ARTICLE TYPE

Extraction of iridium from acidic aqueous solutions and separation from platinum(IV) using ionic liquids

Nicolas Papaiconomou^{*a}, Isabelle Billard^{b,c} and Eric Chainet^a*Received (in XXX, XXX) Xth XXXXXXXXXX 20XX, Accepted Xth XXXXXXXXXX 20XX*

DOI: 10.1039/b000000x

Anionic complexes of iridium(IV), IrCl_6^{2-} , were extracted from acidic solutions using ionic liquids (IL). Influence of the cation structure of IL and of the aqueous phase pH on the distribution coefficients of IrCl_6^{2-} was investigated. Liquid-liquid extraction and precipitation of iridium(IV) were studied. It appears that iridium(IV) is efficiently extracted using simple hydrophobic ionic liquids, exhibiting D values ranging up to 77. Investigations on the extraction mechanism tend to show that iridium(IV) in exchanged with two $[\text{NTf}_2]^-$ anions from the IL phase. Precipitation of iridium(IV) using water-soluble ionic liquids was also carried out. Iridium(IV) was removed from water forming a precipitate based on two cations from the ionic liquid. Pyridinium cations appear to be the most efficient at precipitating out iridium(IV). Finally, the back-extraction of iridium(IV) from ionic liquid towards aqueous solutions was carried out from $[\text{BMIM}][\text{NTf}_2]$ or $[\text{OdmIM}][\text{NTf}_2]$ into solutions containing high amounts of hydrochloric acid or nitric acid.

Introduction

Iridium is a rare and precious metal found in the earth crust in extremely low concentration, typically 2 ppb. It is found in primary ores of platinum, such as those found in South Africa. In such ores, iridium can be found in various proportions, ranging from above 25 % down to less than 1 %. It is however generally low, typically below 1 % in weight of the overall precious metals content, an amount similar to that of gold.¹⁻³ Iridium, platinum and other platinum group metals, so-called PGMs, are generally present together in ores and are difficult to separate because they are very similar elements. Ir and Pt are neighbours in the periodic table and exhibit oxidation states of II and IV. Both Pt(IV) and Ir(IV) are able to form octahedral complexes such as PtCl_6^{2-} or IrCl_6^{2-} . For the latter anions, typical extraction process involve ternary amines such as trioctylamine or phosphate compounds as extracting agents and kerosene as the extracting phase.⁴⁻⁷ Ionic liquids are now well-known organic salts melting at or near room temperature. The diversity of available cations and anions confers them very specific physicochemical properties. Used as extracting phases, and with or without extracting agents, ionic liquids have proven to be promising phases for the selective extraction of numerous metallic ions.⁸ Even though the extraction mechanism are still the subject of discussions, the extraction of negatively charged metal complexes appears to be mainly due to some anion exchange between the anion from the ionic liquid (such as bis(trifluoromethanesulfonyl)imide) and the metal complex.⁹⁻¹⁴ Removal of metal from water is also possible by

forming a water-insoluble ion pair formed with one or more cations of the IL and a negatively charged metal complex.^{11,14}

After having recently reported results on the extraction of gold(III) and platinum(IV) and their subsequent separation,^{11,12,14} we focus here on the extraction of iridium(IV) from acidified aqueous solutions using ionic liquids.

Such a study is justified for several reasons. First, iridium is a precious metal with a high price (approximately 10^3 €/kg), which confers a significant added-value to any alternative extraction and purification process of the metal. Second, iridium is used in several industrial and high technology applications such as electronics and telecommunications. It is also used in several other applications including alloys with platinum to yield highly resistant anodes,¹⁵ high temperature crucibles,¹⁶ specific catalysts in organic chemistry¹⁷ and even more recently catalysts for the electrocatalytic reduction of carbon dioxide.¹⁸ It is also used as electrodes together with platinum in spark plugs in internal combustion engines. Such spark plugs electrodes usually range between 5 to 15 % in mass of iridium, the rest being composed with platinum.¹⁹ Third, efficient and selective extraction of iridium from ores or wastes such as spark-plug electrodes is difficult using current processes. Fourth, on a more fundamental level, studying the extraction of iridium and its separation from gold or platinum, its immediate neighbour in the periodic table, is useful for gaining better insight into the extraction abilities of ionic liquids towards negatively charged metallic complexes. Our previous works dealing with Au(III) and Pt(IV) reported extraction of chloro-, bromo-, or thiocyanocomplexes of these metals.^{11,14} However, the formation of IrBr_6^{2-} starting from IrCl_6^{2-}

salt is the subject of contradictory reports in the literature. We were not able to obtain such hexabromoiridate(IV) complexes in water, even after heating the solution for a week at 60 °C. On the other hand, iridium(IV) was reported to oxidize thiocyanate anion in water leading to the formation of cyanide anion.²⁰ Therefore, the study reported in this article focussed on the extraction of IrCl_6^{2-} in aqueous solutions containing 10^{-2} to 12 M HCl, using two ways of removing IrCl_6^{2-} , namely liquid-liquid extraction or precipitation.

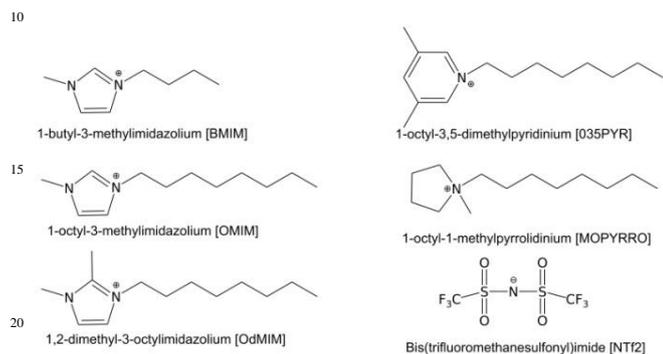

Fig 1 - Structures and abbreviations of ionic liquids used in this study.

Liquid-liquid extraction experiments were carried out using hydrophobic ionic liquids 1-butyl-3-methylimidazolium bis(trifluoromethanesulfonyl)imide [BMIM][NTf₂], 1-octyl-3-methylimidazolium bis(trifluoromethanesulfonyl)imide [OMIM][NTf₂], 1-octyl-2,3-dimethylimidazolium bis(trifluoromethylsulfonyl)imide [OdMIM][NTf₂], 1-octyl-1-methylpyrrolidinium bis(trifluoromethanesulfonyl)imide [MOPYRRO][NTf₂] or 1-octyl-3,5-dimethylpyridinium bis(trifluoromethanesulfonyl)imide [O35PYR][NTf₂] as extracting phases. All structures and abbreviations are presented in Fig. 1. [BMIM]⁺ and [OMIM]⁺ cations are based on the same unsaturated heterocycle containing a delocalised positive charge, and two different alkyl chain lengths. [OdMIM]⁺ cation include a methyl group on the carbon bound to the two nitrogens, which replaces the labile hydrogen present on the [BMIM]⁺ and [OMIM]⁺ cations. These three cations were chosen because they belong to the family of ionic liquids most studied in the literature. [O35PYR]⁺ is a six-membered unsaturated heterocycle containing a delocalised positive charge. On the other hand, [MOPYRRO]⁺ cation is a saturated five-membered heterocycle embedding a localized positive charge, as opposed to the unsaturated imidazolium cation.

Precipitation experiments were carried out using hydrophilic ionic liquids [OMIM][Br], [OdMIM][Br] or [O35PYR][Br], accordingly. Since no reaction of IrCl_6^{2-} and bromide anions were observed in our studies, the presence of bromide anions did not modify the nature of the iridium(IV) complex during the time of the investigation.

The extraction mechanism for the liquid-liquid extraction of iridium(IV) using [OMIM][NTf₂] was studied experimentally adding Li[NTf₂] to aqueous phases containing H_2IrCl_6 prior to the extraction experiments.

Back extraction studies were carried out starting from several ionic liquids phases with IrCl_6^{2-} and several leaching phases

containing either HCl or HNO₃.

60 Experimental

The pH of the aqueous solutions prior and after the extraction experiments carried out at 0.01 and 0.1 M HCl were measured using a HI221 pHmeter from Hanna Instruments and a HI1131 pH electrode. No variation of the HCl concentration was observed during the experiments.

Precipitation of IrCl_6^{2-}

A stock solution containing 1M HCl and 1.1mM K_2IrCl_6 was first prepared. Precipitation experiments were then carried out typically mixing 2 mL of the above mentioned aqueous solution with 2 mL of a solution containing 1 M HCl with various concentrations of either [OMIM][Br], [OdMIM][Br] or [MOPYRRO][Br]. The mixture was left on a shaker for one hour. When a precipitate was observed, the tube was then centrifuged at 3000 ppm for 15 min. The aqueous phase was then analysed by UV-Vis spectroscopy as detailed further.

Liquid-liquid extraction of IrCl_6^{2-}

Stock solutions containing various amounts of HCl were prepared by mixing millipore water with 37% HCl solution. 48 mg of K_2IrCl_6 was then added to the solutions to obtained so-called initial solutions containing 1 mM K_2IrCl_6 and 0.01, 0.1, 1, 4, 7.8 or 12 M HCl accordingly.

Liquid-liquid extraction experiments were then carried out contacting in a centrifuge tube, 3 g of any of the initial solutions mentioned above with a volume of ionic liquid yielding a volume ratio V_w/V_{IL} of 5. Densities of HCl solution are available in the literature.²¹ Densities of ionic liquids were assumed to be $1.3 \pm 0.02 \text{ g}\cdot\text{cm}^{-3}$ for all octyl-based ionic liquids. The density of [BMIM][NTf₂] was taken as $1.40 \pm 0.02 \text{ g}\cdot\text{cm}^{-3}$.

The tube was then left on a shaker for 12 hours and then centrifuged at 3000 g for 15 min. An aliquot of the aqueous phase was then taken from the tube and the concentration of IrCl_6^{2-} was measured with the help of UV-Vis spectroscopy as detailed below.

In addition, six aqueous solutions containing 0.01, 0.017, 0.024, 0.051, 0.074 and 0.1 M Li[NTf₂] were prepared by adding the desired mass of Li[NTf₂] into a solution at pH 1 and 1 mM K_2IrCl_6 . Then, 3 mL of each solution was mixed with 0.6 mL of [OMIM][NTf₂]. After mixing and centrifuging as detailed above, the aqueous phase was analysed using UV-Vis spectroscopy.

100 Back extraction

Back extraction experiments were carried out starting from several ionic liquid phases obtained after liquid-liquid extraction, thus containing IrCl_6^{2-} . Typically, 0.5 mL of the ionic liquid was mixed with 4 mL of an aqueous phase containing either 5 M HCl, 12 M of HCl or 5 M HNO₃. After mixing and centrifuging as detailed above, the aqueous phase was analysed using UV-Vis spectroscopy.

Measurements

UV-Vis spectra of the aqueous phase prior and after extraction were recorded with a Cary 50 spectrophotometer from Varian. The final concentration of IrCl_6^{2-} was determined by UV-Vis

spectrophotometry, applying the Beer-Lambert's law at the maximum absorption wavelength ($\lambda_{max} = 489$ nm) of iridium and using calibration solutions ranging from 10 to 100 μ M. In all cases, a correlation factor of 0.999 and above for the Beer-Lambert's law was obtained.

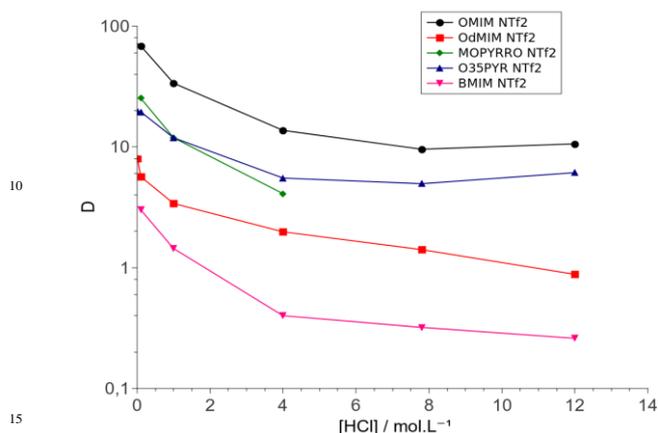

Fig. 2 - Distribution coefficients for IrCl_6^{2-} as a function of HCl concentration in water. (●): [OMIM][NTf₂]. (◆): [MOPYRRO][NTf₂]. (▲): [O35PYR][NTf₂]. (■): [OdmIM][NTf₂]. (▼): [BMIM][NTf₂].

For the precipitation experiments, the extraction efficiency of iridium from water ($I_{r,extr}\%$) is calculated as following:

$$I_{r,extr}\% = 100 \frac{[\text{IrCl}_6^{2-}]^{Init} - [\text{IrCl}_6^{2-}]^{Final}}{[\text{IrCl}_6^{2-}]^{Init}} \quad (1)$$

where $[\text{IrCl}_6^{2-}]$ refers to the concentration of $\text{Ir}_2\text{Cl}_6^{2-}$ in water, and the superscripts *Init* and *Final* refer to the values measured prior or after the extraction experiment, respectively. The value of $I_{r,extr}\%$ is calculated within $\pm 0.2\%$.

For the liquid-liquid extraction experiments, the distribution coefficient (*D*) was calculated using the following formula.

$$D = \frac{[\text{IrCl}_6^{2-}]^{Init} - [\text{IrCl}_6^{2-}]^{Final} V_w}{[\text{IrCl}_6^{2-}]^{Final} V_{IL}} \quad (2)$$

with V_w and V_{IL} the volumes of water and ionic liquid, respectively. The volume ratio V_w/V_{IL} used in the extraction experiments is 5. The maximum *D* value measurable in this study was assumed to be 10^3 . The relative uncertainty on *D* is $\pm 5\%$. All experiments are performed in duplicates

Results and discussions

Precipitation of Ir(IV)

Precipitation of iridium(IV) complexes was carried out using aqueous solutions containing various concentrations of water-soluble ionic liquids. Concentrations of ionic liquids, IrCl_6^{2-} and values for the extraction efficiency are collected in Table 1.

Results show that no precipitation occurs when 1.1 mM IrCl_6^{2-} and 2.2 mM of [OMIM][Br] or [OdmIM][Br] are mixed accordingly. Precipitation was observed using higher concentrations of ionic liquid of 0.01 M and above.

[O35PYR][Br] is the most efficient ionic liquid for precipitating IrCl_6^{2-} out from a 1 M HCl solution. With this cation, iridium was removed so efficiently from the aqueous phase that the remaining concentration was below the detection limit of our analysis

method. Such results are in agreement with those reported for Au(III) precipitation, which had shown that [OPYR][Br] was more efficient at removing AuBr_4^- complexes from water than [OMIM][Br].

Replacing the labile hydrogen of the imidazolium cation by a methyl group yielded lower extraction percentages of IrCl_6^{2-} . For instance, using 0.01 M of [OMIM][Br] or [OdmIM][Br], extraction percentages of 81 or 23 % for IrCl_6^{2-} were obtained accordingly. Increasing the concentration of ionic liquid in the solution led to higher the extraction efficiency. Values of 98 and 71 % were obtained using 0.02 M of [OMIM][Br] or [OdmIM][Br].

As reported previously for Au(III) or Pt(IV) in HCl media, these results fully support the assumption that precipitation of IrCl_6^{2-} in presence of cations of ionic liquids yields the formation of an insoluble ionic liquid containing IrCl_6^{2-} anion. The reaction of precipitation can then be written as following

and the solubility product is then calculated as

$$K_s = [\text{OMIM}]^2[\text{IrCl}_6] \quad (4)$$

A sample of the powder obtained mixing [OMIM][Br] with K_2IrCl_6 in 1 M HCl solution was collected and ^1H NMR spectrum was recorded. As expected, the spectrum obtained was similar to that of [OMIM][Br] cation, confirming the presence of [OMIM]⁺ cation in the precipitate and the formation of $[\text{OMIM}]_2[\text{IrCl}_6]$ as shown in eqn (4).

Solubility products calculated according to eqn (4) are reported in Table 2. The values are found to be below 10^{-8} , and are in the range of the K_s values reported previously for platinum(IV) at 1 M HCl. According to eqn (4), values of $1.35 \cdot 10^{-8}$, $0.62 \cdot 10^{-8}$ and $1.16 \cdot 10^{-8}$ for K_s were calculated from the results obtained using 0.01, 0.02 or 0.04 M [OMIM][Br], respectively. These values are close from one another and are within the experimental error of our analysis method. Therefore, an average value of $1.04 \cdot 10^{-8}$ was assigned to the K_s (see Table 1). Similarly, an average value of $8.40 \cdot 10^{-8}$ was calculated for $[\text{OdmIM}]_2[\text{IrCl}_6]$.

Interestingly, $[\text{O35MPYR}]_2[\text{IrCl}_6]$ exhibits a K_s value below $4 \cdot 10^{-10}$, which is two orders of magnitude lower than that obtained with [OMIM][Br]. Because similar observations had been reported with AuCl_4^- , our results confirm that the pyridinium cation generally interacts in a stronger way with polyhalogenometallate anions than imidazolium. Such a result might be explained by the important electron delocalisation on the pyridinium ring, which yields interactions between the π electrons and the electron pairs of the chloride anions from the anionic metal complex.

Industrial extraction processes regularly use selective precipitation procedures using ammonium chloride in order to precipitate iridium(IV) or platinum(IV) out from water under the form of $(\text{NH}_4)_2\text{IrCl}_6$ or $(\text{NH}_4)_2\text{PtCl}_6$, accordingly. The solubility of ammonium hexachloroiridate(IV), reported to be 7.7 or 12.1 g.kg⁻¹ water at 20 and 30 °C, respectively,²² corresponds to K_s values of $9 \cdot 10^{-6}$ and $3.5 \cdot 10^{-5}$ respectively. In order to extract iridium(IV), typical concentrations of 0.5 M or 1 M NH_4Cl are therefore used in the process. The K_s values of $(\text{NH}_4)_2\text{IrCl}_6$ are therefore up to five orders of magnitude higher than those

reported in this study. This implies that iridium(IV) could be precipitated out from water using a concentration of water-soluble ionic liquid one or two orders of magnitude lower than that of ammonium chloride classically used.

Overall, these results tend to confirm that water-soluble ionic liquids are promising alternative salts for the precipitation of iridium(IV) dissolved in an aqueous solution containing HCl.

Liquid-liquid extraction of IrCl_6^{2-}

All results are reported in Table 2. For comparison reasons, distribution coefficients have been plotted as a function of HCl concentration in Fig. 2.

Because [BMIM][NTf₂] has been used in several articles dealing with the extraction of metallic ions with ionic liquids, this IL was used for the extraction of IrCl_6^{2-} in water. Results show that [BMIM][NTf₂] is a poor extracting phase for iridium(IV), yielding *D* values below 3 whatever the pH of the aqueous phase. Replacing butyl with octyl yields higher distribution coefficients. At the same pH, the *D* values obtained with [OMIM][NTf₂] are systematically 20 to 30 times higher than those obtained with [BMIM][NTf₂]. Compared to other ionic liquids based on pyridinium, pyrrolidinium or dimethylimidazolium cations, [OMIM][NTf₂] yields highest *D* values reported in this study.

[OdmMIM][NTf₂] corresponds to [OMIM][NTf₂] with an additional methyl group replacing the labile hydrogen on the imidazolium ring. Using this IL, distribution coefficients towards iridium(IV) appear to be one order of magnitude lower those obtained using [OMIM][NTf₂], whatever the pH of the aqueous phase.

Obviously, the absence of a labile hydrogen hinders the reduces the interaction between IrCl_6^{2-} and the imidazolium ring. This is most probably due to the fact that the labile hydrogen binds somehow with the iridium(IV) complex such as $\text{Im}\dots\text{H}^+\dots\text{IrCl}_6^{2-}$, either weakly or strongly, the hydrogen moving thus towards the IrCl_6^{2-} anion. In the case of [OdmMIM][NTf₂], this interaction not existing, IrCl_6^{2-} is less attracted towards the imidazolium ring.

Using a different cation such as [O35PYR]⁺ or [MOPYRRO]⁺ yields extraction efficiencies that are lower than that obtained with [OMIM][NTf₂], but higher than that for [OdmMIM][NTf₂]. Surprisingly, even though the *D* values measured here using [O35PYR][NTf₂] and [MOPYRRO][NTf₂] are significantly lower than those obtained with [OMIM][NTf₂], they are of similar values. Even though this proves the influence of the structure of the cation ring (imidazolium vs. other cation ring) on the extraction efficiency of iridium(IV), there appears to be no significant difference between a pyridinium or a pyrrolidinium with regards to their extraction efficiency towards iridium(IV). The relatively low *D* values obtained with [O35PYR][NTf₂] are surprising because [O35PYR]⁺ cation has been found to associate in a stronger way to IrCl_6^{2-} anion in order to form a neutral pair insoluble in water. The interactions involved in the liquid-liquid extraction of IrCl_6^{2-} using ionic liquids are not necessarily the same as those involved in the precipitation of IrCl_6^{2-} .

For all ionic liquids studied here, *D* values decrease monotonously with acid concentration. This tends to show that the extraction mechanism is similar with all ionic liquids used here. As explained in the following sub-section, no straightforward explanation was found so far for the decreased in *D* with HCl concentration.

Because platinum and iridium are neighbour atoms in the periodic table, because they are always present together in ores and because they usually are extracted very similarly in classical solvent extraction process,⁸ comparing the results reported here with those previously obtained for platinum(IV) is relevant. First, unlike previous reports dealing with the extraction of Ir(IV) and Pt(IV), ionic liquids provide extracting phases which are selective towards Ir(IV) at low pH. At higher pH, this trend changes with [OMIM][NTf₂].¹⁴

Second, the results obtained here are consistent with the assumption previously presented stating that the extraction of such anionic metal complexes can be qualitatively correlated with the solvation energy of the cation in water, hence with the charge density of metal complex. The distribution coefficients obtained with [OMIM][NTf₂] for IrCl_6^{2-} is higher than those for PtCl_6^{2-} but lower than those obtained for PtBr_6^{2-} . This trend is consistent with the thermochemical radius of IrCl_6^{2-} (3.35 Å), compared to that of PtCl_6^{2-} (3.13 Å) and PtBr_6^{2-} (3.42 Å).²³

Mechanism of liquid-liquid extraction

The extraction mechanism was first investigated by plotting $\log(D)$ versus $\log(\text{HCl})$. Linear regressions were obtained in most cases. The slopes, however, ranged between -0.2 and -0.6, not giving any clear indication of the involvement of a hydronium cations in the extraction mechanism of IrCl_6^{2-} towards ionic liquids.

Extraction mechanism was thus further investigated by measuring the distribution coefficients for IrCl_6^{2-} from an aqueous phase containing various amounts of Li[NTf₂] salt. Experiments were carried out using [OMIM][NTf₂] and aqueous solutions at pH 1, because the highest value for *D* (68) of this study was obtained under these conditions. Furthermore, the maximum concentration of Li[NTf₂] used in these experiments is 0.1 M, because above that concentration, no significant extraction of IrCl_6^{2-} was observed and no reliable *D* values could be calculated. On the other hand, because the solubility product of [OMIM][NTf₂] in 0.1 M HCl was found to be 1.1 g.L⁻¹, which corresponds to 2.3 10⁻³ mol.L⁻¹ of [OMIM][NTf₂] in water, and because the concentration of [NTf₂]⁻ anion originating from Li[NTf₂] added to the solution needs to be significantly higher than that initially present (2.3 mM), a minimum concentration of Li[NTf₂] 0.01 mol.L⁻¹ was used. Since Li[NTf₂] can be regarded as a hydrophilic salt, Li⁺ and NTf₂⁻ ions were assumed to remain in the aqueous phase during the extraction experiment. The concentration of [NTf₂]⁻ anion was then calculated taking into account the solubility in water of [OMIM][NTf₂]

$$K_s = x(x + [\text{LiNTf}_2]) \quad (5)$$

with *x* the concentration of [OMIM]⁺ cation, and [LiNTf₂] the concentration of Li[NTf₂] salt added to the solution. *K_s* is the solubility product of [OMIM][NTf₂]. The concentration of [NTf₂]⁻ anion in the solution is here simply

$$[\text{NTf}_2^-]_{aq} = x + [\text{LiNTf}_2]$$

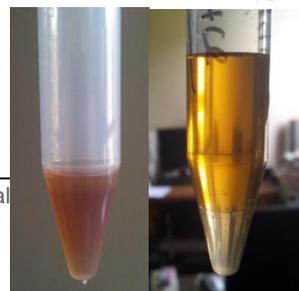

Fig. 3 - Snapshots of back extraction of iridium(IV). First snapshot: iridium(IV) extracted in 0.7 g [BMIM][NTf₂]. Second snapshot: back extraction of iridium(IV) after adding 4 mL of 37 % HCl solution to the ionic liquid phase from the first snapshot.

Results are collected in Table 3 and show that extraction of iridium(IV) decreases with the concentration of salt added in water. Similarly to previous reports dealing with the extraction of gold(III) and platinum(IV),^{11,14} such a behaviour is assumed that be related to an ion exchange between the iridium complex and [NTf₂]⁻ anions. Due to electroneutrality during the extraction process, this exchange can be described as following

where the subscript *aq* refers to the aqueous phase and the overline represents the ionic liquid phase. Following eqn (7), one writes

$$K_{ex} = \frac{[NTf_2^-]_{aq}^2 [IrCl_6^{2-}]}{[IrCl_6^{2-}] [NTf_2^-]^2} \quad (8)$$

where K_{ex} is the equilibrium constant of eqn (6). Taking into account eqn (2), one obtains

$$D = \frac{[NTf_2^-]^2}{K_{ex}} \frac{1}{[NTf_2^-]_{aq}^2} \quad (9)$$

D is therefore expected to vary linearly with $1/[NTf_2^-]^2$. Plotting D as a function of $[NTf_2^-]^2$ as suggested in eqn (9) yields a linear regression with a good correlation factor ($r^2=0.997$). This confirms that the extraction of iridium follows an anion exchange with ILs based on [NTf₂]⁻ anions.

Back extraction

Starting from the results provided in this study, simple back extraction procedures were carried out as presented in Table 4.

First, after extraction of iridium(IV) at 0.01 M HCl using [BMIM][NTf₂], the ionic liquid pregnant with iridium(IV) was contacted with a 12 M HCl aqueous phase. The volume of water was equal to five times that of the ionic liquid. The ionic liquid lost its brown colour upon contact, and after 2 minutes, most iridium was back extracted in the aqueous phase. Fig. 3 presents two snapshots, one from [BMIM][NTf₂] taken after iridium(IV) is extracted towards the ionic liquid phase, and one after [BMIM][NTf₂] was contacted with a concentrated HCl solution. Spectrophotometric analysis revealed that approximately 80 % of the iridium(IV) was recovered from [BMIM][NTf₂] by this method. Because the distribution coefficients at 8 M HCl are very close to those obtained at 12 M, similar results were obtained when contacting [BMIM][NTf₂] containing iridium(IV) with a solution of 12 M HCl. Similar experiments were carried out with [OdmIM][NTf₂].

Results showed that at approximately 56 % of the iridium previously extracted in [OdmIM][NTf₂] could be back extracted in an 8 M HCl solution.

Considering the distribution coefficients reported here for iridium(IV) complexes with [OMIM][NTf₂] are always above 9 whatever the pH, back extraction of iridium(IV) from this ionic liquid using HCl solutions was not possible. Instead, aqueous solutions containing HNO₃ was used. In this case, 67 % of IrCl₆²⁻ was back extracted in a 33 % HNO₃ solution.

Conclusion

Five hydrophobic and three hydrophilic ionic liquids have been used for removing IrCl₆²⁻ from water containing various concentrations of HCl. Ionic liquids based on the NTf₂ anion appear to be promising phases for the selective extraction of iridium from solution containing platinum(IV) and Au(III).

At low HCl concentration (pH 2), liquid-liquid extraction of iridium(IV) ranged between 7 and 70 using octyl-based ionic liquids. Distribution coefficient for IrCl₆²⁻ was found to generally decrease with the HCl concentration. [BMIM][NTf₂] yielded low D values, because it embeds a short butyl chain, reducing the hydrophobicity of the ionic liquid, compared to its octyl homologues presented here. Except for [OMIM][NTf₂] at 12 M HCl, extraction of iridium(IV) was found to be more efficient than that of platinum(IV). Study of the extraction mechanism suggests that IrCl₆²⁻ is extracted along with two [NTf₂]⁻ anions of the ionic liquid.

Precipitation of iridium(IV) using water-soluble ionic liquids was carried out successfully starting from 1 mM IrCl₆²⁻ and concentration of IL ranging from 2 to 40 mM. The precipitate was composed with two ionic liquid cations and one IrCl₆²⁻ complex. K_s values obtained in this study were found to be up to five orders of magnitude lower than that obtained for (NH₄)₂IrCl₆. Back extraction of iridium(IV) from [BMIM][NTf₂] or [OdmIM][NTf₂] was also proven to be also possible using 8 or 12 M HCl solutions. With [OMIM][NTf₂], back extraction was efficient using nitric acid.

Ionic liquids therefore have proven once again to be very versatile compounds for the extraction of a precious metal such as iridium(IV), yielding very different D values depending on its ion structure.

Further works, including separation of Ir(IV) from Au(III) or Pt(IV) using ionic liquids, as well as the selective electrochemical deposition of these metal complexes within an ionic liquid, and the influence of Au(III), Pt(IV) and Ir(IV) contaminants on the electrochemical deposition of each metal will shortly be carried out.
