24 **Abstract**

25 *Blastocystis* sp. is frequently identified in a wide range of animal hosts, including
26 bovids. Because of its burden and zoonotic potential, this parasite has been sought in
27 domestic cattle from various countries, since this livestock may also represent a possible
28 reservoir of human infection. However, epidemiological data regarding the prevalence and
29 ST distribution of *Blastocystis* sp. in this animal group is lacking in Lebanon. Therefore,
30 faecal samples were collected from a total of 254 dairy cattle raised on 55 farms located in
31 the North Lebanon region and screened for the presence of the parasite by quantitative real-
32 time PCR. The overall prevalence of *Blastocystis* sp. was shown to reach 63.4% in cattle
33 livestock. Sequence analysis of positive samples indicated the presence of seven STs, with
34 predominance of ST10 (44.0%) and ST14 (36.8%) and lower proportions of ST2 (8.0%), ST1
35 (7.2%), ST5 (2.4%), ST3 and ST7 (0.8% each). This survey was the first conducted
36 worldwide reporting ST2 and ST7 in domestic cattle and confirmed that ST10 and ST14
37 represent cattle-adapted STs in view of their high prevalence. Faecal samples from in-contact
38 dairy farmers and patients hospitalised in the same Lebanese governorate who reported no
39 contact with cattle livestock were also analysed for the presence of *Blastocystis* sp. The same
40 three STs were identified in both human cohorts, with predominance of ST3, followed either
41 by ST1 or ST2 depending of the group. No other STs, including ST10 or ST14, have been
42 reported. Moreover, even though ST1, ST2 and ST3 were found to be common to dairy cattle
43 and farmers cohorts, only one ST3 isolate showed 100% sequence identity between both
44 hosts. Consequently, the presence and low prevalence of ST1, ST2, ST3, ST5 and ST7
45 identified herein in domestic cattle, most of which exhibit low host specificity, could be
46 derived from occasional direct exposure to faecal material from human and non-human hosts
47 or by ingestion of contaminated drinking water or food in the enclosure of the farms.

48 Together with the absence of ST10 and ST14 in the human population, these data suggest that
49 cattle play a negligible role as zoonotic reservoirs of *Blastocystis* sp.

52 Transmission, Zoonosis

53

54 **1. Introduction**

55 *Blastocystis* sp. is currently the most common single-celled intestinal parasite found in
56 humans, since its prevalence can greatly exceed 50% in developing countries (El Safadi et al.,
57 2014; Forsell et al., 2016) and reach an average of around 20% in industrialised regions of
58 Europe (Bart et al., 2013; El Safadi et al., 2016). This protozoan has also been frequently
59 found in many groups of animals, including non-human primates and various groups of
60 mammals, birds, reptiles, amphibians and insects (Tan, 2004; Stensvold and Clark, 2016;
61 Yoshikawa et al., 2016; Cian et al., 2017). The principal mode of transmission of *Blastocystis*
62 sp. is the faecal-oral route, essentially through consumption of water or food contaminated by
63 environmentally resistant cystic forms of the parasite (Tan, 2008). Due to the very common
64 asymptomatic carriage of the parasite in the human population worldwide, its pathogenic
65 potential and clinical significance is remained uncertain (Andersen and Stensvold, 2016).
66 However numerous recent *in vitro* studies have identified the mechanisms and molecules
67 involved in the virulence of the parasite (Clark et al., 2013; Wawrzyniak et al., 2013;
68 Ajjampur and Tan, 2016; Stensvold and Clark, 2016).. *Blastocystis* sp. infection would thus
69 be associated with various gastrointestinal disorders (Tan, 2008; Tan et al., 2010) and/or
70 urticaria (Lepczynska et al., 2015) in numerous human clinical cases.

71 An extensive genetic diversity has been demonstrated within the genus *Blastocystis*
72 based on the comparison of small subunit (SSU) rRNA gene sequences (Noël et al., 2005;
73 Stensvold et al., 2007). Indeed, 17 subtypes (STs) have been identified so far in mammalian
74 and avian hosts (Alfellani et al., 2013a), ten of which infect humans with varying prevalence
75 (Alfellani et al., 2013b; Clark et al., 2013; Ramirez et al., 2016; Stensvold and Clark, 2016).
76 Briefly, more than 90% of human isolates belong to ST1 to ST4, in large part likely related to
77 human-to-human transmission (Alfellani et al., 2013b; Clark et al., 2013). Most other STs
78 found in the human population are considered to be of animal origin, with low host

79 specificity and are potentially zoonotic. For instance, ST5 frequently infects pigs (Wang et
80 al., 2014), whereas ST6 and ST7 are predominant in birds (Cian et al., 2017). Based on large-
81 scale epidemiological surveys, these last STs were considered to be pig- and avian-adapted
82 STs respectively, and corresponding isolates were shown to be possibly transmitted from
83 these animals to their in-contact workers at intensive commercial piggeries and poultry
84 slaughterhouses (Wang et al., 2014; Greige et al., 2018). In addition, ST8, which is common
85 in non-human primates, was identified with unexpected high prevalence in their keepers
86 (Stensvold et al., 2009). In view of these data, it became necessary to determine the infection
87 rate and ST distribution of *Blastocystis* sp. in other animal groups, such as bovids and
88 particularly livestock cattle. In the main recent molecular epidemiological surveys including a
89 large number of specimens (Zhu et al., 2017; Lee et al., 2018; Masuda et al., 2018; Wang et
90 al., 2018; Maloney et al., 2019), the prevalence of the parasite in domestic dairy/beef cattle
91 varied between 2.9% and 54.1%, depending on the country. The potential significant
92 occurrence of *Blastocystis* sp. in livestock cattle could thus generate a risk of zoonotic
93 transmission, especially in dairy farmers. Moreover, the same molecular studies and a few
94 others identified ST10 and ST14 as the predominant STs in cattle, likely reflecting bovids as
95 natural hosts for both STs (Cian et al., 2017; Zhu et al., 2017; Masuda et al., 2018).
96 Strikingly, ST10 and ST14 have never yet been reported in human infections, suggesting
97 minimal risk of zoonotic transmission (Cian et al., 2017; Wang et al., 2018). However,
98 neither of these STs has so far been sought in cattle and their in-contact farmers to confirm
99 this hypothesis.

100 The objectives of this study was thus to obtain the first molecular data regarding the
101 prevalence and ST distribution of *Blastocystis* sp. in dairy cattle in Lebanon. A particular
102 purpose was to confirm that bovids represent natural hosts of ST10 and ST14. In addition, the
103 potential zoonotic transmission of the parasite was assessed through a comparative analysis

104 of the ST distribution of isolates identified in dairy cattle and in-contact farmers, as well as in
105 individuals reporting no contact with these animals.

106

107 **2. Materials and methods**

108 2.1. Ethics statement

109 The protocol of this study was approved by the Lebanese Minister of Public Health
110 with reference number 2014/4/39716 and by the research ethics committee of Hamidi
111 Medical Centre in Tripoli, Lebanon, with reference number Hamidi-7-2017. Oral and written
112 informed consent was obtained from all subjects included in this study after a clear
113 explanation of the research objectives prior to enrolment. The subjects' data were collected
114 anonymously (with encryption of the identity of individuals). This study was conducted in
115 accordance with the Code of Ethics of the World Medical Association (Declaration of
116 Helsinki). All dairy cattle samples were collected under the supervision of the farmers. No
117 approval from the Institutional Animal Care and Use Committee or ethics committee was
118 necessary, as no invasive sampling approach was performed.

119

120 2.2. Study sites and sample collection

121 The study was conducted in the two governorates comprising the North Lebanon
122 region, namely Akkar and North governorates, the latter including the regional capital Tripoli
123 (Figure 1). All healthy adult dairy cattle included in this study were older than 12 months and
124 were of the Holstein-Friesian breed (*Bos taurus*). In Akkar governorate, 157 faecal specimens
125 were randomly collected from 22 villages and 36 farms from July to November 2016. In
126 order to obtain epidemiological data from dairy cattle in different geographical areas in
127 Lebanon, 97 samples were also randomly obtained from 15 villages and 19 farms from July
128 to November 2017 in North governorate, for an overall total of 254 cattle samples screened in

129 this survey (one specimen per animal). Briefly, faecal samples were collected in the early
130 morning with the assistance of the breeders and veterinarians. Specimens were either
131 collected directly from the rectum of the animal with a gloved hand or directly from the
132 ground immediately after defecation to prevent potential contamination between animals.
133 Each fresh faecal sample was recovered in a sterile plastic container, respecting the
134 conditions of asepsis and hygiene. The containers were stored in ice and then immediately
135 transported to the Laboratoire Microbiologie Santé et Environnement (LMSE) at the AZM
136 Centre in Tripoli. To evaluate the zoonotic potential of *Blastocystis* sp. isolates identified in
137 dairy cattle, human stool samples were obtained during the same period from 40 farmers
138 working at the same 19 dairy cattle farms located in North governorate and from 40
139 individuals followed up for different pathologies or who presented for routine medical check-
140 ups at Hamidi Medical Centre in Tripoli who reported no contact with cattle (control
141 population). A standardised questionnaire was designed to collect data of interest, such as
142 age, sex, residency and gastrointestinal symptoms (abdominal pain, bloating, constipation,
143 diarrhoea and/or vomiting) for each volunteer, as well as number of years as in-contact
144 worker with cattle for the cohort of dairy farmers.

145

146 2.3. DNA extraction

147 Total genomic DNA was extracted directly from approximately 250 mg of animal or
148 human faecal samples using the QIAamp DNA Stool Mini Kit (Qiagen GmbH, Hilden,
149 Germany) according to the manufacturer's recommended procedures. The DNA was eluted in
150 200 µl of elution buffer and stored at -20°C at the LMSE in Tripoli. The DNA samples were
151 then transported to the Pasteur Institute in Lille (France) for molecular screening and
152 subtyping of *Blastocystis* sp.

153

154 2.4. Detection and molecular subtyping of *Blastocystis* sp. isolates

155 SSU rRNA gene detection of the parasite was performed by quantitative real-time
156 PCR (qPCR) using 2 µl of extracted DNA and the *Blastocystis*-specific primer pair
157 BL18SPPF1 / BL18SR2PP, as described previously by Poirier et al. (2011). DNA extraction
158 controls (isolation of DNAs without stool and from a *Blastocystis* sp.-negative stool)
159 subsequently used in qPCR assays and positive (DNA obtained from *Blastocystis* sp. ST7
160 strain B axenic culture maintained in the laboratory) and negative (DNA matrix replaced by
161 water) qPCR controls were performed. The qPCR product from each positive sample was
162 purified and sequenced in both strands by Genoscreen (Lille, France). For 3 human samples
163 obtained from breeders and 3 others collected from patients followed at Hamidi Medical
164 Centre in Tripoli, sequence chromatogram analysis revealed the presence of double traces,
165 suggesting mixed infection by different STs. Mixed signals were also generated for numerous
166 qPCR products obtained from dairy cattle samples. All 6 human samples and a selection of 9
167 animal samples corresponding to mixed infections were thus re-analysed by non-qPCR using
168 the same primer pair as for qPCR. Non-qPCR amplification, as well as purification and
169 cloning of the non-qPCR product, were performed as described previously (Cian et al., 2017).
170 Briefly, the purified non-qPCR product cloned in the T-vector, pCR 2.1-TOPO (Invitrogen,
171 Carlsbad, USA) was amplified in *Escherichia coli* One Shot TOP10 competent cells and
172 minipreparations of plasmid DNA were done using the NucleoSpin Plasmid kit (Macherey-
173 Nagel, Düren, Germany). Five positive clones containing inserts of the expected size were
174 selected arbitrarily and sequenced on both strands. The SSU rRNA gene sequences obtained
175 in this study were deposited in GenBank under accession numbers MH883051 to MH883225.
176 The sequences obtained were compared with all *Blastocystis* sp. homologous sequences
177 available from the National Centre for Biotechnology Information (NCBI) using the
178 nucleotide Basic Local Alignment Search Tool (BLAST) program. The STs were identified

179 by determining the exact match or closest similarity to all known mammalian and avian
180 *Blastocystis* sp. STs according to the most recent classification of the parasite (Alfellani et al.,
181 2013a).

182

183 2.5. Statistical analyses

184 Statistical analyses were performed using GraphPad Prism software, version 6
185 (GraphPad Software, La Jolla, CA, USA). The chi-squared test was used to compare the
186 *Blastocystis* sp. prevalence between the Akkar and North governorate dairy cattle groups.
187 Fisher's exact test was used to compare the ST distribution of the parasite between the two
188 human cohorts, as well as those of the two animal groups. All tests were two-sided and the
189 general significance level was set at a *P* value of below 0.05.

190

191 3. Results and discussion

192 A total of 254 single dairy cattle samples collected from 37 villages and 55 farms located
193 in two governorates of North Lebanon were screened in this study (Table 1). Of these
194 samples, 157 were obtained at Akkar governorate from cattle raised on 36 different farms. Of
195 these 157 samples, 78.3% ($n = 123$) were identified as positive for *Blastocystis* sp. by qPCR.
196 Of the 97 dairy cattle samples collected from 19 different farms in North governorate, 38
197 (39.2%) were also positive for the parasite by qPCR. The statistically significant difference of
198 *Blastocystis* sp. prevalence in cattle between the two geographical regions (chi-squared test, Z
199 $= 4.498$, $P < 0.05$) may possibly be due to the lower quality hygiene and sanitary conditions
200 at farms in the rural governorate of Akkar, thus facilitating the transmission of the parasite
201 between livestock. By combining the molecular data obtained from the two governorates, the
202 prevalence of *Blastocystis* sp. reached 63.4% (161/254) among dairy cattle samples. This
203 high infection rate in Lebanon was roughly similar to that observed using molecular methods

204 in other countries, including Japan (54.1%) (Masuda et al., 2018), Thailand (50.0%)
205 (Udonsom et al., 2018), Colombia (80.0%) (Ramirez et al., 2014) and Libya (41.7%)
206 (Alfellani et al., 2013a) but was significantly higher than that reported in Korea (6.7%) (Lee
207 et al., 2018), China (9.5% and 10.3%) (Zhu et al., 2017; Wang et al., 2018, respectively), Iran
208 (9.6%) (Badparva et al., 2015), the United Kingdom (22.6%) (Alfellani et al., 2013a) and the
209 United States (19.1% and 2.9%) (Fayer et al., 2012; Maloney et al., 2019, respectively).
210 Additional surveys also revealed a prevalence of 71.0%, 21.4% and 1.8% in Japan (Abe et
211 al., 2002), Brazil (Franco Moura et al., 2018) and Spain (Quilez et al., 1995) respectively,
212 using direct light microscopy of faecal smears, in the knowledge that this identification
213 method has been shown to be less sensitive than PCR (Poirier et al., 2011). Although the
214 prevalence of the parasite in domestic cattle may vary between geographical areas, it is
215 nevertheless common worldwide, thus generating a potential risk of transmission to in-
216 contact humans.

217 To start assessing the zoonotic potential of the parasite, single stool samples were
218 collected from a total of 80 volunteers divided into two cohorts (Table 1). The first cohort
219 included 40 individuals (26 males and 14 females), all working on dairy cattle farms in North
220 governorate for a period of between 6 months and 30 years, with a median of 8 years,
221 indicating a potentially long period of contact with animals. The age of the individuals in this
222 cohort was between 22 and 65 years (mean age of 36 ± 10 years) and 21 of these 40 breeders
223 (52.5%) were shown to be infected with *Blastocystis* sp. by qPCR. Moreover, only 5 breeders
224 presented gastrointestinal symptoms and 3 of them were infected by the parasite. The second
225 cohort (or control group) consisted of 40 patients (12 males and 28 females) aged 21 to 70
226 years (mean age of 24 ± 12 years), hospitalised at Hamidi Medical Centre in Tripoli for
227 various pathologies or medical check-ups, who reported no contact with cattle. 62.5% of the
228 patients (25/40) presented one or more gastrointestinal symptoms. Using qPCR, the

229 prevalence of *Blastocystis* sp. in this second human cohort was not significantly different to
230 that of the dairy farmers, i.e. 57.5% (23/40). In addition, 52.0% of symptomatic patients
231 (13/25) were infected by the parasite. Interestingly, the infection rate observed in each of
232 these two groups (52.5% and 57.5% respectively) was very similar to that recently reported in
233 North Lebanon region in a large cohort of schoolchildren (63.0%) (Osman et al., 2016) and
234 two groups of individuals working in a poultry slaughterhouse (56.0%) or hospitalised at
235 Hamidi Medical Centre in Tripoli (54.0%) (Greige et al., 2018). On the other hand, the
236 similar prevalence observed between all these Lebanese groups of individuals suggested that
237 people working closely with animals, including for instance domestic cattle or poultry
238 (Greige et al., 2018) but also pigs (Wang et al., 2014), did not systematically have a higher
239 risk of acquiring *Blastocystis* sp. infection as previously proposed (Rajah Salim et al., 1999),
240 without affecting the possibility that some STs are of zoonotic origin.

241 In a second step, the genetic diversity of *Blastocystis* sp. isolates was explored in dairy
242 cattle and human cohorts. In this study, all partial SSU rRNA gene sequences obtained from
243 animal or human samples showed 99 to 100% identity with homologous sequences available
244 in databases allowing the direct subtyping of the corresponding isolates (Table 1). Regarding
245 the 123 positive dairy cattle samples identified in Akkar governorate, 84 corresponded to
246 single infections by either ST1 ($n = 4$, 3.3%), ST5 ($n = 3$, 2.4%), ST7 ($n = 1$, 0.8%), ST10 (n
247 $= 40$, 32.5%) and ST14 ($n = 36$, 29.3%). The 39 remaining positive dairy cattle samples
248 (31.7%) from this governorate presented mixed infections with at least 2 unidentified STs
249 according to the resulting sequence chromatograms. Of the 38 positive animal specimens
250 identified in North governorate, 21 corresponded to single infections with the detection of
251 ST2 ($n = 1$, 2.6%), ST3 ($n = 1$, 2.6%), ST10 ($n = 12$, 31.6%) and ST14 ($n = 7$, 18.4%) and the
252 17 other samples (44.8%) to mixed infections. Given the large number of mixed infections
253 identified in animal samples collected in both governorates, only a selection of them was thus

254 re-analysed by non-qPCR to have a partial overview of the STs found in these specimens.
255 Therefore, one sample from each farm presenting mixed infection in North governorate was
256 selected. Cloning of the non-qPCR products was performed from these 9 representative
257 animal specimens for subtyping, and 5 positive clones were selected arbitrarily and
258 sequenced for each cloning. Seven of the 9 selected samples showed mixed infections with
259 two different STs (ST2/ST1, $n = 4$; ST2/ST10, $n = 1$; ST2/ST14, $n = 2$) whereas the two
260 remaining samples harboured 3 different STs (ST1/ST2/ST10 and ST2/ST10/ST14
261 respectively). Taking into account these 9 mixed infections consisting of either two or three
262 different STs, the ST distribution in dairy cattle from this governorate was as follows: ST1 (n
263 = 5), ST2 ($n = 10$), ST3 ($n = 1$), ST10 ($n = 15$) and ST14 ($n = 10$). The major difference
264 observed between these two animal cohorts in terms of distribution of STs was the presence
265 of ST2 only in the group of North dairy cattle, while it was absent from the Akkar group of
266 animals (Fisher's exact test, 24.4% vs. 0%, $P < 0.05$). By merging all molecular data
267 obtained from dairy cattle samples in North Lebanon region, a total of 125 isolates were
268 subtyped and belonged to 7 different STs with, in order of prevalence, ST10 (55/125, 44.0%),
269 ST14 (46/125, 36.8%), ST2 (10/125, 8.0%), ST1 (9/125, 7.2%), ST5 (3/125, 2.4%), ST3 and
270 ST7 (1/125 each, 0.8%). Herein, ST10 and ST14 were thus largely predominant by
271 accounting for more than 80% of the subtyped isolates. As shown in Table 2 reporting all the
272 isolates subtyped from domestic cattle in various geographical areas, ST10 and ST14 also
273 globally represented the most widely distributed STs (64.5% of total isolates). This was
274 clearly the case, for instance, in Denmark (Stensvold et al., 2009), Japan (Masuda et al.,
275 2018), Korea (Lee et al., 2018), China (Zhu et al., 2017) and Libya (Alfellani et al., 2013a).
276 Strikingly, ST10 and ST14 were the only two STs identified in cattle in two studies
277 conducted in the USA (Santin et al., 2011; Fayer et al., 2012). Therefore, all of these data
278 confirmed that domestic cattle would be natural hosts for *Blastocystis* sp. ST10 and ST14. In

279 addition to these two predominant STs, five minor STs (ST1, ST2, ST3, ST5 and ST7) were
280 identified in the livestock investigated in this study. Briefly, it was the first report of the
281 presence of ST2 and ST7 in domestic cattle, while the three other STs had previously been
282 detected with varying prevalence in the same animal group in different countries (Table 2).

283 Regarding the dairy farmers cohort, 18 individuals presented single infections by the
284 parasite, and 3 others had mixed infections with two STs. With the addition of these mixed
285 infections, a total of 24 isolates was subtyped. As shown in Table 1, ST3 was predominant
286 (12/24, 50.0%), followed by ST2 (7/24, 29.2%) and ST1 (5/24, 20.8%). In the case of the
287 second human cohort comprising patients enrolled at Hamidi Medical Centre in Tripoli, 20
288 and 3 of them presented single and mixed infections with two STs respectively. Therefore, a
289 total of 26 isolates was subtyped and three different STs were identified as follows: ST3
290 (13/26, 50.0%), ST1 (8/26, 30.8%) and ST2 (5/26, 19.2%). Interestingly, no other ST was
291 identified in these two human groups. Moreover, although the number of samples analysed in
292 each cohort remained limited, the distribution of the different STs was not significantly
293 different between the two human groups (Fisher's exact test, $P = 0.67$). Strikingly, this
294 distribution with predominance of ST3 followed by either ST1 or ST2 was also similar to that
295 observed in previous studies conducted recently among patients at the same hospital in
296 Tripoli, staff members working in poultry slaughterhouses in North Lebanon (Greige et al.,
297 2018) and among schoolchildren in Tripoli (Osman et al., 2016).

298 By analysing all the molecular data obtained herein, the zoonotic potential of *Blastocystis*
299 sp. was evaluated through the comparison of the ST distribution reported in animal and
300 human cohorts in North Lebanon. Despite the high prevalence of ST10 and ST14 in cattle
301 livestock, neither ST was identified especially in dairy farmers despite these workers having
302 intimate, long-term and repeated contact with these animals. To our knowledge, these two
303 STs have also never been documented in human infections worldwide (Clark et al., 2013;

304 Stensvold and Clark, 2016), suggesting that humans would not be susceptible to their
305 infection. Another hypothesis that remains to be further confirmed could be that these two
306 STs produce non-resistant cystic environmental forms, thus limiting possible transmission of
307 the parasite to another host through indirect contact. ST5 was also infrequently identified in
308 dairy cattle, as in previous studies conducted in various countries (Table 2) and herein only in
309 animals raised at Akkar governorate. Recently, ST5 was proposed as a pig-adapted ST (Wang
310 et al., 2014) and consequently cannot likely be assigned to domestic cattle at this time. Its
311 zoonotic potential was confirmed through the frequent infection of piggery staff by this ST
312 (Wang et al., 2014) and pig-rearing villagers (Yan et al., 2007). However, despite the large
313 number of samples screened, ST5 has not yet been identified in this study as in other
314 Lebanese human cohorts (Osman et al., 2016; Greige et al., 2018). The only known case of
315 ST7 infection in cattle was identified in this study at a farm located at Akkar governorate.
316 This ST was proposed as an avian-adapted ST with potential zoonotic risk (Alfellani et al.,
317 2013a; Cian et al., 2017) and its sporadic prevalence in cattle livestock likely reflected
318 opportunistic infection through contact with bird faeces. Again, ST7 has never been yet
319 identified in the Lebanese human population (Osman et al., 2016; Greige et al., 2018), as
320 confirmed herein. Interestingly, three STs (ST1, ST2 and ST3) were found in common in
321 dairy cattle and their in-contact farmers in North governorate, suggesting potential
322 transmission between the hosts. However, only six animal isolates belonging to these STs and
323 as part of single or mixed infections were identified on 4 different farms at which dairy
324 farmers were infected by the same STs. By comparing the corresponding dairy cattle and in-
325 contact farmer isolate sequences, 100% identity was shown for only one ST3 isolate infecting
326 both hosts. Since ST3 is known to be predominantly harboured by the human population
327 (Clark et al., 2013; Stensvold and Clark, 2016) including Lebanon and not frequently found
328 in domestic cattle as shown in Table 2, this case of *Blastocystis* sp. ST3 infestation in

329 livestock can likely be explained by reverse zoonosis from human handlers to animals, as
330 suggested in previous studies focused on various animal hosts (Ramirez et al., 2014) and pigs
331 (Wang et al., 2014). Regarding the two others, ST1 and ST2, considered to be STs linked to
332 human infection (Clark et al., 2013; Stensvold and Clark, 2016), their origin in Lebanese
333 domestic cattle remains uncertain according to our sequence data. Globally, the low
334 prevalence of ST1, ST2, ST3, ST5 and ST7 observed in the Lebanese cattle population
335 suggests that these animals are unlikely to be natural hosts of these STs and are potentially
336 opportunistically infected through direct exposure to faecal material from human and non-
337 human hosts or by ingestion of contaminated drinking water or food in their environment, as
338 proposed in both stray and household dogs (Wang et al., 2013; Osman et al., 2015). The
339 difference in the prevalence of ST2 observed between dairy cattle raised in the two Lebanese
340 governorates, while this ST is known to infect humans and numerous animal groups (Clark et
341 al., 2013; Stensvold and Clark, 2016; Cian et al., 2017), reinforced this hypothesis by
342 highlighting different infection sources in two different Lebanese geographical areas.
343 However, since domestic cattle carry potential zoonotic STs, these animals are thus capable
344 of shedding the corresponding isolates and may therefore represent secondary zoonotic
345 reservoirs of infection.

346

347 **4. Conclusion**

348 This study presents the first molecular epidemiological data on *Blastocystis* sp. infection
349 in cattle livestock in Lebanon. Through both the high number of samples screened and
350 isolates subtyped, it provided new insights into the prevalence and ST distribution of the
351 parasite in this animal host. This survey conducted in North Lebanon demonstrated that dairy
352 cattle were frequently infected by *Blastocystis* sp., with an overall prevalence of the parasite
353 exceeding 60%. This clearly raised the question of the impact of this infection in the bovid

354 sector, which is of major importance in this country. The variety of STs colonising this
355 animal group was also highlighted, with a total of seven STs identified, including ST1, ST2,
356 ST3, ST5, ST7, ST10 and ST14. ST10 and ST14 were largely predominant in this animal
357 population, confirming that both STs could be considered cattle-adapted STs. Others STs
358 were all identified with low prevalence and their presence was suggested to be related to
359 opportunistic contamination from various animal or even human and environmental sources.
360 Finally, by comparing the ST distribution of the parasite in cattle and in-contact dairy
361 farmers, as well as in individuals without contact with bovids, the risk of zoonotic
362 transmission of *Blastocystis* sp. was highlighted to be likely minimal. However, further large-
363 scale studies should be conducted to fully understand the exact role of domestic cattle in the
364 epidemiology of *Blastocystis* sp. and as potential sources of transmission of the parasite to
365 humans, at least as secondary reservoirs.
