Received 2001 May 19; accepted 2001 June 26

Revised orbital elements of the visual binary stars STT 515, BU 4 AB, STF 183 AB, A 207, STT 43 and A 2413 are given. Dynamical parallaxes and total masses of the systems have been calculated.

Key words: visual binaries: orbits – stellar masses – dynamical parallaxes

1. Introduction

The present work is a continuation of the revision of some orbits of visual binary stars (Aristidi et al. 1999, Scardia et al. 2000 a), which are no longer valid, using the speckle observations obtained by the PISCO speckle camera developed by Observatoire Midi-Pyrénées and used on the Cassegrain focus of the 2-meter *Télescope Bernard Lyot* (TBL) of the Pic du Midi Observatory (Aristidi et al. 1997, Aristidi et al. 1999, Scardia et al. 2000 b). The procedures used for the revision of the orbital elements, the calculation of the sum of the masses of the system, and respective uncertainty, and the graphic representation of the results are the same as in the previous work (Scardia et al. 2000a). The values of the stellar masses as a function of the spectral type, used as reference, have been taken from Straizys and Kuriliene (1981). In the tables containing the ephemerides column 1 contains the date in years, column 2 the separation ρ in arcsec and column 3 the position angle θ in degrees. In the tables of the O-C, restricted for reasons of space to the observations following 1978, column 1 contains the date in years, column 2 the observed separation ρ in arcsec, column 3 the $\Delta\rho(O - C)$, column 4 the observed position angle θ (reduced to 2000) in degrees, column 5 the $\Delta\theta(O - C)$, column 6 the number of nights and column 7 the name of the observer. The figures show the apparent orbit obtained by us and the observations used for the calculation of the orbital elements. The orientation of the orbit is in conformity with the convention accepted by the observers of visual binary stars.

2. WDS 01095 +4715 – STT 515 – ADS 940

The binary star has been well observed. The observations are quite numerous, but very scattered before 1940 when, because of the narrow separation and the strong brightness of the principal star, the couple was difficult to observe. The previous orbit of Baize (1958), although still acceptable in position angle, shows systematic residuals in separation. Thus we have recalculated the orbital elements obtaining:

| | | | |
|-------|---|----------|--------------|
| node | = | 142.3 | (2000) |
| omega | = | 249.0 | |
| i | = | 148.0 | A = -0.09028 |
| e | = | 0.258 | B = -0.38062 |
| T | = | 1886.926 | F = -0.41605 |
| P | = | 391.0 | G = 0.14864 |
| n | = | 0.92072 | |
| a | = | 0.450 | |

This orbit is preliminary. The real period is probably long ($P > 400$ years), but for the moment it is, like the other orbital elements, still uncertain (Fig. 1). The parallax measured by the satellite Hipparcos is $0''.00443 \pm 0''.00080$. The sum of the masses of the system, corresponding to such a measurement, is $6.9 M_{\odot}$, slightly in excess for a binary of a spectral type B7Ve, while the semi-major axis is 101.6 A.U.. The dynamical parallax is $0''.0033$, in reasonable agreement with the measured one; but this calculated parallax is not acceptable because it leads to an exaggerated sum ($16.8 M_{\odot}$) of the masses of the system.

3. WDS 01213 +1132 – BU 4 AB – ADS 1097

The previous orbit of Muller (1954) has a period which is too short and no longer represents the observations either in position angle or in separation. At the small separations BU 4 AB is a difficult couple to observe because of the great difference in magnitude between the components. Our observation (1998.679 PIC) is the first speckle observation of this binary. The orbit is very eccentric and there are no observations near the perihelion between 1920 and 1945 when the components were at a distance of less than $0''.15$ (Fig. 2). Thus we have recalculated the orbital elements of BU 4 AB obtaining:

```

node = 147.0          (2000)
omega = 242.4
i = 133.1            A = 0.02362
e = 0.868             B = -0.30558
T = 1943.069          F = -0.36809
P = 242.7             G = 0.08730
n = 1.48331
a = 0.402

```

Our geometrical elements do not differ much from those found in 1954 by Muller, but our orbit, of degree 3, is however more eccentric and the period is longer. The Hipparcos parallax is $0''.00616 \pm 0''.00141$, to which corresponds a sum of the masses of the system of $4.7 M_{\odot}$, in excess for a binary of spectral type F1III (but C.D.S. report F0), while the semi-major axis is 65.3 A.U..

4. WDS 01551 +2847 – STF 183 AB – ADS 1522

The binary star has been well observed. The orbits of Couteau (1973) and Starikova (1982) do not represent recent observations. The observations made before 1950 appear very scattered both in separation and position angle perhaps because of the considerable difference in magnitude between the components. Some perplexity is caused by the most recent observation available (1999.736 WSI) using speckle interferometry, because it leaves a strangely large residual in position angle.

| | | | | |
|---------|----------|-----|-------|--------------|
| node = | 174.0 | +/- | 1.2 | (2000) |
| omega = | 304.9 | " | 5.5 | |
| i = | 116.6 | " | 1.3 | A = -0.29155 |
| e = | 0.473 | " | 0.032 | B = -0.14660 |
| T = | 1969.505 | " | 1.3 | F = -0.37866 |
| P = | 276.1 | " | 26.4 | G = 0.16344 |
| n = | 1.30388 | " | 0.12 | |
| a = | 0.480 | " | 0.024 | |

Our orbit, of degree 3, has a shorter period and less eccentricity. The orbital elements are quite well defined, only the period is still rather uncertain (Fig. 3). The Hipparcos parallax is $0''.00727 \pm 0''.00189$. The sum of the masses of the system, corresponding to such a measurement, is $3.8 M_{\odot}$, with an uncertainty of 82%, in excess for a binary of spectral type F2, while the semi-major axis is 66.0 A.U.. The dynamical parallax is $0''.0074$, agreeing well with the observed one.

5. WDS 02182 +3920 – A 207 – ADS 1762

The orbit of Heintz (1975) no longer represents observations and the most recent one of Scardia (1982), although still acceptable, is based on visual observations which stopped in 1976. Our observation (1998.679 PIC), carried out at Pic du Midi with the B. Lyot telescope, is the first speckle observation of this binary. The measurement taken in 1991.25 by the satellite Hipparcos appears to be in disagreement with the observations made from the ground in the same years.

| a = | 0.310 | " | 0.048 | |

Our orbit is preliminary because all the orbital elements are still rather uncertain (Fig. 4). The measurement of the parallax taken by the satellite Hipparcos is $0''.01200 \pm 0''.00311$; it seems to be overestimated and leads to a sum of the masses of the system of $0.46 M_{\odot}$, which is frankly unacceptable for a system of spectral type F5. In 1981 Scardia, on the basis of a spectrum taken at Merate with the telescope Ruths, having a diameter of 137 cm, and a spectrograph Boller and Chivens mod. 31523 (dispersion 114 Å/mm), classified this star as being of spectral type F9 (Scardia, 1982). The dynamical parallax is $0''.0065$; the corresponding sum of the masses of the system is $2.87 M_{\odot}$.

6. WDS 02407 +2637 – STT 43 – ADS 2034

Heintz's orbit (1962) has not represented observations in separation for a long time. For that reason we recalculated a new set of orbital elements having a substantially shorter period. Although this star lends itself well to observation with speckle interferometry (the magnitudes of the components are 7.55 and 8.77) up to now there have been only three observations made with this technique and they have been concentrated within the last 5 years. The observations are quite numerous, but very scattered in separation.

```

node = 39.0      (2000)
omega = 203.8
i     = 124.2    A = -0.75647
e     = 0.324    B = -0.35398
T     = 1804.422  F = -0.00889
P     = 289.2    G = 0.57912
n     = 1.24481
a     = 0.886

```

Our orbit must be considered as being preliminary (degree 4) because the arc of the observed orbit is only 90° and is placed completely around the aphelion (Fig. 5). The parallax measured by Hipparcos is 0".01385 ± 0".00125. The corresponding total mass of the system is $3.1 M_{\odot}$, overestimated for a star of spectral type F7V, while the semi-major axis is 64.0 A.U. long. The dynamical parallax is 0".0149 agreeing well with the measured one.

7. WDS 02572 +0153 – A 2413 – ADS 2236

The previous orbits of Scardia (1980) and Heintz (1991) by now leave systematic residuals on the observations both in position angle and in separation. We therefore recalculated the orbital elements obtaining:

```

node = 4.6      +/- 0.7      (2000)
omega = 274.5   "      3.4
i     = 69.7     "      1.1      A = 0.06516
e     = 0.4593   "      0.014    B = -0.20815
T     = 1929.241 "      0.44     F = 0.60979
P     = 115.8    "      4.5      G = 0.06586
n     = 3.10880  "      0.12
a     = 0.615    "      0.036

```

This orbit, of degree 3, is by now well defined and will certainly change very little in the future. Only the period is still slightly uncertain. The parallax measured by Hipparcos is 0".02012 ± 0".00150. The sum of the

masses of the system, corresponding to such a value, is $2.1 M_{\odot}$, with an uncertainty of 29%, agreeing very well with the values foreseen for a system of spectral type G0. The semi-major axis is 30.6 A.U.. Compared to the orbit calculated by Scardia in 1980, the total mass of the system, whose uncertainty was then of 55%, is now much better defined. The dynamical parallax is $0''.0193$, well in agreement with the measured parallax (Fig. 6).
