LOCAL LIMIT THEOREM IN DETERMINISTIC SYSTEMS

ZEMER KOSLOFF AND DALIBOR VOLNY

Dedicated to Manfred Denker whose work is an inspiration for us.

Abstract. We show that for every ergodic and aperiodic probability preserving system, there exists a \( \mathbb{Z} \)-valued, square integrable function \( f \) such that the partial sums process of the time series \( \{ f \circ T^n \}_{n=0}^{\infty} \) satisfies the lattice local limit theorem.

1. Introduction

Given an ergodic, aperiodic and probability measure preserving dynamical system \((X, \mathcal{B}, m, T)\), we show the existence of a measurable square integrable function \( f \) with zero mean such that its corresponding ergodic sums process \( S_n(f) := \sum_{k=0}^{n-1} f \circ T^k \) satisfies the lattice local central limit theorem.

A centered function \( f : X \to \mathbb{R} \) satisfies the central limit theorem if for all \( u \in \mathbb{R} \)
\[
m \left( \frac{S_n(f)}{\|S_n(f)\|_2} \leq u \right) \xrightarrow{n \to \infty} \int_{-\infty}^{u} e^{-x^2/2} dx.
\]

A function \( f : X \to \mathbb{Z} \) with \( \int f dm = 0 \) such that \( \lim_{n \to \infty} \frac{\|S_n(f)\|_2}{n} = \sigma^2 > 0 \) satisfies a lattice local central limit theorem if
\[
\sup_{x \in \mathbb{Z}} \left| \sqrt{n} \cdot m (S_n(f) = x) - \frac{e^{-x^2/(2n\sigma^2)}}{\sqrt{2\pi n\sigma^2}} \right| \xrightarrow{n \to \infty} 0.
\]

There is also a non-lattice version of the local limit theorem which we do not consider in this paper. A function which satisfies the central limit theorem will be called a CLT function and if \( f \) satisfies a local central limit theorem (whether lattice or non-lattice) we will say that \( f \) is a LCLT function.

In case the measure theoretic entropy of the system is positive, it follows from the Sinai factor theorem that there exists a function \( f : X \to \mathbb{Z} \) taking finitely many values such that the sequence \( \{ f \circ T^n \}_{n=0}^{\infty} \) is distributed as an i.i.d. sequence. From this it is easy to construct a LCLT function.

The question of existence of a central limit function for a zero entropy system such as an irrational rotation is more subtle. In the case of certain zero entropy Gaussian dynamical systems, Maruyama showed in [17] existence of CLT functions such that the variance of \( S_n(f) \) grows linearly with \( n \). Some years later, the seminal paper of Burton and Denker [4] showed that for every aperiodic dynamical system there exists a function \( f \) which satisfies the central limit theorem.

By [20], the set of CLT functions is a meagre set in \( L^2_0 := \{ f \in L^2(m) : \int f dm = 0 \} \). See also [16] and [17] for such results in other function spaces.

Following [4], several extensions and improvements regarding existence and bounds of the regularity of CLT functions were done, see for example [12, 14, 15, 6]. The most relevant to this work is [21] where for every aperiodic dynamical system, a function satisfying the invariance principle and the almost sure invariance principle was constructed. More recently the question of weak convergence to other distributions was studied in [3, 19].

In the dynamical systems setting, it is in general a nontrivial problem to determine whether a function which satisfies the central limit theorem also satisfies the local central limit theorem. In fact, even in the nicer setting of chaotic (piecewise) smooth dynamical systems a local CLT is usually proved under more stringent spectral conditions, see for example [18, 11, 4, 2] and

The research of Z.K. was partially supported by ISF grant No. 1570/17.
For sequences \( a \) measure preserving transformations. See [10], [13] for results in a similar flavor. This section is concerned with the following realization of triangular arrays in arbitrary ergodic formation. For every finite set \( A \) be an \( \mathbb{A} \)-valued triangular array. In our setting this means \( \{X_{n,m}\}_{n \in \mathbb{N}, m \in \{1, \ldots, d_n\}} \) is an independent array of random variables.

This section is concerned with the following realization of triangular arrays in arbitrary ergodic measure preserving transformations. See [10], [13] for results in a similar flavor.

**Proposition 1.** Let \((X, \mathcal{B}, \mu, T)\) be an ergodic invertible probability measure preserving transformation. For every finite set \( A \), and an \( A \)-valued triangular array \( \mathcal{X} := \{X_{n,m}\}_{n \in \mathbb{N}, m \in \{0, \ldots, d_n - 1\}} \), there exists a sequence of functions \( f_n : X \to A \) such that \( \{f_n \circ T^m\}_{n \in \mathbb{N}, m \in \{0, \ldots, d_n - 1\}} \) and \( \mathcal{X} \) have the same distribution.

The construction of the functions \( f_n \) is by induction on \( N \in \mathbb{N} \) so that \( \{f_n \circ T^m\}_{1 \leq n \leq N, m \in \{0, \ldots, d_n - 1\}} \) and \( \{X_{n,m}\}_{1 \leq n \leq N, m \in \{1, \ldots, d_n\}} \) have the same distribution. For a fixed \( N \) one can consider \( \xi \), the finite partition of \( X \) according to the value of the vector valued function

\[
(G_N)_{n,m}(x) := f_n \circ T^m(x), \quad 1 \leq n \leq N, \quad 0 \leq m \leq d_n - 1.
\]

For this reason the previous Proposition is a corollary of the following proposition.

**Proposition 2.** Let \((X, \mathcal{B}, m, T)\) be an ergodic invertible probability measure preserving transformation and \( \xi \) a finite measurable partition of \( X \). For every finite set \( A \) and \( X_1, X_2, \ldots, X_l \) a collection of \( A \) valued i.i.d. random variables, there exists \( f : X \to A \) such that \( \{f \circ T^i\}_{i=0}^{l-1} \) and \( \{X_i\}_{i=1}^{l} \) are equally distributed and \( \{f \circ T^i\}_{i=0}^{l-1} \) is independent of \( \xi \).

The proof makes use of Alpern-Rokhlin castles. Given \( N \in \mathbb{N} \), a \( \{N, N+1\} \) Alpern-Rokhlin castle for \((X, \mathcal{B}, m, T)\) is given by two measurable sets \( B_N, B_{N+1} \) such that

- \( \{T^j B_L : L \in \{N, N+1\}, \quad 0 \leq j < L \} \) is a partition of \((X, \mathcal{B}, m)\) to pairwise disjoint sets.
- We call \( B_N, B_{N+1} \) the base elements of the castle and the atoms in the corresponding partition are referred to as runs. We call \( T^N B_N \uplus T^{N+1} B_{N+1} \) the top of the castle.
Given $\xi$, a finite partition of $X$, a $\{N, N + 1\}$ castle is $\xi$ independent if every rung in the castle is independent of $\xi$. All equalities of sets mean equality modulo null sets.

**Proof.** By [3][Corollary 1], there exists a $\xi$-independent $\{2l, 2l + 1\}$ castle with bases $B = B_{2l}$ and $F = B_{2l+1}$. Note that as $T$ is invertible then,

$$T (T^{2l-1}B \cup T^{2l}F) = B \cup F.$$ 

Let $\zeta_1$ be the partition of the top of the tower $\{T^{2l-1}B, T^{2l}F\}$ which is its refinement according to $\vee_{i=0}^l T^i \xi$. First we define $f : \cup \{T^{-j}C : C \in \zeta_1, 0 \leq j < l\} \to A$ as follows. Partition each $C \in \zeta_1$ to $A^l$ elements $\{C_a : a \in A^l\}$ such that for every $a = (a_i)_{i=0}^{l-1} \in A^l$,

$$m(C_a) = m(C) \prod_{i=0}^{l-1} \mathbb{P}(X_{i+1} = a_i).$$

and set $f(T^{-l+1+i}x) = a_i, i = 0, \ldots, l-1$, if there exists $a \in A^l$ and $C \in \zeta_1$ such that $x \in C_a$.

It remains to define $f$ in the bottom rungs of the tower. By $\zeta_1'$ we denote the refinement of $\zeta_1$ by the sets $C_a$. By $\zeta'$ we denote the joint partition of the base of the castle by $T^{-2l+1}(\zeta_1' \cap T^{2l-1}B), T(\zeta_1' \cap T^{2l+1-2}B), T^{-2l}(\zeta_1' \cap T^{2l}F), T(\zeta_1' \cap T^{2l+1}F)$.

For every $C \in \zeta'$ we do as follows. If $C \subset B$ then partition $C$ to $A^l$ elements $\{C_a : a \in A^l\}$ such that for every $a = (a_i)_{i=0}^{l-1} \in A^l$,

$$m(C_a) = m(C) \prod_{i=0}^{l-1} \mathbb{P}(X_{i+1} = a_i)$$

and set $f(T^ix) = a_i$ if there exists $a \in A^l$ and $C \in \zeta$ such that $x \in C_a$.

If $C \subset \zeta \cap F$ we do the same with $l+1$ replacing $l$.

For any $C \in \zeta_1$ we thus have

$$m\left((T^{-l+1}C) \cap \left(\cap_{i=0}^{l-1} \left[f \circ T^i = a_{i+1}\right]\right)\right) = m(T^{-l+1}C) \prod_{i=1}^{l} \mathbb{P}(X_i = a_i),$$

for $C \in \zeta \cap B$ we have

$$m\left(C \cap \left(\cap_{i=0}^{l-1} \left[f \circ T^i = a_{i+1}\right]\right)\right) = m(C) \prod_{i=1}^{l} \mathbb{P}(X_i = a_i),$$

and for $C \in \zeta \cap F$ we have

$$m\left(C \cap \left(\cap_{i=0}^{l} \left[f \circ T^i = a_{i+1}\right]\right)\right) = m(C) \prod_{i=1}^{l+1} \mathbb{P}(X_i = a_i).$$

Moreover, for $C \in \zeta_1 \cap T^{2l-1}B$ the sets $T^{-2l+1}C_a$ are independent of $(f \circ T^i)_{i=0}^1$ (conditionally on $T^{-2l+1}C$) hence

$$m\left((T^{-2l+1}C) \cap \left(\cap_{i=0}^{2l-1} \left[f \circ T^i = a_{i+1}\right]\right)\right) = m(C) \prod_{i=1}^{2l} \mathbb{P}(X_i = a_i) \tag{1}$$

and for $C \in \zeta_1$ with $T^{-2l}C \subset F$ we have

$$m\left((T^{-2l}C) \cap \left(\cap_{i=0}^{2l} \left[f \circ T^i = a_{i+1}\right]\right)\right) = m(C) \prod_{i=1}^{2l+1} \mathbb{P}(X_i = a_i). \tag{2}$$

Let $C \in T^{-2l+1}(\zeta_1 \cap T^{2l-1}B)$ or $C \in T^{-2l}(\zeta_1 \cap T^{2l}F)$, $0 \leq k \leq l$. We have

$$T^kC \cap \left(\cap_{i=0}^{2l-1-k} \left[f \circ T^i = a_{i+k+1}\right]\right) = T^k(C \cap \left(\cap_{i=k}^{2l-1-k} \left[f \circ T^i = a_{i+1}\right]\right)).$$
by (1) and (2) we get
\[ m \left( \left( T^k C \right) \cap \left( \cap_{i=0}^{2l-k} \left[ f \circ T^i = a_{i+k+1} \right] \right) \right) = m(T^k C) \prod_{i=k+1}^{2l} \mathbb{P}(X_i = a_i). \] (3)

Let us show a similar equation for \( T^{-l+1} C, C \in \zeta \).

We have
\[ T^l \left( \left( T^{-l+1} C \right) \cap \left( T^{-1} B \right) \cap \left( \cap_{i=0}^{2l-1} \left[ f \circ T^i = a_{i+1} \right] \right) \right) = (B \cap TC_a) \cap \left( \cap_{i=0}^{2l} \left[ f \circ T^i = a_{i+l+1} \right] \right) \]
and the same equality holds for \( F \), hence
\[ m \left( \left( T^{-l+1} C \right) \cap \left( T^{-1} B \right) \cap \left( \cap_{i=0}^{2l-1} \left[ f \circ T^i = a_{i+1} \right] \right) \right) = \]
\[ m \left( (B \cap TC_a) \cap \left( \cap_{i=0}^{2l} \left[ f \circ T^i = a_{i+l+1} \right] \right) \right) \]
and
\[ m \left( \left( T^{-l+1} C \right) \cap \left( T^{-1} F \right) \cap \left( \cap_{i=0}^{2l-1} \left[ f \circ T^i = a_{i+1} \right] \right) \right) = \]
\[ m \left( (F \cap TC_a) \cap \left( \cap_{i=0}^{2l} \left[ f \circ T^i = a_{i+l+1} \right] \right) \right). \]

Therefore,
\[ m \left( \left( T^{-l+1} C \right) \cap \left( \cap_{i=0}^{2l-1} \left[ f \circ T^i = a_{i+1} \right] \right) \right) = m \left( (T^{-1} C) \cap \left( \cap_{i=0}^{2l} \left[ f \circ T^i = a_{i+l+1} \right] \right) \right) \]
and by independence of \( \zeta \) and \( f, \ldots, f \circ T^{l-1} \) on \( B \cup F \) we deduce
\[ m \left( \left( T^{-l+1} C \right) \cap \left( \cap_{i=0}^{2l-1} \left[ f \circ T^i = a_{i+1} \right] \right) \right) = m(TC_a) m \left( (B \cup F) \cap \left( \cap_{i=0}^{2l} \left[ f \circ T^i = a_{i+l+1} \right] \right) \right) \]
= \[ m(C_a) \prod_{i=1}^{l} \mathbb{P}(X_i = a_{i+l+1}) \]
\[ = m(C) \prod_{i=1}^{2l} \mathbb{P}(X_i = a_{i}). \]

Recall that if \( C \in \zeta \) and \( a = (a_i)_{i=1}^{l} \in A^l \) then
\[ T^{-l+1} C_{a} = T^{-l+1} C \cap \left( \cap_{i=0}^{2l} \left[ f \circ T^i = a_{i+1} \right] \right). \]

Therefore,
\[ m \left( \left( T^{-l+1} C \right) \cap \left( \cap_{i=0}^{2l-1} \left[ f \circ T^i = a_{i+1} \right] \right) \right) = m \left( (T^{-l+1} C) \cap \left( \cap_{i=0}^{2l} \left[ f \circ T^i = a_{i+l+1} \right] \right) \right) \]
\[ = m(C) \prod_{i=1}^{2l} \mathbb{P}(X_i = a_{i}), \]

hence
\[ m \left( \left( T^{-l+1} C \right) \cap \left( \cap_{i=0}^{2l} \left[ f \circ T^i = a_{i+1} \right] \right) \right) = m(\left( T^{-l+1} C \right)) \prod_{i=1}^{2l} \mathbb{P}(X_i = a_{i}). \]

For \( 0 \leq k \leq l - 1 \) we thus have
\[ m \left( \left( T^{-l+k+1} C \right) \cap \left( \cap_{i=0}^{2l} \left[ f \circ T^i = a_{i+1} \right] \right) \right) = m(\left( T^{-l+1} C \right)) \prod_{i=1}^{2l} \mathbb{P}(X_i = a_{i}). \] (4)

We show that \( f \) satisfies the conclusion of the proposition. Let \( D \in \xi \) and \( a \in A^l \). We claim that
\[ m \left( D \cap \left( \cap_{i=0}^{l} \left[ f \circ T^i = a_{i+1} \right] \right) \right) = m(D) \prod_{i=1}^{l} \mathbb{P}(X_i = a_{i}). \] (5)

Let \( Y \) be a rung of the castle. Since the castle is \( \xi \)-independent, \( m(D \cap Y) = m(D)m(Y) \) and \( D \cap Y \) is a finite union of sets of the form \( T^{-r} C \) with \( C \in \zeta_1 \) and \( r \) a fixed integer, \( 0 \leq r \leq 2l - 1, 2l \). (Depending on the tower of the castle to which \( Y \) belongs.) Denote \( C' = T^{-r} C \).
Let us define \( f \) a realization of this triangular array. This step is crucial in what follows.

However, Proposition 2 enables us to get property (b) which is more than needed. To explain how we apply the proposition, the values of the functions \( g \) and \( f \) into this definition the sequence of functions \( \bar{X} \) sequence of i.i.d. random variables with values \( \xi \) distribution.

Proof. Proposition 3. \( f \) is a triangular array. It is worth to note that each of the function \( f \) is a coboundary with transfer function \( U \). For \( k \in \mathbb{N} \), we define \( p_k := \begin{cases} 2^k, & k \text{ even} \\ 2^k - 1, & k \text{ odd} \end{cases} \) and \( d_k := 2^{k^2} \) and \( \alpha_k := \frac{1}{p_k \sqrt{k \log k}} \).

By a repeated inductive iteration of Proposition 2 there exists a sequence of functions \( \hat{f}_k : X \to \{-1, 0, 1\} \) such that:

(a) For every \( k \in \mathbb{N} \), \( \{\hat{f}_k \circ T^j\}_{j=0}^{2d_k + p_k} \) is an i.i.d. sequence, \( \{-1, 0, 1\} \) valued and \( \mu(\hat{f}_k = 1) = \mu(\hat{f}_k = -1) = \frac{\alpha_k^2}{2} \).

(b) For every \( k \geq 2 \), the finite sequence \( \{\hat{f}_k \circ T^j\}_{j=0}^{2d_k + p_k} \) is independent of \( \mathcal{A}_k := \{\hat{f}_l \circ T^j : 1 \leq l < k, 0 \leq j \leq 2d_k + p_k\} \).

To explain how we apply the proposition, the values of the functions \( g \in \mathcal{A}_k \) induce a partition \( \xi \) of \( X \) into \( 3^{2d_k + p_k} \) elements. Write \( X_1, X_2, X_3, \ldots, X_{2d_k + p_k} \) for an i.i.d. sequence such that \( X_1 \) is \( \{-1, 0, 1\} \) distributed with \( \mathbb{E}(X_1) = 0 \) and \( \mathbb{E}(X_1^2) = \alpha_k^2 \) and apply Proposition 2. In this definition the sequence of functions \( \{\hat{f}_k \circ T^j : k \in \mathbb{N}, 0 \leq j \leq 2d_k + p_k\} \) is a triangular array. However, Proposition 2 enables us to get property (b) which is more than a realization of this triangular array. This step is crucial in what follows.

Let us define \( f := \sum_{k=1}^{\infty} f_k \) where for each \( k \in \mathbb{N} \),

\[
f_k := \sum_{i=0}^{p_k - 1} U^i \hat{f}_k - U^{d_k} \left( \sum_{i=0}^{p_k - 1} U^i \hat{f}_k \right).
\]

It is worth to note that each of the function \( f_k \) is a coboundary with transfer function \( g_k := \sum_{j=0}^{d_k - 1} \sum_{i=0}^{p_k - 1} U^{i+j} \hat{f}_k \). \( f_k = g_k - Ug_k \).

**Proposition 3.** \( f \in L^2(X, \mu) \).

**Proof.** Fix \( k \in \mathbb{N} \) and write \( V_{k,i} := U^i \hat{f}_k - U^{d_k + i} \hat{f}_k \) where \( i \in \{0, 1, \ldots, p_k - 1\} \). This is a sequence of i.i.d. random variables with \( f_X V_{k,i} d\mu = 0 \) and \( \|V_{k,i}\|^2 = 2\alpha_k^2 \). Therefore

\[
\|f_k\|_2^2 = \int_X \left( \sum_{i=0}^{p_k - 1} V_{k,i} \right)^2 \, d\mu
\]
By condition (b) in the definition of the $f_k$’s, the functions $f_1, f_2, \ldots$ are independent. As they are also centered,
\[
\|f\|^2 = \sum_{k=1}^{\infty} \|f_k\|^2 \leq \sum_{k=1}^{\infty} \frac{2}{p_k} < \infty.
\]
We conclude that $f$ is well defined. \hfill \Box

**Theorem 4.** The function $f : X \to \mathbb{R}$ satisfies the local limit theorem with $\sigma^2 := 2(\log 2)^2$. That is
\[
\sup_{x \in \mathbb{Z}} \left| \sqrt{n} \mu(S_n(f) = x) - \frac{e^{-x^2/(2n\sigma^2)}}{\sqrt{2\pi n}} \right| \xrightarrow{n \to \infty} 0.
\]

**Discussion on the steps in the proof of Theorem 4.** The beginning of the proof is done by an argument similar to the one in Terence Tao’s blogpost on local limit theorems. The first step, which is done in the next subsection, is to prove the central limit theorem. This is done by calculating the second moments and verifying the Lindeberg condition. The choice of $d_k$ instead of an exponential sequence as in [21] is used in this step.

In the course of the proof of the CLT, $S_n(f)$ is decomposed into a sum of several independent random variables and we identify the main term, which we will call in this discussion $Y_n$. By Proposition 16, the local limit theorem for $S_n(f)$ is equivalent to the local limit theorem for the main term $Y_n$.

In Section 4 we show the local limit theorem for $Y_n$. There we use Fourier inversion and the CLT to reduce the local limit theorem to a question about uniform integrability of certain functions. In this step the choice of $p_k$ will help with a strong aperiodicity type statement which appears in the proof of Lemma 12. One problem we encounter, which is not present in the proof of classical local limit theorems, is that it seems a difficult problem to control the Fourier expansion of $Y_n$ around zero for an interval of fixed size (or a scaled interval of length constant times $\sqrt{n}$). We overcome this problem by obtaining a sharp enough aperiodicity bound which reduces the estimate around zero to an interval of length constant times $\sqrt{n}$ as in Lemma 13.

### 3.1. Proof of the CLT.

We start by presenting $S_n(f)$ as a sum of three terms depending on the scale of $k$ with respect to $n$. That is
\[
S_n(f) = Z_{Sm}(n) + \hat{Y}(n) + Z_{La}(n).
\]

where
\[
Z_{Sm}(n) := \sum_{k : d_k \leq n} S_n(f_k),
\]
\[
\hat{Y}(n) := \sum_{k : p_k < n < d_k} S_n(f_k),
\]
\[
Z_{La}(n) := \sum_{k : n \leq p_k} S_n(f_k).
\]

**Lemma 5.** For every $n \in \mathbb{N}$ the random variables $Z_{Sm}(n), \hat{Y}(n), Z_{La}(n)$ are independent and
\[
(a) \|Z_{Sm}(n) + Z_{La}(n)\|^2 = O \left( \frac{n}{\sqrt{\log n}} \right).
\]
\[
(b) \frac{1}{\sqrt{n}} \hat{Y}(n) - \frac{1}{\sqrt{n}} S_n(f) \xrightarrow{n \to \infty} 0 \text{ in } L^2(X, \mu).
\]

**Proof.** For each $k \in \mathbb{N}$, $S_n(f_k)$ is a sum of functions from the sequence $\{f_k \circ T^i\}_{i=0}^{n+d_k+p_k-1}$.

For all $k$’s appearing in the sums describing $\hat{Y}(n)$ and $Z_{La}(n)$, one has $n < d_k$, therefore $\hat{Y}(n)$ and $Z_{La}(n)$ are sums of functions of the form $\{f_k \circ T^i\}_{i=0}^{2d_k+p_k}$ with $k > \sqrt{\log n}$ and $Z_{Sm}(n)$ is
a sum of functions from \( \{ f_k \circ T^i \}_{i=0}^{2d_k + p_k} \) with \( k \leq \sqrt{\log n} \) and \( k^* \) is the smallest integer such that \( k^* > \sqrt{\log n} \).

By property (b) in the definition of the \( f_k \)'s we see that \( Z_{Sm}(n) \) is independent of \( \hat{Y}(n) \) and \( Z_{La}(n) \). A similar reasoning using property (b) of the functions \( f_k \) shows that \( Z_{Sm}(n), \hat{Y}(n), Z_{La}(n) \) are independent.

We now turn to prove part (a). Since \( f_k = g_k - U g_k \) then

\[
Z_{Sm}(n) = \sum_{k: \text{ } d_k \leq n} (g_k - U^n g_k).
\]

By independence of \( \{ f_k \circ T^i \}_{i=0}^{2d_k + p_k} \),

\[
\|g_k\|_2^2 = \sum_{j=0}^{d_k + p_k - 1} (\# \{ (l, i) \in [0, d_k) \times [0, p_k) : l + i = j \})^2 \|f_k\|_2^2
\]

\[
< \alpha_k^2 p_k^2 (p_k + d_k) \leq \frac{2k^2 + 1}{k \log k}.
\]

The functions \( \{ g_k \}_{k=1}^\infty \) are centered and independent, thus

\[
\left\| \sum_{k: \text{ } d_k \leq n} g_k \right\|_2^2 = \sum_{k: \text{ } d_k \leq n} \|g_k\|_2^2
\]

\[
\leq 2 \sum_{k: d_k \leq n} \frac{2k^2}{k \log k}
\]

\[
= 2 \sum_{k: \log n \leq k \leq \sqrt{n}} \frac{2k^2}{k \log k} = O \left( \frac{n}{\sqrt{\log n}} \right),
\]

where the last inequality follows from Lemma 17. As \( U \) is unitary it follows that

\[
\|Z_{Sm}(n)\|_2^2 = O \left( \frac{n}{\sqrt{\log n}} \right). \tag{7}
\]

It remains to bound \( \|Z_{La}(n)\|_2^2 \). First note that for \( k \) such that \( n \leq p_k \), by independence of the summands

\[
\|S_n (f_k)\|_2^2 = 2 \sum_{j=0}^{p_k - 1 + n} (\# \{ (i, l) \in [0, p_k - 1] \times [0, n - 1] : i + l = j \})^2
\]

\[
\leq 2n^2 (n + p_k) \alpha_k^2 \leq 4n^2 \left( \frac{1}{p_k k \log k} \right)
\]

where the last inequality holds as \( n \leq p_k \). The random variables \( \{ S_n (f_k) \}_{k: \text{ } p_k \geq n} \) are independent and their sum is \( Z_{La}(n) \), therefore

\[
\|Z_{La}(n)\|_2^2 = \sum_{k: \text{ } n \leq p_k} \|S_n (f_k)\|_2^2 \leq 4n^2 \sum_{k: \text{ } n \leq p_k} \frac{1}{p_k k \log k}.
\]

Since in addition, \( p_k \leq 2^k \), then

\[
\sum_{k: \text{ } n \leq p_k} \frac{1}{p_k k \log k} \leq \frac{1}{\log n} \sum_{k: \text{ } n \leq p_k} \frac{1}{p_k} \leq \frac{4}{n \log n},
\]

and \( \|Z_{La}(n)\|_2^2 = O \left( \frac{n}{\log n} \right) \). This together with (7) implies part (a). Part (b) is a direct consequence of part (a).

**Lemma 6.** \( \lim_{n \to \infty} \left( \frac{1}{n} \|S_n (f)\|_2^2 \right) = 2(\ln 2)^2 =: \sigma^2 \)
Proof. By Lemma 5(b) it is enough to show that
\[
\lim_{n \to \infty} \left\| \hat{Y}(n) \right\|_2^2 = 2(\ln 2)^2.
\] (8)

For a \( k \) with \( p_k < n < d_k \) we have,
\[
S_n(f_k) = \sum_{j=0}^{n-1} \sum_{i=0}^{p_k-1} U^{i+j} \tilde{f}_k - U^{d_k} \sum_{j=0}^{n-1} \sum_{i=0}^{p_k-1} U^{i+j} \tilde{f}_k
\]

hence
\[
\hat{Y}(n) = \sum_{k: p_k < n < d_k} S_n(f_k) = \sum_{k: p_k < n < d_k} [(A_k + B_k + C_k) - U^{d_k} (A_k + B_k + C_k)]
\]

where
\[
A_k := \sum_{i=0}^{p_k-1} (i + 1) U^{i} \tilde{f}_k, \quad B_k := n \sum_{i=0}^{p_k-1} U^{i} \tilde{f}_k, \quad C_k := (n + p_k - 1) \sum_{i=0}^{n-p_k} U^{i} \tilde{f}_k.
\]

Using independence of \( U^i \tilde{f}_k \), \( 0 \leq i \leq p_k - 1 \), we deduce
\[
\|A_k\|_2^2 \leq \sum_{i=0}^{p_k-2} (i+1)^2 \frac{1}{p_k^2 k \log k} \leq \frac{p_k}{k \log k} \leq \frac{2^k}{k}
\]

By Lemma 18 we derive,
\[
\sum_{k: p_k < n < d_k} \|A_k\|_2^2 \leq \sum_{k: p_k < n < d_k} \frac{2^k}{k} \leq \sum_{k: \sqrt{\log n} < k < \log n} \frac{2^k}{k} = O\left( \frac{n}{\log n} \right).
\]

Similarly we derive
\[
\sum_{k: p_k < n < d_k} \|C_k\|_2^2 = O\left( \frac{n}{\log n} \right).
\]

Finally,
\[
\sum_{k: p_k < n < d_k} \|B_k\|_2^2 = \sum_{k: p_k < n < d_k} (n + 1 - p_k) \alpha_k^2 \frac{2^k}{k \log k} \sim \left[ n \sum_{k: p_k < n < d_k} \frac{1}{k \log k} - \sum_{k: p_k < n < d_k} \frac{p_k}{k \log k} \right].
\]

By Lemma 18
\[
\sum_{k: p_k < n < d_k} \frac{p_k}{k \log k} \sim \sum_{k: \sqrt{\log n} < k < \log n} \frac{2^k}{k} = O\left( \frac{n}{\log n} \right).
\]

Since \( \lim_{k \to \infty} \frac{\log p_k}{k} = 1 \), then
\[
\sum_{k: p_k < n < d_k} \frac{1}{k \log k} \sim \sum_{k: \sqrt{\log n} < k < \log n} \frac{1}{k \log k}
\]

\[
\sim \int_{\sqrt{\log n}}^{\log n} \frac{dx}{x \log x} = (\ln 2)^2.
\]

\[
\int_{\sqrt{\log n}}^{\log n} \frac{dx}{x \log x} = \ln 2 \left( \ln \ln(\log x) - \ln \ln(\sqrt{\log x}) \right) = (\ln 2)^2
\]
The random variables $A_k, B_k, C_k, U^{d_k}A_k, U^{d_k}B_k, U^{d_k}C_k$, where the index $k$ satisfies $p_k < n < d_k$ are all independent, whence
\[
\frac{\|Y(n)\|^2}{n} = \frac{2}{n} \sum_{k: p_k < n < d_k} \left( \|A_k\|^2 + \|B_k\|^2 + \|C_k\|^2 \right) = 2(\ln 2)^2 + o(1),
\]
showing that (8) holds. □

Define for $i \in \{1, \ldots, n\}$ a function $Y_i(n) : X \to \mathbb{Z}$ by
\[
Y_i(n) := \sum_{\{k: p_k \leq i+1, \ p_k < n < d_k\}} p_k \left( U^i \hat{f}_k - U^{d_k+i} \bar{f}_k \right).
\]
Because
\[
\sum_{i=1}^{n-1} Y_i(n) = \sum_{\{k: p_k < n < d_k\}} (B_k - U^{d_k} B_k),
\]
the following is deduced from Lemma 5 and the proof of Lemma 6.

**Proposition 7.** For every $n \in \mathbb{N}$, the random variables $S_n(f) - \sum_{i=1}^{n} Y_i(n)$ and $\sum_{i=1}^{n} Y_i(n)$ are independent and
\[
\left\| S_n(f) - \sum_{i=1}^{n} Y_i(n) \right\|_2^2 = O \left( \frac{n}{\sqrt{\log n}} \right).
\]

**Proposition 8.** $S_n(f)$ converges in distribution to the normal law $\mathcal{N}(0, \sigma^2)$ with $\sigma^2 = 2(\ln 2)^2$.

**Proof.** By Proposition 7 it is sufficient to prove the convergence for $\frac{1}{\sqrt{n}} \sum_{i=1}^{n} Y_i(n)$. Since for every $n \in \mathbb{N}$, the random variables $Y_1(n), \ldots, Y_n(n)$ are independent and centered, this will follow once we verify the Lindeberg’s condition
\[
\forall \epsilon > 0, \frac{1}{n\sigma^2} \sum_{i=1}^{n-1} \int_X (Y_i(n)1_{[Y_i(n)^2 > \epsilon^2 \sigma^2 n]})^2 \, d\mu \xrightarrow{n \to \infty} 0.
\]
Because $p_k \leq 2^k$, if $J \subset \mathbb{N}$ is such that for all $j \in J$, $2^j < \epsilon \sigma \sqrt{n}$ then
\[
\left| \sum_{j \in J} p_j \left( U^j \hat{f}_j - U^{d_j+j} \bar{f}_j \right) \right| \leq 2 \sum_{j \in J} 2^j \leq \epsilon \sigma \sqrt{n}.
\]
Therefore, writing $A_{n, \epsilon} := \{ k : \log(\sigma \epsilon) - \frac{1}{2} \log n \leq k \leq \log n \}$, if $|Y_i(n)| > \epsilon \sigma \sqrt{n}$ then,
\[
|Y_i(n)| \leq 2 \left| \sum_{k \in A_{n, \epsilon}} p_k \left( U^i \hat{f}_k - U^{d_k+i} \bar{f}_k \right) \right|.
\]
We conclude that
\[
(Y_i(n)1_{[Y_i(n)^2 > \epsilon^2 \sigma^2 n]})^2 \leq 4 \left( \sum_{k \in A_{n, \epsilon}} p_k \left( U^i \hat{f}_k - U^{d_k+i} \bar{f}_k \right) \right)^2.
\]
The terms $p_k U^i \hat{f}_k$ which appear in the right hand side are mutually independent, thus for all $i \in \{1, \ldots, n-1\}$,
\[
\int_X (Y_i(n)1_{[Y_i(n)^2 > \epsilon^2 \sigma^2 n]})^2 \, d\mu \leq 4 \int_X \left( \sum_{k \in A_{n, \epsilon}} p_k \left( U^i \hat{f}_k - U^{d_k+i} \bar{f}_k \right) \right)^2 \, d\mu = 8 \sum_{k \in A_{n, \epsilon}} p_k^2 \|\hat{f}_k\|_2^2 = 8 \sum_{k \in A_{n, \epsilon}} \frac{1}{k \log k}.
\]
Proposition 9. The random variables $B_k \in \mathbb{k}$ for $k$ and for each $k \in I_n$ set
$$V_k := \sum_{i=2^k}^{n-1} \left( p_k \left( U^i \tilde{f}_k - U^{i+d_k} \tilde{f}_k \right) + p_{k+1} \left( U^i \tilde{f}_{k+1} - U^{i+d_{k+1}} \tilde{f}_{k+1} \right) \right)$$
To explain, $I_n$ roughly denotes the even integers in the segment $p_k < n < d_k$ and for each $k \in I_n$, $V_k$ is, up to an independent term with small second moment, almost equal to $B_k - B_{k+1} - U^{d_k} (B_k) - U^{d_{k+1}} (B_{k+1})$. The next Proposition makes this claim precise. We use the notation
$$U_n := \sum_{k \in I_n} V_k, \quad W_n := \sum_{i=1}^{n} Y_i(n)$$

**Proposition 9.** The random variables $U_n$ and $E_n := W_n - U_n$ are independent and
$$\|E_n\|^2 = O \left( \frac{n}{\sqrt{\log n}} \right).$$

**Proof.** There are three types of terms appearing in $E_n$. The first is if there exists an even integer $k$ such that $p_k < n < d_k$ and $n \leq p_{k+1} = 2^k + 1$. Since for $k$ even, $p_k = 2^k$, this happens if and only if $\log(n-1) = k \in 2\mathbb{N}$. In this case, writing $k = \log(n-1)$, then $V_{\log(n-1)}$ contains the term
$$\sum_{i=2^k}^{n-1} p_{k+1} \left( U^i \tilde{f}_{k+1} - U^{i+d_{k+1}} \tilde{f}_{k+1} + 1 \right) = n \left( U^{n-1} \tilde{f}_{\log(n-1)+1} - U^{n-1+d_{\log(n-1)+1}} \tilde{f}_{\log(n-1)+1} \right) = A(n),$$
where we have used that $2^k = n - 1$ and $p_{k+1} = n$.

The second type is when there exists an even $k$ such that $d_k \leq n < d_{k+1}$. In this case $p_{k+1} < n < d_{k+1}$, therefore $B_{k+1} - U^{d_{k+1}} B_{k+1}$ appears in $W_n$ and does not appear in $U_n$. Since $n < d_{k+1}$ we see that
$$\sqrt{\log n} < k + 1.$$ 
This implies that
$$\|B_{k+1}\|^2 = (n + 1 - p_{k+1}) a_{k+1} \leq \frac{n}{k+1} \leq \frac{n}{\log n}. \quad (9)$$

Finally the third type of terms comes from the fact that for each $k \in I_n$ we are not including $p_k \left( U^{p_k-1} \tilde{f}_k - U^{d_k+p_k-1} \tilde{f}_k \right)$ in the definition of $V_k$ while it does appear in $B_k$. We conclude that
$$E_n = -1 \|A(n)\| + \sum_{k \in I_n} p_k \left( U^{p_k-1} \tilde{f}_k - U^{d_k+p_k-1} \tilde{f}_k \right)$$
$$+ 1 \delta_{k \in 2\mathbb{N}} \{ d_k \leq n < d_{k+1} \} \left( B_{k+1} - U^{d_{k+1}} B_{k+1} \right).$$
The independence of $E_n$ and $U_n$ follows from properties (a) and (b) in the construction of the functions $f_k$. Finally as the terms in the sum of $E_n$ are independent, using the bound on the last term (if and when it appears)
$$\|E_n\|^2 = 2 \left( n^2 \|A(n)\| \|f_{\log(n-1)+1}\|^2 + \sum_{k \in I_n} p_k^2 \|\tilde{f}_k\|^2 \right) + O \left( \frac{n}{\sqrt{\log n}} \right).$$
\[ \leq 2 \left( n^2 \left( \alpha_{\log(n-1)} \right)^2 + \sum_{k \in I_n} p_k^2 \alpha_k^2 \right) + O \left( \frac{n}{\sqrt{\log n}} \right) \]
\[ = o(1) + \sum_{k: \sqrt{\log(n)} < k < \log(n)} \frac{1}{k \log k} + O \left( \frac{n}{\sqrt{\log n}} \right) = O \left( \frac{n}{\sqrt{\log n}} \right). \]

\[ \square \]

Combining this with Proposition \[7\] we have shown.

**Corollary 10.** The random variables \( S_n(f) - U_n \) and \( U_n \) are independent and
\[ \|S_n(f) - U_n\|^2 = O \left( \frac{n}{\sqrt{\log(n)}} \right). \]

Consequently, \( \frac{1}{\sqrt{n}} U_n \) converges in distribution to a normal law with variance \( \sigma^2 = 2 (\ln n)^2 \).

In the remaining part of this section we will prove that \( U_n \) satisfies a local CLT and use Proposition \[16\] to deduce the local CLT for \( S_n(f) \).

**Theorem 11.** Writing \( \sigma^2 = 2 (\ln n)^2 \) then,
\[ \sup_{x \in \mathbb{Z}} \left| \sqrt{n} \mu (U_n = x) - \frac{1}{\sqrt{2\pi \sigma^2}} e^{-x^2/2\sigma^2} \right| \xrightarrow{n \to \infty} 0. \]

**Deduction of Theorem 2** By Corollary \[10\] the random variables \( S_n(f) \) and \( U_n \) satisfy the conditions of \( X_n \) and \( Y_n \) in Proposition \[16\]. Thus by Theorem \[11\] and Proposition \[16\] we see that
\[ \sup_{x \in \mathbb{Z}} \left| \sqrt{n} \mu (S_n(f) = x) - \frac{1}{\sqrt{2\pi \sigma^2}} e^{-x^2/2\sigma^2} \right| \xrightarrow{n \to \infty} 0. \]

\[ \square \]

For the proof of Theorem \[11\] introduce the characteristic function of \( U_n \),
\[ \phi_n(t) := \int \exp (itU_n) d\mu. \]

The following two Lemmas are the core estimates which are used in the domination part, as in the proof of the local CLT in Terence Tao’s blog.

**Lemma 12.** There exists \( c > 0 \) such that for all \( \sqrt{n} \leq |x| \leq \pi \sqrt{n} \),
\[ \left| \phi_n \left( \frac{x}{\sqrt{n}} \right) \right| \leq \exp (-c \sqrt{n}) \leq \exp (-d \sqrt{|x|}) \]
where \( d := \frac{c}{\sqrt{\pi}} \).

**Lemma 13.** There exists \( N \in \mathbb{N} \) and a constant \( L > 0 \) such that for all \( n > N \) and \( |x| \leq \sqrt{n} \),
\[ \left| \phi_n \left( \frac{x}{\sqrt{n}} \right) \right| \leq \exp (-L x^2). \]

**Proof of Theorem 11** Let \( m \in \mathbb{Z} \). By Fourier inversion,
\[ \mu (U_n = m) = \frac{1}{2\pi} \int_{-\pi}^{\pi} \phi_n (t) e^{-itm} dt \]
Applying the change of variable, \( t = \frac{x}{\sqrt{n}} \), we see that
\[ \sqrt{n} \mu (U_n = m) = \frac{1}{2\pi} \int_{-\pi \sqrt{n}}^{\pi \sqrt{n}} \phi_n \left( \frac{x}{\sqrt{n}} \right) e^{-ixm/\sqrt{n}} dx \]
Since,
\[ \frac{1}{\sqrt{2\pi \sigma}} e^{-m^2/2\sigma^2} = \frac{1}{2\pi} \int_{\mathbb{R}} e^{-\sigma^2 x^2/2} e^{-ixm/\sqrt{n}} dx \]
then it remains to show that
\[
\sup_{m \in \mathbb{Z}} \left| \frac{1}{2\pi} \int_{-\pi}^{\pi} \phi_n \left( \frac{x}{\sqrt{n}} \right) e^{-ixm/\sqrt{n}} dx - \frac{1}{2\pi} \int_{\mathbb{R}} e^{-\sigma^2 x^2/2} e^{-ixm/\sqrt{n}} dx \right| = o(1).
\]
Using the triangle inequality and
\[
\int_{|x| \geq \pi \sqrt{n}} e^{-\sigma^2 x^2/2} dx \longrightarrow 0,
\]
it suffices to show that
\[
\int_{-\pi \sqrt{n}}^{\pi \sqrt{n}} \phi_n \left( \frac{x}{\sqrt{n}} \right) e^{-\sigma^2 x^2/2} dx \longrightarrow 0. \tag{10}
\]
Since \( \frac{\pi}{\sqrt{n}} \) converges in distribution to a centered normal with variance \( \sigma^2 \), it follows from Levy’s continuity theorem that for all \( x \in \mathbb{R} \),
\[
\Psi_n(x) := |\phi_n \left( \frac{x}{\sqrt{n}} \right) - e^{-\sigma^2 x^2/2}| \rightarrow_{n \to \infty} 0.
\]
In addition, by Lemmas 12 and 13 for every \( n \) large, for all \( |x| \leq \pi \sqrt{n} \),
\[
\Psi_n(x) \leq G(x)
\]
where
\[
G(x) = e^{-\sigma^2 x^2/2} + \max \left( \exp \left( -L x^2 \right), \exp \left( -d \sqrt{|x|} \right) \right).
\]
and \( L \) and \( d \) are the constants in the Lemmas. Since \( G \) is integrable, it follows from the dominated convergence theorem that
\[
\int_{-\pi \sqrt{n}}^{\pi \sqrt{n}} |\phi_n \left( \frac{x}{\sqrt{n}} \right) - e^{-\sigma^2 x^2/2}| dx = \int_{\mathbb{R}} \Psi_n(x) dx \longrightarrow 0.
\]
The proof is thus concluded. \( \square \)

**Remark 14.** For \( k \in I_n \) and \( j \leq n \) we let \( X_k(j) \) be an i.i.d. sequence which is distributed as \( p_k U^{j} \bar{f}_k + p_{k+1} U^{j+1} \bar{f}_{k+1} \).

The random variable \( X_k(j) \) takes values in \( \{ 0, \pm 1, \pm 2^k, \pm (2^k + 1), \pm (2^{k+1} + 1) \} \).

We assume \( \{ X_k(j) \}_{k \in I_n, j \leq n} \) are independent. Note that writing
\[
X_n := \sum_{k \in I_n} \sum_{j=2^k}^{n} X_k(j),
\]
then if \( X_n, X'_n \) are independent identically distributed, then \( U_n \overset{d}{=} X_n + X'_n \). Therefore
\[
\phi_n(t) = \prod_{k \in I_n} \left| \mathbb{E} \left( \exp(itX_k(1)) \right) \right|^{2(n-2^k)}
\]

**Proof of Lemma 12** First note that for all \( k \in I_n \)
\[
\mathbb{P}(X_k(1) = z) = \begin{cases} 
\frac{(1 - \alpha^2)}{2}(1 - \alpha^2_{k+1}), & z = 0 \\
\frac{\alpha^2}{2}(1 - \alpha^2_{k+1}) & z \in \{ \pm 2^k \} \\
\frac{\alpha^2_{k+1}}{4}(1 - \alpha^2) & z \in \{ \pm (2^k + 1) \} \\
\frac{\alpha^2_{k+1}}{4}(1 - \alpha^2) & z \in \{ \pm 1, \pm (2^{k+1} + 1) \}
\end{cases}
\]
so substituting \( t = \frac{x}{\sqrt{n}} \in [-\pi, \pi] \),
\[
\phi_n \left( \frac{x}{\sqrt{n}} \right) = \prod_{k \in I_n} \left| \mathbb{E} \left( \exp(i t X_k(1) / \sqrt{n}) \right) \right|^{2(n-2^k)}
\]

\[
= \prod_{k \in I_n} \left| \mathbb{E} \left( \exp(i t X_k(1)) \right) \right|^{2(n-2^k)}
\]
A calculation shows that
\[ \sum_{k \in I_n} \left( 1 - \frac{(\alpha_k \alpha_{k+1})^2}{2} (1 - \cos t) \right)^{2(n-2^k)} \]

For the bound of \( \sqrt{n} \leq |x| \leq \pi \sqrt{n} \) note that for such \( x \),
\[ \cos(t) \leq \cos \left( \frac{1}{\sqrt{n}} \right) \leq 1 - \frac{1}{4\sqrt{n}}. \]
This shows that for \( \sqrt{n} \leq |x| \leq \pi \sqrt{n} \),
\[ |\phi_n\left( \frac{x}{\sqrt{n}} \right)| \leq \prod_{k \in I_n} \left( 1 - \frac{(\alpha_k \alpha_{k+1})^2}{8\sqrt{n}} \right)^{2(n-2^k)} \leq \exp \left( -\frac{1}{4\sqrt{n}} \left( \sum_{k \in I_n} n (\alpha_k \alpha_{k+1})^2 - \sum_{k \in I_n} (2^k \alpha_k^4) \right) \right). \]
A calculation shows that
\[ \sum_{k \in I_n} (2^k \alpha_k^4) \leq \sum_{k \in I_n} (2^k) 2^{-4k} = o(1), \text{ as } n \to \infty, \]
and
\[ \sum_{k \in I_n} (\alpha_k \alpha_{k+1})^2 \sim \sum_{k \in 2^n : \log n \leq k \leq \log n} \alpha_k^4 \geq \sum_{k \in \mathbb{N} : \log n \leq 2k \leq \log n} 32^{-2k} \geq C 2^{-10} (\sqrt{\log n}/2) = C 2^{-5\sqrt{\log n}} \]
for some global constant \( C \) which does not depend on \( n \). Since
\[ \sqrt{n} 2^{-5\sqrt{\log n}} \geq \sqrt{n} \]
we have shown that there exists \( c > 0 \) such that for all \( \sqrt{n} \leq x \leq \pi \sqrt{n} \),
\[ |\phi_n(x)| \leq \exp \left( -c \sqrt{n} \right) \leq \exp \left( -d |x| \right). \]
where \( d = \frac{c}{\sqrt{n}}. \]
Define for \( n \in \mathbb{N} \),
\[ J_n := \left\{ k \in \mathbb{N} : 2^k \leq \frac{n}{3}, \ n < 2^{k+1} \right\} = \left( \sqrt{\log n} \cdot \frac{\log n}{4} - \log 3 \right) \cap \mathbb{N}, \]
and for \( 1 \leq j \leq n \),
\[ Y_n(j) = \sum_{k \in J_n : 2^k \leq j} p_k U_j f_k \]
and finally \( Z_n = \sum_{j=1}^n Y_n(j) \). Note that \( \{ Y_n(j) \}_{j=1}^n \) are independent and that \( U_n - Z_n \) and \( Z_n \) are independent by the construction.

**Lemma 15.** There exists \( N \in \mathbb{N} \) and a constant \( L > 0 \) such that for all \( n > N \) and \( |x| \leq \sqrt{n} \),
\[ |\mathbb{E} (\exp(ixZ_n/\sqrt{n})| \leq \exp \left( -Lx^2 \right) \]
**Proof.** Now \( Y_n(j), \ 1 \leq j \leq n \) are independent, for all \( 1 \leq j \leq n \), \( \mathbb{E}(Y_n(j)) = 0 \) and
\[ \mathbb{E}\left( (Y_n(j))^2 \right) = \sum_{(k \in J_n, 2^k \leq j)} p_k^2 \alpha_k^2 \]
\[ = \sum_{(k \in J_n, 2^k \leq j)} \frac{1}{k \log k}. \]
For all \( \frac{n}{2} \leq j \leq n \)\(^2\)
\[
\sum_{k \in J_n : 2^k \leq j} \frac{1}{k \log k} = \sum_{k \in J_n} \frac{1}{k \log k}.
\]

(11)

A similar argument as in the proof of Lemma 6 shows that there exists \( \beta > 0 \) such that
\[
\sum_{k \in J_n} \frac{1}{k \log k} \sim \int_{\log(n)}^{\log(n) - \log 3} \frac{dx}{x \log x} = \ln 2 \left( \ln \ln \left( \frac{\log n}{4} \right) - \ln \left( \ln \left( \frac{\log n}{2} \right) \right) \right) + o(1) = (\ln 2)^2 + o(1).
\]

Consequently, for all \( \frac{n}{2} \leq j \leq n \),
\[
E \left( \left( \Upsilon_n(j) \right)^2 \right) \sim (\ln 2)^2, \quad \text{as } n \to \infty,
\]

(12)

Note that the latter asymptotic equivalence is uniform when \( n \to \infty \) and \( \frac{n}{2} \leq j \leq n \).

Since for all \( k \in J_n \),
\[
p_k \leq \frac{2^k}{\sqrt{n}} \leq \frac{\sqrt{n}}{3},
\]

for all \( k \in J_n \) and \( 1 \leq j \leq n \),
\[
E \left( (p_k U_j \bar{f}_k)^4 \right) = p_k^4 \alpha_k^2 = \frac{p_k^2}{k \log k} \leq \frac{\sqrt{n}}{9} \frac{1}{k \log k}.
\]

By this, the independence of \( \{p_k U_j \bar{f}_k\}_{k \in J_n} \) and that for all \( k \in J_n \) and \( j \in \mathbb{N} \), \( E(p_k U_j \bar{f}_k) = 0 \) we see that for all \( \frac{n}{2} \leq j \leq n \),
\[
E \left( (\Upsilon_n(j))^4 \right) \leq \sum_{k \in J_n} E \left( (p_k U_j \bar{f}_k)^4 \right) + \left( \sum_{k \in J_n} E \left( (p_k U_j \bar{f}_k)^2 \right) \right)^2 \leq \frac{\sqrt{n}}{9} \sum_{k \in J_n} \frac{1}{k \log k} + \left( E \left( (\Upsilon_n(j))^2 \right) \right)^2 \leq \frac{\sqrt{n}}{9} (\ln 2)^2 + o(\sqrt{n}).
\]

There exists \( N \) such that for all \( n > N \), and \( \frac{n}{2} \leq j \leq n \)
\[
E \left( (\Upsilon_n(j))^2 \right) \geq \frac{(\ln 2)^2}{2}
\]

and in addition
\[
E \left( (\Upsilon_n(j))^4 \right) \leq \frac{2(\ln 2)^2}{9} \sqrt{n} \leq \frac{4\sqrt{n}}{9} E \left( (\Upsilon_n(j))^2 \right).
\]

Furthermore, \( \{U_j \bar{f}_k\}_{k \in J_n : 2^k \leq j} \) is a sequence of independent and symmetric random variables, thus
\[
E(\Upsilon_n(j)) = E \left( (\Upsilon_n(j))^3 \right) = 0.
\]

\(^2\)For all \( k \in J_n \), \( 2^k \leq \sqrt{n}/3 < n/2 \)
It follows that for all \( n/2 \leq j \leq n \) and \(|t| \leq \frac{1}{\sqrt{n}}\)

\[
|\mathbb{E} (\exp(it\mathbb{Y}_n(j)))| \leq 1 - \frac{E \left( \left( \mathbb{Y}_n(j) \right)^2 \right)}{2} t^2 + \frac{t^4}{4!} \mathbb{E} \left( \left( \mathbb{Y}_n(j) \right)^4 \right)
\leq 1 - E \left( \left( \mathbb{Y}_n(j) \right)^2 \right) t^2 \left( \frac{1}{2} - \frac{4\sqrt{n}}{9} t^2 \right) \sqrt{n} t^2 \leq 1 \text{ and } (13)
\]

Finally by independence of \( \{\mathbb{Y}_n(j)\}_{j=1}^n \), for all \(|x| \leq \sqrt{n}\),

\[
|\mathbb{E} (\exp(ix\mathbb{Z}_n/\sqrt{n}))| = \prod_{j=1}^n |\mathbb{E} (\exp(ix\mathbb{Y}_n(j)/\sqrt{n}))| \leq \prod_{j=n/2}^n |\mathbb{E} (\exp(ix\mathbb{Y}_n(j)/\sqrt{n}))| \leq \prod_{j=n/2}^n \exp \left(- \frac{(ln 2)^2}{36n} x^2 \right) = \exp \left(- \frac{(ln 2)^2}{72} x^2 \right).
\]

The conclusion follows with \( L = \frac{(ln 2)^2}{72} \).

**Proof of Lemma 13.** Let \( N \) and \( L \) be as in Lemma 13. Since \( \mathbb{Z}_n \) and \( \mathbb{U}_n - \mathbb{Z}_n \) are independent, then for all \( n > N \), and \(|x| \leq \sqrt{n}\),

\[
|\mathbb{E} (\exp(ix\mathbb{U}_n/\sqrt{n}))| = |\mathbb{E} (\exp(ix(\mathbb{U}_n - \mathbb{Z}_n)/\sqrt{n}))| |\mathbb{E} (\exp(ix\mathbb{Z}_n/\sqrt{n}))| \leq |\mathbb{E} (\exp(ix\mathbb{Z}_n/\sqrt{n}))| \leq \exp \left(-Lx^2 \right).
\]

\[\Box\]

5. **Appendix**

The first result in the appendix is that the local limit theorem persists under addition of small independent noise. These type of arguments and statements are not new. We include a statement which is especially tailored for our construction.

**Proposition 16.** Suppose that \( X_n = Y_n + Z_n \) which are for each \( n \in \mathbb{N} \), \( Y_n \) and \( Z_n \) are \( \mathbb{Z} \)-valued independent random variables. If

\[
\sup_{x \in \mathbb{Z}} \sqrt{n} \mathbb{P} \left( Y_n = x \right) - \frac{1}{\sqrt{2\pi}\sigma^2} e^{-x^2/2\sigma^2} \xrightarrow{n \to \infty} 0 \tag{15}
\]

and \( \mathbb{E} \left( |Z_n|^2 \right) = O \left( \frac{n}{\log(n)} \right) \) then

\[
\sup_{x \in \mathbb{Z}} \sqrt{n} \mathbb{P} (X_n = x) - \frac{1}{\sqrt{2\pi}\sigma^2} e^{-x^2/2\sigma^2} \xrightarrow{n \to \infty} 0.
\]

In order to simplify the notation in the proof, we would make use of the following reformulation of (15): There exists \( r : \mathbb{N} \to [0, \infty) \) such that \( r(n) \sqrt{n} \to 0 \) and for all \( x \in \mathbb{Z}, \)

\[
\mathbb{P} (Y_n = x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-x^2/2\sigma^2} \pm r(n).
\]

In the course of the proof, the function \( r(n) \) will denote a \( o \left( \frac{1}{\sqrt{n}} \right) \) function which may change from line to line.

\[\text{See for example } [8] \text{ pp. 101-103}\]
Proof. By changing from $X_n$ to $\frac{1}{\sigma}X_n$ we can and will assume that $\sigma^2 = 1$. Write $a(n) = \left(\frac{n}{\sqrt{\log(n)}}\right)^{\frac{1}{2}}$. By Markov inequality,

$$\mathbb{P}(|Z_n| \geq a(n)) \leq \frac{D}{\sqrt{\log(n)}},$$

where $D$ is any constant such that $\sup_{n \in \mathbb{N}} \left[\frac{\sqrt{\log(n)}}{n} \mathbb{E}\left(|Z_n|^2\right)\right] \leq D$.

Fix $x \in \mathbb{Z}$ and note that as $Y_n$ and $Z_n$ are independent,

$$\mathbb{P}(X_n = x) = \sum_{z \in \mathbb{Z}} \mathbb{P}(Y_n = x-z) \mathbb{P}(Z_n = z).$$

We split the sum into $|z| \leq a_n$ and $|z| > a_n$.

A consequence of (15) is that there exists $C > 0$ such that for all $y \in \mathbb{Z}$ and $n \in \mathbb{N}$,

$$\mathbb{P}(Y_n = y) \leq \frac{C}{\sqrt{n}}.$$

And,

$$\sum_{z \in \mathbb{Z}[-a(n),a(n)]} \mathbb{P}(Y_n = x-z) \mathbb{P}(Z_n = z) \leq C\mathbb{P}(|Z_n| \geq a(n)) \leq \frac{CD}{\sqrt{\pi} \sqrt{\log(n)}}. \tag{16}$$

If $|z| \leq a(n)$ and $|x| > \sqrt{n}\log^{1/2}(n)$ then for all large $n$, uniformly in $z = \pm a(n)$,

$$\exp\left(-\frac{(x-z)^2}{2n}\right) \leq \exp\left(-\frac{x^2}{4n}\right) = \exp\left(-\frac{x^2}{2n}\right) + o(1).$$

The last equality up to a $o(1)$ term follows from $x^2/n \geq \log^{2/9}(n)$ as $n \to \infty$.

If $|z| \leq \sqrt{n}\log^{1/2}(n)$ then $|xz| \leq \frac{n}{(\log(n))^{9/2}}$, thus

$$\exp\left(-\frac{(x-z)^2}{2n}\right) = \exp\left(-\frac{x^2}{2n}\right) \exp\left(\pm \frac{|xz|}{2n}\right) = \exp\left(-\frac{x^2}{2n}\right) \exp\left(\pm \frac{1}{2(\log(n))^{9/2}}\right) = \exp\left(-\frac{x^2}{2n}\right) + o(1).$$

Using these rather trivial bounds and the reformulation of (15) we conclude that

$$\sum_{z \in \mathbb{Z}[-a(n),a(n)]} \mathbb{P}(Y_n = x-z) \mathbb{P}(Z_n = z) = \sum_{z \in \mathbb{Z}[-a(n),a(n)]} \exp\left(-\frac{(x-z)^2}{2n}\right) \mathbb{P}(Z_n = z) \pm r(n)$$

$$= \sum_{z \in \mathbb{Z}[-a(n),a(n)]} \left[\exp\left(-\frac{x^2}{2n}\right) + o(1)\right] \mathbb{P}(Z_n = z) \pm r(n)$$

$$= \mathbb{P}(|Z_n| \leq a_n) \left[\frac{1}{\sqrt{2\pi n}} \exp\left(-\frac{x^2}{2n}\right) \right] \pm (o(1) + r(n))$$

As $\mathbb{P}(|Z_n| \leq a_n) = 1 + o(1),$

$$\sum_{z \in \mathbb{Z}[-a(n),a(n)]} \mathbb{P}(Y_n = x-z) \mathbb{P}(Z_n = z) = \frac{1}{\sqrt{2\pi n}} \exp\left(-\frac{x^2}{2n}\right) + o(1).$$

The conclusion follows from the latter asymptotic equality and (16).
Lemma 17. There exists a constant $K > 0$ such that for all $n \in \mathbb{N}$,
\[
\sum_{k \in \mathbb{N} : 2 \leq k \leq \sqrt{\log n}} \frac{2k^2}{k \log k} \leq K \frac{n}{\sqrt{\log(n)}}.
\]

Lemma 18.
\[
\sum_{k : 2^k \leq n} \frac{2^k}{k} = O \left( \frac{n}{\log n} \right).
\]

Proof of Lemmas 17 and 18. Both results follow from the following reasoning. If $(a_k)_{k=1}^{\infty}$ is a sequence of positive reals such that there exists $q > 1$ for which for all $n \in \mathbb{N}$, $a_{n+1}/a_n \geq q$ then for all $n \in \mathbb{N}$,
\[
\sum_{k=1}^{n} a_k \leq a_n \sum_{k=1}^{\infty} q^{-k} \leq \frac{a_n}{1-q}.
\]
