6

7 **SUMMARY STATEMENTS**

8 Marine heterotrophic bacteria play a crucial role in the carbon cycle since some species have
9 developed important enzymatic machineries to degrade algal polysaccharides. We show here that the
10 model algae-associated bacterium *Zobellia galactanivorans* is also involved in biodegradation of
11 hemicellulose through the activity of a horizontally-acquired endo- β -D-glucanase.

12

1 **ABSTRACT**

2 Cell walls of marine macroalgae are composed of diverse polysaccharides that provide abundant
3 carbon sources for marine heterotrophic bacteria. Among them, *Zobellia galactanivorans* is
4 considered as a model for studying algae-bacteria interactions. The degradation of typical algal
5 polysaccharides, such as agars or alginate, has been intensively studied in this model bacterium, but
6 the catabolism of plant-like polysaccharides is essentially uncharacterized. Here we identify a
7 polysaccharide utilization locus in the genome of *Z. galactanivorans*, induced by laminarin (β -1,3-
8 glucans), and containing a putative GH5 subfamily 4 (GH5_4) enzyme, currently annotated as a
9 endoglucanase (*ZgEngA_{GH5_4}*). A phylogenetic analysis indicates that *ZgEngA_{GH5_4}* was laterally
10 acquired from an ancestral *Actinobacteria*. We performed the biochemical and structural
11 characterization of *ZgEngA_{GH5_4}* and demonstrate that this GH5 is in fact an endo- β -glucanase, most
12 active on mixed-linked glucan (MLG). Although *ZgEngA_{GH5_4}* and GH16 lichenases both hydrolyze
13 MLG, these two types of enzymes release different series of oligosaccharides. Structural analyses of
14 *ZgEngA_{GH5_4}* reveal that all the amino acid residues involved in the catalytic triad and in the negative
15 glucose binding subsites are conserved, when compared to the closest relative, the cellulase EngD
16 from *Clostridium cellulovorans*, and some other GH5s. In contrast, the positive glucose binding
17 subsites of *ZgEngA_{GH5_4}* are different and this could explain the preference for MLG, with respect to
18 cellulose or laminarin. Molecular dynamics computer simulations using different hexaoses reveal that
19 the specificity for MLG occurs through the +1 and +2 subsites of the binding pocket that display the
20 most important differences when compared to the structures of other GH5_4 enzymes.

21

1 INTRODUCTION

2 For a long time, the presence of mixed-linked glucans (β -(1,3-1,4)-glucans, MLG) in primary
3 cell walls was considered a unique feature that has evolved in flowering plants (for review see for
4 example [1]). This vision was first challenged by a large and systematic analysis across the plant
5 kingdom using a glycan microarray approach, which highlighted that MLG were also present in some
6 less commonly found, early diverging vascular plants and freshwater green algae [2, 3]. Surprisingly
7 and more recently, β -(1,3-1,4)-glucans have been identified in the cell wall of brown macro-algae [4].
8 Well studied for their occurrence in the cell walls of grasses, these β -(1,3-1,4)-glucans are a major
9 component of carbohydrate storage compounds in the endosperm of cereals, such as barley, rice, or
10 wheat [2]. These glucans consist of linear chains of β -1,3- and β -1,4-linked glucosyl residues, and the
11 pattern of distribution of these two linkages varies according to the plant botanical origin and growth
12 conditions [4], in particular the distribution of β -1,3-linkages was found to be more frequent in the
13 marine brown algae [4].

14 Involved in important carbon storage catabolizing processes, enzymes that efficiently hydrolyse
15 these substrates (frequently named lichenases, mixed-linked-glucanases or termed β -(1,3-1,4)-
16 glucanases) are found largely distributed in many kingdoms of life (*i.e.*, plants, bacteria, fungi) and
17 their sequences are present in numerous glycoside hydrolase (GH) families, which are GH5, GH9,
18 GH16, GH17 and GH26 according to the CAZY (Carbohydrate Active Enzymes) database
19 (<http://cazy.org>; [5]). Among these different GH families, to date most characterized bacterial β -(1,3-
20 1,4)-glucanases are found in the families GH16 [6] and GH5 [7] based on the CAZY database [5].

21 GH5 is one among the large families in the CAZY database, with more than 12,000 available
22 sequences. Enzymes belonging to this family are retaining glycoside hydrolases that operate *via* the
23 classical Koshland double-displacement mechanism [8]. The first crystallographic structure of a
24 member of the GH5 family, solved in 1995 [9], was considered a pure β -1,4-glucanases (cellulase). It
25 revealed a $(\beta/\alpha)_8$ barrel fold, common to several other GH families, founding the structural clan GH-A.
26 Since then, up to 20 different activities have been reported for this large family [7], hindering
27 assignment of enzyme specificity, although they are predicted to be involved mainly in plant cell wall

1 degradation. Family GH5 has recently been subdivided into 51 subfamilies to improve correspondence
2 between specificity and sequence [7]. Several recent structure-function studies [10-12], covering
3 various GH5 subfamilies with formerly undefined specificities, have shed new light on important
4 residues lining the catalytic active site cleft that govern substrate specificity.

5 GH5 enzymes are relatively frequent in marine *Bacteroidetes*, especially in *Flavobacteriia*,
6 which are the prevalent class of *Bacteroidetes* in marine ecosystem [13]. However *Flavobacteriia*
7 species do not efficiently degrade crystalline cellulose [14, 15]. Regrettably, and without taking into
8 account its polyspecificity, the GH5 family has often been used as a ‘marker’ for cellulose occurrence
9 in marine environments in microbial ecology studies. Nonetheless, a study highlights that the
10 abundance of GH5 enzymes (mainly belonging to *Gammaproteobacteria*, *Firmicutes* and
11 *Actinobacteria*) positively correlates with chlorophyll concentration in the eastern part of the North
12 Atlantic Ocean, and that the diversity of GH5 enzymes was greater in coastal water than in the open
13 ocean [16].

14 In the present study, we have analyzed, using multiple biochemical approaches, the detailed
15 structure-function relationship of one of the three GH5 enzymes from *Zobellia galactanivorans* Dsij^T,
16 a model macroalgae-associated bacterium [13]. The gene name of this GH5 enzyme (*engA*) was given
17 in the initial genome annotation of *Z. galactanivorans* [13] by homology to the closest characterized
18 enzyme, the endoglucanase EngD from *Clostridium cellulovorans* [17]. The corresponding
19 recombinant enzyme will thus be named here ZgEngA_{GH5_4}. The evolutionary trail of this enzyme
20 leading to its presence in the genome of this marine flavobacterium is also discussed.

21

1 **EXPERIMENTAL**

2 Unless otherwise stated, all chemicals were purchased from Sigma.

3 **Phylogenetic analysis**

4 Homologues *ZgEngA_{GH5_4}* (gene: *engA*; systematic ID: ZGAL_208) were identified using
5 BlastP at the GenBank database. These sequences were aligned using MAFFT with the iterative
6 refinement method and the scoring matrix Blosum62 [18]. This multiple alignment allowed
7 calculation of model tests and maximum likelihood trees with MEGA version 6.0.6 [19]. Tree
8 reliability was tested by bootstrap using 100 resamplings of the dataset. The trees were displayed with
9 MEGA 6.0.6.

10 **Cloning and site-directed mutagenesis**

11 The *engA* gene encodes a 397 amino acids protein which includes a peptide signal (residues 1 to
12 20, analyzed with LipoP 1.0 [20]) and a large GH5 module (residues 21 to 397) (Figure S1). For the
13 biochemical and structural characterizations, the precise boundaries of the catalytic module were
14 identified using Hydrophobic Cluster Analysis (HCA) plot [21]. Genomic DNA from *Zobellia*
15 *galactanivorans* was prepared as previously described [22]. The primers forward (5'-
16 gggggggatctaatatgaggagatagcccctaag-3'; BglII restriction site is underlined) and reverse (5'-
17 ccccccaattgttacttaacaatggcctcggaatttc-3'; MfeI restriction site is underlined), deduced from the *engA*
18 gene of *Z. galactanivorans* (GenBankTM accession no. CAZ94281.1), were used to amplify the
19 sequence encoding for the catalytic module (residues 56 to 385) (Figure S1). After digestion with the
20 restriction enzymes BglII and MfeI, the purified PCR product was ligated using the T4 DNA ligase
21 into the expression vector pFO4 predigested by BglII and MfeI, resulting in a recombinant protein
22 with a N-terminal hexahistidine tag. The plasmid was then used to transform *E. coli* DH5 α strain for
23 storage and *E. coli* BL21 (*DE3*) strain for expression as described in [23]. The sequence of the gene
24 was checked using a genetic analyzer ABI 3130xl (Applied Biosystems) equipped with 50 cm
25 capillaries and POP7TM polymer. Site directed mutagenesis of *ZgEngA_{GH5_4}* was performed using the
26 QuickChange II XL site-directed mutagenesis kit according to the manufacturer's instructions (Agilent
27 Technologies). Sixteen individual mutations were produced using specific forward and reverse primers

1 described in Table S1. Mutated plasmids were then used to transform *E. coli* XL-10 Gold^R
2 ultracompetent cells (Agilent Technologies) for storage and *E. coli* strains BL21(DE3) (Novagen^R) for
3 protein expression. Mutated plasmids were sequenced to confirm the effectiveness and the position of
4 the mutation.

5 **Production and purification of ZgEngA_{GH5_4} and mutant ZgEngA_{GH5_4_E323S}**

6 Unless otherwise stated, experiments were performed at 20°C. Transformed *E. coli* strains
7 BL21(DE3) (Novagen^R) were grown for 72 hours in 250 mL ZYP 5052 medium [24] containing 100
8 µg mL⁻¹ ampicillin. *E. coli* BL21 (DE3) bearing pFO4 without insert was used as the negative control.
9 Culture was stopped by centrifugation at 3,000 g for 20 min. at 4°C and the pellet was stored at -20°C
10 until further use. The pellet was then suspended in 5 mL 25 mM Tris HCl (pH 7.5), 100 mM NaCl, 15
11 mM imidazole (Buffer A) containing 5 µL DNase I (500 units µL⁻¹). The suspension was incubated
12 for 20 min. at 4°C. The cells were then disrupted using a Cell disruption system (Constant Systems
13 Ltd). After centrifugation for 1 hour at 29,000 g and 4°C, the cell-free supernatant was then 0.2 µm
14 filtered before being loaded at a flow rate of 1 mL min⁻¹ onto a HisPrep FF 16/10 column (1.6 x 10
15 cm, GE Healthcare) equilibrated in buffer A. The column was washed at a flow rate of 2 mL min⁻¹
16 with buffer A until the absorbance at 280 nm was negligible. Elution of the protein was performed at
17 the same flow rate using a linear gradient increasing from 15 mM to 500 mM imidazole. The final
18 concentration of imidazole was reached after 10 column volumes. 2 mL fractions were collected
19 during the elution step. Fractions containing the recombinant tagged enzyme were estimated by SDS-
20 PAGE analysis and by Western blot. Transfer from SDS gel onto ready to use 0.2 µm nitrocellulose
21 membrane (BioRad) was performed using a Trans Blot Turbo system in the conditions specified by
22 the manufacturer (BioRad). Monoclonal anti-polyhistidine peroxidase conjugate (Sigma) was used at a
23 final concentration of 1/10000 to specifically recognize the His-tagged fusion protein. Immuno-
24 detection was performed by chemiluminescence using the Clarity Western ECL Substrate kit (BioRad)
25 and visualization was achieved using the Chemi-Capt 50001 software. Fractions containing the his-
26 tagged protein were then pooled prior being loaded at a 2 mL min⁻¹ flow rate on top of an HiPrep
27 Desalting FF 26/10 column (2.6x 10 cm, GE Healthcare) previously equilibrated in 25 mM Tris HCl

1 (pH 7.5), 100 mM NaCl (Buffer B). The same flow rate was used during the elution step and 1 mL
2 fractions were collected. Purity of the desalted ZgEngA_{GH5_4} and ZgEngA_{GH5_4_E323S} was further
3 checked by SDS PAGE analysis and dynamic light scattering (DLS).

4 **Protein quantification**

5 Protein amount was estimated at 280 nm using a Thermo Scientific NanoDrop One
6 spectrophotometer. A molar extinction coefficient of 85,500 M⁻¹ cm⁻¹ and a molecular weight of 37.5
7 kDa, both deduced from the protein sequence, were used to calculate the concentration of
8 ZgEngA_{GH5_4} protein solutions.

9 **Enzymatic activity assay of pure enzymes**

10 Unless otherwise stated, assays were performed using β-D-glucan from barley (0.2 % (W/V) in
11 50 mM MES buffer pH 6.5) as substrate. The activity was determined using the reducing sugar assay
12 described by Kidby and Davidson [25]. Reactions were performed at 30°C upon incubation of 180 μL
13 of substrate with 20 μL ZgEngA_{GH5_4} (100 nM). 20 μL of reaction mixture were withdrawn every 15
14 seconds and up to 105 seconds and added to 180 μL of ferricyanide reagent. The samples were then
15 incubated for 15 minutes at 95°C and cooled down to 20°C. The absorbance was read at 420 nm using
16 a Spark 10M microplate reader (Tecan, Switzerland). A calibration curve was performed under the
17 same conditions, using glucose solutions at different concentrations (from 0.1 to 1.2 mM) as standard.

18 **Substrate specificity of ZgEngA_{GH5_4}**

19 To assess the enzymes specificity among glycan polysaccharides, degradation of the following
20 substrates were assayed: β-D- glucan from barley, lichenan, glucomannan, xyloglucan, CMC, Avicel,
21 Laminarin and curdlan. Activity was measured using the ferricyanide assay described above. Unless
22 otherwise stated, all these substrates were used at a final concentration of 0.2% W/V in 50 mM MES
23 pH 6.5. The enzymatic activity was expressed in min⁻¹.

24 To refine the characterization of substrate specificity for ZgEngA_{GH5_4}, standard commercial
25 oligosaccharides were used as substrates and the hydrolysis products were analyzed by HPAEC
26 coupled with pulse amperometry. Based on the major activities on polysaccharides, the following

1 oligosaccharide substrates were chosen: laminaribiose (G3G), and different cello oligosaccharides
2 (G2, G3, G4, G5 and G6), and also β -(1,3-1,4)- oligosaccharides (G3GG, GG3G, GGG3G and
3 GG3GG). All oligosaccharide substrates were purchased from Megazyme except for GG3GG
4 (Carbosynth). Briefly, 2 mL of oligosaccharides (100 μ M) were incubated with 150 μ L recombinant
5 ZgEngA_{GH5_4} (0.5 μ M). Aliquots (170 μ L) of the reaction mixture were taken at different times (from
6 0 to 120 min.) and boiled for 15 min. to stop the reaction. Samples were then filtered through 4 mm
7 syringe filter (Millipore) and 20 μ L were injected onto a CarboPac PA1 column (4x 200 mm, Thermo
8 Scientific) equipped with the accompanying guard column (4x 50 mm, Thermo Scientific), both
9 thermostated at 30°C. Elution was carried out using an isocratic flow rate of 1 mL min⁻¹ with 175 mM
10 NaOH containing 50 mM NaOAc. Detection of the oligosaccharides was performed by integrated
11 amperometry using a quadruple pulse waveform (E1 +0.1, E2, -2.0, E3 +0.6 and E4 -0.1). Integration
12 of signal intensities was performed using the Chromeleon 6.80 software. Calibration of the different
13 oligosaccharides was done using different concentrations of appropriate oligosaccharides from which a
14 dose-response was determined using the Chromeleon software.

15 Fluorophore assisted carbohydrate electrophoresis (FACE) was performed to further analyze the
16 specificity of ZgEngA_{GH5_4} on oligo- and poly-saccharides. Depending on the objective, labelling of
17 oligosaccharides was either performed prior hydrolysis with ZgEngA_{GH5_4} or after hydrolysis.
18 However, the applied reaction conditions were the same. Briefly, 100 μ g of poly- or oligo- saccharides
19 were labelled with 2 μ L 150 mM 8-aminonaphthalene-1,3,6-trisulfonate (ANTS) and incubated for 30
20 min. at 37°C before the addition of 5 μ L of 1M NaBH₃CN in DMSO. Incubation at 37°C was further
21 continued for about 4 to 5 hours. Samples were then dried under vacuum before being suspended. The
22 labeled oligosaccharides were either suspended at \sim 2- 2.5 μ g μ L⁻¹ in 25% glycerol (W/V) or, if used as
23 substrate for enzymatic hydrolysis, at \sim 3.5 μ g μ L⁻¹ in 50 mM MES (pH 6.5).

24 Conditions used for the hydrolysis of oligosaccharides were as follows: 50 μ g of oligosaccharides (2
25 μ g μ L⁻¹ non labeled and \sim 3.5 μ g μ L⁻¹ labeled) in 50 mM MES (pH 6.5) were incubated overnight at
26 30°C with 4 μ L of 100 nM ZgEngA_{GH5_4}. Hydrolysis of β -D- Glucan (450 μ g in 50 mM MES pH 6.5)
27 was performed overnight at 30°C using either 10 μ L of 100 nM ZgEngA_{GH5_4} or 10 μ L of lichenase

1 (0.18 U mg⁻¹, 0.7 U mL⁻¹; Megazyme). After incubation, enzymes were inactivated for 10 minutes at
2 100°C. For each reaction, a blank was made under the same conditions except that the enzyme was
3 first inactivated for 10 minutes at 100°C prior to the incubation with the poly- or oligo-saccharides.
4 About 8-10 µg labeled oligo- and ~12.5 µg labeled β-D glucan (both in 25% glycerol (w/v) final
5 concentration) were loaded on a chilled 27% polyacrylamide gel. The electrophoresis was performed
6 in the dark at 125 volts (constant voltage), 4°C, using chilled migration buffer (25 mM Tris, 192 mM
7 Glycine, pH 8.5). Visualization of the fluorescent oligosaccharides was achieved under UV using a
8 UV Transilluminator (Thermofisher Scientific Bioblock).

9 **Optimal pH determination of ZgEngA_{GH5_4}**

10 The Teorell and Stenhagen buffer (pH 4.2 to 8.5) [26] was used at a final concentration of 100
11 mM to evaluate the pH optimum. Both enzyme and MLG were diluted in this buffer prior hydrolysis
12 reactions which were performed as described above. The enzymatic activity was estimated using the
13 ferricyanide assay. Results are expressed as percentage of relative activity.

14 **Optimal temperature determination of ZgEngA_{GH5_4}**

15 For this measurement both ZgEngA_{GH5_4} and β-D-glucan from barley were incubated at
16 different temperatures (from 5 to 60°C), in steps of 5°C. The produced amount of reducing sugars was
17 determined as described above. Results are expressed as the percentage of relative activity.

18 **Thermostability analysis**

19 The thermostability of ZgEngA_{GH5_4} was studied by DLS using a Zetasizer Nano instrument
20 (Malvern). ZgEngA_{GH5_4} (1.15 mg mL⁻¹) was filtered through a 0.2 µm membrane filter prior to being
21 heated from 5 to 65°C in steps of 1°C. The hydrodynamic gyration radius (R_g) was measured at each
22 step and the denaturation temperature is defined as the temperature for which the gyration radius
23 sharply increases.

24 **Oligomerization state studies**

25 The oligomerization state of ZgEngA_{GH5_4} was determined both by size exclusion
26 chromatography (SEC) and by size exclusion chromatography coupled to multiple angle laser light

1 scattering (SEC-MALLS). For the SEC experiments, ~ 600 µg of affinity chromatography purified
2 ZgEngA_{GH5_4} in 1 mL of buffer B were loaded on top of a Superdex 75HiLoad 16/60 column (GE
3 Healthcare) previously equilibrated in buffer B. The elution was performed at a 0.7 mL min⁻¹ flow
4 rate. Calibration of the column was carried out in the same conditions using the appropriate calibration
5 standards (GE Healthcare). For the experiments of size exclusion chromatography coupled with
6 MALLS, 100 µL at 300 µg mL⁻¹ of ZgEngA_{GH5_4} from the Superdex 75 chromatography were loaded
7 onto a Superdex 200 Increase 10/300 GL column (GE Healthcare), previously equilibrated for at least
8 24 hours in buffer B. Elution of the protein was performed for 80 minutes at a flow rate of 0.5 mL min⁻¹
9 and the detection was carried out using both an Optilab rEX detector (Wyatt) and Dawn Heleos light
10 Scattering detector (Wyatt). Results were analyzed using the ASTRA V software (Wyatt Technology)

11 **Crystallization and structure determination**

12 Crystals for ZgEngA_{GH5_4}, in solution at a concentration of 15 mg mL⁻¹, were obtained using the
13 hanging drop vapor diffusion method by mixing 2 µL of protein solution with 1 µL of crystallization
14 solution composed of 14% PEG 6000, 200 mM CaCl₂, 100 mM sodium acetate buffer at pH 5.0.
15 Crystals were cryo-protected using the crystallization buffer supplemented with 10% glycerol and
16 flash frozen in a N₂-stream at 100K. X-ray diffraction data were collected at 1.2 Å resolution at the
17 European Synchrotron Radiation Facilities (ESRF, Grenoble France) on beamline ID23-1. The images
18 were integrated using XDS [27] in the space group P2₁. The structure was solved by molecular
19 replacement with MolRep [28] using EngD (PDB ID: 3NDZ) as the search model. An initial model
20 was built automatically with the CCP4 version of ARP-wARP, [29] with several cycles of manual
21 rebuilding in Coot [30] and refinement with Refmac5 [31].

22 Crystals of ZgEngA_{GH5_4_E323S} in complex with cellotriose were obtained using the same hanging drop
23 method, in drops containing 2 µL of ZgEngA_{GH5_4_E323S} mutant at 7 mg mL⁻¹ mixed to 1 µL of well
24 solution consisting in 24-24.5% PEG 3350, 160 mM MgCl₂, 100 mM Bis- Tris pH 5.5.
25 ZgEngA_{GH5_4_E323S} mutant was co-crystallized with 0.04% of a mixture of oligohexa- to oligonona-
26 saccharides obtained from limited digestion of MLG by ZgEngA_{GH5_4}. Crystals were soaked in
27 crystallization buffer supplemented with 30% glycerol before being frozen in liquid nitrogen. Data

1 were collected at the Soleil synchrotron on beamline Proxima1 to 2.2 Å resolution. The images were
2 integrated using XDS [27] and the space group P3₂. The structure of ZgEngA_{GH5_4_E323S} in complex
3 with substrate was solved by molecular replacement, using the software Phaser [32] and the structure
4 of ZgEngA_{GH5_4} as the search model. The structure was refined using REFMAC [31] in iterative cycles
5 with manual corrections using the graphic interface Coot [30]. All Figures representing the structures
6 were prepared using the program PyMol (Schrödinger, LLC). The atomic coordinates and the atomic
7 factors of both ZgEngA_{GH5_4} and ZgEngA_{GH5_4_E323S} have been deposited at the Protein Data Bank
8 collection (<http://www.pdb.org/>) as PDB ID: 6GL2 and PDB ID: 6GL0 respectively.

9 **Molecular Dynamics simulations**

10 Molecular dynamics (MD) simulations were performed to predict the cellulose recognition
11 properties of native ZgEngA_{GH5_4} and ZgEngA_{GH5_4_E323S}. The input starting protein structures for the
12 calculations were generated using the experimental crystal coordinates, and the cellulose substrate was
13 built into the binding pocket of the enzyme. Specifically, four different oligo-glucose, hexameric
14 chains were tested in the simulations: a cellohexaose chain with β-1,4 linkages between all sugars, and
15 three mixed-linked oligoglucans with the β-1,3 linkage at different positions (Fig. S2). The simulations
16 are summarized in Supporting Information (Tables S2-S5) together with details of the model
17 construction and simulation protocols. Each model was named according to the position and type of
18 linkage present in the oligosaccharide substrate: β(1,4) for the oligosaccharide with β-1,4 linkages
19 between all units; -1/+1 β(1,3) for that with a β-1,3 linkage between units -1 and +1; +1/+2 β(1,3) for
20 that with a β-1,3 linkage between units +1 and +2; and +2/+3 β(1,3) for that with a β-1,3 linkage
21 between units +2 and +3. The final coordinates for all trajectories can be accessed through the
22 following link: https://1drv.ms/f/s!ArX4zU6cjMUQnHQ9m5ScGJkyY_Kr

1 RESULTS

2 The *engA* gene was acquired from an ancestral clostridial bacterium

3 The *engA* gene (systematic ID: ZGAL_208), coding a single CAZyme module, is localized within
4 a potential polysaccharide utilization locus (PUL_4) [13] (Fig. 1). Besides *engA*, PUL_4 also includes
5 a gene encoding a lipoprotein of unknown function (ZGAL_209) displaying a C-terminal carbohydrate
6 binding module (CBM4) and two tandem susD/SusC-like pairs (ZGAL_211/212 and ZGAL_213/214)
7 (Fig. 1). PUL_4 was previously identified as strongly induced by β -1,3-glucans [33]. In the context of
8 the development of a new screening method for carbohydrate-related proteins, the susD-like protein
9 ZGAL_213 was shown to specifically bind xyloglucans [34]. Altogether, these transcriptomic and
10 biochemical results suggest that PUL_4, and thus likely the *engA*-encoded protein, which will be
11 named ZgEngA_{GH5_4}, could be involved in the degradation of hemicelluloses.

12 Homology searches in the GenBank database indicate that close homologues of ZgEngA_{GH5_4} are
13 relatively rare in other marine flavobacteria. Unexpectedly, this protein is highly similar to numerous
14 subfamily GH5_4 beta-glucanases from *Firmicutes* (e.g. 51% sequence identity with the cellulase
15 EngD from *Clostridium cellulovorans* [17]). A phylogenetic analysis of the GH5_4 subfamily
16 indicates that ZgEngA_{GH5_4} belongs to a clade only composed of marine flavobacterial proteins. This
17 late-diverging clade is rooted by two successive clades of GH5_4 proteins from *Firmicutes* (*Clostridia*
18 class) (Fig. 2). Therefore, the paucity of ZgEngA_{GH5_4} homologues in marine flavobacteria and their
19 phylogenetic position support that marine flavobacteria have horizontally acquired these GH5_4 genes
20 from an ancestral clostridial bacterium.

21 ZgEngA_{GH5_4} is a β -glucanase with broad substrate specificity

22 In the genome of *Z. galactanivorans*, *engA* was annotated as encoding for an endoglucanase,
23 referred here to as ZgEngA_{GH5_4}. To verify the prediction of this activity, the nucleotide sequence
24 corresponding to the catalytic module was cloned into a pFO4 plasmid. The protein was produced with
25 a yield of ~ 130 mg L⁻¹ in *E. coli* BL21(DE3) strain using an auto-inducible medium. The protein was
26 purified to electrophoretic homogeneity by nickel affinity chromatography (Fig. S3). The purity of the
27 enzyme was further confirmed by DLS (Fig. S3). Both SEC and SEC-MALLS were used to verify that

1 ZgEngA_{GH5_4} is a monomer in solution (Fig. S3). SEC-MALLS additionally showed that the enzyme is
2 characterized by a molecular weight of 36.5 kDa. This value is slightly lower than the theoretical
3 molecular weight of 37.5 kDa deduced from the amino acid sequence of the recombinant protein using
4 the ProtParam tool [35] (Fig. S1).

5 DLS was also used to study the thermostability of ZgEngA_{GH5_4} (Fig. S4A). Indeed, in the range of
6 temperatures from 5 to 37 °C, the protein is characterized by a hydrodynamic radius of gyration of
7 5.59 ± 0.12 nm. This value increases when temperature reaches 40°C and is almost doubled at a
8 temperature of 44°C, indicating the enzymatic denaturation which then further increases with
9 temperature.

10 The ferricyanide reducing sugar assay was used to screen for the hydrolytic activity of the
11 enzyme on several soluble β -glucans such as the carboxymethyl cellulose, lichenan, β -D-glucan from
12 barley, xyloglucan and konjac glucomannan. Activity was also screened on β -1,3-glucans such as
13 laminarin, a β -1,3-glucan from *Euglena gracilis* and carboxy methyl curdlan (a bacterial
14 exopolysaccharide) but revealed to be non detectable (Table 1). Although the enzyme is active on
15 soluble cellulose derivatives, its activity towards this substrate is very low, compared to its activity
16 towards mixed linked β -(1,4-1,3)-glucans, such as β -D-glucan from barley and lichenan from Iceland
17 moss. ZgEngA_{GH5_4} is also able to degrade substituted β -1,4-glycosides such as glucomannan and, to
18 some extent, xyloglucan (Table 1). Taken together, these results classify this enzyme as a β -(1,3-1,4)-
19 endoglucanase.

20 Prior to the determination of which linkage and which minimal substrate the enzyme is able to
21 hydrolyze, an evaluation of its optimal conditions was carried out. Using β -D-glucan (MLG) from
22 barley as substrate, the universal buffer of Teorell and Stenhagen, was used to study the pH
23 dependence of the activity of ZgEngA_{GH5_4}. The enzyme shows activity between pH 5.0 and 8.5 but
24 the optimum of activity is observed at pH 6.0-6.5 (Fig. S4B). At pH 5.5, the enzyme loses about 40%
25 of its activity, as it does at pH values above 8. Similar results have been observed using biological

1 buffers such as MES, MOPS, phosphate and Tris, further showing that the activity of the enzyme in
2 the MES buffer is higher than in the other ones (Fig. S4B).

3 β -D-glucan from barley was also used as substrate to study the influence of the temperature on
4 the enzyme activity. In this case, the substrate was first thermostated at different temperatures,
5 between 5 and 60°C, prior to the enzymatic reaction. As shown on Fig. S4C, the enzyme displays an
6 optimal activity at 45°C. At 50°C, the enzyme loses almost half of its activity, which drops to only
7 about 10 % at 60°C. In order to avoid denaturation, all the subsequent enzymatic reactions were
8 however performed at 30°C, a compromise temperature between enzymatic activity and stability. The
9 influence of NaCl was evaluated at different concentrations, up to 1M and seems to have no
10 significant effect on the enzymatic activity

11 **ZgEngA_{GH5_4} is able to cleave both β -1,3 and β -1,4 linkages**

12 To establish which linkages are cleaved by ZgEngA_{GH5_4}, different standard β -1,4 and β -(1,4-
13 1,3)-oligosaccharides were used as substrates. The hydrolysis products were identified by HPAEC
14 using a CarboPac PA1 column, specifically dedicated to the separation of small oligosaccharides.
15 From these experiments, it appears that, even when the reaction lasts overnight, ZgEngA_{GH5_4} is unable
16 to hydrolyze di- and tri-saccharides, whether they originate from cellulose or MLG polymers. A
17 minimum of 4 glucose units (G4) is therefore essential for the activity of the enzyme.

18 In a first step, the nature and the concentration of different products released during hydrolysis
19 of cello- oligosaccharides by ZgEngA_{GH5_4} were measured as a function of time (Fig. 3). While after
20 60 minutes, 20 % of cellotetraose (G4) remain to be hydrolyzed (Fig. 3A), hydrolysis of cellopentaose
21 and cellohexasaccharide are a lot faster as they both are completely hydrolyzed within 1 and 2 minutes,
22 respectively (Fig. 3B and C) Hydrolysis of cellopentaose (G5) is straightforward and produces only
23 cellobiose (G2) and cellotriose (G3) (Fig. 3B). Hydrolysis of cellohexasaccharide (G6) proceeds in two steps,
24 since both cellotetraose (G4) and cellotriose (G3) are produced within the first two minutes, however,
25 as hydrolysis proceeds, cellotetraose (G4) is further hydrolyzed into cellobiose (G2) (Fig. 3C).

26 In a next step, and to evaluate the ability of ZgEngA_{GH5_4} to hydrolyze β -1,3 linkages, two β -
27 (1,4-1,3)-tetrasaccharides, namely GGG3G and GG3GG, differing from each other by the position of

1 the β -1,3 linkage, were used as substrates. In GGG3G the β -1,3 linkage is at the reducing end, while it
2 is flanked by a β -1,4 linkage on both sides in GG3GG. Hydrolysis of GGG3G (G4B) yielded glucose
3 (G1), cellobiose (G2), cellotriose (G3) and laminaribiose (G3G; L2) (Fig. 3D) whilst only cellobiose
4 (G2) was produced upon hydrolysis of GG3GG (G4C) (Fig. 3E). Altogether, these results indicate that
5 ZgEngA_{GH5_4} is able to accommodate both β -1,4 and β -1,3 linked glucose in the +1 binding subsite,
6 whereas only β -1,4 linkages are accepted in the negative binding subsites (Fig. 4E and F). It also
7 shows that the specificity of ZgEngA_{GH5_4} is dictated by the position of the β -1,3 linkages.

8 Hydrolysis of oligosaccharides, as well as of β -D glucan from barley, was also followed by
9 FACE (Fig. 4A-D). The ANTS was used as a fluorophore to label the reducing end of the
10 oligosaccharides, which were then separated by electrophoresis. In addition to corroborating the
11 results obtained by HPAEC about the products formed upon hydrolysis of the oligosaccharides, this
12 technique showed in particular that cellotetraose and cellohexaose are hydrolyzed with different
13 modes. Indeed, depending on whether labeling was performed on the substrate or on the hydrolysis
14 products, the end products of these oligosaccharides are different: when cellotetraose (G4) is labeled
15 before hydrolysis (Fig. 4A), the fluorescent oligosaccharides migrate as cellotriose (G3) and minor
16 amounts of cellobiose (G2). When labeling is performed after hydrolysis (Fig. 4B), the major
17 oligosaccharide is cellobiose (G2), although there are traces of cellotriose (G3) and even of glucose
18 (G). Similarly, when labeling cellohexaose (G6) before hydrolysis mostly cellotriose (G3) but also
19 some cellobiose (G2) oligosaccharides are detected (Fig. 4A), whilst when cellohexaose (G6) is first
20 hydrolyzed and then labeled, both cellobiose (G2) and cellotriose (G3) are detected at the same
21 intensity (Fig. 4B).

22 Comparison of the end products generated from the hydrolysis of β -D-glucan with the
23 lichenase and with ZgEngA_{GH5_4} reveals that the size of the products are similar but the cleavage sites
24 of the enzymes are different (Fig. 4C). As expected, GG3G and GGG3G are the end products of the
25 MLG hydrolysis by lichenase, whilst G2, G3, G4 and to some extent G5 are the end products observed
26 after hydrolysis with ZgEngA_{GH5_4}. These oligosaccharides, as well as the complete absence of
27 oligosaccharides with β -1,3 bonds such as GG3G, GGG3G, G3GG and GG3GG attest therefore that,

1 at the polymer level, the preferred cleavage site of the *ZgEngA_{GH5_4}* are β -1,3 bonds that are
2 neighbored by β -1,4 bonds, at least towards the non-reducing end (Fig. 4G).

3 Further hydrolysis overnight with *ZgEngA_{GH5_4}* of the labeled oligosaccharides produced by the
4 lichenase shows that GG3G is not hydrolyzed whilst the complete hydrolysis of GGG3G into
5 laminaribiose (G3G) (Fig. 4D) is attained, again attesting thereby that, on small oligosaccharides,
6 *ZgEngA_{GH5_4}* is able to cleave the β -1,4 bond that precedes a β -1,3 bond (Fig. 4F). Altogether, these
7 experiments allow deducing the subsites and their involvement in substrate binding, and they also
8 show that the +1 or +2 binding subsites do not tolerate/accommodate the fluorophore (Fig. 4E and F).
9 Further interpretation of these results is described in the discussion below.

10 **Three-dimensional structure of *ZgEngA_{GH5_4}***

11 In order to determine the molecular basis of substrate recognition by *ZgEngA_{GH5_4}*, we solved the
12 crystal structure of *ZgEngA_{GH5_4}* wild-type and the E323S mutant (*ZgEngA_{GH5_4}E323S*) in complex with
13 the cellotriose (three glucose units linked by β -1,4 bonds) (Table 2). The structure of *ZgEngA_{GH5_4}* was
14 solved at 1.2 Å resolution by molecular replacement using the structure of EngD (PDB ID: 3NDZ,
15 51% sequence identity, Fig. 5) as a search model. There is only one molecule in the asymmetric unit.
16 The *ZgEngA_{GH5_4}* adopts a typical TIM-barrel (β/α)₈ fold. An additional helix (α 0) closes the β -barrel
17 at its N-terminal face, consistent with other GH5 enzymes (Fig. 6A). Structural similarity searches
18 using the DALI server [36] identified close relationship to other GH5 enzymes. The closest ones were
19 the structure of endoglucanase E from *Ruminiclostridium thermocellum* (PDB ID: 4IM4) and of
20 endoglucanase D from *Clostridium cellulovorans* (PDB ID: 3NDZ). Both are GH5 enzymes that
21 exhibit broad substrate specificity, preferentially displaying high activity on β -1,4 linked glucans and
22 xylans.

23 Like other GH5 enzymes, the active site is formed by a catalytic cleft, which runs across the
24 whole protein, where specific binding subsites recognize each glucose unit. Two glutamic acid
25 residues (E200 and E323, in *ZgEngA_{GH5_4}*) correspond to the catalytic acid-base and nucleophile
26 respectively, and are positioned between the -1 and +1 sub-binding sites (Figs. 6B, 7A). Consistently

1 with all other TIM-barrel hydrolases, these residues are located at the end of β -strands β 4 and β 7 (Fig.
2 5).

3 The co-crystallization of *ZgEngA*_{GH5_4_E323S} with a mixture of oligosaccharides (mainly hexa- to
4 nona-saccharides, all produced by the native enzyme upon hydrolysis of MLG) resulted in the
5 complex structure solved at 2.2 Å resolution, with three molecules in the asymmetric unit. A clear
6 electron density corresponding to a cellotriose (G3) oligosaccharide, linked by β -1,4 bonds only, is
7 present in the active site of each of the three monomers (Fig. 6B). The presence of this substrate
8 molecule could either be due to a contamination of our oligosaccharide mixture by cellotriose, which
9 are preferentially selected by *ZgEngA*_{GH5_4_E323S}, or additional units at the non-reducing end are
10 completely disordered in the crystal structure. These substrate molecules (further on named cellotriose
11 or G3) occupy the negative binding subsites from -3 to -1. The glucose unit bound to the -3 subsite
12 establishes a stacking interaction with W89. In the -2 subsite, N77 and N358 are involved in substrate
13 binding *via* hydrogen bonds. The glucose unit bound to the -1 subsite is the most stabilized one,
14 stacked against W356, and hydrogen bonded to H155, H156, Y277 and E200 (Fig. 6B).

15 A particular feature in *ZgEngA*_{GH5_4} is the loop following the β -strand β 8 that is shorter by 4
16 residues when compared to *CcEngD* (PDB ID: 3NDZ) or *CcCel5A* (PDB ID: 1EDG). This feature
17 creates a more open active site at the non-reducing end (negative binding subsites), which could
18 accommodate branched substrates (Fig.7B). Indeed, in the above mentioned other GH5 enzymes, this
19 loop binds the glucose unit occupying the -3 subsite, by forming hydrogen bonds between an Asp or
20 Glu residue and the O6 of this glucose unit. Here, the residue E363 is located too far to interact with
21 the substrate (Fig.7A).

22 Another outstanding feature is the conformation of residue Y280. Indeed, the loop between β -
23 strand β 6 α -helix α 6, carrying this residue, has a completely different conformation than in other GH5
24 enzymes (Fig. 7B). First, the presence of T287 directed towards the short α 6' helix can be noted,
25 whereas in other GH5, this threonine is substituted by a short residue which points to the solvent. This
26 feature forces D285 to adopt a different conformation compared to all other GH5 enzymes. To avoid a
27 steric clash with T287 or D285, the neighboring Y280 is orientated in the opposite direction compared

1 to tyrosine residues at this position of other GH5 enzymes. The change of conformation of this residue
2 is also possible by the presence of Q281, instead of an aromatic residue at this position in most of the
3 other GH5 enzymes, which would clash with Y280 in this orientation. Overall, the presence of Y280
4 that changes the loop position also leads to a narrowing of the binding cleft on the positive binding
5 subsites (Fig. S22A). Notably, when replacing Y280 by alanine (Fig. S22B) by computational
6 mutation, the overall substrate binding cleft resembles closely that of F32EG5 (Fig. S22C).

7 **Site directed mutagenesis of selected residues and molecular modeling to explore the catalytic** 8 **active site**

9 In order to investigate the role of a selection of residues in the active site, we undertook site
10 directed mutagenesis experiments. Based on the 3D structure analyses, we chose to mutate residues
11 that potentially interact with different polysaccharide substrates, outside the -1 sub-binding site, since
12 the importance of residues surrounding the -1 sub-binding site in substrate recognition and catalytic
13 activity has already been demonstrated [10, 37]. We also included two residues, Y82 and E363, which
14 are not directly involved in interaction with a linear polysaccharide but that could accommodate
15 branching in substrates, such as xyloglucan or glucomannan. However, mutation of both of these
16 residues does not affect the activity, even on branched substrate (Table 3). On the other hand,
17 replacement of the residues N77, H156, W210 or N358 by alanine substantially decreases or even
18 completely abolishes the catalytic activity. These residues interact with glucose units bound to the -2, -
19 1 and +1 subsites in the model obtained by molecular dynamics, respectively (Fig. 6B, C and D).
20 Mutation of W210 to phenylalanine partially restores the activity (about 40% of activity when
21 compared to ZgEngA_{GH5_4WT}), which supports the fact that this residue establishes van der Waals
22 contacts with the glucose unit positioned in the +1 subsite. Surprisingly, mutations of Y280 and K211,
23 which are thought to interact with glucose units bound to +2 and +3 subsites, respectively, did not
24 decrease the activity.

25 *Computed protein structure and molecular dynamics:*

26 We used atomic resolution molecular dynamics computer simulations to model the binding of the full
27 range of putative hexaose ligands (poorly resolved in the crystal structures) to wild type ZgEngA_{GH5_4}
28 and the mutant ZgEngA_{GH5_4_E323S} endoglucanases. The ligand structures are described in Methods.

1 Both native and mutated structures show preservation of the protein secondary structure throughout
2 the few-hundred nanosecond simulations (Figs. S5-S8 and Figs. S9-S12), even in cases where the
3 glucan substrate leaves the binding pocket. The computed Root Mean Square Deviations (RMSD) of
4 protein backbone non-hydrogen atoms in both mutant and native *ZgEngA_{GH5_4}* (Figs. S13, S14) were
5 within 0.2-0.3 nm, indicating a stable protein structure throughout the simulations. Calculated Root
6 Mean Square Fluctuations (RMSF) (Figs. S15, S16) show the steric freedom of the more flexible and
7 loose parts of the crystal structure such as turns and loops (residues 85-90, 125-126, 162-164 and 207-
8 211).

9 *Computed substrate dynamics – glucan in the binding site:*

10 The -1/+1 (β -1,3) oligosaccharide with a β -1,3 linkage between units -1 and +1 (see Experimental) and
11 the +1/+2 (β -1,3) glucan remain bound in 5 and 3 out of 8 repeats, respectively. The -1/+1 (β -1,3) and
12 +1/+2 (β -1,3) glucans remain bound in 5 and 3 out of 8 repeats, respectively. Computed glucan RMSD
13 values (Figs. S17-S18) show that -1/+1 (β -1,3) forms a stable binding interaction with both the native
14 (RMSD 0.24 ± 0.04 nm) and mutated *ZgEngA_{GH5_4_E323S}* (RMSD 0.26 ± 0.04 nm). The next most
15 strongly bound ligand was +1/+2 (β -1,3), followed by +2/+3 (β -1,3). The (β -1,4) glucan either
16 dissociates (4 out of 8 repeats) or else forms a loose complex with both the native and mutated enzyme
17 (4 out of 8 repeats) with high glucan RMSD values of up to 0.44 ± 0.14 nm. In all other simulations,
18 we observe either loose unstable binding of a substrate or dissociation into solution, and we did not
19 include these dissociated structures in the analysis of binding energetics below.

20 *Computed sugar – protein interactions:*

21 The number of hydrogen bonds forming between the protein and substrate were monitored over time
22 (Tables S6-S19) to identify protein residues contributing strongly to glucan binding (Figs. S19-S20).
23 Eight hydrogen bonds (Tables S20-S21) stabilize the glucan in both native and mutated enzyme
24 binding pockets. Namely, N77, E200, T253, H275, Y277, W356, N358, and E363.
25 The -1/+1 (β -1,3) glucan exhibits the most favorable affinity for both wildtype and mutated
26 *ZgEngA_{GH5_4_E323S}*, as it stays strongly bound to the protein by 6 or more hydrogen bonds (Tables S20-
27 S21) in 80% of the simulations. The computed MD structures in Fig. 6C and D show that T253 and

1 Y277 stabilize the sugar unit bound at the +3 subsite, W210 and E209 form H-bonds with +2, H275
2 and Y280 bind to +1, E200 binds to -1, and N358, W356, Y82 and N77 bind to the -2 subsite.
3 Aromatic residues also contribute to carbohydrate recognition and orientation (Tables S22-S23 and
4 Fig. 6C and D). Eight aromatic residues Y82, H155, W210, H275, Y277, Y280, W356 and F364 (Fig.
5 6C and D) interact with the substrate as it hydrogen bonds with adjacent polar and charged residues.
6 Computed binding energies (Table S24) show significantly stronger time-averaged substrate binding
7 to mutated ZgEngA_{GH5_4_E323S} than wildtype (-38.2 ± 10.6 kcal.mol⁻¹ vs. -22.5 ± 8.5 kcal.mol⁻¹). The -
8 1/+1 (β -1,3) glucan showed the strongest binding energy (-42.7 ± 9.0 kcal.mol⁻¹), consistent with its
9 low RMSD (Figs. S17-S18) and extensive H-bonding (Figs. S19-S20). By contrast, (β -1,4) showed the
10 weakest binding energies, reflecting its poor fit to the ZgEngA_{GH5_4} active site pocket. In the most
11 stable binding trajectories, the glucose chain is stabilized by H-bonding to approximately six polar and
12 charged residues and makes close contacts with adjacent aromatic residues. The ‘S-shaped’ binding
13 pocket better fits the natural conformation of the -1/+1(β -1,3)-linked glucan than the linear all (β -1,4)
14 ligand.

15 *Other insights from molecular modelling:*

16 In the last frame of two simulations between ZgEngA_{GH5_4_E323S} and GGGG3GG, the substrate is
17 correctly positioned in the catalytic cleft. Then, the glucose in the +1 binding subsite interacts by
18 stacking with W210. This interaction seems to be of high importance to position the substrate in such
19 way to enable catalysis. The β -1,3 linkage induces a turn, which allows stacking interaction between
20 glucose in +2 and Y280. However, this interaction seems to be more labile since it is present in only
21 one model out of three. The glucose in +3 seems to have more degrees of liberty, and it establishes
22 only weak contact with K211 and S252 (Fig. 6C).

23 In the simulations between ZgEngA_{GH5_4_E323S} and GGG3GGG, the turn induced by the β -1,3 does not
24 affect the stacking with W210, which is in a flexible loop. Indeed, in all simulations, it adapts its
25 position to interact with glucose in +1. Y280 does not establish stacking contact with the glucose in +2
26 but it interacts with the glucose unit in +3 via a hydrogen bond (Fig. 6D)

- 1 Fixation of the whole β -1,4 substrate or GGGGG3G, seems to be weaker, as only W210 interacts with
- 2 the substrate in the positive binding subsites.
- 3

1 DISCUSSION

2 The frequent classification of family GH5 enzymes as cellulases in marine *Flavobacteriia* [13,
3 16], despite the fact that these bacteria usually do not degrade crystalline cellulose [14, 15], is
4 puzzling. Therefore, and in the context of recent work highlighting that GH5 enzymes belong to one of
5 the largest, multi-specific glycoside hydrolase families [7, 10-12], covering a very large range of
6 activities, we applied a combination of methods spanning phylogeny, enzymology, crystallography
7 and molecular modeling to explore key enzyme-substrate interactions in *ZgEngA_{GH5_4}* that define its
8 substrate specificity. The comparison to other enzymes within GH5_4 reveals how substrate
9 specificity is fine-tuned, even within the GH5_4 subfamily, and sheds further light on the roles of this
10 subfamily in glucan catabolism. Taking the occurrence of this gene in a PUL that possibly is involved
11 in the catabolism of hemicelluloses as starting point, we show that cellulose and soluble β -1,4-glucan-
12 derivatives are not the preferred substrates. Instead, we demonstrate that *ZgEngA_{GH5_4}* is a β -(1,3-1,4)-
13 glucanase that preferably cleaves β -1,3 linkages flanked by β -1,4 linkages, but is also able to
14 hydrolyze β -(1,4)-linkages in glucomannan, or in short oligosaccharides, depending on the linkage
15 positions. The ability to hydrolyze β -(1,4) linkages in various substrates is common to EngD from *C.*
16 *cellulovorans* (the closest structural relative of *ZgEngA_{GH5_4}*), which has been described as a true
17 cellulase [38]. However, the relative activity of these two enzymes differs radically when using
18 xyloglucan or CMC as substrates. In those cases, *ZgEngA_{GH5_4}* is closer to other family GH5_4
19 members, such as PbGH5A from *Prevotella bryantii* and F32EG5 from *Caldicellulosiruptor* (Table 1).

20 Mapping the *ZgEngA_{GH5_4}* active site by the combination of crystallographic structure
21 determination together with molecular modeling and product analyses using different substrate
22 oligosaccharides, suggests the presence of six well defined binding subsites, evenly distributed with
23 respect to the cleavage point, three negative and three positive subsites. The crystal structure of the
24 inactivated mutant highlights the binding subsites on the non-reducing end to which the cellotriose
25 molecule (GGG) is bound. The molecular dynamic simulations using β -(1,3-1,4)-hexasaccharides that
26 differ by the position of the β -1,3-linkage corroborate this biochemically observed preference, since

1 GGG3GGG, spanning the positions from -3 to +3 displayed the most favorable affinity for the
2 catalytic cleft of ZgEngA_{GH5_4}. In this configuration, the β -1,3-linkage is positioned at the cleavage
3 site, in accordance with the preferred hydrolytic activity of the enzyme on polysaccharide.

4 The biochemical analyses also revealed that the smallest hydrolyzed substrates are
5 tetrasaccharides. More generally, the mode of hydrolysis of minimal substrates showed that activity is
6 favored when oligosaccharides are spanning the cleft using the -2 \rightarrow +2 subsites, but hydrolysis does
7 occur with modes spanning more subsites on the non-reducing end for GGG3G or on the reducing-end
8 for G4. Notably, oligosaccharides containing β -1,4-linkages only, such as cellulo-oligosaccharides G4
9 to G6 are also hydrolyzed, however at a much slower rate than the preferred substrates. This is
10 supported by molecular dynamics showing that cellulo-oligosaccharides were indeed much less
11 stabilized in the active site cleft than the MLG oligosaccharides. In the case of G6, G4 is the first
12 reaction product, meaning that for small oligosaccharides occupation of negative subsites
13 predominates over positive ones. The hydrolysis of the mixed linkage oligosaccharides GGG3G and
14 GG3GG also revealed the importance of the negative binding subsites in ZgEngA_{GH5_4}. GGG3G is
15 mainly hydrolyzed according to the -3 \rightarrow +1 binding mode, demonstrating therefore that binding in
16 subsite +2 is not essential for the hydrolysis of mixed linkage oligosaccharides. However, the absence
17 of hydrolysis of GG3GG in the same mode suggests that ZgEngA_{GH5_4} only tolerates β -1,4 bonds in
18 the negative subsites, and that the presence of β -1,4 linkage in these positions is essential for
19 hydrolysis of the neighboring β -1,3 linkage. In this respect, ZgEngA_{GH5_4} is closer to cellulases [9, 37,
20 38]. Indeed, eight residues (Figs. 5 and 6) present in the negative binding subsites (N77, H155, H156,
21 H275, Y277, W356 and N358) are well conserved throughout GH5_4 and typically bind to successive
22 β -1,4-linked glucose units. This binding mode is completely different to that of family GH16 enzymes
23 that cleave MLG (the so-called “lichenases”) that require a β -1,3 linkage in the negative subsites, a
24 feature common to the β -glucanases ZgLamA_{GH16} and ZgLamC from *Zobellia galactanivorans* [39,
25 40]. Interestingly, these enzymes are also able to cleave both β -1,3 and β -1,4 linkages but, unlike
26 ZgEngA_{GH5_4}, ZgLamA_{GH16} tolerate β -1,3 bonds in its negative subsites, rather than in the positive
27 subsites.

1 The ability to cleave both β -1,3 and β -1,4 bonds has been previously described for GH5_4
2 enzymes [41] and it has been recently studied in light of 3D structures for PbGH5A [11], F32EG5 [10]
3 and SdGluc5_26 [12]. Like *ZgEngA*_{GH5_4}, these enzymes have β -(1,3-1,4) glucanase activities 3 to 7
4 times higher than on CMC or cellulose. All of these enzymes require β -1,4-linkages between the -1
5 and -2 subsites and tolerate β -1,3-linkages in positive binding subsites. Nevertheless, subtle
6 differences in accommodating the MLG substrate in the active site cleft can be noted between these
7 enzymes. Although both *ZgEngA*_{GH5_4} and F32EG5 [10] tolerate both β -1,3 and β -1,4 bonds at the +1
8 and +2 subsites, they differ from each other by the fact that *ZgEngA*_{GH5_4} is unable to hydrolyze
9 oligotrioses and has strict specificity for β -1,4-linkages between the -1 and -2 subsites, whereas
10 F32EG5 only needs the -1 subsite to be occupied for activity [10]. The only structural difference
11 between these enzymes in the negative binding sites consists in a loop that carries N358 and E363
12 (N362 and E370 in F32EG5 PDB ID: 4X0V; N367 and E375 in [10]) (Fig. 7A). In F32EG5, E370
13 interacts with O6 of the glucose-unit bound in the -1 subsite, while the different loop conformation in
14 *ZgEngA*_{GH5_4} positions this residue far too distant (more than 7 Å between E363-OE1 and O6 of the
15 glucose unit bound in -1, making this interaction impossible (Fig. 7A). Indeed, the point mutant of
16 E363 in our study did not have any effect on the enzymatic activity. Contrarily, this additional
17 stabilization of a glucose unit bound to the -1 subsite in F32EG5 thus plausibly explains the major
18 difference between these two enzymes. The need to bind several β -1,4-linked glucose units at negative
19 subsites, in turn, is shared with PbGH5A and SdGluc5_26, although their sequence identities to
20 *ZgEngA*_{GH5_4} are lower (32% and 22% respectively) than to F32EG5 (41.5% sequence identity).
21 Notably, both in PbGH5A and SdGluc5_26 the binding cleft displays a more open space beyond
22 binding subsite -1 towards the non-reducing end, although the corresponding loops and residues are
23 highly diverse in these three enzymes. Apparently less tight binding of the unit bound to -1 implies
24 that more sites need to be occupied for substrate stabilization prior to cleavage.

25 Differences in loop arrangements are also present at the positive end of the active site cleft, even
26 within the GH5_4 subfamily. In this respect, *ZgEngA*_{GH5_4} has a uniquely featured loop between β 6
27 and α 6 (Fig. 7B) that influences the positioning of the substrate at the +1 and +2 binding sites. The

1 molecular dynamic simulations show that *ZgEngA*_{GH5_4} seems to display a rather flexible binding
2 mode in these sites, in agreement with the fact that the mutation of Y280, to our surprise, did not affect
3 activity. Apparently the general difference of the loop structure in *ZgEngA*_{GH5_4} is sufficient to shape
4 the binding cleft such that a mixed linked chain with the β -1,3-linkage positioned at the -1 \rightarrow +1
5 cleavage site is favored. In addition, the results of the product analyses of small oligosaccharides also
6 indicate that binding at the positive subsites +2 and +3 are not crucial for the enzymatic activity or
7 substrate specificity. In this context, it is interesting to note that activity at the level of the MLG
8 polysaccharide differs from that on small oligosaccharides, highlighting that although powerful and
9 useful for dissecting subtle substrate specificities, biochemical *in vitro* product analyses of
10 oligosaccharides artefactually show activities that might not be relevant under natural conditions.
11 Indeed MLG polysaccharides appear to be hydrolyzed by *ZgEngA*_{GH5_4} almost exclusively at the β -
12 1,3-linkages (Fig. 4C). *ZgEngA*_{GH5_4} also shows substantial activity on glucomannan as compared to
13 CMC and no activity at all on laminarin-like substrates that only contain β -1,3-linkages. These results
14 on polysaccharides seem to point towards the fact that the overall 3D structural conformation of the
15 polymeric chain also plays an important role for substrate specificity, and the kinked polysaccharide
16 chain of MLG (or a non-regular structure, as in glucomannan) is the preferred site of hydrolysis of this
17 enzyme. Interestingly, the bent or kinked active site cleft has also been described to be an important
18 feature of other GH5_4 members.

19 In summary, *in vitro* *ZgEngA*_{GH5_4} appears to be most active on plant hemicellulose substrates,
20 such as the polymers β -(1,3-1,4)-glucan and glucomannan, which raises the question of the functional
21 rationale behind this activity in the context of its ecologic and marine occurrence in *Z. galactanivorans*.
22 While its evolutionary origin clearly points towards acquisition through lateral gene transfer from
23 typical land-plant polysaccharide degrading bacteria, such as *C. cellulovorans*, the question remains
24 whether the enzyme in the context of the physiology of *Zobellia galactanivorans* has ‘specialized’ for
25 marine macro-algal cell wall components or if it remains specific of plant hemicelluloses. Arguments
26 can be found for both scenarios: several macroalgal species of the red lineage have been reported to
27 contain glucomannan as cell wall component [42], and mixed linkage glucans are reported in red and

1 brown algal species [4, 42]. Moreover, *engA* is found in a PUL like genetic context, next to
2 hypothetical proteins that are indicative of a potential involvement in degradation of to date
3 undescribed polysaccharide components. On the other hand, hemicellulosic polysaccharides, which
4 strongly resemble those of land plants, can also be found in the marine environment in seagrasses,
5 which could be the targeted natural substrate of this enzyme together with the adjacent PUL, for which
6 the SusD-like protein was found to recognize xyloglucan. The elucidation of the biochemical activities
7 and substrate specificities of the adjacent other components of the PUL-like structure may be the key
8 to unravel the precise natural cell wall substrates that are targeted by these proteins.

9

10 **ACCESSION NUMBERS**

11 The atomic coordinates and the atomic factors of both *ZgEngA_{GH5_4}* and *ZgEngA_{GH5_4_E323S}* have
12 been deposited at the Protein Data Bank collection (<http://www.pdb.org/>) as PDB ID: 6GL2 and PDB
13 ID: 6GL0 respectively. The modeling coordinates can be accessed through the following link:
14 https://1drv.ms/f/s!ArX4zU6cjMUQnHQ9m5ScGJkyY_Kr

15

1 **ACKNOWLEDGMENTS**

2 We are deeply grateful to Alexandra Jeudy for technical assistance especially in the crystallization
3 experiments of the wild-type enzyme. We thank the local contact support on the beamlines ID-14-4
4 and Proxima2 at the ESRF (Grenoble, France) and SOLEIL (Paris, France). JDo, SR, MG, AO, JDa
5 and MC are grateful to the EU for its support with regards to the CellulosomePlus Program (FP7-
6 NMP, project 604530). GM acknowledges support from the Agence Nationale de la Recherche (ANR)
7 with regard to the “Blue Enzymes” project (Reference ANR-14-CE19-0020-01). GM and MC are also
8 grateful to ANR for its support with regards to the investment expenditure program IDEALG
9 (<http://www.idealg.ueb.eu/>, grant agreement No. ANR-10-BTBR-04). DT thanks Science Foundation
10 Ireland (SFI) for support (Grant Number 15/CDA/3491) and for computing resources at the
11 SFI/Higher Education Authority Irish Center for High-End Computing (ICHEC).

12

13 **DECLARATION OF INTERESTS**

14 The authors declare that there are no competing interests associated with the manuscript.

15

16 **AUTHOR CONTRIBUTION STATEMENT**

17 GM, MC and SG conceived the study; AL performed the protein expression experiments of the wild
18 type enzyme. SR crystallized the wild type enzyme with ligand molecule. GM performed the
19 bioinformatics and phylogenetic analysis. MCB performed some preliminary hydrolysis kinetic
20 analysis of the wild type enzyme. SG produced and characterized the wild type enzyme. MC and JDa
21 solved the structure of the wild type enzyme. SR produced the mutants. SR also produced the ligand
22 she used for the crystallization of the mutant. JDo and SG performed the kinetic analysis of the
23 mutants. SG also performed the HPAEC and FACE experiments. JDo determined the X-Ray structure
24 of the mutants. MG, AO and DT performed the computer simulations. JDo, GM, MC and SG wrote

1 the manuscript with the help of AL and input from other co-authors. All authors approved the final
2 version of the manuscript.

1 **FIGURE LEGENDS**

2 **Figure 1: Gene composition of the Polysaccharide Utilization Locus 4 (PUL_4) from *Zobellia***
3 ***galactanivorans*.** The gene encoding the *ZgEngA_{GH5_4}* is colored in green; the other genes are colored
4 in blue. Abbreviations: CBM4, family 4 of carbohydrate binding modules; TBDT, TonB-dependent
5 transporter.

6 **Figure 2: Phylogenetic tree of *ZgEngA_{GH5_4}* homologues.** The phylogenetic tree was derived using
7 the maximum-likelihood approach with the program MEGA6 [19]. Numbers indicate the bootstrap
8 values in the maximum likelihood analysis. The sequence marked by a brown diamond correspond to
9 *ZgEngA_{GH5_4}*. The characterized enzymes are indicated by a black dot (biochemically characterized) or
10 a black triangle (biochemically and structurally characterized). For these latter enzymes, the PDB code
11 is indicated after the protein name. On the right, clades are delimited by brackets and their taxonomic
12 affiliations are indicated. The sequences used are listed in supplementary Table S25.

13 **Figure 3: Substrate specificity of *ZgEngA_{GH5_4}* studied by HPAEC.** Hydrolysis of cellotetraose (A),
14 cellopentaose (B), cellohexaose (C), tetraose B (GGG3G; G4B) (D) and tetraose C (GG3GG; G4C)
15 (E) from the mixed-linked glucan lineage with 0.5 μ M *ZgEngA_{GH5_4}*. Hydrolysis was performed as a
16 function of time at 30°C. Aliquots of the reaction mixture were withdrawn periodically and analyzed
17 by HPAEC-PAD on a CarboPac-PA1 column. The oligosaccharides produced were identified and
18 quantified via a standardization of the column performed with the different commercially available
19 oligosaccharides used at different concentrations.

20 **Figure 4: Terminal products of *ZgEngA_{GH5_4}* upon hydrolysis of standard oligocelluloses (A and**
21 **B), β -D- Glucan (C) or its hydrolysis products (D) and schematic representation of the**
22 **oligosaccharides accommodation in the active site (E and F).** In these experiments, incubations
23 were performed overnight at 30°C using 1 μ L of *ZgEngA_{GH5_4}* (100 nM) to hydrolyze 12.5 μ g
24 oligosaccharides (A, B and D) or 45 μ g of β -D glucan from barley (C). Commercial lichenase was
25 also used to completely hydrolyze β -D glucan from barley and to produce oligosaccharides that were
26 then incubated for 10 minutes at 100°C prior to being labeled and further hydrolyzed overnight at

1 30°C with ZgEngA_{GH5_4} (D). Commercial cello- and MLG- oligosaccharides were used as references.
2 The ¹⁰⁰ denotes oligosaccharides incubated with inactive ZgEngA_{GH5_4} and the * indicates that the
3 oligosaccharides were labelled before the enzymatic incubation with ZgEngA_{GH5_4}. (A and D).

4 (E and F): Schematic representation of cello- (E) and MLG- (F) oligosaccharides accommodation in
5 the active site of ZgEngA_{GH5_4}. The proposed cleavage sites deduced from HPAEC and/or FACE
6 experiments are indicated by a grey arrow. The grey circles represent the reducing end of the
7 oligosaccharides and the yellow circles represent the fluorophore used to label the reducing end sugar.
8 The modes of hydrolysis observed with the FACE experiments exclusively are depicted with yellow
9 circles and black outlines. When the mode of hydrolysis has been observed both by HPAEC and
10 FACE, the yellow circles are outlined in grey. The arrow between the cellohexaose (G6) and the
11 cellotetraose (G4) means that the hydrolysis product from the cellohexaose is further hydrolyzed into
12 cellobiose (G2). Cellobiose and cellotriose are not represented as they are not hydrolyzed by
13 ZgEngA_{GH5_4}. (G) Hydrolysis sites of MLG by ZgEngA_{GH5_4} deduced from FACE experiments (see
14 above for details). The proposed cleavage sites are indicated by grey arrows. In a comparative
15 purpose, the GH16 lichenase cleavage sites are indicated by dotted arrows.

16 **Figure 5:** Sequence alignment of ZgEngA_{GH5_4} with structurally characterized GH5_4. The sequence
17 alignment has been performed using MAFFT [18] and has been manually edited in Bioedit (©Tom
18 Hall) based on the superimposition of the different crystal structures. The final figure has been created
19 with using ESPript [43]. The sequences used in this alignment were as follows: CcEngD: the endo β-
20 1,4-glucanase/xylanase EngD from *Clostridium cellulovorans* (GenBank accession no. AAA23233.1;
21 residues 32-376; PDB ID: 3NDY); PbGH5A: the Mixed-linkage beta-Glucanase/Xyloglucanase from
22 *Prevotella bryantii* B14 (GenBank accession no. AAC97596.1, residues 584-924, PDB ID: 3VDH);
23 F32EG5: the β-(1.3-1.4) glucanase from *Caldicellulosiruptor* sp. (GenBank accession no.
24 AGM71677.1, residues 38-401, PDB ID: 4XOV), BpCel5C: Cel5C from *Butyvirbio proteoclasticus*
25 (GenBank accession no. ADL34447.1, residues 32-399, PDB code: 4NF7) and CcCel5A: the cellulase
26 Cel5A from *Clostridium cellulolyticum* (GenBank accession no. AAA23221.1; residues 40-403, PDB
27 ID: 1EDG). The α- and ₃₁₀ helices and the β-strands are represented as helices and arrows,

1 respectively, and β -turns are marked with TT. Dark shaded boxes enclose invariant positions, and light
2 shaded boxes show positions with similar residues. The catalytic residues and the residues chosen for
3 site-directed mutagenesis are marked by red triangles and blue dots, respectively.

4 **Figure 6:** Crystal structure of ZgEngA_{GH5_4} and the relative MLG substrate locations after molecular
5 modeling in all-atom simulations. (A) Crystal structure of ZgEngA_{GH5_4}. The central β -sheet
6 constituting the TIM barrel is shown in yellow, the additional α helix $\alpha 0$ in pale blue and the loop
7 between β -strand $\beta 6$ and α -helix 6 in red. Both catalytic residues are shown in sticks. (B) View of the
8 active site of ZgEngA_{GH5_4_E323S}. The cellotriose is shown in green and the position of the two catalytic
9 residues are shown in grey. The experimental electron density calculated as an 2Fo-Fc map and
10 contoured at a 2σ level is shown as grey mesh. The stereochemistry of the substrate molecule has
11 been validated using Privateer and the details are given in Table S26. (C) Resulting view of molecular
12 dynamics with GGGG3GG. The active site of ZgEngA_{GH5_4_E323S} in the last frame of the all-atom
13 simulation and the relative position of the GGGG3GG (in orange) substrate molecule are represented.
14 The positions of the different sub-binding sites are indicated. The arrow indicates the β -1-3 linkage.
15 (D) Resulting view of molecular dynamics with GGG3GGG. The active site of ZgEngA_{GH5_4_E323S} in
16 the last frame of the all-atom simulation and the relative position of the GGG3GGG (in orange)
17 substrate molecule are represented. The arrow indicates the β -1-3 linkage.

18 **Figure 7:** Superimposition of GH5_4 active sites. (A) Superimposition of the catalytic active sites of
19 ZgEngA_{GH5_4} (in yellow) with those of F32EG5 (PDB ID:4XOV in dark blue), of CcEngD in complex
20 with cellotriose (PDB ID:3NDZ in cyan, and cellotriose in green) and that of PbGH5A (PDB
21 ID:3VDH in light grey). The highly conserved residues surrounding the -1 binding subsite are shown,
22 highlighting the two major features that are different in the sugar binding subsites of ZgEngA_{GH5_4},
23 namely E363 and Y280. (B) Superimposition of the structure of ZgEngA_{GH5_4_E323S} (in blue) and the
24 structure of F32EG5 from *Caldicellulosiruptor sp.* F32 (in purple) showing the conformation of the
25 loop harboring Y280 between β -strand $\beta 6$ and α -helix 6. The GGG cellotriose molecule in the crystal
26 structure of ZgEngA_{GH5_4_E323S} is shown in green. The residue numbers for ZgEngA_{GH5_4_E323S} are
27 underlined.

Table 1. Activity of ZgEngA_{GH5_4} on different polysaccharides.

For comparative purpose, the relative activity of ZgEngA_{GH5_4} is compared to the relative activity of the commercial lichenase (Megazyme) and 3 GH5_4 enzymes characterized at the 3D structure level. Results for EngD *C. cellulovorans* [38], *Caldicellulosiruptor* sp. F32 [10] and PbGH5 from *Prevotella bryantii* [11] were calculated based on published enzymatic activities.

Substrate	ZgEngA _{GH5_4}	Lichenase	EngD	F32EG5	PbGH5A

SUPPLEMENTARY INFORMATION

Description of the simulated systems

The simulated systems were named after the position and type of linkage present in the sugar chain substrate in the simulation, (β -1,4 –for β -1,4 linkages between all units, -1/+1 β -1,3 – for β -1,3 linkage between units -1 and 1, +1/+2 β -1,3 – for β -1,3 linkage between units +1 and +2, +2/+3 β -1,3 – for β -1,3 linkage between units +2 and +3), so the full simulation name consists of two parts (protein name-linkage type and position) and an ‘M’ was added at the end in the case of the mutated structure. All the simulations and their lengths are listed in Tables S1-S2 and number of molecules and atoms in each simulation type is provided in Tables S3-S4.

Atomistic Molecular Dynamics Simulations - protocols

The CHARMM36 force field [1-3] was used to describe protein and glucan, with water simulated using the CHARMM36-compatible TIP3P model.[4] Periodic boundary conditions were employed in all three dimensions. The length of each covalent bond to hydrogen atom was preserved using the LINCS algorithm [5] which allowed a 2 fs time step. The simulations were carried out at constant pressure (1 bar) and temperature (310 K) using the Parrinello-Rahman and velocity-rescale methods, respectively [6,7]. For pressure, an isotropic scaling was employed, and the temperatures of the solute and the solvent were coupled separately. Lennard-Jones interactions were truncated at 1.0 nm and the particle mesh Ewald method [8] was used to compute all electrostatic interactions with a real space cut-off at 1.0 nm, 6th order beta spline interpolation, and a direct sum tolerance of 10^{-6} . Simulations were run at physiological salt concentrations of 150 mM KCl and counter ions were introduced to neutralize the total charge of the system. The binding of each glucan chain was simulated eight times (three repeats for native and five repeats for mutated GH5). All simulations were performed using the GROMACS 5.1 simulation package [9]

Binding energies - calculations

The molecular mechanics Poisson-Boltzmann surface area (MM-PBSA) method was used to estimate the binding energies ΔG_{bind} between glucan and protein by decomposing into contributions from gas phase energy (ΔE_{gas}), solvation energy (ΔG_{solv}), and an entropy term (T ΔS) as represented in the following equation [10]:

$$\Delta G_{\text{bind}} = \Delta E_{\text{gas}} + \Delta G_{\text{solv}} - T\Delta S \quad (1)$$

ΔE_{gas} is composed of bonded (bond, angle, torsion) and non-bonded interactions (van der Waals, electrostatic) and constitutes the MM part of MM-PBSA. The ΔG_{sol} term contains polar solvation and non-polar solvation energies and is usually computed using the solvent-accessible surface area (SASA) model, where the SASA is linearly dependent on the non-polar term.

In this work we use the gromacs tool `g_mmpbsa` [11] to calculate the MM-PBSA terms for the protein-glucan complex. Note the bonded contribution is by definition zero in the single-trajectory approach [11] and the entropy term is assumed negligible for similar ligands binding to the same pocket.(12) Therefore, binding energy is calculated as follows:

$$\Delta G_{\text{bind}} = \Delta E_{\text{MM}} + \Delta G_{\text{polar}} + \Delta G_{\text{nonpolar}} \quad (2)$$

ΔE_{MM} denotes the gas-phase energy consisting of electrostatic and van der Waals interactions, ΔG_{polar} represents polar solvation energy, and $\Delta G_{nonpolar}$ is the nonpolar solvation energy. Subsequently, the energy components ΔE_{MM} , ΔG_{polar} and $\Delta G_{nonpolar}$ of each complex were calculated for 100ns of simulations when the glucan is stably bound to the protein. The vacuum and solvent dielectric constants were set at 1 and 80, respectively. The solute dielectric constant was set to 4.

Visualization

All the snapshots and movies presented in this work were prepared using the VMD package [13].

Binding energies results

The computed binding energies stem from favorable van der Waals energy, electrostatic energy, and SASA energy, which are offset by polar solvation energy which opposes binding. For β -1,4 systems (least favorable binding), the average van der Waals energy, electrostatic energy, polar solvation energy and SASA energy were -33.0, -30.0, 42.5 and -27.8 kcal/mol, respectively. The van der Waals energy contribution among the three different substrate chains that included a β -1,3 linkage varied from -34.0 to -46.8 kcal/mol, electrostatic energy varied more strongly from -42.1 to -76.3 kcal/mol with the corresponding polar solvation energy penalties varying from +44.6 to +88.9 kcal/mol. The highest magnitude values of van der Waals, electrostatic and polar solvation energy were recorded in systems with β -1,3 linkage between the -1 and +1, again supporting the hypothesis that -1/+1 β -1,3 results in effective interactions between substrate and the GH5 binding pocket. The estimated free energies of binding are relatively high compared to studies carried out on similar proteins,[14,15] which may be due to force field effects and/or choice of dielectric constant for the buried protein pocket;[16] nevertheless the rank orderings of substrate binding should be predictive unless different substrate topologies cause large-scale resculpting of the binding pocket and/or diffuse to alternative binding sites at timescales beyond the sub-microsecond sampling of the simulations.

15 linkage is marked by the blue dot in the lefthand panel and the orange sphere in the righthand panel).
16 (C) +1/+2 β(1,3). (D) +2/+3 β(1,3). Protein (mutant ZgEngA_{GH5_4} E323S) is shown in cartoon
17 representation, colored according to secondary structure and overlaid with a space-filling cyan,
18 transparent surface; glucan is shown in as sticks and the β-1,3 linkage site is marked with an orange
19 van der Waals sphere. Water molecules are omitted for clarity.

20

21 **Figure S3: Purity (A and B) and oligomerization state (C and D) analysis of ZgEngA_{GH5_4}.**
22 (A and B) SDS- PAGE analysis (A) and DLS (B) were performed to check the purity of ZgEngA_{GH5_4}.
23 (A) in the SDS PAGE, the Precision Plus markers from BioRad (S) were used as standards. (B)
24 Dynamic light scattering (DLS) was carried out to estimate the size distribution of the molecules as a
25 function of their volume.

26 (C and D) Oligomerization state studies of ZgEngA_{GH5_4} using size exclusion chromatography (C) and
27 size exclusion chromatography coupled to multiple angle laser light scattering (MALLS)(D). Size
28 exclusion chromatography (C) was performed using a Superdex 75 HiLoad 16/60 column previously
29 equilibrated in 25 mM Tris HCl + 100 mM NaCl (pH 7.5) (Buffer B) and calibrated using the
30 following standard proteins: Conalbumin (C) (MW: 75 kDa); Ovalbumin (O) (MW: 43 kDa);
31 Carbonic anhydrase (CA) (MW: 29 kDa); Ribonuclease (R) (MW: 13.7 kDa) and Aprotinin (A) (MW:
32 6.5 kDa). Exclusion volume of the column was evaluated using a fresh solution of Dextran Blue 2000
33 (B) (MW > 2000 kDa). (D) Size exclusion chromatography coupled to MALLS was performed using a

1 Superdex 200 Increase 10/300GL previously equilibrated in Buffer B. Elution of ZgEngA_{GH5_4} was
2 performed at a flow rate of 0.5 mL min⁻¹ and its calculated molar mass is shown (dotted line).

3
4 **Figure S4: Thermostability of ZgEngA_{GH5_4} (A) and influence of pH (B) and temperature (C) on**
5 **its activity.** All these experiments have been carried out in triplicate. The activity was measured using
6 the ferricyanide assay and the results are expressed as percentage of relative activity. (A) The
7 thermostability of ZgEngA_{GH5_4} was studied by DLS in a temperature range of 5 to 65 ° C in steps of 1
8 ° C. The hydrodynamic gyration radius (R_g) was measured at each step and the values are the average
9 of triplicate experiments. (B) The pH optimum was determined using the Teorell and Stenhagen buffer
10 in a range of pH from pH 4.2 to pH 8.5. This buffer was used at a 100 mM concentration to prepare
11 both enzyme (100 nM) and β-D-glucan (0.2%) solutions. pH optimum of the enzyme was further
12 checked using biological buffers (MES, MOPS, Tris and Phosphate) in similar conditions. Note that
13 these later experiments have only been performed in duplicate. (C) Optimal temperature of
14 ZgEngA_{GH5_4} was determined by incubating both enzyme and substrate at the appropriate temperature
15 before performing the hydrolysis reaction.

16

17 **Figure S5. Secondary structure of the protein in time for β-1,4 during three repeats.** Even if no
18 protein-glucan binding was observed for this complex, the protein shows relative structural stability in
19 all three trajectories as seen in panels A, B and C below.

20

21 **Figure S6. Secondary structure of the protein in time for model -1/+1 β-1,3 during three repeats**
22 **are shown in panels A, B and C below.** Out of the three trajectories, protein-glucan binding was
23 observed in only B. However, on comparing panels A, B and C it can be seen that the relative
24 secondary structure (mainly α-helices and β-sheets) of the protein is not affected by glucan
25 binding/dissociation.

26

34 **are shown in panels A, B and C below.** Out of the three trajectories, protein-glucan binding was
35 observed in only B. However, on comparing all three trajectories, panels A, B and C, it can be

1 observed that the relative secondary structure (mainly α -helices and β -sheets) of the protein, in this
2 complex, is not affected by glucan binding/ dissociation.

3

4 **Figure S9. Secondary structure of the protein in time for model β -1,4_M during five repeats** are
5 shown in panels A, B, C, D and E below. Out of the five trajectories, protein-glucan binding was
6 observed in C and E. However, on comparing all five panels it can be seen that the relative secondary
7 structure (mainly α -helices and β -sheets) of the protein is not affected by glucan binding/dissociation.

8

9 **Figure S10. Secondary structure of the protein in time for model -1/+1 β -1,3_M during five**
10 **repeats** are shown in panels A, B, C, D and E below. Protein-glucan binding was observed in four (B,
11 C, D and E) of the five trajectories and all panels below show relative secondary structure stability
12 through the simulations.

13

14 **Figure S11. Secondary structure of the protein in time for model +1/+2 β -1,3_M during five**
15 **repeats** are shown in panels A, B, C, D and E below. Out of the five trajectories, protein-glucan
16 binding was observed in A and C. However, on comparing all five panels it can be seen that the
17 relative secondary structure (mainly α -helices and β -sheets) of the protein is not affected by glucan
18 binding/ dissociation.

19

20 **Figure S12. Secondary structure of the protein in time for model +2/+3 β -1,3_M during five**
21 **repeated simulations** are shown in panels A, B, C, D and E below. Out of the five trajectories,
22 protein-glucan binding was observed in A and D. However, on comparing all five panels it can be seen
23 that the relative secondary structure (mainly α -helices and β -sheets) of the protein is not affected by
24 glucan binding/ dissociation.

25

26 **Figure S13. Root mean square deviation plots of backbone non-hydrogen atoms in mutated**
27 **ZgEngA_{GH5_4_E323S} simulations.** A, B, C, D, E – -1/+1 β -1,3_M (repeats 1-5 respectively); F, G, H, I, J
28 – +1/+2 β -1,3_M; K, L, M, N, O – +2/+3 β -1,3_M; P, Q, R, S, T – β -1,4_M are shown below. In
29 panels I, J, P and S, simulations were not continued when the respective glucan chain was seen to
30 dissociate from the protein binding cleft. The most stable RMSD (plateau) is observed in panels A-E,
31 corresponding to mutated ZgEngA_{GH5_4_E323S} complex β -1,3_M.

32

33 **Figure S14. Root mean square deviation graphs of backbone non-hydrogen atoms in wildtype**
34 **ZgEngA_{GH5_4} simulations.** A, B, C – -1/+1 β -1,3 (repeats 1-3 respectively); D, E, F – +1/+2 β -1,3; G,
35 H, I – +2/+3 β -1,3; J, K, L – β -1,4 are shown below. Simulations were not continued when the glucan

1 chain was seen to dissociate from the protein binding cleft early on in the trajectory. These are panels
2 A, E, G and I

3

4 **Figure S15. Root mean square fluctuations of C α atoms in the mutant ZgEngA_{GH5_4_E323S}**
5 **simulations.** A, B, C, D, E – -1/+1 β -1,3_M (repeats 1-5 respectively); F, G, H, I, J – +1/+2 β -1,3_M;
6 K, L, M, N, O – +2/+3 β -1,3_M; P, Q, R, S, T – β -1,4_M are shown below. From these, it can be
7 observed that the more flexible and loose parts of the crystal structure such as turns and loops are
8 along residue regions 85-90, 125-126, 162-164 and 207-211

9

10 **Figure S16. Root mean square fluctuations of C α atoms in the wildtype ZgEngA_{GH5_4} simulations.**

11 A, B, C – -1/+1 β -1,3 (repeats 1-3 respectively); D, E, F – +1/+2 β -1,3; G, H, I – +2/+3 β -1,3; J, K, L –
12 β -1,4. Similar to mutated ZgGH5, the more flexible and loose parts of the crystal structure such as
13 turns and loops are along residue regions 85-90, 125-126, 162-164 and 207-211.

14

15 **Figure S17. Root mean square deviation of glucan backbone structure atoms in mutated**

16 **ZgEngA_{GH5_4_E323S}.** A, B – β -1,4_M (repeats 3 and 5 respectively); C, D, E, F – -1/+1 β -1,3_M
17 (repeats 2-5 respectively); G, H – +1/+2 β -1,3_M (repeats 1 and 3 respectively); I – +2/+3 β -1,3_M
18 (repeat 1). Trajectories where glucan dissociation is observed are not shown in the graphs below.
19 Panels C-F show highly stable binding of glucan -1/+1 β -1,3 with mutated ZgEngA_{GH5_4_E323S}.

20

21 **Figure S18. Root mean square deviation of glucan backbone structure atoms in native**

22 **ZgEngA_{GH5_4}.** A, B – β -1,4 (repeats 1 and 2 respectively); C – -1/+1 β -1,3 (repeat 2); D – +1/+2 β -1,3
23 (repeat 3); E – +2/+3 β -1,3 (repeat 2). Stable glucan-protein binding is observed in panels C and E.

24

25 **Figure S19. Timelines of hydrogen bonds for glucan binding to mutant ZgEngA_{GH5_4_E323S}.** A, B,

26 C, D, E – -1/+1 β -1,3_M (repeats 1-5 respectively); F, G, H, I, J – +1/+2 β -1,3_M; K, L, M, N, O –
27 +2/+3 β -1,3_M; P, Q, R, S, T – β -1,4_M are shown below. Total loss of hydrogen bonding in panels I,
28 J, L, M, P, Q and S correspond to glucan dissociation from the protein. Most stable binding is
29 observed in panels B-E for -1/+1 β -1,3_M complex

30

31 **Figure S20. Timelines of hydrogen bonds for glucan binding to wildtype ZgEngA_{GH5_4}.** A, B, C – -

32 -1/+1 β -1,3 (repeats 1-3 respectively); D, E, F – +1/+2 β -1,3; G, H, I – +2/+3 β -1,3; J, K, L – β -1,4.
33 Glucan dissociates from the protein in trajectories A, E, G, I and L, hence the number of hydrogen
34 bonds between glucan-protein goes down to zero in these cases.

35

1 **Figure S21. Percentage of occurrence of interatomic contacts < 0.35 nm in the last 200 ns of the**
2 **simulations of mutant ZgEngA_{GH5_4_E323S}.** A – -1/+1 β -1,3_M repeat 2, B – -1/+1 β -1,3_M repeat 3,
3 C – +1/+2 β -1,3_M repeat 1, D – +1/+2 β -1,3_M repeat 3, E – +2/+3 β -1,3 repeat 1, F – β -1,4 repeat 3
4 are shown below. Main residues involved in ZgEngA_{GH5_4_E323S} and glucan binding involve H155,
5 E200, E209, W210, T253 H275, Y277, Y280, W356, N358 and F364

6

7 **Figure S22: Conformation of the loop harboring Y280, between β -strand β 6 and α -helix 6.** (A)
8 Surface representation of the structure of the active site of ZgEngA_{GH5_4_E323S}. (B) Surface
9 representation of the ZgEngA_{GH5_4_E323S} Y280A model. (C) Surface representation of the structure of
10 the active site of F32EG5. The surface of the active site of F32EG5 is quite identical to that of Y280A
11 mutant.

Table S2. List of the simulated systems with the number of simulations and sampling lengths (in ns) for mutated protein ZgEngA_{GH5_4_E323S}. Bound structures were sampled for approx. 500 ns (0.5 μ s); simulations in which the substrate completely unbound were terminated early.

No	Name	Description	Number of simulations with stable bound glucan	Number of simulations	Lengths (ns)
1	β -1,4_M	Mutated protein ZgEngA _{GH5_4_E323S} with 6 glucose units substrate with 1,4 linkages	2	5	232, 336, 500, 250, 521
2	-1/+1 β -1,3_M	Mutated protein ZgEngA _{GH5_4_E323S} with 6 glucose units substrate with 1,3 link between -1 and +1 subsites	4	5	500, 500, 500, 515, 521
3	+1/+2 β -1,3_M	Mutated protein ZgEngA _{GH5_4_E323S} with 6 glucose units substrate with 1,3 link between +1 and +2 subsites	2	5	500, 500, 500, 350, 200
4	+2/+3 β -1,3_M	Mutated protein ZgEngA _{GH5_4_E323S} with 6 glucose units substrate with 1,3 link between +2 and +3 subsites	1	5	500, 500, 415, 510, 522

Table S3. List of the simulated systems with the number of simulations and lengths (in ns) for native protein ZgEngA_{GH5_4}.

No	Name	Description	Number of simulations with stable bound glucan	Number of simulations	Lengths (ns)
1	β-1,4	Protein with 6 glucose units substrate with 1,4 linkages	0	3	520, 520, 520
2	-1/+1 β-1,3	Protein with 6 glucose units substrate with 1,3 link between -1 and +1 subsites	1	3	250, 509, 535
3	+1/+2 β-1,3	Protein with 6 glucose units substrate with 1,3 link at position between +1 and +2 subsites	1	3	500, 242, 528
4	+2/+3 β-1,3	Protein with 6 glucose units substrate with 1,3 link between +2 and +3 subsites	1	3	355, 503, 223

Table S4. Composition of the simulated systems – mutated protein *ZgEngA*_{GH5_4_E323S}.

No	Name	Protein molecules	Substrate	K+	Cl-	Water molecules	Total number of atoms
1	β -1,4_M	1	1	68	48	15 660	52 391
2	-1/+1 β -1,3_M	1	1	68	48	15 664	52 403
3	+1/+2 β -1,3_M	1	1	66	46	15 189	50 974
4	+2/+3 β -1,3_M	1	1	66	46	15 193	50 986

Table S5. Composition of the simulated systems – native protein.

No	Name	Protein molecules	Substrate	K+	Cl-	Water molecules	Total number of atoms
1	β -1,4	1	1	68	48	15 660	52 420
2	-1/+1 β -1,3	1	1	69	48	15 666	52 414
3	+1/+2 β -1,3	1	1	69	48	15 669	52 423
4	+2/+3 β -1,3	1	1	69	48	15 193	52 438

Table S6. Percentage of hydrogen bond occurrence during the last 200 ns of the simulation β -1,4 repeat 1. BGLC stands for the glucose unit (numbering 1 to 6 corresponds to +3 to -3 range). Values below 5% are not shown in the table.

Notes: ^a ΔE_{vdw} van der Waals contribution; ΔE_{ele} , electrostatic contribution; the sum of ΔE_{vdw} and ΔE_{ele} represent gas-phase energy; ΔG_{polar} , polar solvation energy; $\Delta G_{\text{nonpolar}}$, non-polar solar energy; the sum of ΔG_{polar} and $\Delta G_{\text{nonpolar}}$ is the solvation free energy; $\Delta G_{\text{bind}} = \Delta E_{\text{ele}} + \Delta E_{\text{vdw}} + \Delta G_{\text{polar}} + \Delta G_{\text{nonpolar}}$. Error values were obtained by calculating standard deviation.

BGC	C	0.569	299.804	3.76075	beta	D	⁴ C ₁	0.87	33.0627	Ok

¹Q is the total puckering amplitude, measured in Angstroems.

²Whenever N is displayed in the D/L column, it means that Privateer has been unable to determine the handedness based solely on the structure.

³RSCC, short for Real Space Correlation Coefficient, measures the agreement between model and positive omit density. A RSCC below 0.8 is typically considered poor.
