ABSTRACT
In the domain of e-learning for a linguistic field, active reading interfaces are useful tools for learning new languages. For a learner of a given language, the goal is to assist in knowledge development in other known languages, in order to enhance their learning. An active reading program enriches the understanding of the input sentence in different ways, such as adding the pronunciation of each word or displaying a definition or a translation taken from a dictionary. By the process of analogy, the users would then be able to synthesize the information and produce by themselves a better interpretation or translation that would be, at their convenience, both syntactically and semantically appropriate.

We coin sinograms as an alternative proposal to 'Chinese characters' in order to distinguish the contemporary political entity from the past cultural dominant ideology over Eastern Asia and its most visible representative: the graphic system. Consequently, Sinographic languages (SL) [7] refer to the languages sharing a history including cultural loans through literary corpora and standards, the graphic system conveying them and so the lexicon still in use in these languages nowadays. Defined as such, SL include all the Sinitic languages among which standard Mandarin as the legitimate variant, but also typologically distinct languages such as Japanese, Korean and Vietnamese. In this paper, we will just deal with Japanese and Mandarin.

We propose two new features for an active reading interface that aims to help in the understanding of Sinographic languages. We focus on Japanese and Mandarin languages. The first feature identifies the reading (on'yomi, kun'yomi...) of the sinograms; the second feature displays, for certain words of the input text, their equivalent in another language that is etymologically close to the source one. In our case, the words with on'yomi reading will be associated with their Mandarin equivalents, in their Pinyin form. This tool can be useful for learners of Japanese with some knowledge of Mandarin or the contrary.

1. INTRODUCTION
In the domain of e-learning for a linguistic field, active reading interfaces are useful tools for learning new languages. For a learner of a given language, the goal is to assist in knowledge development in other known languages, in order to enhance their learning. While a straightforward translation can be useful to grasp a meaning or to get a syntactically correct output sentence, it can still be semantically incorrect. Furthermore, it does not help the learner to increase her own knowledge of the language.

Instead, an active reading program enriches the understanding of the input sentence in different ways, such as adding the pronunciation of each word or displaying a definition or a translation taken from a dictionary. By the process of analogy, the users would then be able to synthesize the information and produce by themselves a better interpretation or translation that would be, at their convenience, both syntactically and semantically appropriate.

In this paper, we will proceed as follows: the second section will present an overview of the Japanese writing systems and the question of reading sinograms in Japanese texts. The third section will focus on the active reading process. Then, the Jibiki lexical resources management platform will be described in the fourth section. Lastly, we will present the new features for intercomprehension [5] between SL. In conclusion, we will discuss how these features might be improved and applied to other linguistic contexts.

2. THE JAPANESE WRITING SYSTEM AND THE READINGS OF SINOGRAMS
2.1 Japanese language vs 'Chinese'
As mentioned above, Japanese language [6] is typologically distinct from the contemporary Sinitic languages among which Modern Mandarin [9], but historically under cultural influence including Classical Chinese literature written in sinograms as early as the 5th century. By the 6th century, in order to write down reading information and Japanese-specific words, sentences and texts, several initiatives became soon two sets of syllabaries that are derived from the sinographic script. In the same time, the Japanese crafted their own readings of the
sinograms and by doing so emancipated from Classical Chinese. We insist on the fact that through this historical process, ‘Chinese’ never refers to the legitimate language spoken nowadays known as Mandarin.

2.2 Contemporary graphic typology for Japanese

As a result today, the Japanese writing system is composed of four different types of characters:

1. **kanji** (漢字) are sinograms borrowed through this historical process and sometimes derived from initial forms. They are syllabic, commonly used in nouns, verbs and adjectives (e.g. 東京 respectively read as Tō and kyō, meaning the city of Tokyo);

2. **hiragana** (平仮名) is one of the both sets mentioned above. Hiragana are ‘syllabic’ – moraic is more accurate [6]– signs used for particles, pronouns, adverbs, inflections (also referred as **okurigana** (送り仮名), etc. (e.g. そして soshite, “then”);

3. **katakana** (片仮名) refers to the second set and an alternate version of hiragana. Nowadays, they are used for non-Chinese foreign loan words (e.g. クロワッサン kurowassan, “croissant”).

4. **rōmaji** (ローマ字) are the Latin characters also used nowadays in Japanese contemporary texts (e.g. ABC Mart).

Furthermore, when small **kana** (usually hiragana) are written above kanji, they are called **furigana** (振り仮名) and are used to indicate the reading of the sinogram below. They appear usually in texts for children or above sinograms for indicating rare readings. At last, for non-Japanese speakers, there are two main transliteration standards of **rōmaji**: the Hepburn and Kunrei-shiki (訓令式), which differs from each other only by some subtleties (e.g. shi/si for transliterating シ, シ, or し).

2.3 Reading sinograms in Japanese

Beyond this graphic typology of Japanese texts, we also have to introduce shortly how the sinograms can be read in Japanese. As already mentioned above, kanji have two types of readings:

1. **on’yomi** (音読み), referred here after as ‘Chinese pronunciation’ or **on reading** inherited from Chinese loans over the history, (e.g. 東京 Tokyo);

2. **kun’yomi** (訓読み), referred here after as ‘Japanese pronunciation’ or **kun reading**, usually used for Japanese indigenous lexicon (e.g. 東 higashi, East).

The point is that beyond their belonging to differently originated lexical stocks, they also do not share the same phonological patterns. Indeed, while the latter can be polysyllabic – three for 東 higashi – the former will always conform the sinosyllabic structure shared by all the SL (cf. below 2.4).

Each kanji may have at least one reading and frequently have one or more of each of these two types of readings. In order to be complete in this overview, we have to distinguish polysynigraphic – composed of at least two sinograms – words with mixed readings. The are two types conventionally referred as **jūbako yomigatari** (重箱読読み) on/kun reading words – じゅばこ’ box’ and **yutō yomigatari** (湯桶読読み) kun/on reading words, yu-tō ’hot pot’, At last, there is a last type referred as **ateji** (当て字) where kanji are used to phonetically represent native or borrowed words with less regard to the underlying meaning of the characters such as in 寿司 sushi.

2.4 On readings and the sinosyllable

As this paper deals with features shared by SL and so Mandarin and Japanese on readings, we have to discriminate several categories of on’yomi corresponding to the different times during which the under going standard reading of a given word was borrowed from Chinese by Japanese speakers and introduced into their lexicon. Through this process, a given sinogram could be borrowed several times with diachronic variation of its reading. Three different on reading categories are conventionally discriminated as follows:

1. **go’on** (呉音) were the earliest readings introduced to Japan during the Nara period (e.g. 唐人 rônin, ‘romin’);

2. **kan’on** (漢音) followed (e.g. 外国人 gaikokujin, ‘foreigner’);

3. **tósō’ on** (唐宋音) came later during Heian and Edo period (e.g. 浦団 futon ‘futon’).

Even if these readings evolved, they all conform to the sinosyllable structure as long as it was the basis of literary composition into Classical Chinese and the institution of rhyming. The structure is organized as Figure 1.

**Figure 1:** The sinosyllable and its structure

Any sinosyllable – whatever Japanese on reading included – will conform this pattern distributed between the onset and the rhyme subdivided itself as glide (or 0), nucleus, vocalic or consonantonic coda (or 0) plus tone (or 0).

Among the examples above, such as 东 read as nin or jin, n- and -e are the onset, -i is the nucleus, and -t is the consonantonic coda. Compared to the kun reading of the sinogram 人, hito, we can see that this reading does not conform the sinosyllable distribution.

2.5 Sinogram and sinosyllable as potential of intercomprehension

Beyond this stricking diversity of various graphic systems in Japanese texts and diverse reading types for kanji, either it is challenging especially for foreign learners, there are short cuts even for this latter population as soon as learning and teaching are emancipated from language ideologies. Thus, English loan easily identified through their notation in katakana might provide a huge stock of lexicon semantically transparent and very helpful for phonological awareness. Furthermore, for foreign learners already familiar with sinograms – such as those coming from China, Taiwan, Hongkong etc., kanji are – with some exceptions – not only visually accessible for their meaning. The point now is that as long as Mandarin is becoming the first SL to be learnt abroad beyond the few aeras previously mentioned, katakana and semantic informations provided by kanji are not the only potential of intercomprehension: sinograms are also a resource through their on reading and so a feature on which learners can rely in order to transfer their reading knowledge in Mandarin into Japanese.

This is our didactic statement [4] and the theory for which our tool is designed. As far as we know, such a tool does not exist and so is our contribution.

3. THE ACTIVE READING PROCESS

3.1 Description of the generic process

The active reading tool [1] proceeds as follows:

1. The text received as input is sent to a morphological analyzer to obtain the lemma and grammatical information for each word.
2. Using the lemmas received from the analyzer, the tool then looks up a monolingual or bilingual dictionary to obtain lexical information about each lemma. It can be a definition or a translation.

3. The tool displays the input text by adding additional information either above or below the text, or by displaying words with different colors, or by adding a code that will display a pop-up window when the mouse hovers over the word.

3.2 Active reading for Japanese

3.2.1 Description of the active reading

The active reading service offers to display the reading of a Japanese text in the form of furigana and the French translations coming from a Japanese-French dictionary. The list of the corresponding translations from the dictionary appears in a textbox when hovering the mouse over certain words. The service is available online from the jibiki.fr website. This active reading instance is tailored for the following scenario: a learner of Japanese with a good knowledge of French. It could be enlarged to learners fluent in other languages by using different dictionaries. For example, the use of Jim Breen’s JMDict [2] could be useful for users fluent in English, Russian, German, Dutch, etc.

3.2.2 The morphological analysis

The parsing and analysis of the input text is performed with the Conditional Random Field based MeCab morphological analyzer and tokenizer. Figure 2 shows the result of the analysis by Mecab of the sentence entered by the user in Figure 3. Each line represents a token. The first left column is the token itself. Then follows a series of 8 items separated by commas. The first one is the part-of-speech + 名词 is a noun, 動詞 is a verb, 助詞 is a particle and 記号 is a punctuation mark. The next 4 ones are used for subcategorization. Then, the next item is the lemma (e.g: for the item 掛かり , the lemma is the infinitive form of the verb 掛かる). The next item is the writing form of the token in katakana and the last item is the reading form in katakana (e.g. the particle は has the writing form ハ and the reading form わ). For our purpose, we use the lemma and the reading form.

One can see in the example of Figure 2 that the numbers are actually parsed each figure separately by Mecab. In order to render correctly the furigana of the numbers, we encoded a specific function. That is especially important in Japanese because of the 万 (man) ‘10 000’ counting unit which differs from the Western 10000 counting unit.

3.2.3 The Japanese-French dictionary

The jibiki.fr Japanese-French dictionary [8] combines 3 main sources:

- a digitized version of the Cesselin [3] Japanese-French dictionary edited by Gustave Cesselin and published in 1940. It contains more than 82,000 articles with detailed microstructure: French translations, examples, locations, etc;
- completed with 47,630 Japanese-French or Japanese-English entries from the JMDict [2] for modern vocabulary and
- 23,486 Japanese-French or Japanese-English Wikipedia links for recent terminology.

The articles from JMDict and Wikipedia were imported if they appeared also in the Super Daidirin dictionary, in order to avoid a large number of useless entries. The resulting resource thus built contains more than 153,000 entries and 140,000 examples. It can be considered as the most reliable source for Japanese-French translations.

The result of the OCR process is never perfect. Thus, some articles coming from the Cesselin need corrections. The dictionary can be edited online by any user who detect an error. So far, more than 81,000 contributions were established in the 4 years of the project life.

Mecab analyzer is distributed with a generic dictionary called ipadic with 392,126 entries in total. Despite its consequent size, several words in our dictionary are not present in the ipadic dictionary. Thus, we decided to generate a Mecab dictionary from the content of Jibiki.fr dictionary in order to enlarge the coverage of Mecab. Our dictionary contains 22,321 entries that are not present in ipadic. The first version is still beta. On going work is on its way to produce a correct dictionary particularly concerning the subcategories of the verbs. Once this work will be completed, we will publicly release this dictionary on the Jibiki.fr project website.

Figure 3 shows the new active reading interface with these new features. These new features are aimed to learners of Japanese with some clues for intercomprehension whose objective is to highlight the words of the text with different readings depending on their stock, for Japanese spellings, katakana for foreign loan words. The objective is to highlight the words of the text with different colors according to their stock, in order to tell them apart and get knowledge of the links between them and their various influences. Then, the Pinyin is displayed below the words whose kanji are on’yomi (see Figure 4). This information gives some clues for intercomprehension between sinogramic languages [4].

These new features are aimed to learners of Japanese with some knowledge of Mandarin or the contrary.

Figure 3 shows the new active reading interface with these new features. The top half of the window is the same as Figures 2. The result is then still displayed on the bottom half of the window with the furigana on top of the Japanese sentence and a French translation when the mouse is over a word (here the word “osoi”, translated in French by “tardif”) but two new features can be seen:

4. ENRICHING THE ACTIVE READING FOR INTERCOMPREHENSION

4.1 Purpose of the new features

We will now present two new features aiming at making the active reading output display even more informative. As explained previously, Japanese language uses different writing systems and readings depending on which lexicon stock a given word belongs to: on’yomi for kanji whose pronunciation was borrowed from Chinese during different periods, kun’yomi for Japanese spellings, katakana for foreign loan words. The objective is to highlight the words of the text with different colors according to their stock, in order to tell them apart and get knowledge of the links between them and their various influences. Then, the Pinyin is displayed below the words whose kanji are on’yomi5 (see Figure 4). This information gives some clues for intercomprehension between sinogramic languages [4].

These new features are aimed to learners of Japanese with some knowledge of Mandarin or the contrary.

Figure 3 shows the new active reading interface with these new features. The top half of the window is the same as Figures 2. The result is then still displayed on the bottom half of the window with the furigana on top of the Japanese sentence and a French translation when the mouse is over a word (here the word “osoi”, translated in French by “tardif”) but two new features can be seen:

2 https://jibiki.fr/reading/
3 https://taku910.github.io/mecab/
4 http://jibiki.fr/
5 https://jibiki.fr/reading/pierric_f.php
The words in violet background are in *kun'yomi* (Yokohama, *kakari*, *oso*);
The words in red background are in *on'yomi* and below them, the *Pīnyīn* of the Mandarin equivalent word is displayed in red (Tokyō, *densha*, *jun*, *hou*);
The words in green background are in *katakana* here an English loan word (*baiku*).
As already mentioned above, among the Chinese imperial literary standards, there was the fundamental practice of Classical riming system. If it is abolished nowadays, this institution is still the potential of intercomprehension between SL through the conformation to the sinossyllable structure. Thus, on the Figure 3, one can already see that a constant pattern emerges between *Pīnyīn* and *rōmaji* for Japanese words in *on'yomi*. For example, the Mandarin “*dōng*” is transcribed with the Japanese “*den*”, etc.

![Figure 3: Active reading with on'yomi, kun'yomi and Pīnyīn](image_url)

4.2 Challenges of the implementation
The implementation of such features presents some particularities to take into account:
- We made the assumption that all the *kanji* of a same word have the same nature, since there does not seem to exist any counter-example to this rule, at least in modern-day Japanese. Although MeCab provides the information about the pronunciation of the *kanji*, it does not give the *on/kun'yomi* nature. The information being also absent from the Cesselin, we have to collect it from KANJIDIC, an online *kanji* database from James Breen’s JMdict/EDICT project [2]. The KANJIDIC has been imported also on the Jibiki platform.
- Since we lack exhaustive resources able to indicate from which foreign language a loan word written in *katakana* comes from, we will not be able to tell them apart with different colors so far.
- There are also numerous cases where a word has a special pronunciation that cannot be deducted from the pronunciations of the individual *kanji* it contains (e.g. 今日 *kyō*, today). These cases will appear with a different color.

4.3 Details of the implementation
We modified the active reading PHP program by incorporating a piece of code composed of four main parts: information extraction, decision making, *Pīnyīn* addition and display.

4.3.1 Program overview
The active reading’s PHP code consists in the following steps, the green ones being our new features’ implementation:
- Catching user’s input
- Parsing it through MeCab morphological analyzer

4.3.2 Information extraction (f)
The *on/kun'yomi* nature of the *kanji* has to be retrieved from KANJIDIC. The data is organized in XML tree structures that can be accessed with a Curl request to the Jibiki REST API. The entries to be checked are those of each *kanji* for each word in the text that possesses *furigana*. If a word also contains *hiragana* (as *okurigana*, e.g. 買い物 *kaimono*, ‘shopping’), the XML structure of this said sinogram will be empty; we nevertheless keep the *hiragana* as is. For *katakana* words, we will use a regular expression with a pre-established list of *katakana*. Instead of immediately processing the data, we store it in an array to make it available for further use and to ensure code clarity. Considering the aforementioned hypothesis of one *yomi* per word, the *on* and *kun* *yomi* will be stored separately, to be later processed independently.

Before going to the decision part, the pronunciation data has to be formatted:
- Some pronunciations are preceded or followed by a dash (–), indicating a restriction on their position in the word (e.g. 何:なん– *nan*– (what) cannot be used at the end of a word). This information will be used to skip some cases in the decision part. We also remove the dash.
- Some also include a dot (.), usually separating the radical of a verb or adjective from its inflection (e.g. 会:あ.う a.u, meet). We then remove the inflection and the dot.

4.3.3 Decision making (g)
Once all the data has been collected and formatted, for each word, we will compare the different possible *on/yomi* combinations of their *kanji* (and potential *okurigana*) with the known *furigana* of the word. If there is a match, we know that the word is *on/yomi* and we label it as such. If not, we repeat the process for the *kun/yomi*. If ultimately no match is found, the word will be labeled as special pronunciation.

Once the word’s reading has been figured out, the highlight color value is drawn from a correspondence array: red for *on/yomi* *kanji*, purple for *kun/yomi* *kanji*, gold for special pronunciation and green for *katakana*.

4.3.4 *Pīnyīn* addition (i)
To retrieve the *Pīnyīn* of the *on/yomi* words, we used HanLP parsing toolkit for Mandarin to retrieve the individual information for each *kanji* (Figure 4). HanLP is a powerful java library for processing Mandarin texts. We developed a simple

---

6 http://www.edrdg.org/kanjidic/kanjidic.html

7 https://github.com/hankcs/HanLP
java program that displays the Pīnyīn relative information for each sinogram received in input. The first line displays each sinogram separated by a comma; the next line displays the Pīnyīn with tones in numbers, the next one the Pīnyīn with tones with diacritics, the next one the Pīnyīn without tone and the other lines give more detailed information about the reading. For our purpose, we use the third line that gives us the Pīnyīn with tones represented by diacritics.

Figure 4. analysis of a sinogramic word by HanLP

4.3.5 Display (i)
On the HTML side, we need to add the highlight variable as a style attribute in the start tag of the output element in the case of kanji or katakana words. The tag is a Ruby HTML tag, which allows to write furigana on top of Japanese text.

In order to display Pīnyīn below as well, the Ruby <rtc> tag is used in conjunction with the <rt> tag for furigana and a CSS style option has to be added: {ruby-position: under;}. Unfortunately, even if the ruby tags including the <rtc> one are now part of the HTML5 specifications, few browsers implement it. At the moment, only Firefox is correctly rendering the Pīnyīn below the text. The webkit family (Safari, Chrome, etc.) and Opera browser are rendering the Pīnyīn next to the Japanese.

5. CONCLUSION AND PERSPECTIVES
This article explains the development of a first version of an active reading tool for Japanese texts enriched for intercomprehension between sinogramic languages by displaying the Pīnyīn of the Japanese on’yomi words. This work is promising. We are waiting for the feedback of potential users in order to improve it.

Several perspectives are on their way.

Concerning the implementation of the tool itself, as the code currently constitutes a draft of a more formalized future clean version, some improvements can be imagined for code optimization, performance improvements and trustful case handlings. This latter point can be challenging, since it requires exhaustive data sets of special cases (e.g. counters, Japanese names), most of them being virtually infinite. In the case of our feature, the extent of handled cases depends on the coverage of KANJIDIC. A more thorough (but costly) process would be to cross-check different sources. Other technical optimizations could be to display the Pīnyīn below the Japanese even on browsers that do not render the <rtc> tag correctly.

The described active reading scenario of Japanese texts could be extended at least in two different ways:

• looking up etymological information for katakana words from rich dictionaries (the Cesselin contains such information) and displaying precise information about the origin of the words. For example, the word “baiku” comes from the English word “bike”.

• Computing automatically analogies between rōmaji and Pīnyīn.

We are working also on different active reading scenarios for other languages:

• It would be interesting to include other sinogramic languages such as Korean, Vietnamese and Sinitic languages among which Taiwanese very soon.

• A study has also been driven for Berber and Arabic speaking learners of French and English [1].

• Other language families could be addressed like Romance languages, Slavic languages, Germanic languages, pidgins and creoles, etc.

6. REFERENCES
