurl.com/hq8v1ou>.

Domains	Best F1-measure	$(\sigma_c, \mu_c, \sigma_p, \mu_p)$	Confidence
VSAO	0.68	(0.40,0.35,0.25,0.20)	07/25=28%
PIZZA	0.79	(0.40,0.35,0.35,0.30)	08/25 = 32%
SSN	0.63	(0.40,0.35,0.55,0.50)	08/25=32%

Table 6: Confidence for VSAO, PIZZA and SSN calculated at the best F1 score.

4.3. Results Analysis

The analysis of our results shows that:

- For the three domain ontologies, the best F1-measure is obtained with low thresholds. Indeed, σ_c is under 0.40 and σ_p is less than 0.60. It means that, usually, the NL phrases in definitions are built upon a terminology wider than the one covered by domain ontologies. Additionally, NL definitions are not concise and surround the key pieces of information with attractive phrasing and wordy details. Consequently, to gain in logical expressiveness, lightweight ontologies need to represent a more important number of real world entities.
- 425
- 430

- 435
 • The best 4-uple of parameters differ from a domain to another. This discrepancy underlines well the differences between the three ontologies. For instance, a domain and a range of almost all the properties within PIZZA ontology are provided, when it is the case for very few of them in VSAO. Hence, the list of compatible properties between two concepts in PIZZA is less noisy properties (hence a better matching) than a similar list in VSAO. Another key point here is the number of tokens used for labels of entities. The average number of tokens for SSN is 1.49, 1.66 for PIZZA
 440
 when it reaches 2.08 for VSAO. These values impact the best parameters of each ontology. Indeed, thresholds decrease from SSN to PIZZA and to VSAO (third column of Table 6): higher threshold to match a 1.5-token expression than for the matching of a 2 or more tokens expression.
- 445
 • The values of the confidence, as defined in BEAUFORD benchmark [21], are very low - under 30 %, especially when compared to F1 measures. It means that, in about 70 % of the formal expression, NALDO misidentifies at least one entity. We present the main sources of errors in the next section.

4.4. Errors Analysis

450
 The main sources of errors in NALDO and some possible improvements follow.

- 455
 • **OIE.** The first step of the formalization process is the splitting of the definition. Although OIE helps to handle long and complex sentences, it is not free of error. Hence, when OIE fails, even if we can identify some entities correctly, the final expression may be wrong. The result of OIE itself depends directly of the quality of the parser. CSD-IE, that we use for OIE, uses the Stanford parser. For example the sentence “A *spicy topping is a kind of topping*” leads to incorrect tuple (A spicy, is topping) because topping is tagged as a verb (VBG), instead of a noun (NN), by
 460
 the parser. A training of parsers on annotated corpus built from resources

of the domain of interest may lead to better result of parsing, and thus improve information extraction from definitions of this domain.

- 465 • **Thresholds for entities identification.** The identification of entities relies strongly on the values of σ_c and σ_p . These thresholds can lead to the refusal of a good matching or the approval of a wrong one.
- 470 • **Paraphrases resolution (PR).** Although the advantages of such task are indisputable, PR causes some problems. PPDB [16] is a general and incomplete database. Consequently, some paraphrases that are true in general are false in a given domain and some paraphrases may be missing. These phenomena may cause unwanted alignments. The use of a paraphrase resource, built specially for the domain of the ontology one aims to enrich, should improve results of this task.
- 475 • **“One to one alignment”.** Except the syntactic and semantic prunings, which allow us to avoid useless tokens in string matching, we consider that each NL phrase and each triple is worth for the formalization process. However, in practice, a whole piece of a definition may be useless. For instance, in the definition 11 “Deployment is the ongoing process of entities **deployed for a particular purpose.**” of the SSN-BEAUFORD corpus, the phrase in bold is useless for the formalization suggested by the gold standard in BEAUFORD. We must enhance our pruning method to
480 achieve a higher precision.

4.5. NALDO in practice

Here we discuss briefly how one can use NALDO in practice. For example for a new ontology, the first step may consist in finding suitable parameters ($\sigma_c, \mu_c,$
485 σ_p, μ_p) for concepts and properties matching. This can be done by evaluating the approach on a small set of definitions (training set) for many values and choose the parameters which provide the best F1-measure on that training set. Then using these parameters (or default ones), an ontology designer can use NALDO to get a proposal of formal expressions of concepts given their NL

490 definitions. Outputs of NALDO can be then added, with or without update, to
the ontology.

5. Comparison of Naldo, Lexo [9] and the work of De Azevedo et al. [10]

In this section, we detail the comparison between NALDO and some state-
495 of-the art approaches. Table 7 presents the characteristics of each of these
works. This table uses the issues (\mathcal{F}_1) - (\mathcal{F}_5), provided in section 1.1, to ease the
comparison between approaches and to see clearly what is done and what is still
to address by future works. In addition, this table shows that the main difference
between NALDO and the existing works is the ability of NALDO to link the
500 terms of the NL definition with the entity of the domain ontology. Hence, the
expression that NALDO provides can be added directly to the ontology.

This table shows that:

- Neither Lexo, nor De Azevedo et al.’s work tackle issues (\mathcal{F}_1)-(\mathcal{F}_5) (see
section 1.1), while Naldo addresses issues (\mathcal{F}_3) and (\mathcal{F}_5). In other words,
505 NALDO implements mechanisms for ”basic” linking ((\mathcal{F}_3), as explained in
section 1.1.3) and for pruning of meaningless phrases found in definitions.
- The evaluation of the three approaches in three different domains high-
lights that NALDO outperforms both Lexo and De Azevedo et al. ap-
proach by at least 0.13 up to 0.38 of F1 measure.

510 6. Conclusion and perspectives

In this paper, we present NALDO, an automatic approach that provides
formal expression of concepts from their textual definitions. After the presenta-
tion of the research problems related to the automatization of such approach, we
show how NALDO focuses on the issues of basic linking and pruning. To address
515 these issues and to provide expressions with a given semantics, NALDO uses
entities of existing ontologies describing the domain of these concepts. NALDO

Characteristics	Lexo [9]	Work of De Azevedo et al. [10]	NALDO
Input	NL definition	NL definition	NL definition and Domain ontology
Expressiveness of output	SHROIQ	ALC	SHROIQ
Issues			
(\mathcal{F}_1)	No	No	No
(\mathcal{F}_2)	No	No	No
(\mathcal{F}_3)	No	No	Yes
(\mathcal{F}_4)	No	No	No
(\mathcal{F}_5)	No	No	Yes
Results on VSAO			
Precision	0.52	0.61	0.70
Recall	0.44	0.44	0.66
F1	0.48	0.51	0.68
Results on PIZZA			
Precision	0.40	0.42	0.82
Recall	0.40	0.4	0.77
F1	0.40	0.41	0.79
Results on SSN			
Precision	0.47	0.53	0.68
Recall	0.45	0.48	0.59
F1	0.46	0.50	0.63

Table 7: Comparison of NALDO with Lexo and De Azevedo et al. [10]

can achieve up to 0.79 of F1-measure and a confidence of 31% i.e. 23 of the 75 tested definitions. The given score is obtained for a unique combination, for a given domain, of the four key parameters which support NALDO. The combination can be used to extrapolate NALDO on a larger corpus. This work also revealed several crucial issues, of which one is prominent: the pruning, from

a text, of meaningless phrases w.r.t. to a knowledge base and thus useless for formal expressions of concepts. NALDO addresses this issue using semantic and syntactic prunings, however evaluation results suggest that we should strengthen this filtering. In addition, NALDO employs a general paraphrase database; we intend to make use of domain resources for future works. Another issue needs a closed look: "Strong" entity linking where the formalization approach is able to identify suitable entities in the domain ontology, but which are not lexically found in the definition. Finally, NALDO is being adapted to deal with sentences out of the scope of definitions such as business rules and policies.
