HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

27 **Abstract**

28 Central Africa is known as a major center of diversification for extant Old World Monkeys
29 (OWM) and yet has a poorly documented fossil record of monkeys. Here we report a new
30 colobine monkey (*Cercopithecoides bruneti* sp. nov.) from the Central African hominin-bearing
31 fossiliferous area of Toros-Menalla, Chad at ca. 7 Ma. In addition to filling a gap in the spatial
32 and temporal record of early OWM evolutionary history, we assess the ecomorphological
33 diversity of early OWM by providing evidence on the onset of a folivorous diet and a partial
34 reacquisition of terrestrial locomotor habits among Miocene colobines. We also support the
35 phylogenetic affinities of the genus *Cercopithecoides* among the stem group of the extant
36 African colobine monkeys.

37

60 **Introduction**

61 With an extensive geographical distribution, a rich taxonomy and a marked ecomorphological diversity,
62 extant Cercopithecidae (i.e., Colobinae and Cercopithecinae) represent one of the most successful adaptive
63 radiations of Neogene primates on the African and Eurasian continents. Old World Monkeys (OWM) are
64 known to diverge from an ancestral African stock (i.e., Victoriapithecidae) presenting dentognathic and
65 postcranial morphologies adaptively linked to frugivory and terrestrial locomotion (Harrison, 1989; Benefit,
66 1993). Extant African (i.e., Colobini) and Asian (i.e., *Presbytini*) representatives of the subfamily Colobinae
67 depart from this adaptive zone in exhibiting morphological and physiological adaptations associated with
68 folivory and arboreal locomotion. While a rich Miocene OWM fossil record is documented in Eurasia at 8.5-
69 6 Ma with the radiation of the putative stem colobine *Mesopithecus* spp. (Delson, 1973), the fossil record
70 of Miocene OWM in Africa is sparse. Dating back as far as 12.5 Ma, the African cercopithecoid fossil record is
71 known from only a handful of localities mostly restricted to East (Benefit and Pickford, 1986; Leakey et al.,

72 2003; Hlusko, 2007; Frost et al., 2009; Gilbert et al., 2010; Nakatsukasa et al., 2010; Suwa et al., 2015) and
73 North Africa (Delson, 1973; Benefit et al., 2008). In spite of being suggested as a cradle of diversity for
74 extant Cercopithecidae (Böhm and Mayhew, 2005; Ting, 2008), Central Africa has provided little evidence
75 of the early evolutionary history of OWM (Gundling and Hill, 2000). The Central African hominin-bearing
76 fossiliferous area of Toros-Menalla (TM), Chad at ca. 7 ± 0.2 Ma (Brunet et al., 2002; Lebatard et al., 2010)
77 has yielded colobine remains, giving us the unique opportunity to assess current hypotheses regarding the
78 paleobiology and phylogenetic relationships of Late Miocene colobines in Africa. Particularly, the well-
79 preserved dentognathic materials from TM fill a temporal gap between a primitive dental morphology
80 related to frugivory (Benefit et al., 2008; Merceron et al., 2009; Rossie et al., 2013; Suwa et al., 2015; Thiery
81 et al., 2017) and a derived dental morphology linked to a leaf-dominated diet (Gilbert et al., 2010).
82 Moreover, the discovery of a nearly complete forelimb allows us to reconsider the emergence of terrestrial
83 locomotor behavior among Miocene colobines (Leakey et al., 2003; Youlatos et al., 2012). In addition, the
84 chronological setting of TM encompassed the estimated divergence times of extant crown Colobini taxa
85 (Ting, 2008), permitting to assess hypotheses regarding the placement of the Chadian colobine among the
86 stem or crown Colobini group (Jablonski and Frost, 2010; Frost et al., 2015). Here we describe
87 *Cercopithecoides bruneti* sp. nov. from the Late Miocene of Central Africa, at ca. 7 Ma and provide new
88 evidence for terrestrial locomotor habits and an increase in leaf consumption among Miocene colobines.
89 We also provide insights into the phylogenetic affinities of the Chadian colobine, and discuss the
90 contribution of TM to our understanding of cercopithecoid evolution in light of the ecomorphological
91 diversity of Late Miocene OWM in a previously unknown spatial and temporal setting.

92

93 **Materials and methods**

94 ***Material availability and imaging***

95 All the materials described here have been collected between 2000 and 2003 by the Mission
96 Paléoanthropologique Franco-Tchadienne (P.I. Michel Brunet) and are currently curated at the
97 Service de Valorisation des Collections de Paléontologie (CNRD de N'Djamena). Apart from glue
98 consolidation, the fossil material was not subjected to any modification. All the fossil material
99 described here has been scanned at the Université de Poitiers, France. An Easy Tom XL duo μ CT-
100 scanner yielded virtual image stacks of the Chadian fossil material with resolutions ranging from
101 21.5 μ to 45.6 μ . Virtual reconstruction and visualization were obtained with the software Avizo
102 Standard Edition.

103 ***Comparative sample***

104 Qualitative and quantitative data for *Cercopithecoides williamsi* were gathered from μ -CT scan
105 data provided by the Ditsong National Museum of Natural History (Plio-Pleistocene Section).

106 Qualitative and quantitative data for all other early African colobines derived from the
107 literature. Qualitative and quantitative data for the dentognathic fossil material of early
108 Eurasian Colobinae (i.e., *Mesopithecus* ssp.) were gathered from μ -CT scans data of high quality
109 dental casts provided by Dr. Gildas Merceron. *Mesopithecus pentelicus* postcranial data were
110 taken directly from specimens of the Pikermian sample curated at the Museum National
111 d'Histoire Naturelle (MNHN, France).

112 Postcranial and odontometric data for extant Cercopithecidae were gathered directly from
113 specimens provided by PALEVOPRIM (Université de Poitiers, France); the Museum National
114 d'Histoire Naturelle (MNHN, France); the Royal Museum of Central Africa (RMCA, Belgium); the
115 Natural History Museum of Basel (NMB, Switzerland); the Anthropological Institute and

116 Museum, University of Zurich (AIM-UZH, Switzerland) and the Musée des Confluences, Lyon
117 (MHNL, France). Additional odontometric data of extant Colobini were also gathered from high
118 quality dental casts provided by Dr. Gildas Merceron.

119 Mandibular data of extant Colobinae were extracted from virtual specimens provided by the
120 Smithsonian Institution (Division of Mammals, USA); Harvard University (Museum of
121 Comparative Zoology (MCZ), USA)); the Digital Morphology Museum (Primate Research
122 Institute, Kyoto University) and the American Museum of Natural History (Department of
123 Anthropology, USA).

124 Humeral geometric cross-sectional properties were obtained on virtual specimens provided by
125 the Harvard University (Museum of Comparative Zoology (MCZ), USA) and the Royal Museum of
126 Central Africa (RMCA, Belgium).

127 ***Odontometric, morphological and biomechanical analyses***

128 *Odontometric*

129 Odontometric data of the *C. bruneti* holotype and hypodigm were acquired using a Mitutoyo
130 Digimatic caliper CD-8''CX on the original fossil material and on selected photographs obtained
131 in Avizo Standard Edition and measured with ImageJ. Selected photographs of generated
132 surfaces obtained in Avizo Standard Edition from μ -CT scans data of extant and extinct colobines
133 (i.e., *C. bruneti*, *C. williamsi* and *M. pentelicus*) were used to calculate the NH/NR ratio (Benefit,
134 1993) as well as additional dental metrics. Odontometric data of extant Colobinae were
135 acquired directly on specimens as well as on high quality dental casts using a Mitutoyo Digimatic
136 caliper CD-8''CX.

137 Further information regarding odontometric measurement protocols, sample size, ratio
138 formulas and references are presented in footnotes of Fig. 1, SOM Figure S2, Table 3-4 and SOM
139 Table S2.

140 *Mandibular*

141 Mandibular morphometric data from *C. bruneti*, *C. williamsi* and the extant Colobinae
142 comparative sample were obtained from selected symphyseal and corporeal cross-sections
143 obtained via GeoMagic Studio and Avizo Standard Edition on virtual specimens. Measurements
144 of the symphyseal and corporeal cross-sections were obtained via ImageJ.

145 Further information regarding mandibular morphometric measurement protocol, sample size
146 and ratio formulas can be found in footnotes of Fig. 6 and Table 5 as well as in SOM Fig. S1.

147 *Postcranial*

148 Data of the *C. bruneti* postcranial specimen were acquired via a Mitutoyo Digimatic caliper CD-
149 8" CX on the original fossil material as well as from selected photographs obtained in Avizo
150 Standard Edition and measured in ImageJ. All data from extant Cercopithecidae were acquired
151 directly on specimens using a Mitutoyo Digimatic caliper CD-8" CX and from digital photographs
152 using Image J. Further information regarding samples size and measurement protocol can be
153 found in footnotes of Figure 9 and Table 6 as well as in SOM Figure S1.

154 Humeral geometric cross-sectional properties were obtained via Image J's plugin Bone J on
155 virtual specimens. In order to acquire humeral mid-diaphyseal cross-sectional properties, the
156 virtual image stacks were first aligned at their moments of inertia and then subjected to the
157 calculation of geometric properties. The zone of interest (*i.e.*, slice at mid-diaphysis) was
158 subsequently obtained from the virtual image stack. Due to the lack of the humeral head of TM

159 266 03-034, the mid-diaphysis of the specimen was inferred at the midpoint of actual humeral
160 length +5%.

161 *Body mass estimation*

162 All equations for estimating body mass were taken from Delson et al., 2000. Further details and
163 extended interpretations of body mass can be found in footnotes of Table 2 and SOM Table S1.

164

165 **Results**

166 ***Systematic paleontology***

167 Order **Primates** Linnaeus, 1758;

168 Suborder **Anthropoidea** Mivart, 1864;

169 Infraorder **Catarrhini** E. Geoffroy, 1812;

170 Superfamily **Cercopithecoidea** Gray, 1821;

171 Family **Cercopithecidae** Gray, 1821;

172 Subfamily **Colobinae** Blyth, 1863;

173 genus ***Cercopithecoides*** Mollet, 1947.

174 Type species: *Cercopithecoides williamsi* Mollet, 1947.

175 Generic diagnosis: As stated in Frost and Delson, 2002 “Medium to very large colobines with globular,

176 rounded calvaria. The rostrum is short in comparison to neurocranial length, very different from

177 *Paracolobus*, *Rhinocolobus*, *Dolichopithecus*, and *Nasalis*. It is not as short as that of *Rhinopithecus*,

178 however. The frontal process of the zygomatic bone is narrow, unlike *Paracolobus* and *Rhinocolobus*. The

179 inter-orbital region is broad, which is distinct from *Libypithecus*, *Rhinocolobus*, and *Nasalis*. The

180 supraorbital tori are thick and separated from the calvaria by a deep ophryonic groove, which is distinct

181 from *Colobus*, and most species of *Presbytis* and *Trachypithecus*. The calvaria itself lacks a sagittal crest, at
182 least anteriorly, which separates it from *Paracolobus* and *Procolobus*. The P³ lacks a protocone, which is
183 similar to modern African colobines, but different from *Libypithecus*, *Kuseracolobus*, *Paracolobus* and
184 *Rhinocolobus*. The mandibular symphysis is steep, but shallow and pierced by a median mental foramen
185 (except in *C. meaveae*), which is different from all colobines other than *Procolobus* (*Procolobus*) and
186 *Rhinocolobus* from the Turkana Basin. The mandibular corpus is shallow and thick, which contrasts greatly
187 with that of *Kuseracolobus*, *Rhinocolobus*, *Paracolobus* and to some degree *Colobus*, but is not unlike that
188 of *Procolobus* (*Piliocolobus*). The gonial region is unexpanded or expanded only a small amount. This
189 contrasts with mandibles of *Kuseracolobus*, *Rhinocolobus*, *Paracolobus mutiwa*, and *Colobus*. Associated
190 postcrania are known for *C. williamsi* from an associated skeleton from Koobi Fora (the morphology of
191 which may not be typical for the South African material, see remarks below). It is distinguished from all
192 other known colobines, except *Dolichopithecus*, in the degree of its adaptations for terrestrial habitus
193 (Birchette, 1981; 1982; Ting, 2001).”

194 On a taxonomic level, the combination of a faint P³ protocone, a precocious and marked dental wear, an
195 orthognathic subnasal region with short premaxillae and maxillary sinuses (MS), a buttressed corpus
196 bulging below M₁₋₂ as well as a symphysis with a straight, smooth and vertical labial face align the Chadian
197 cercopithecoid with the East and South African genus *Cercopithecoides* (Freedman, 1957; Frost and Delson,
198 2002; McKee et al., 2011) (Table 1-2).

199 ***Cercopithecoides bruneti*** sp. nov. Holotype: TM 266 03-100, left and right hemimaxillae preserving dl¹,
200 dC¹, dP³⁻⁴, C¹, P³⁻⁴, M¹⁻². Paratype: TM 266 03-034, a fragmented left and right maxilla with I², C¹-P⁴; TM 266
201 03-099, partial mandible preserving left P₃-M₃ and associated right P₃-M₁; TM 112 00-093, partial mandible
202 preserving left P₃; TM 219 01-102, partial mandible preserving left C₁ and right I₁-M₂; TM 266 03-036, a right

203 partial forelimb with sub-complete humerus, ulna and radius; TM 266 03-307, a sub-complete right femur.

204 Type locality: Locality n°266 from the fossiliferous area of Toros-Menalla, western part of the Djurab

205 desert, northern Chad basin. Type horizon: Anthracotherid Unit. Age: ca. 7 ± 0.2 Ma. Etymology: In honor

206 of Pr. Michel Brunet for his significant contribution to paleoanthropology in Central Africa. Since 1994, he

207 has initiated, led and directed the fieldwork of the Mission Paléoanthropologique Franco-Tchadienne

208 (MPFT) in Chad.

209 Specific diagnosis: A colobine of moderate size, similar in overall dental dimensions and inferred body mass

210 to *Paracolobus enkorikae* (Lemudong'o Formation (Fm.), Kenya), *Mesopithecus pentelicus*, *Libypithecus*

211 *markgrafi* (Wadi Natrun Fm., Egypt), colobine gen. and sp. A from Mpesida (Mpesida Beds, Tugen Hillas,

212 Kenya) and colobine sp. B from Lower (LN) and Upper Nawata (UN) (Nawata Fm., Lothagam, Kenya).

213 Upper dentition with moderate cusp relief and molar flare, M^2 paraloph width enlarged relative to tooth

214 length, P^3 protocone highly reduced relative to paracone, dP^4 paraloph width enlarged relative to tooth

215 length and marked breadth differential between P^3 and P^4 . Lower dentition with a narrow P_4 crown, a

216 marked size differential between M_1 and M_2 , M_3 lacking a tuberculum sextum and possessing a bucco-

217 lingually narrow hypoconulid relative to hypolophid breadth. Craniofacial morphology characterized by

218 maxillary sinuses and an orthognathic sub-nasal region. Mandibular morphology characterized by a

219 prominent inferior transverse torus (ITT), a corpus of moderate robustness with marked prominentia

220 lateralis and a deep mandibular symphysis with a flat and vertical labial face that lacks a median mental

221 canal.

222 Differential diagnosis *Cercopithecoides bruneti* specimens are larger than *Microcolobus tugenensis*

223 (Ngorora Fm., Tugen Hills, Kenya), *Microcolobus* sp. (Nakali Fm., Baringo, Kenya) and the indeterminate

224 small colobines from Kabasero (Ngorora Fm., Tugen Hills, Kenya), Teso Tadecho (Chorora Fm., Ethiopia),

225 Beticha (Chorora Fm., Ethiopia), Lukeino (Lukeino Fm., Tugen Hills, Kenya), Lemudong'o (Lemudong'o Fm.,
226 Kenya) and colobine sp. A from LN-UN (Nawata Fm., Lothagam, Kenya). The Chadian colobine is smaller
227 than the Miocene colobines from Menacer (Algeria) and Adu Asa (Adu Asa Fm., Ethiopia) as well as from
228 the early Pliocene *Kuseracolobus hafu*. *C. bruneti* exhibits an enlarged paraloph relative to M^2 length with a
229 crown shape ratio (CSR) matched by the small colobine from Lemudong'o (Fig. 1). *C. bruneti* further differs
230 from *M. tugenensis* by the presence of an ITT, enlarged prominentia lateralis, a marked size differential
231 between M_1 and M_2 , a less developed talonid on P_3 and a narrow P_4 crown. *C. bruneti* is distinct from the
232 Kabasero colobines in having a more developed hypoconulid and a narrow hypolophid relative to M_3
233 length. Forelimb morphology of *C. bruneti* is unlike the Nakali colobine in having a reduced and straight
234 ulnar olecranon process and a short and retroflexed humeral medial epicondyle. *C. bruneti* is distinguished
235 from the Teso Tadecho colobine, *Paracolobus enkorikae*, the small Lemudong'o colobine and *L. markgrafi*
236 by having a reduced P^3 protocone. A marked breadth differential between P^3 and P^4 further differentiates
237 *C. bruneti* from *P. enkorikae*, the small colobine from Lemudong'o and *L. markgrafi*. *C. bruneti* is also
238 distinguished from the Teso Tadecho colobine by a broader P^4 crown. *C. bruneti* further differs from *P.*
239 *enkorikae* by a narrow P_4 crown, maxillary sinuses and a flat symphyseal labial face with no break in slope.
240 *C. bruneti* is morphologically distinct from *L. markgrafi* in having a narrow C^1 . *C. bruneti* differs from the
241 Mpesida Beds colobine gen. and sp. A in lacking a buccally curved hypoconulid and accessory cuspsules
242 between entoconid and hypoconulid and in exhibiting a broader hypolophid relative to tooth length. *C.*
243 *bruneti* differs from *Kuseracolobus aramisi* by a reduced P^3 protocone (a feature described as variable in *K.*
244 *aramisi*), an early eruption of molars relative to the anterior dentition, a marked dp^4 CSR, a moderate flare
245 on M^2 with a marked M^2 CSR (i.e., with a value > 100), a marked P^{3-4} breadth differential, a corpus with a
246 sharp inferior margin, the presence of a double mental foramen and an absence of tuberculum sextum.

247 *C. bruneti* is one of the smallest species of the East and South African genus *Cercopithecoides*, with dental
248 dimensions similar to *Cercopithecoides kerioensis*, *C. meavae*, *C. alemayehui* and *C. haasgati*. It differs from
249 the large taxa *C. williamsi* and *C. kimeui* in lacking a median mental canal and in possessing a gracile corpus.
250 It further differs from *C. williamsi* in possessing a shorter planum alveolare, a relatively smaller
251 hypoconulid, a superiorly placed genioglossal fossa, a less marked size differential between ITT and STT
252 (Superior Transverse Torus), a less developed humeral deltoid crest, a less developed humeral medial
253 trochlear keel and a broader zona conoidea. *C. bruneti* is distinct from *C. meavae* in having a marked
254 breadth differential between P^{3-4} , a broader dP^4 , a less marked size differential between M_{1-2} , a shorter
255 humeral medial epicondyle, a less developed humeral medial trochlear keel, a less rounded radial head
256 and a gracile radial neck. *C. bruneti* also differs from *C. alemayehui* by a narrower P^3 crown and a broader
257 M^2 paraloph relative to tooth length. *C. bruneti* displays an increased breadth differential between P^{3-4}
258 relative to *C. kerioensis* (Fig. 1) and is distinguished from *C. haasgati* by a narrower P^3 crown, an elongated
259 P_4 crown and a less marked size differential between M_1 and M_2 .

260 **Description of *C. bruneti* dentognathic morphology**

261 TM 266 03-100 The type specimen TM 266 03-100 is a right and left hemimaxilla belonging to a juvenile
262 individual and preserving much of the upper postcanine dentition (Table 3, Fig. 2). Of the upper anterior
263 dentition, the dl^1 are highly worn, a small portion of the left dC^1 root is preserved and a large portion of the
264 C^1 crown remained intact in the dental crypt. The dl^1 exhibits a lingual rootward extension of enamel onto
265 the cervix and a mesiodistally compressed root unfused at its apex. The upper canine displays the features
266 characteristic of male cercopithecids (i.e., deep mesial sulcus, a sharp distal margin, a convex buccal face
267 and a mesiodistal elongation of the canine crown relative to breadth). Deciduous premolars are severely
268 worn, consistent with a J5 dental wear stage while the postcanine dentition already show an A2 wear stage

269 (Ingicco et al., 2012). This early and heavy wear of the dentition is unusual among extant colobines,
270 especially when considering the ontogenetic status of the specimen. The deciduous upper premolars
271 exhibit a large amount of flaring and a CSR consistent with a bucco-lingual enlargement of those teeth. The
272 dP³ is bilophodont and devoid of *crista obliqua*; the dP⁴ possesses a paraloph broader than the metaloph
273 and a mesial shelf longer than the distal one (SOM Table 2). M¹⁻² are in occlusion while dI¹ is still in place,
274 confirming the presence of an early eruption of M² relative to the anterior dentition. The permanent
275 premolars are preserved in their crypts and exhibit a characteristic colobine morphology. The P³ crown is
276 moderately broad and exhibits heteromorphic cusps with a faint protocone, a well-developed mesiobuccal
277 flange, a paracone set distally relative to the protocone and a relatively narrow triangular mesial shelf
278 compared to a squared-shape distal shelf. The P⁴ crown is broad, displays a paracone higher than a distally
279 set protocone, a high paracone relative to crown length, a high and sharp transverse loph, a marked
280 mesiobuccal flange, a slight lingual cleft and a moderate length differential between mesial and distal
281 shelves. In addition, there is a marked breadth differential between P³⁻⁴ (Fig. 1). The M²s exhibit
282 qualitatively thin enamel (Fig. 2) as well as a moderate amount of flare and crown relief relative to extant
283 colobines. Note that the buccal parts of both M1 are missing as well as the hypocone of both M2 (Fig. 2).
284 M¹⁻² present deep and marked median lingual clefts, a poor development of the mesiodistal
285 developmental groove, widely spaced lophs and moderately developed shelves (SOM Table S2) that
286 support the taxonomic status of TM 266 03-100 as a colobine (Benefit, 1993). A marked buccal cingular
287 ridge is present on M² and a poorly developed interconulus is observed at the base of the M¹ lingual cleft. A
288 body mass of ~16.5kg is inferred from M¹⁻² mesio-distal dimensions (SOM Table S1). Considering
289 craniofacial morphology, TM 266 03-100 exhibits an orthognathic subnasal region with an anteriorly placed
290 zygomatic process which originates low on the maxilla and above M¹. This morphological pattern is seen in

291 extant juvenile Colobinae and Cercopithecini of similar dental eruption stage (Fig. 3). The nasal aperture is
292 straight in lateral view and tapers inferiorly to form an acute inferior margin in anterior view. The
293 premaxilla is reduced and gives a square aspect to the premaxillo-maxillary complex. No maxillary or
294 infraorbital fossae are observed. A large infraorbital foramen is present on the inferior portion of the orbital
295 margin of the right hemimaxilla. The hard palate extends posteriorly at the level of M². Maxillary sinuses
296 (MS) invade the lower portion of the maxilla, extend anteriorly at the level of M¹ and are pierced by the
297 roots of M¹⁻².

298 TM 266 03-034 is a fragmented anterior maxilla preserving most of the adult anterior dentition (Fig. 2). I²
299 displays a parallelogram-shaped and mesially angled crown with a poorly developed basal cingulum, a faint
300 lateral prong, a thin layer of enamel on the occlusal surface, a well-defined and horizontal cervix, a
301 markedly convex labial face and no sulcus. C¹ presents a narrow crown with a long axis obliquely oriented
302 relative to P³⁻⁴, a low crown cusp with a raised cingulum on the mesial margin, a raised distal margin on the
303 talonid and a mesial groove continuing from the crown onto the roots. TM 266 03-034 exhibits a female
304 morphology with a low crowned C¹ relative to tooth length. Although fragmented, the P³ bucco-lingual
305 dimension is in the size range of TM 266 03-100 (SOM Table S2) and is morphologically consistent with the
306 *C. bruneti* holotype in exhibiting a flange-like buccal margin and a raised paracone associated with a faint
307 and mesially offset protocone. A slight portion of the lateral margin of the right nasal aperture is preserved
308 and set vertically relative to the occlusal plane.

309
310 TM 266 03-099, TM 112 00-093 and TM 219 01-102 consist of adult mandibular remains
311 allocated to the *C. bruneti* hypodigm (Fig. 4-5).

312 TM 266 03-099 displays a wear pattern consistent with an A6 dental wear stage (Ingicco et al.,
313 2012). The P₃ crown is narrow and presents a large protoconid but no paraconid nor metaconid,

314 the mesiobuccal flange is developed, upright, and does not extend below the alveolar margin.
315 The degree of development of the P₃ flange is consistent with a male morphology. The P₄ is
316 bicuspid, lacks an entoconid and displays a protoconid broader than the distally offset
317 metaconid and an elongated crown with a moderate mesiobuccal flange. Mesial and distal
318 lophids are of nearly equal width on M₁₋₂ but there is a marked size differential between M₁ and
319 M₂ (SOM Fig. S2). The trigonid basin is reduced on all molars, and the M₃ lacks a tuberculum
320 sextum but bears a buccally placed hypoconulid which is small relative to hypolophid breadth.
321 The labial symphyseal face is flat and vertical with a minute symphyseosum foramen placed at
322 its mid-height. It lacks rugosities, sub-incisal hollowing and a median mental canal (Fig. 4-5). The
323 inferior margin of the symphysis is sharp with a rugose infero-lingual portion, a developed
324 digastric spine and a poorly imprinted digastric fossa. The planum alveolare is straight and
325 extends to the mesial part of P₃. The symphysis is robust (Fig. 4-5) and presents a bulbous and
326 extensive ITT that reaches the mesial part of P₄. The infero-lingual margin of the corpus is sharp
327 and inferiorly lacks an imprinted digastric fossa at M₁ level and superiorly an inter-toral sulcus.
328 Prominentia laterales are prominent and extend anteriorly to the mesial portion of P₄. The
329 corpus is deep and bulges below M₁, the linea obliqua merges with the corpus at the level of M₁₋₂
330 contact and the extramolar sulcus is narrow.

331 TM 112 00-093 morphology is consistent with that of TM 266 03-099 in exhibiting a similar
332 symphyseal topography but with a less developed ITT extending only to the level of P₃ and a less
333 acute symphyseal inferior margin. The planum alveolare is slightly concave and the STT
334 overhangs a shallow genioglossal fossa. The corpus morphology is also consistent with TM 266
335 03-099 but exhibits a marked imprinting of the digastric fossa and submandibular fossa,

336 respectively below P₄-M₁ and M₂₋₃. Of the entire dental row, only the P₃ crown is preserved. The
337 mesiobuccal flange is short and in accordance with a female morphology. The incisor row is
338 narrow. The base of the M₃ crown tapers distally.

339 TM 219 01-102 is a fragmented mandible preserving the symphysis and hints of the superior
340 portion of the right and left corpus. TM 219 01-102 exhibits peg-like incisors with poorly
341 developed cingulum and a narrow incisal row. Canines are robust, labially recurved, and present
342 an extensive talonid devoid of any tubercles. The canine root bears a faint mesial groove. The
343 inferior margin of the symphysis is eroded but the toral morphology is clearly colobine-like with
344 an extensive and bulbous ITT reaching the mesial part of M₁. The symphysis is vertical, and a
345 slight hint of the linea obliqua is preserved on the upper part of the corpus at the level of M₂.
346 Canine dimensions and morphology are consistent with identification as a male. In addition,
347 dental and mandibular dimensions of TM 219 01-102 are congruent with those of TM 266 03-
348 034 (Tables 4-5).

349 Body masses inferred from dental dimensions ranged from ~ 8.45kg for TM 112 00-093 to ~
350 13.3kg and ~14.4kg (using equations from Delson et al., 2000), respectively for TM 219 01-102
351 and TM 266 03-099 (SOM Table S1).

352

353 ***Comparative aspect of C. bruneti dentognathic anatomy***

354 The *C. bruneti* dP⁴ possess a paraloph broader than the metaloph (SOM Table S2), a
355 characteristic variable among Cercopithecoidea but mostly observed on Victoriapithecidae and
356 Cercopithecinae (Benefit, 1994). Nevertheless, the absence of a crista obliqua, the bilophodont
357 state of dP³⁻⁴ and the marked dP⁴ mesial shelf length relative to the distal one clearly aligns *C.*

358 *bruneti* with crown cercopithecids (Benefit, 1994). The dP⁴ CSR is consistent with an
359 enlargement of the tooth, similar to victoriapithecids but also to the putative colobine dP⁴ from
360 Menacer (SOM Fig. S2). Furthermore, the early eruption of M² relative to the anterior dentition
361 observed in *C. bruneti* is typical of Colobinae (Harvati and Frost, 2007). Although an early molar
362 eruption relative to anterior dentition was previously documented in *M. pentelicus*, the extreme
363 condition of the early eruption of M² relative to I¹ observed in *C. bruneti* was previously
364 unknown among fossil colobines whereas it is documented either as a variant (e.g *Colobus*
365 *angolensis*) or as a constant (e.g *Presbytis* spp.) among extant Colobinae (Harvati and Frost,
366 2007). *C. bruneti* upper molar morphology is similar to those of early Eurasian as well as North
367 and East African colobines in exhibiting a basal flaring associated with a lack of sharp shearing
368 crests (Benefit and Pickford, 1986; Rossie et al., 2013; Suwa et al., 2015). Even slightly worn, a
369 quantification of *C. bruneti* left M² occlusal relief (i.e., NH/NR ratio, Fig. 1) yields a value higher
370 than those observed among the penecontemporaneous Eurasian colobine *M. pentelicus* and the
371 North African colobines from Menacer and As Sahabi (Delson, 1973; Benefit et al., 2008). *C.*
372 *bruneti* subnasal morphology is consistent with the poor maxillary projection observed in
373 *Cercopithecoides* spp. and *Kuseracolobus* spp. The deep and slender corpus as well as the deep
374 symphysis of *C. bruneti* is similar to the early Pliocene *C. kerioensis* (Leakey et al., 2003). The
375 Chadian *Cercopithecoides* further shares with *C. kerioensis* and *C. meavae* a moderate breadth
376 of the M₃ hypolophid relative to tooth length and an absence of a median mental canal. *C.*
377 *bruneti* is similar to the South African *C. williamsi* sample in exhibiting a marked P³⁻⁴ breadth
378 differential (Fig. 1,3) and a marked M₁₋₂ size differential (SOM Fig. S2). The enlargement and the
379 square aspect of the *C. bruneti* upper second molar are also consistent with the South African

380 *Cercopithecoides* sample (i.e., *C. williamsi* and *C. haasgati*) (Fig. 1,3). Relative to extant
381 colobines, *C. bruneti* dentognathic morphology is consistent with a Colobini morphology.
382 Indeed, a narrow P³ crown with heteromorphic cusps (Swindler and Orlosky, 1974), a height
383 differential between lingual and buccal P⁴ cusp (Gilbert et al., 2010), a distally offset P₄
384 metaconid (Swindler and Orlosky, 1974), a broad P₄ protoconid relative to metaconid (Swindler
385 and Orlosky, 1974), a narrow P₄ crown, an elongated C¹ (Pan, 2006) and a poorly developed (i.e.,
386 *Colobus*-like) digastric fossa (Groves, 2007) aligns *C. bruneti* with the extant Colobini (Fig. 3). In
387 spite of morphological affinities with the African colobine tribe, *C. bruneti* lacks the long and
388 steeply inclined planum alveolare, the inferiorly placed genioglossal fossa and the diminutive ITT
389 seen among several taxa of *Colobus* (Fig. 5-6). *C. bruneti* symphyseal topography is most
390 consistent with the morphology exhibited by *Piliocolobus* but it does not exhibit the marked
391 dental occlusal relief seen in the extant genus (Fig. 5-6).

392 ***Description of C. bruneti postcranial morphology***

393 A sub-complete right forelimb (i.e., TM 266 03-036) composed of humerus, radius and ulna as
394 well as a partial femur (i.e., TM 266 03-307) are here included in the *C. bruneti* hypodigm (Fig.
395 7). Collected from the same locality, it is parsimonious to assume that the fore- and hindlimbs
396 come from the same taxon (i.e., *C. bruneti*). Joint congruency supports the hypothesis of the
397 forelimb elements belonging to the same specimen.

398 TM 266 03-036 The postero-distal portion of the humeral head is preserved and is flanked by
399 well-defined distal margin of the greater and lesser tuberosities. In posterior view, the medial
400 part of the surgical neck is markedly concave and accommodates the insertion of the

401 coracobrachialis profundus muscle. The humeral proximal diaphysis is fractured in its proximal
402 and distal portion. It is surrounded by sharp crista tuberculi majoris and crista tuberculi minoris.
403 Those crests are poorly developed and accommodate proximally set attachment sites for teres
404 major and pectoralis major muscles. The posterior aspect of the proximal diaphysis is salient
405 and bears moderate sites of attachment for the lateral head of the triceps brachii muscle. The
406 deltoid tuberosity is flat, poorly developed, and does not extend below mid-diaphysis. The
407 humeral diaphysis is gracile and elliptical in cross-section at mid-diaphysis, with a long-axis
408 running anterolateral-to-posteromedially. The humeral shaft is straight in the anteroposterior
409 plane but curved medially in the mediolateral plane. The posterior aspect of the distal portion of
410 the diaphysis is flattened and exhibits a poorly developed lateral supracondylar ridge. The distal
411 epiphysis is fractured and separated from the humeral shaft. Most of the humeral trochlea and
412 zona conoidea are preserved (Fig. 7). The antero-proximal part and a slight hint of the proximo-
413 lateral portion of the capitulum are preserved. The anterior aspect of the distal epiphysis is
414 characterized by a wide and deep radial fossa, a shallow and poorly delineated coronoid fossa, a
415 moderate-sized trochlea, a moderately developed medial trochlear keel compared to
416 cercopithecins that is set obliquely relative to the long-axis of the shaft, a well-defined anterior
417 margin of the medial trochlear keel, a faint lateral trochlear keel and a large zona conoidea (Fig.
418 7). The posterior aspect of the distal epiphysis exhibits a deep and oval-shaped olecranon fossa
419 that presents a septal aperture, a moderate breadth differential between its lateral and medial
420 pillar, a short and retroflexed medial epicondyle and a salient posterior margin of the lateral
421 pillar of the olecranon fossa.

422 The cresting of the proximal portion of the ulnar olecranon process is damaged (Fig. 7). The

423 olecranon process is short and aligned with the long axis of the diaphysis. The posterior margin
424 of the proximal epiphysis is slightly convex. The anconeal process is short and does not project
425 markedly anteriorly. Although eroded, the proximal margin of the anconeal process is
426 asymmetric, with a proximal projection of its lateral margin. The ulnar sigmoid notch is
427 fractured at its mid-height. The ulnar trochlear surface is poorly waisted and congruent with the
428 moderate enlargement of the humeral trochlea. The postero-medial portion and the most
429 anterior portion of the coronoid process is missing as is the postero-lateral portion of the radial
430 notch. The anterior margin of the coronoid process is wide and is antero-distally slanted,
431 consistent with a shallow humeral coronoid fossa. The radial notch is expanded, presents a
432 waisting between its anterior and posterior facet and bears a lateral margin oriented
433 posteriorly. The medial face of the proximal epiphysis is fractured longitudinally but exhibits a
434 deep and wide insertion surface for the flexor digitorum profundus muscle that extends distally
435 through the proximal part of the diaphysis. The ulnar diaphysis is fractured in its mid- and distal
436 portion, resulting in separate fitting parts. The proximal portion of the diaphysis exhibits a
437 raised supinator crest that borders a large insertion surface for the supinator muscle. The
438 diaphysis is gracile and straight in lateral view. A raised pronator ridge is present on the distal
439 portion of the diaphysis. The distal epiphysis is broken away.

440 The radius preserves the damaged proximal half. Only the antero-lateral portion of the radial
441 head is missing (Fig. 7). The radial head is elliptical with the long-axis running antero-posteriorly.
442 The articular fovea of the radial head is placed posteriorly and is bordered anteriorly by a wide
443 peripheral articular surface and posteriorly by a proximally-raised margin. The radial head is
444 strongly tilted in medio-lateral view. The neck is short, gracile, and bears a marked bicipital

445 tuberosity divided in two components by a deep sulcus. The medial margin of the proximal
446 portion of the diaphysis is slightly concave and exhibits a faint interosseous crest whereas the
447 lateral margin bears signs of rugosities for the supinator muscle.

448 TM 266 03-307 is a right femur with a damaged proximal epiphysis preserving the femoral neck,
449 the postero-proximal aspect of the greater trochanter, a slight hint of the proximal portion of
450 the intertrochanteric crest and the medial portion of the lesser trochanter. The distal third is
451 broken away (Fig. 7). The neck is antero-posteriorly compressed, bears no grooving for the
452 obturator externus tendon, forms an obtuse neck-shaft angle with the femoral shaft and is
453 poorly anteverted. The cortical bone distribution of the femoral neck is asymmetric with a
454 cortical bone distribution skewed toward the inferior margin of the neck, as in most extant
455 cercopithecids (Rafferty, 1998). The trochanteric fossa is rounded, shallow and does not extend
456 distally below the insertion for quadratus femoris. The shaft is robust and slightly bowed
457 anteriorly. The medial margin of the lesser trochanter is salient and projects postero-medially.
458 Inferiorly to the lesser trochanter is a rugose zone for the pectineal line and gluteal tuberosity.
459 Although fragmented, TM 266 03-307 is here included in the *C. bruneti* hypodigm based both on
460 its estimated body mass (SOM Table S1), which is consistent with values obtained from dental
461 dimensions, and on its provenance from the *C. bruneti* type locality (i.e., locality n°266).

462 ***Comparative anatomy and functional morphology of C. bruneti postcranial anatomy***

463 *C. bruneti* upper limb morphology presents clear colobine affinities in exhibiting a
464 prominent zona conoidea (Frost and Delson, 2002), a marked breadth differential between the
465 lateral and medial pillar of the olecranon fossa, an extensive ulnar insertion site for flexor

466 digitorum profundus (Krentz, 1993; DeSilva et al., 2013), a marked asymmetry of the peripheral
467 articular surface of the radial head (Nakatsukasa et al., 2010) and a poorly defined interosseous
468 crest on the radius (DeSilva et al., 2013). Considering humeral morphology, *C. bruneti* is similar
469 to *C. williamsi*, *C. kimeui* and *C. meavae* in exhibiting a retroflexed medial epicondyle and a deep
470 distal articular surface antero-posteriorly (i.e., *HDB* variable in Table 6) (Frost and Delson, 2002;
471 Jablonski and Leakey, 2008). An abbreviated and retroflexed medial epicondyle has been linked
472 to terrestrial locomotor behavior and particularly to stability enhancement of the humero-ulnar
473 joint in pronated position (Jolly, 1967; Birchette, 1982). A moderate extension of the deltoid
474 tuberosity and a proximal insertion of the teres major and pectoralis major illustrate an
475 enhancement of rapid flexion/adduction of the *C. bruneti* elbow. The Chadian colobine exhibits
476 an elliptical cross-section of the humeral mid-diaphysis, consistent with a structural adaptation
477 related to stress dissipation of mechanical loadings engendered during terrestrial locomotor
478 behavior (Fig. 9) (Carlson et al., 2011; Patel et al., 2013). Although structurally adapted to
479 withstand mechanical stress and rapid flexion/extension in a terrestrial context, the functionally
480 mosaic humeral morphology of *C. bruneti* exhibits characters reminiscent of arboreal locomotor
481 habits. The enlargement of the humeral trochlea of *C. bruneti* is moderate, translating a weight-
482 bearing function to the humero-ulnar joint as in extant arboreal Colobinae (Birchette, 1982).
483 Although marked relative to extant Colobinae (Fig. 8), the development of the medial trochlear
484 keel of *C. bruneti* is moderate relative to *C. williamsi* and *C. meavae* and reflects a humero-ulnar
485 joint poorly adapted to restrict medial movement as occurred during leaping and/or terrestrial
486 activities (Fig. 9) (Birchette, 1982; Harrison, 1989; Frost and Delson, 2002). The humeral shaft of
487 *C. bruneti* is gracile and accords well with generating low reaction forces and an adaptation to

488 compliant substrate, as found in an arboreal context (Nakatsukasa, 1994). The insertion for the
489 coracobrachialis profundus muscle is depressed and the insertion for the flexor digitorum
490 profundus muscle on the ulna is marked and extensive, as in arboreal cercopithecids (Krentz,
491 1993). Relative to ulnar morphology, the olecranon process of *C. bruneti* is short and, coupled
492 with a deep humeral olecranon fossa, reflects an important degree of elbow extension. The
493 olecranon process is straight and not consistent with the anteflexed olecranon of arboreal
494 colobines (Fig. 8) nor with the retroflexed olecranon of highly terrestrial Cercopithecinae
495 (Birchette, 1982). In addition, the straight ulnar shaft contrasts with the posteriorly convex shaft
496 of arboreal colobines (Fig.e 8) (Birchette, 1982). Consistent with the previously inferred weight-
497 bearing function of the humero-ulnar joint, *C. bruneti* exhibits an enlarged humeral articular
498 facet of the ulnar sigmoid notch (Table 6). A short anconeal process and a distally slanted
499 coronoid process confirm the presence of a poorly stabilized humero-ulnar joint in *C. bruneti*.
500 This flexibility of the elbow joint is consistent with an arboreal component in the locomotor
501 behavior of the Chadian colobine. In accordance with the humeral morphology, the ulnar shaft
502 is gracile. A marked elliptical radial head is observed in both extant *Colobus* and *C. bruneti*
503 (Birchette, 1982). With a marked proximal projection of its posterior margin and a strong medial
504 tilt, the radial head of *C. bruneti* is consistent with a reinforcement of the humero-radial joint in
505 pronated position (Rose, 1988). The radial neck of *C. bruneti* is gracile and confirms the patterns
506 of a poorly buttressed brachium and antebrachium. Considering femoral morphology, the neck-
507 shaft angle of *C. bruneti* is obtuse, contrasting with the acute angle seen among hyper-
508 terrestrial cercopithecids and reflecting an increase in hindlimb range of motion (Bacon, 2001;
509 Frost).

510

511

512 **Discussion**

513 *Cercopithecoides bruneti* sp. nov. from the Late Miocene of Central Africa, Chad adds to the
514 antiquity and to the extensive geographical range of the genus *Cercopithecoides*. The
515 mandibular morphology of *C. bruneti* corroborates the presence of a relatively deep and slender
516 corpus among early representatives of this genus (Fig. 4) (Leakey et al., 2003; Jablonski and
517 Frost, 2010). It also documents a departure from the cercopithecine-like symphyseal
518 topography documented in Miocene East African stem Colobinae (Benefit and Pickford, 1986)
519 and brings evidence of a diversity in mandibular morphology among *Cercopithecoides*.
520 Discrepancies in corporeal and symphyseal cross-sectional geometry and morphology further
521 inform us on divergent structural adaptations to withstand at least different stress and loading
522 regimes during feeding behavior (Ross et al., 2012). The relationships between diet, feeding
523 behavior and mandibular morphology are not straightforward among primates (Daegling and
524 McGraw, 2001; Daegling and Grine, 2017), blurring the ecomorphological signal inferred from
525 corporeal and symphyseal morphology among early and late representatives of
526 *Cercopithecoides* taxa. A frugivorous component was identified in the *C. williamsi* diet through
527 Dental Microwear Textural Analysis (DMTA) (Williams and Geissler, 2014), and several proxies
528 point to a fruit-dominated diet among Eurasian and several Late Miocene early colobines
529 (Merceron et al., 2009; Rossie et al., 2013; Thiery et al., 2017). In contrast, the East African
530 Miocene colobines from Lukeino Fm. and Mpesida Beds, respectively at ca. 5.7 and 6.37 Ma,

531 bear qualitative and quantitative (i.e., NH/NR) dental morphological hallmarks of adaptation to
532 a leaf-dominated diet (Gilbert et al., 2010). *C. bruneti* occlusal relief is moderate relative to
533 extant colobines but stands apart from the cercopithecine-like occlusal relief documented in
534 North African (Benefit et al., 2008) and Eurasian Miocene colobines (Fig. 1). Accordingly, *C.*
535 *bruneti* dental morphology provides evidence of an increase in occlusal relief and thus supports
536 an increase in leaf consumption at ca. 7 Ma among African colobines relative to
537 penecontemporaneous early African and Eurasian colobines. Subsequent adaptation to the
538 consumption of abrasive food items had been postulated in regard to the severe degree of
539 dental attrition wear stages observed among several *Cercopithecoides* taxa (Szalay and Delson,
540 1979; Jablonski and Frost, 2010). *C. bruneti* provides the earliest evidence of this peculiar dental
541 wear pattern which may be linked to grit transport due to the onset of the Sahara Desert in
542 Central Africa at ca. 7 Ma (Schuster, 2006).

543 The associated colobine postcranial remains from Nakali shed light on arboreal locomotor
544 behavior among Late Miocene African stem Colobinae (Fig. 8) (Nakatsukasa et al., 2010).
545 Further evidence of arboreality was inferred among several groups of early colobine postcranial
546 remains from other Miocene East African localities (Hlusko, 2007; Gilbert et al., 2010).
547 Contrasting with a plesiomorphic arboreal postcranial bauplan, the radiation of the Plio-
548 Pleistocene *Cercopithecoides* taxa has been associated with locomotor behavior that includes
549 moderate to marked terrestrial locomotor habits (Jablonski and Leakey, 2008). Morpho-
550 functional adaptation to terrestrial locomotor behavior is inferred among Eurasian Miocene
551 colobines (Fig. 8) (Youlatos et al., 2012; Youlatos and Koufos, 2010) but tenuous evidence of
552 terrestriality was postulated from fragmentary and isolated Miocene colobine forelimb remains

553 from East Africa (Leakey et al., 2003). A nearly complete forelimb attributed here to *C. bruneti*
554 firmly demonstrates a partial reacquisition of terrestrial locomotor behavior among colobines as
555 early as the Late Miocene (Fig. 8-9) and confirms the autapomorphic condition of terrestrial
556 habits in the locomotor behavior of the genus *Cercopithecoides*. Additionally, the Chadian
557 colobine documents a morpho-functional trade-off typical of *Cercopithecoides*, with an elbow
558 joint adapted to withstand stress engendered by terrestrial locomotor habits and to promote
559 joint flexibility during foraging and frequent arboreal locomotor habits (Jablonski and Leakey,
560 2008). In addition to shedding light on the locomotor diversity of early African colobines, *C.*
561 *bruneti* also establishes the presence of an extreme variant of early molar eruption pattern
562 among Late Miocene African colobines and confirms the diversity of dental eruption pattern
563 inferred among early colobines (Harvati and Frost, 2007).

564 Toros-Menalla is similar to other East African Miocene cercopithecoid-bearing localities in
565 exhibiting an abundance of Colobinae relative to Cercopithecinae (Harrison, 2011). It also brings
566 evidence for a substantial ecomorphological diversity among Miocene colobines, giving support
567 to the hypothesis of a short-fused model of the adaptive radiation of Colobinae (Frost et al.,
568 2009). The affinity of the East African *C. williamsi* with the tribe Colobini was recently reinforced
569 by the demonstration of its marked pollical reduction (Frost et al., 2015). However, the affinity
570 of the genus *Cercopithecoides* with crown or stem Colobini remains unclear. Fragmentary
571 remains from an indeterminate colobine from the Lukeino Fm. demonstrates the presence of a
572 synapomorphic Colobini astragalar morphology at ca. 6.1 Ma (Gilbert et al., 2010). Unlike the
573 colobine gen. and sp. B from Lukeino Fm., no clear synapomorphic postcranial characters permit
574 to assign *C. bruneti* within the Colobini crown group. However, the molecularly estimated

575 divergence times of extant Colobini taxa (i.e., 8-6 Ma) is clearly in the time range spanned by *C.*
576 *bruneti* (Ting, 2008). On one hand, the Chadian colobine exhibits clear dental and mandibular
577 morphological affinities with the African tribe (Fig. 3, 5). On the other hand, it retains
578 plesiomorphic features observed among morphologically conservative Miocene colobines (i.e.,
579 square molars, moderate occlusal relief and MS) (Fig. 3). Additionally, the temporal setting of *C.*
580 *bruneti* and its phenetic affinities with the early Pliocene *C. kerioensis* are in favor of its basal
581 position in the *Cercopithecoides* lineage. Altogether, *C. bruneti* supports a placement of the
582 genus *Cercopithecoides* among the stem (rather than crown) Colobini group.

583 **Summary and conclusions**

584 The newly described postcranial and dentognathic fossil cercopithecoid material from the Late
585 Miocene hominin-bearing fossiliferous area of Toros-Menalla sheds light on a previously
586 unknown spatial setting during a poorly sampled, yet critical, period of the adaptive radiation of
587 colobine monkeys in Africa.

588 We demonstrate the oldest occurrence of a speciose early colobine genus previously and
589 securely known only from Plio-Pleistocene deposits of eastern and southern Africa. In addition
590 to further documenting the morphological diversity of *Cercopithecoides*, *C. bruneti* supports the
591 presence of gracile mandibular morphology as well as the autapomorphic condition of
592 terrestrial locomotor habits among early representatives of its genus. While phenetic affinities
593 of *Cercopithecoides* with the Colobini crown group are corroborated, in-depth analysis of the
594 dentognathic morphology of *C. bruneti* underlined its basal position by revealing its
595 morphological departure from the mandibular and dental anatomy of extant African colobines,

596 lending further support to a phylogenetic placement of *Cercopithecoides* into the stem Colobini
597 group.

598 As an anatomical hallmark of extant colobines, the emergence of a folivorous dental
599 morphology is of prime interest in the understanding of the colobine adaptive radiation. On this
600 aspect, *C. bruneti* departs from the cercopithecine-like occlusal relief and the subsequently
601 inferred frugivory documented among penecontemporaneous colobines, bringing evidence of
602 an increase in leaf consumption among African Miocene colobines. Similarly, we demonstrate
603 the presence of a terrestrial signal in the *C. bruneti* postcranial morphology, confirming the
604 alteration of the colobine postcranial arboreal bauplan as early as 7 Ma in Africa.

605 By providing evidence of substantial ecomorphological diversity among Miocene colobines, we
606 highlight the role of Central Africa not only in the radiation of extant cercopithecids but also in
607 the early evolutionary history of those widespread primates.

608

609 **Acknowledgements**

610 We are grateful to the Chadian authorities and to the Ministère en charge de l'Enseignement
611 Supérieur et de la Recherche, N'Djamena (CNRD ex-CNAR and Université de N'Djamena), to all
612 the members of the field surveys and excavations lead by the MPFT (P.I. M. Brunet) and to the
613 Ambassade de France (Commission des Fouilles, Paris et Ambassade de France à N'Djamena).

614 We acknowledged the contribution of M. Adoum, D. Merci and Dr. C. D. Nekoulng. We thank
615 S. Riffaut, X. Valentin, G. Renaud, M. Pourade, Dr. A. Mazurier, J. Surault and A. Walker for
616 technical support and administrative guidance. We are grateful to Dr. G. Merceron and Dr. G.
617 Thierry for fruitful scientific discussion. We thank the Smithsonian's Division of Mammals (Dr.

618 Kristofer Helgen) and Human Origins Program (Dr. Matt Tocheri) for the scans of USNM
619 specimens used in this research. These scans were acquired through the generous support of
620 the Smithsonian 2.0 Fund and the Smithsonian's Collections Care and Preservation Fund. We
621 also thank the Museum of Comparative Zoology of the Harvard University, Lynn Lucas and Lynn
622 Copes as well as the Wenner Gren Foundation for providing access to their virtual data,
623 deposited on www.MorphoSource.org, Duke University. We are grateful to Dr. Eric Delson and
624 the AMNH Department of Mammalogy for providing access to their data, the collection of which
625 was funded by AMNH and NYCEP and deposited on www.MorphoSource.org, Duke University.
626 We also express gratitude to Dr. Justin W. Adams who collaborated with the Plio-Pleistocene
627 Section of the Ditsong National Museum of Natural History to provide us access to these data
628 originally appearing in (Adams et al., 2015) the collection of which was funded by the
629 Department of Anatomy and Developmental Biology, Monash University and deposited on
630 www.MorphoSource.org, Duke University. We thank Dr. Emmanuel Gilissen and Dr. Walter
631 Coudyzer for giving us access to the collection of the Royal Museum of Central Africa (Tervuren,
632 Belgium) and to the imagery facilities of the Université Catholique de Louvain. We
633 acknowledged the Mammalian Crania Photographic Archive Second Edition (MCPA2) of the
634 Dokkyo Medial University (<http://1kai.dokkyomed.ac.jp/mammal/en/mammal.html>) for the use
635 of juvenile Colobini photographs. We are grateful to Jacques Cuisin (MNHN, France), Dr. Marcia
636 Ponce de Leon (AIM-UZH), Dr. Loïc Costeur and Florian Dammeyer (NMB) and Dr. Didier Berthet
637 (MHNL) for access to specimens under their care. We also thank Associate Editor M. Tallman
638 and reviewers E. Delson and two anonymous others for their comments, which helped to
639 improve our manuscript.

903 mid-M₃.

904 Abbreviations: S= Superior; A=Anterior; M=Medial, P=Posterior, L=Lateral.

905

906 Figure 5. Comparative anatomy of *Cercopithecoides spp.* (i.e., *C. bruneti* and *C. williamsi*)
907 mandibular morphology relative to extant Colobini (i.e., *Colobus guereza occidentalis*,
908 *Ptilocolobus badius badius* and *Procolobus verus*). **A.1-3** anterior view, **B.1-3** lateral view, **C.1-3**
909 superior view, **D.1-3** saggital cross-section at symphysis, **E.1-3** coronal cross-section at mid-M₁.

910 Abbreviations: Sup=Superior, Lat=Lateral, Post= Posterior, Ant= Anterior.

911

912 Figure 6. Mandibular morphometric indices of *C. bruneti* paratypes (i.e., TM 266 03-099, TM 219
913 01-102, TM 112 00-093), *C. williamsi* (i.e., KB680, STS 394) and extant African ($n=37$) and Asian
914 colobines ($n=66$). Morphologies of extant Colobinae associated with the maximum and
915 minimum ratio value are figured on the right of the graphs. Violin plots of extant Colobini and
916 Presbytini on the right. Boxplots of early colobines on the left. Miocene colobines in underlined
917 brown font and boxplot in brown background. Plio-Pleistocene colobine boxplots in grey
918 background. Boxplots with mean (red circle), median (black line), first quartile, third quartile,
919 minimum and maximal values as well as outliers (red diamonds). *C. bruneti* values identified by
920 a black arrow. For extended measurement protocol, refer to SOM Figure S1. **(A.)** STT/ITT ratio of
921 *C. bruneti* ($n=3$), *C. williamsi* ($n=1$; KB680) and extant African and Asian Colobinae with STT/ITT
922 as $[(SBSTT/SBITT)*100]$. **(B.)** Symphyseal angle of *C. bruneti* ($n=3$), *C. williamsi* ($n=1$; KB680) and
923 extant African and Asian Colobinae. **(C.)** Relative position of the genioglossal fossa (GFP) of *C.*
924 *bruneti* ($n=2$; TM 219 01-102, TM 112 00-093), *C. williamsi* ($n=1$; KB680) and extant African and
925 Asian Colobinae with GFP as $[(GFH/SL)*100]$. **(D.)** Symphyseal robustness (SR) in *C. bruneti* ($n=3$;

926 TM 266 03-099, TM 219 01-102, TM 112 00-093), *C. williamsi* (n=1; KB680) and extant African
927 and Asian Colobinae with SR as [(SB/SL)*100]. **(E.)** Planum alveolare extension (PAE) in *C.*
928 *bruneti* (n=3), *C. williamsi* (n=1; KB 680) and extant African and Asian Colobinae with PAE as
929 [(PAL/SL)*100]. **(F.)** Corpus robustness (CR) at M₁ in *C. bruneti* (n=2; TM 266 03-099, TM 112 00-
930 093), *C. williamsi* (n=2; KB 680, STS 394) and extant African and Asian Colobinae with CR as
931 [(CWM1/CLM1)*100].

932
933 Figure 7. Digital photographs of *C. bruneti* postcranial remains (i.e., TM 266 03-100 and TM 266
934 03-307) with *C. bruneti* ulna **(A.-D.)**, radius **(E.-H.)**, humerus **(I.-L.)** and femur **(M.-P.)**.

935 Abbreviations: Px=Proximal; A= Anterior; M= Medial, P= Posterior, L= Lateral.

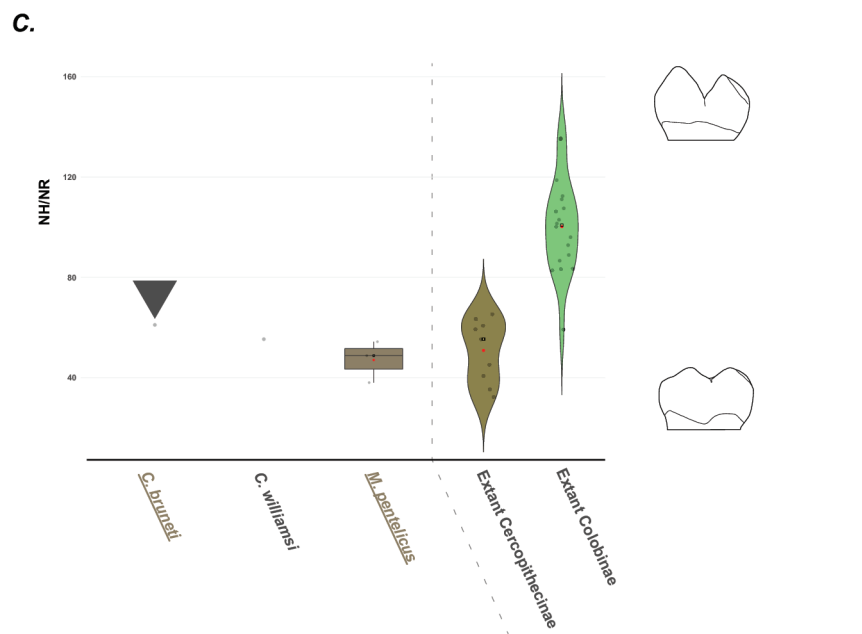

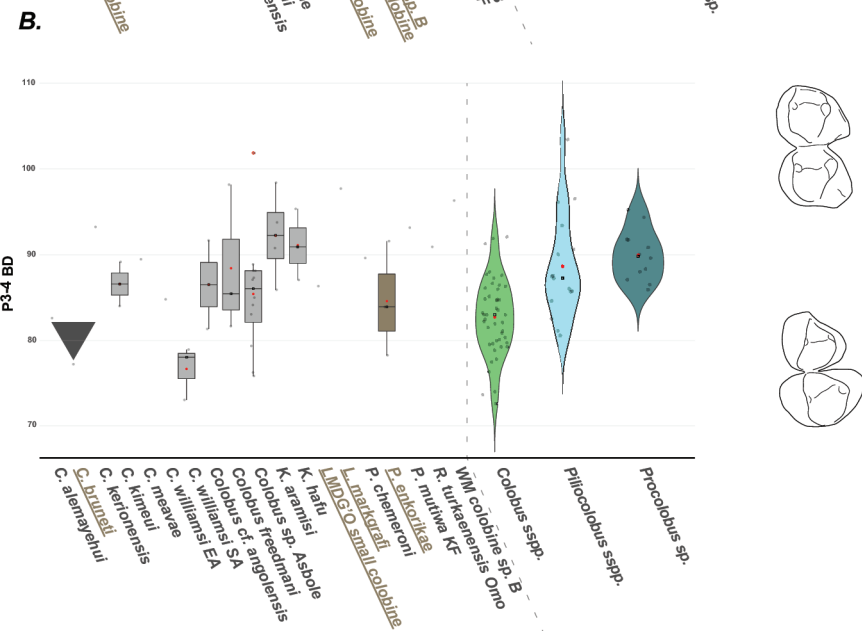

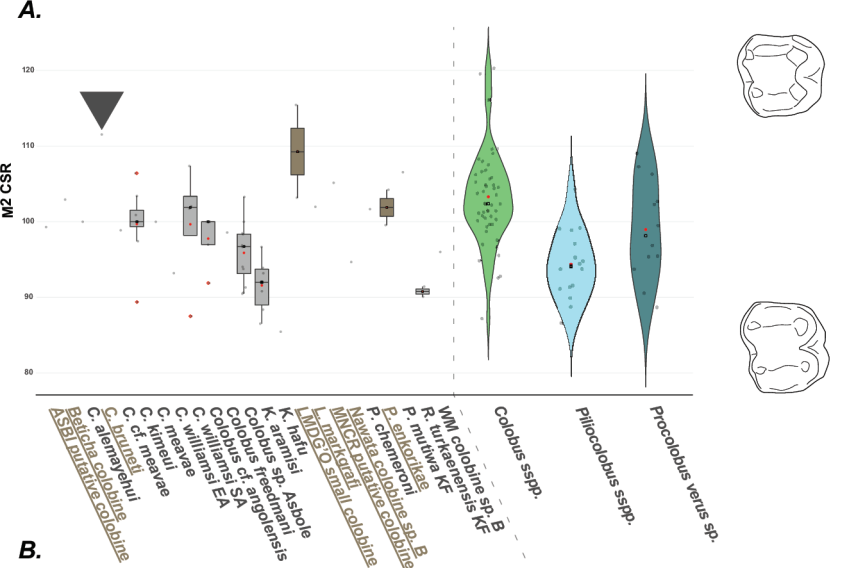

936
937 Figure 8. Comparative anatomy of extant and extinct Colobinae forelimbs. **(A.)** *C. guereza*
938 *guereza*. **(B.)** *P. rufomitratus langi*. **(C.)** *M. pentelicus*. **(D.)** *Microcolobus*. sp. with photographs
939 reproduced from (Nakatsukasa et al., 2010)). **(E.)** Forelimb anatomy of *C. bruneti*. Abbreviations:
940 Prox= Proximal; Med= Medial, Post= Posterior, Lat=Lateral.

941
942 Figure 9. Postcranial indices of extant cercopithecids, *C. bruneti* and early colobines (i.e.,
943 *Mesopithecus pentelicus*). Morphologies of extant cercopithecids associated with the maximum
944 and minimum ratio value are figured on the right of the graphs. Violin plots of extant
945 cercopithecids on the right. Boxplots of early colobines on the left. Miocene colobines in
946 underlined brown font and boxplot in brown background. Boxplots with mean (red circle),
947 median (black square), first quartile, third quartile, minimum and maximal values as well as

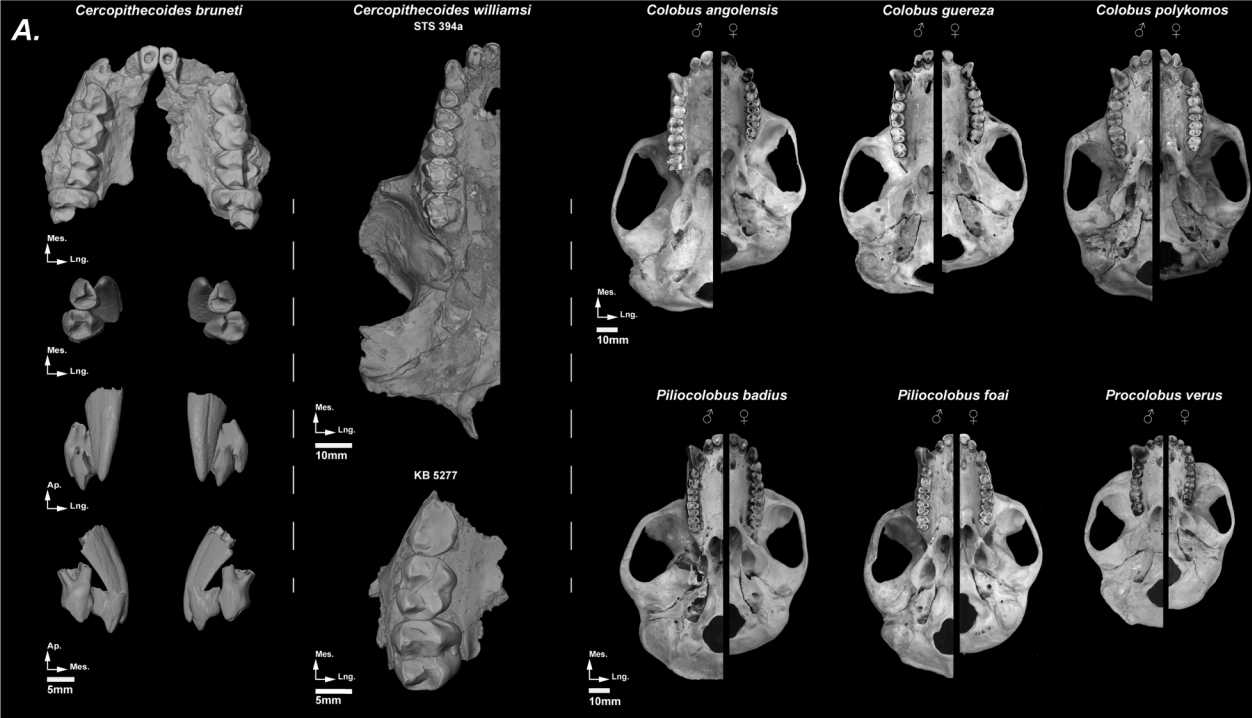

948 outliers (red diamonds). *C. bruneti* values identified by a black arrow. For extended
949 measurement protocol of medial epicondyle angulation, refer to SOM Figure S1.

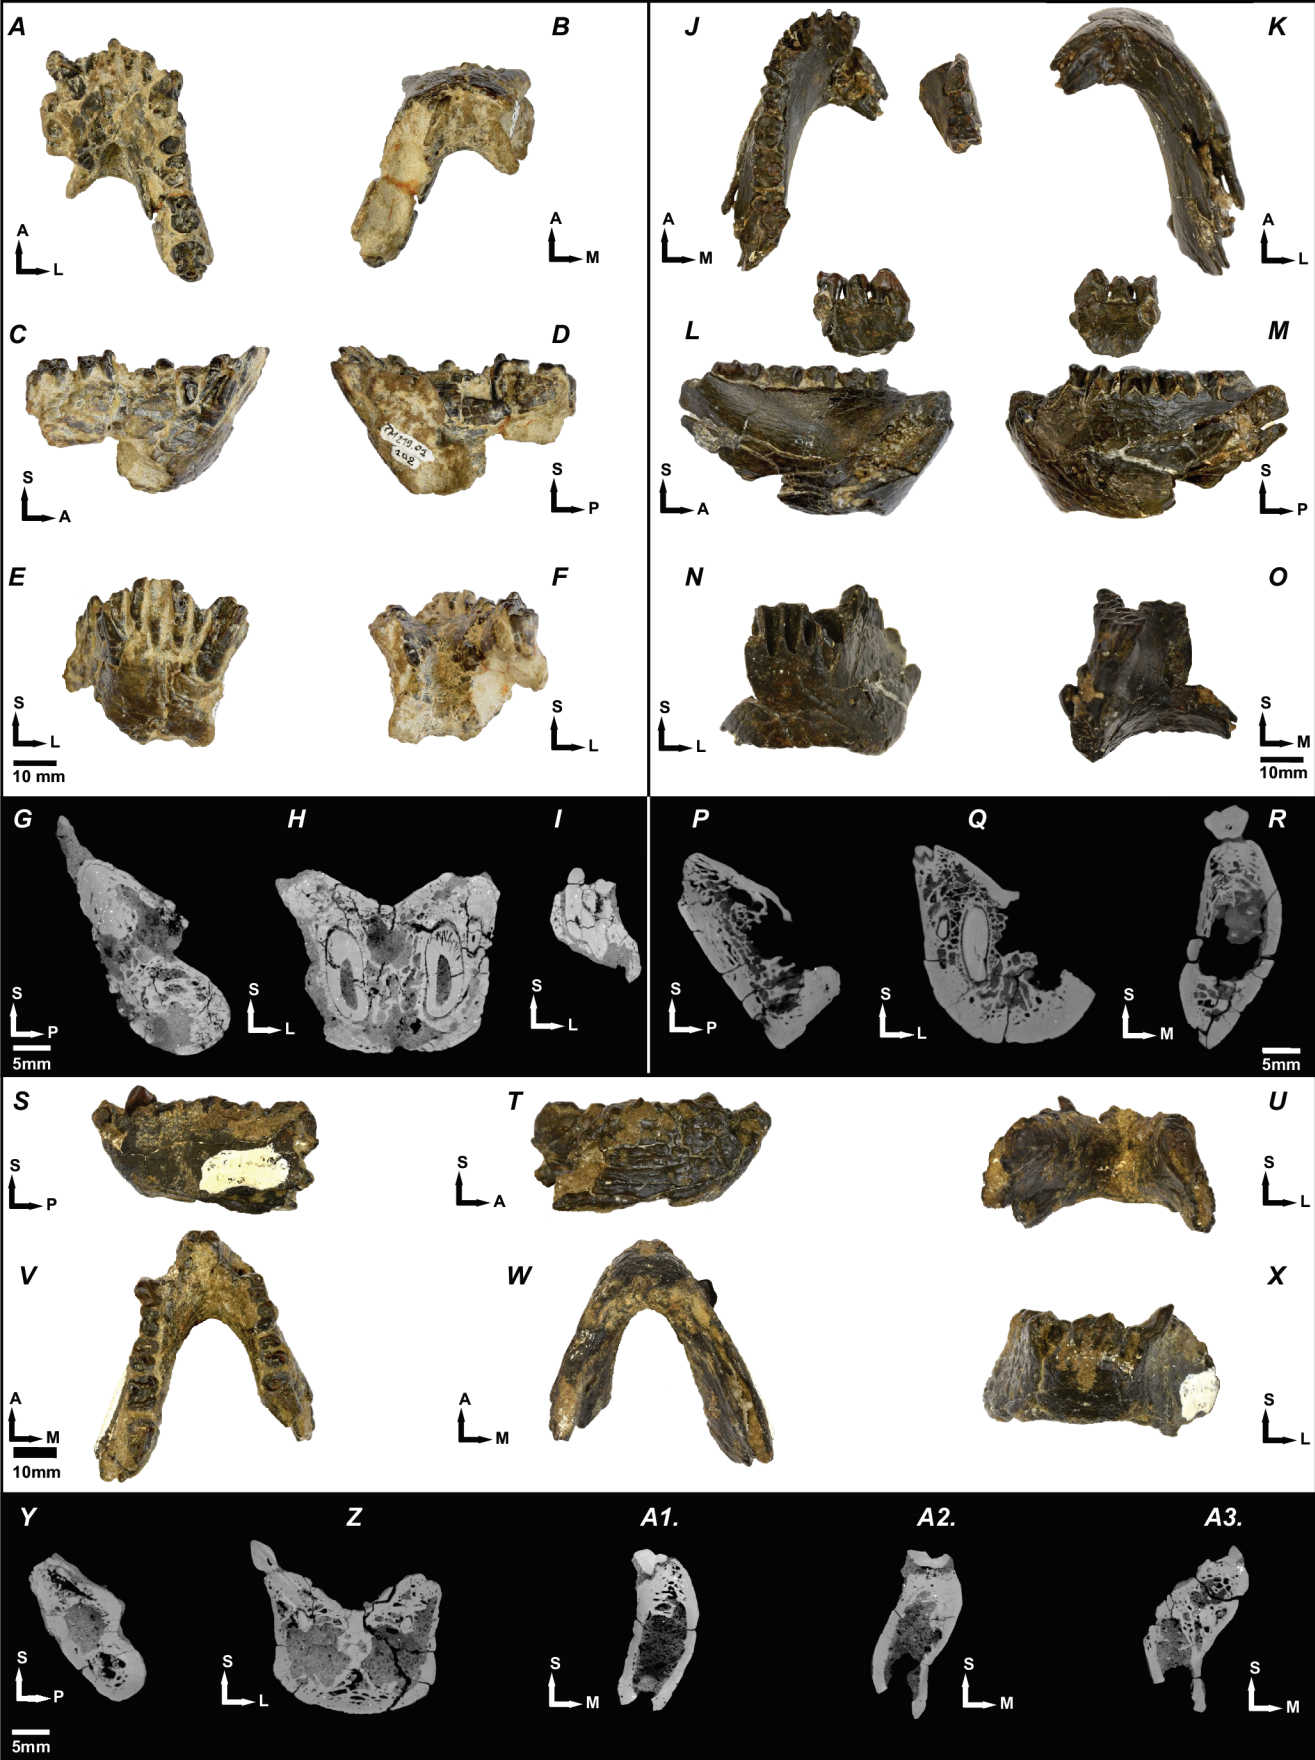

950 **(A.)** Boxplot of the medial epicondyle angulation of *C. bruneti* ($n=1$; TM 266 03-036), *M.*
951 *pentelicus* ($n=6$; PIK 244, 245, 355, 356, 1429, 1727), extant *Papio* ssp. ($n=26$), extant Colobini
952 ($n=44$) and extant Presbytini ($n=38$). **(B.)** Boxplot of the medial trochlear keel relative
953 development of *C. bruneti* ($n=1$; TM 266 03-036), *C. williamsi* ($n=1$; KNM-ER 4420 with data from
954 Frost and Delson, 2002), *C. meavae* ($n=1$; AL2-64 with data from Frost and Delson, 2002), *M.*
955 *pentelicus* ($n=7$; PIK 244, 245, 355, 356, 1727, 1728, 1729), extant *Papio* ssp. ($n=17$), extant
956 Colobini ($n=34$) and extant Presbytini ($n=22$). Medial trochlear keel development calculated and
957 measured as in (Frost and Delson, 2002). **(C.)** Boxplot of the I_{max}/I_{min} ratio of *C. bruneti* ($n=1$;
958 TM 266 03-034), extant cercopithecines ($n=6$) and extant colobines ($n=17$).

Table 1: Spatial and temporal setting of the *Cercopithecoides* representatives

	Type locality	Temporal record	Spatial record
<i>C. bruneti</i>	Toros-Menalla, Chad, Central Africa .	ca. 7 Ma.	Only known from its type locality.
<i>C. kerioensis</i>	Lothagam, Kenya, East Africa .	ca. 5-4.2 Ma. ¹	Only known from its type locality.
<i>C. meavae</i>	Leadu, Ethiopia, East Africa .	3.8 - 3.28 Ma. ²	Hadar, Leadu, Woranso-Mille ² .
<i>C. kimeui</i>	Olduvai Gorge, Tanzania, East Africa	2.5-1.2 Ma.	Olduvai Gorge, Rawi, Koobi Fora, Hadar.
<i>C. haasgati</i>	Haasgat, South Africa .	?Pleistocene. ³	Only known from its type locality.
<i>C. williamsi</i>	Makapansgat, South Africa .	3.5-1.5 Ma.	Makapansgat, Sterkfontein, Swarktrans, Cooper's A, Bolt's Farm, Kromdraai, Drimolen, Koobi Fora, ?Shungura, Leba (Angola).
<i>C. alemayehui</i>	Daka, Ethiopia, East Africa .	1.0 Ma.	Only known from its type locality.
<i>C. sp. indet.</i> Laetoli	Laetoli, Tanzania, East Africa .	3.81-3.63 Ma.	Uncertain taxonomy and known only from Laetoli.
cf. <i>C. sp. indet.</i> Koobi Fora	Koobi Fora, Ethiopia, East Africa .	3.95-3.45 Ma.	Uncertain taxonomy and known only from Allia Bay ⁴ .
<i>i C. sp. indet.</i> Kanapoi	Kanapoi, Kenya, East Africa	4.19-4.11 Ma.	Uncertain taxonomy and known only from Kanapoi.

¹ According to Leakey et al., 2003, there is no secure stratigraphic context relative to *C. kerioensis*.

² It includes here specimens from Woranso-Mille and allocated to *C. cf. meavae*.

³ According to McKee et al., 2011, there is uncertainty relative to the exact temporal setting of the *Cercopithecoides* sample from Haasgat

⁴ According to Jablonski et al., 2008, a partial mandible, KNM-ER 36985, exhibit phenetic affinities with *C. kerioensis* but the authors referred to this specimen as *C. sp. indet.*

⁵ Uncertain age estimation based on faunal assemblage (Jablonski, 1994)

Table 2: Comparative morphology of the cranio-dental anatomy of *Cercopithecoides spp.*

	BM (kg) ¹	M ² CSR	P ³ -P ⁴ BD	P ³ protocone	M ₃ RHD	M ₁₋₂ SD	P ₄ CSR	MS	STT/ITT	CW

Range values of odontometric indices and qualitative assessment of several morphological characteristics of *Cercopithecoides spp.* With Body Mass (BM); Crown Shape Ratio (CSR); Breadth Differential (BD); Relative Hypolophid Development (RHD); Maxillary Sinuses (MS); Superior Transverse Torus (STT); Inferior Transverse Torus (ITT); Corpus Width (CW); Not Available (NA).

¹ Based on the equation provided by Delson et al., 2000.

² Calculated from M¹ MD dimension with "All-colobine" model parameters.

³ Range value calculated from M² MD dimension with "All-colobine" model parameters.

⁴ Values given in Delson et al., 2000 for the "Estimated mass" value.

⁵ Calculated from M² MD dimension with "All-colobine" model parameters.

⁶ Range value calculated from M² MD dimension with "All-colobine" model parameters on minimum and maximum dental dimensions provided in McKee et al., 2011.

⁷ Ratio calculated from mean dental dimensions provided in McKee et al., 2011.

⁸ The presence of MS is not clearly asserted (Frost et al., 2008).

<i>P</i> ₄ BL/MD	73.0		
<i>M</i> ₁₋₂ SD	75.5		
<i>P</i> ₃ BL/OL	55.2	65.8	

Dental metrics in mm and right teeth metrics given in brackets. Dental indices and measurement protocols from (Benefit, 1993; Harrison and Harris, 1996). All measurements acquired using a Mitutoyo Digital Calliper CD-8" CX on original specimens. MD: mesio-distal dimension; BL: bucco-lingual dimension; OL: Occlusal length; TL: Total length; FL: Flange length as in (Benefit, 1993); MBL: bucco-lingual dimension at the metalophid; HBL: bucco-lingual dimension at the hypolophid; HYPOB: bucco-lingual dimension at the hypoconulid.

Table 5: Mandibular morphometry of *C. bruneti* hypodigm

	TM 266 03-099	TM 112 00-093	TM 219 01-102
