HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

23 ABSTRACT

24 Peat layers within alluvial sediments are considered effective arsenic (As) sinks under reducing 25 conditions due to the binding of As(III) to thiol groups in natural organic matter (NOM) and the 26 formation of As-bearing sulfide phases. However, their possible role as sources of As for anoxic 27 groundwaters remains unexplored. Here, we perform laboratory experiments to provide evidence 28 for the role of a sediment peat layer in releasing As. Our results show that the peat layer, 29 deposited about 8,000 years ago in a paleomangrove environment in the nascent Mekong Delta, 30 could be a source of As to porewater under reducing conditions. X-ray absorption spectroscopy 31 (XAS) analysis of the peat confirmed that As was bound to thiol groups of NOM and 32 incorporated into pyrite. Nitrate was detected in peat layer porewater, and flow-through and 33 batch experiments evidenced the release of As from NOM and pyrite in the presence of nitrate. 34 Based on poisoning experiments, we propose that the microbially mediated oxidation of arsenic-35 rich pyrite and organic matter coupled to nitrate reduction releases arsenic from this peat. 36 Although peat layers have been proposed as As sinks in earlier studies, we show here their 37 potential to release depositional- and/or diagenetically-accumulated As.
