Dans cette étude, on présente différentes méthodes numériques pour la simulation du changement de phase liquide-vapeur (ébullition). On utilise un formalisme Level Set pour capturer l'interface liquide-vapeur. Un tel formalisme nécessite une étape de réinitialisation de la fonction Level Set après advection. Cette étape est critique pour la simulation du changement de phase car elle ne doit ni déplacer l'interface, ni introduire de déformations dans le profil de la fonction Level Set, sous peine de détériorer la précision du calcul de la normale à l'interface et de sa courbure, nécessaires pour définir respectivement la vitesse de l'interface due au changement de phase et le saut de pression à l'interface. On présente d'abord les équations résolues et le couplage des équations de Navier-Stokes avec le taux de transfert de masse modélisant le changement de phase. Puis on détaille différents algorithmes de réinitialisation de la Level Set pour la simulation numérique de l'ébullition, sur maillages structurés et non structurés. Ces méthodes sont ensuite validées par un cas-test de croissance de bulle statique à taux de transfert de masse fixé. En particulier, on observe qu'à l'instant correspondant au doublement du rayon de la bulle, ce dernier converge en maillages pour toutes les méthodes présentées. Le test concluant sur maillages non structurés ouvre la voie à la simulation du changement de phase liquide-vapeur dans des géométries complexes.

## *Evaluation of Level Set reinitialization algorithms for phase change simulation on unstructured grids*

In this study, we present different numerical methods for the simulation of liquid-vapor phase change (boiling). We use a Level Set formalism to capture the liquid-vapor interface. Such a formalism requires a reinitialization (aka redistancing) step of the Level Set function after advection. This step is critical for phase change simulation as it must neither move the interface nor induce perturbations in the Level Set function, otherwise the normal vector to the interface and its curvature, two quantities that are crucial to define respectively the interface velocity due to phase change and the pressure jump at the interface, would be in turn too much perturbed. Here we present a comparison of different reinitialization algorithms of the Level Set function for boiling simulation, on structured and unstructured grids. These methods are then validated against the analytical case of a static growing bubble with a fixed mass transfer rate. In particular, we observe that at the time corresponding to a doubled bubble radius, the error on the bubble radius decreases with the grid cell size for all presented methods.

**KEYWORDS:** two-phase flows, phase change, unstructured grids, Level Set, boiling

## I INTRODUCTION

Two-phase flows are encountered in a wide range of industrial applications such as heat exchangers, nucleate boiling or spray cooling. The particularity of two-phase flows is the existence of an interface between the two phases. Numerical simulations of two-phase flows require the localization of the interface. Two-phase flow simulations including liquid-vapor phase change are even more challenging, as the motion of the liquid-vapor interface depends also on the mass transfer rate. There exist several numerical methods to keep track of the interface. In this study we describe different versions of the Level Set method [Osher and Sethian, 1988] on both structured and unstructured grids. These methods are then validated and compared on the analytical case of a static growing bubble with an imposed mass transfer rate.

## 50 II GOVERNING EQUATIONS

51 We solve the incompressible Navier-Stokes equations

$$52 \quad \frac{\partial \vec{u}}{\partial t} + (\vec{u} \cdot \vec{\nabla}) \vec{u} = -\frac{\vec{\nabla} p}{\rho} + \frac{1}{\rho} \vec{\nabla} \cdot \Sigma, \quad (1)$$

53 where  $\vec{u}$  is the velocity,  $p$  the pressure,  $\rho$  the density and  $\Sigma$  the viscous stress tensor of the given phase. The  
54 discontinuity in the velocity field at the interface is given by

$$55 \quad [\vec{u}]_{\Gamma} = -\dot{m} \left[ \frac{1}{\rho} \right]_{\Gamma} \vec{n}, \quad (2)$$

56 where  $[q]_{\Gamma} = q_{liq} - q_{vap}$  denotes the discontinuity, or jump, of the quantity  $q$  across the interface  $\Gamma$ ,  $\dot{m}$  is  
57 the mass transfer rate (in  $\text{kg m}^{-2} \text{s}^{-1}$ ) responsible for phase change, and  $\vec{n}$  is the interface normal vector pointing  
58 towards the liquid phase. When solving (1) we also have to take into account the pressure jump at the interface  
59 given by

$$60 \quad [p]_{\Gamma} = \sigma \kappa - \dot{m}^2 \left[ \frac{1}{\rho} \right]_{\Gamma}, \quad (3)$$

61 where  $\sigma$  is the surface tension and  $\kappa$  the curvature of the interface. Both jumps (2) and (3) are used in the  
62 projection method to solve (1) [Tanguy *et al.*, 2014].

63 In this study, as we focus on the different Level Set approaches available to accurately capture the interface,  
64 we assume that the mass transfer rate is fixed. These methods have been implemented in the YALES2 solver  
65 [Moureau *et al.*, 2011] and are presented in the next section.

## 66 III LEVEL SET METHODS ON STRUCTURED GRIDS

67 The most challenging task in two-phase flow simulations is the accurate localization and advection of the  
68 interface at every time step. Perturbations in interface localization result in a loss of precision and, in the more  
69 severe cases, in physical aberrations. With phase change, this well-known problem is even more restrictive.  
70 There are several methods to represent the interface. In this work, the Level Set method is used. A Level Set  
71 function is a function seen as a set of iso-levels. The liquid-vapor interface is identified as one specific iso-  
72 level [Osher and Sethian, 1988]. The Level Set method has two major advantages. First, the advection of the  
73 Level Set function in all the computational domain enables the implicit capture of the interface. Second,  
74 geometrical properties such as normal vector and curvature of the interface are embedded in the Level Set  
75 field. The main drawback of the Level Set method is the mandatory need of a reinitialization step of the Level  
76 Set function.

### 77 III.1 Case 1 - Signed Distance Function reinitialized by a Hamilton-Jacobi equation

78 We start our investigations by the method described by Tanguy *et al.* [2014]. In this method, the Level Set  
79 function is the Signed Distance Function  $\phi$  to the interface  $\Gamma$  defined for any  $\vec{x}$  in the computational domain  
80  $\Omega$  by

$$81 \quad \phi(\vec{x}) = \min_{\vec{x}_{\Gamma} \in \Gamma} \pm \|\vec{x} - \vec{x}_{\Gamma}\|. \quad (4)$$

82 In this case, the interface is identified as the 0 iso-level of the Level Set function [Osher and Sethian, 1988].  
83 The Signed Distance Function is advected by solving the standard advection equation

$$84 \quad \frac{\partial \phi}{\partial t} + u_{vap} \cdot \vec{\nabla} \phi = -\frac{\dot{m}}{\rho_{vap}}, \quad (5)$$

85 where  $u_{vap}$  is the vapor phase velocity,  $\rho_{vap}$  is the vapor density and the source term on the right hand side is  
86 due to phase change. After advection, the function  $\phi$  is reinitialized as a Signed Distance Function by solving  
87 the Hamilton-Jacobi PDE

$$88 \quad \frac{\partial \phi}{\partial \tau} + S(\phi^0) \left( \|\vec{\nabla} \phi\| - 1 \right) = 0, \quad (6)$$

89 where  $\tau$  is a pseudo-time,  $S$  is a smoothed sign function defined by Sussman *et al.* [1994], and  $\phi^0$  is the  
 90 previously advected Level Set that needs to be reinitialized. The equation (6) is solved in pseudo-time until  
 91 convergence, i.e. until  $\|\vec{\nabla}\phi\| = 1$ , which is part of the definition of the Signed Distance Function. The normal  
 92 vector to the interface  $\vec{n}$  and the curvature of the interface  $\kappa$  are then given by

$$93 \quad \vec{n} = \frac{\vec{\nabla}\phi}{\|\vec{\nabla}\phi\|} \text{ and } \kappa = -\vec{\nabla} \cdot \vec{n}. \quad (7)$$

94 Note that high precision is needed in the reinitialization of  $\phi$  to avoid perturbations in the normal vector and  
 95 curvature of the interface. To this purpose, the term  $\vec{\nabla}\phi$  in (6) is computed using a high-order scheme such as  
 96 the Fifth Order WENO scheme [Jiang and Peng, 2000]. High-order schemes require higher computational cost,  
 97 are difficult to implement on unstructured grids and may reduce performance in a parallel code.

### 98 III.2 Case 2 - Signed Distance Function reinitialized by the Fast Marching Method

99 Another method for the reinitialization of the Signed Distance Function is the Fast Marching Method  
 100 [Sethian, 1996]. The Fast Marching Method, based on the solution of an Eikonal equation, can be seen as the  
 101 stationary version of the Hamilton-Jacobi equation (6) and is given by

$$102 \quad \|\vec{\nabla}\phi\| = 1. \quad (8)$$

103 The solution of equation (8) is based on the propagation of the Signed Distance Function values from the  
 104 interface along the normal direction to the interface. To limit the computational time needed to perform the  
 105 Fast Marching Method, we solve it only on a narrow band around the interface, large enough to be able to  
 106 compute the normal vector and the curvature by equations (7).

### 107 III.3 Case 3 - Conservative Level Set on structured grids

108 In order to improve mass conservation in each phase, Olsson and Kreiss [2005] proposed the Conservative  
 109 Level Set method. In this method, the Level Set function  $\psi$  is a smeared-out Heaviside function defined for  
 110  $\vec{x} \in \Omega$  by

$$111 \quad \psi(\vec{x}) = \frac{1}{2} + \frac{1}{2} \tanh\left(\frac{\phi(\vec{x})}{2\varepsilon(\vec{x})}\right), \quad (9)$$

112 where  $\phi$  is the Signed Distance Function and  $\varepsilon$  is a scale parameter roughly of the order of the grid cell size.  
 113 In this case, the interface is identified as the 0.5 iso-level of the Level Set function. The Conservative Level  
 114 Set is advected by solving the conservative form of the standard advection equation with source term

$$115 \quad \frac{\partial\psi}{\partial t} + \vec{\nabla} \cdot (\psi \vec{u}_{vap}) = -\vec{u}_{PC} \cdot \vec{\nabla}\psi - \psi \vec{\nabla} \cdot \vec{u}_{vap}, \quad (10)$$

116 where the source term is composed of the phase change contribution and the divergence of the vapor velocity,  
 117 which should be null, but it is recommended to account for this correction to decrease the sensitivity to errors  
 118 in the evaluation of the velocity field. In (10), the interface velocity due to phase change  $\vec{u}_{PC}$  is given by

119  $\vec{u}_{PC} = \frac{\dot{m}}{\rho_{vap}} \vec{n}$ , and the gradient of the Level Set  $\vec{\nabla}\psi$  is computed as

$$120 \quad \vec{\nabla}\psi(\vec{x}) = \frac{1}{4\varepsilon(\vec{x}) \cosh^2\left(\frac{\phi(\vec{x})}{2\varepsilon(\vec{x})}\right)} \vec{n}, \quad (11)$$

121 where  $\phi$  is again the Signed Distance Function. This technique to compute  $\vec{\nabla}\psi$  is reused from the  
 122 reinitialization step suggested by Chiodi and Desjardins [2017] and presented below. The Conservative Level  
 123 Set embeds the interesting property of volume conservation. The normal vector and the curvature of the  
 124 interface are given by a similar approach as in (7).

125 The reinitialization equation for the Conservative Level Set proposed by Olsson and Kreiss [2005] is

$$126 \quad \frac{\partial \psi}{\partial \tau} + \vec{\nabla} \cdot (\psi(1-\psi)\vec{n}) = \vec{\nabla} \cdot (\varepsilon(\vec{\nabla} \psi \cdot \vec{n})\vec{n}), \quad (12)$$

127 where the normal vector is given by

$$128 \quad \vec{n} = \frac{\vec{\nabla} \psi}{\|\vec{\nabla} \psi\|}. \quad (13)$$

129 Nevertheless, the necessity to set  $\varepsilon$  to a small value to improve volume conservation produces sharp gradients  
130 in  $\psi$  and thus potential oscillations in  $\vec{n}$ . To avoid this problem, and with the aim of increasing accuracy,  
131 Chiodi and Desjardins [2017] built a new reinitialization equation for the Conservative Level Set given by

$$132 \quad \frac{\partial \psi}{\partial \tau} = \vec{\nabla} \cdot \left( \frac{1}{4 \cosh^2 \left( \frac{\phi_{map}}{2\varepsilon} \right)} \left( \|\vec{\nabla} \phi_{map} \cdot \vec{n}\| - 1 \right) \vec{n} \right), \quad (14)$$

133 where the inverse of the Conservative Level Set  $\phi_{map}$  is given by

$$134 \quad \phi_{map} = \varepsilon \log \left( \frac{\psi}{1-\psi} \right). \quad (15)$$

135 The normal vector is computed based on the Signed Distance Function, derived from the Conservative Level  
136 Set function by using the Fast Marching Method:

$$137 \quad \vec{n} = \frac{\vec{\nabla} \phi_{FMM}}{\|\vec{\nabla} \phi_{FMM}\|}, \quad (16)$$

138 where  $\phi_{FMM}$  is the Signed Distance Function given by the Fast Marching Method using boundary conditions  
139 on the closest nodes to the interface.

## 140 IV LEVEL SET METHODS ON UNSTRUCTURED GRIDS

### 141 IV.1 Case 4 - Signed Distance Function on unstructured grids

142 To be able to address complex geometries, algorithms are now extended on unstructured grids. The first  
143 unstructured case is similar to Case 1. Only the reinitialization step of the Signed Distance Function is replaced  
144 by the method developed on unstructured grids by Dapogny and Frey [2012]. We make use of the MshDist  
145 library implementing this method.

### 146 IV.2 Case 5 - Conservative Level Set on unstructured grids

147 Here we want to extend the methodology of Chiodi and Desjardins [2017] described for structured grids in  
148 Section III.3 to unstructured grids. The only difference is the replacement of  $\phi_{FMM}$  by the Signed Distance  
149 Function given by the method proposed by Dapogny and Frey [2012].

## 150 V NUMERICAL RESULTS

151 We validate the different Level Set reinitialization methods presented in the previous section on the case of  
152 a 2D static growing bubble with a fixed mass transfer rate from [Tanguy *et al.*, 2014]. The initial bubble radius  
153 is  $R_0 = 10^{-3}$  m and the imposed mass transfer rate is  $\dot{m} = 10^{-1}$  kg m<sup>-2</sup> s<sup>-1</sup>. The simulations are performed until  
154 final time  $t_f = 10^{-2}$  s needed for the bubble radius to double the initial radius. The other physical parameters  
155 of interest are  $\rho_{liq} = 10^3$  kg m<sup>-3</sup>,  $\rho_{vap} = 1$  kg m<sup>-3</sup>,  $\sigma = 7 \times 10^{-2}$  N m<sup>-1</sup>,  $\mu_{liq} = 10^{-3}$  kg m<sup>-1</sup> s<sup>-1</sup> and  $\mu_{vap} = 1.78$   
156  $\times 10^{-5}$  kg m<sup>-1</sup> s<sup>-1</sup>. In Table 1, the methods used in all cases are summarized.

The five cases have been computed on four different grid cell sizes. As an example, Fig. 1 shows the results of Case 5 at final time on four different unstructured grids. The relative error on the bubble radius with respect to the theoretical radius at final time is given for all cases at final time in Fig. 2 (a). One can see that on the finest grid, the Case 5 detailed in Fig. 1 presents the highest relative error. The five methods have a convergence rate close to one. For the finest grid, all relative errors on the bubble radius are below 1%. The relative errors on the normal vector and the curvature are shown in respectively Fig. 2 (b) and 2 (c). The results show that the error on the normal vector decreases at order 1 for all methods including the Signed Distance Function on unstructured grids (Case 4). For Case 5, i.e. for the Conservative Level Set on unstructured grids, further work is needed to improve the convergence of both normal vector and curvature.

**Fig. 1.** The results for the Case 5 on four different unstructured grids are plotted at final time with a characteristic cell size of (a)  $4 \times 10^{-4}$  m, (b)  $2 \times 10^{-4}$  m, (c)  $1 \times 10^{-4}$  m and (d)  $5 \times 10^{-5}$  m. The initial interface is plotted in blue, the computed interface in black, and the theoretical interface in red. For clarity, only the coarsest grid is represented in (a). The computed liquid and vapor velocity fields are plotted in (b).

**Fig. 2.** The normalized  $L^\infty$  norm of the error on the bubble radius  $\xi$  is plotted at final time for the five cases on four different grid cell sizes (a). The analogous error for the normal vector (b) and for the curvature (c).

172

173 **VI CONCLUSION AND PERSPECTIVES**

174 In this study, several numerical methods for the advection and reinitialization of the Level Set function have  
175 been presented in the context of liquid-vapor phase change. These methods have been validated and compared  
176 on the case of a static growing bubble with a fixed mass transfer rate. All methods present a convergence rate  
177 with the grid cell size close to one. Two of the five methods presented are designed for unstructured grids. The  
178 ability to accurately compute the interface position allows the quantitative simulation of liquid-vapor phase  
179 change on unstructured grids. This opens the path to numerical simulations of liquid-vapor phase change on  
180 complex geometries.

181 The main perspective of our work is the simulation of phase change on unstructured grids with a computed  
182 mass transfer rate which depends on the thermal fluxes at the interface and on the latent heat of the fluid.

183 **VII ACKNOWLEDGMENTS**

184 This work has been supported by the LabEx Tec21 (Investissements d’Avenir-Grant Agreement No. ANR-  
185 11-LABX-0030). Vincent Moureau and Ghislain Lartigue from the CORIA lab and the SUCCESS scientific  
186 group are acknowledged for providing the YALES2 code. G. B. is also grateful for the support from Institut  
187 Universitaire de France. The authors would like to thank Patrick Begou for support on algorithms  
188 implementation and Charles Dapogny for support on the MshDist library.
