## Abstract

The Core Scientific Dataset (CSD) model with JavaScript Object Notation (JSON) serialization is presented as a lightweight, portable, and versatile standard for intra- and interdisciplinary scientific data exchange. This model supports datasets with a p-component dependent variable,  $\{\mathbf{U}_0, \ldots, \mathbf{U}_q, \ldots, \mathbf{U}_{p-1}\}$ , discretely sampled at M unique points in a d-dimensional independent variable  $(\mathbf{X}_0, \ldots, \mathbf{X}_k, \ldots, \mathbf{X}_{d-1})$  space. Moreover, this sampling is over an orthogonal grid, regular or rectilinear, where the principal coordinate axes of the grid are the independent variables. It can also hold correlated datasets assuming the different physical quantities (dependent variables) are sampled on the same orthogonal grid of independent variables. The model encapsulates the dependent variables' sampled data values and the minimum metadata needed to accurately represent this data in an appropriate coordinate system of independent variables. The CSD model can serve as a re-usable building block in the development of more sophisticated portable scientific dataset file standards.

## 1 Introduction

A frustrating and common problem faced by scientists in many disciplines is the lack of a portable scientific dataset format and universal standards for exchanging and archiving multi-dimensional datasets—both experimental and computational. Scientific datasets are too often saved in vendor-specific file-formats using proprietary software, making archiving and data-exchange problematic even within a discipline, let alone across disciplines. A majority of scientists rely on vendor-specific proprietary software to interact with their datasets. These scientists are at a constant risk that the original dataset files could become unreadable if a future version of the software stops supporting older file formats or the vendor stops supporting the software, or even worse, goes out of business.

6

10

As a result of such risks and incompatibilities, many scientists resort to using comma-separated values (CSV) files for dataset exchange and archival. Such an approach, however, is not resourceful, especially in the case of multi-dimensional datasets. Furthermore, such approaches often leave out essential metadata about experimental or computational procedures. Other scientists resort to specialized library packages to import datasets from the vendor-specific file formats into their favorite programming languages such as Matlab, Python, R, Java, or use the third-party software for dataset imports. This is only a temporary fix since it just delays the original problem as the dataset files are translated to yet another third-party software or user-specific file-format—and again, often with metadata loss.

With increasing pressure from the funding agencies and scientific journals to archive and share primary and processed data, there is a growing sense of urgency for a stable, resourceful and future-proof file-format for the exchange of scientific datasets. Here we take the first step in addressing this problem by proposing a *Core Scientific Dataset (CSD) Model* that can encode a wide variety of multi-dimensional and correlated datasets. The objective of the CSD model is to encapsulate the *data values* and the *minimum metadata* needed to accurately represent the data in an appropriate coordinate system. We envision the CSD model as a re-usable building block in a hierarchical description of more sophisticated portable scientific dataset file standards.

## 2 Overview of CSD Model

The CSD model supports a dataset of a continuous physical quantity (dependent variable) discretely sampled on a multi-dimensional grid with vertexes associated with one or more independent quantities (dimensions), e.g., a density as a function of temperature, a current as a function of voltage and time, an ionization energy as a function of element symbol, etc.

Similarly, the CSD model supports a dataset with a multi-component dependent variable. For example, a color image with a red, green, and blue (RGB) light intensity components as a function of two independent spatial dimensions, or the six components of the symmetric second-rank diffusion tensor MRI dataset as a function of three independent spatial dimensions. In the CSD model, a *dataset* is defined as an *p*-component dependent variable,  $\{\mathbf{U}_0, \ldots, \mathbf{U}_q, \ldots, \mathbf{U}_{p-1}\}$ , discretely sampled at M unique points in a *d*-dimensional  $(\mathbf{X}_0, \ldots, \mathbf{X}_k, \ldots, \mathbf{X}_{d-1})$  space. Moreover, this sampling is over an orthogonal grid, *regular* or *rectilinear*, where the principal coordinate axes of the grid are the dimensions. A regular grid is an orthogonal grid where the spacing between vertex coordinates along each dimension is uniform. If the spacing along any one of the dimensions is not uniform, the grid is rectilinear.

The CSD model can also hold multiple datasets when different physical quantities (dependent variables) are sampled on the same multi-dimensional (independent variables) grid. We refer to this case as *correlated datasets*. One such example would be the simultaneous sampling of current and voltage as a function of time. Another example would be datasets for air temperature, pressure, wind velocity, and solar-flux, all simultaneously sampled on a two-dimensional grid associated with the same region of latitude and longitude coordinates.

We adopt the JavaScript Object Notation (JSON) as the file-serialization format [2] for the CSD model because it is human-readable, if properly organized, as well as *easily integrable* with any number of programming languages and field related application-software.

Figure 1. Unified Modeling Language (UML) 1 class diagram of the Core Scientific Dataset (CSD) Model. Each class is represented with a box that contains two compartments. The top compartment contains the name of the class, and the bottom compartment contains the attributes of the class. The enumerations QuantityType, EncodingType, and NumericType are described in Tables 4, 5, and 6, respectively. The enumeration UnsignedIntegerType is a subset of NumericType enumeration with only unsigned integers. The enumerations DimObjectSubtype and DVObjectSubtype are described in Tables 2 and 3 as the description of the type attribute. The **ScalarQuantity** represents a physical quantity containing a numerical value and a unit. Note: When encoding is base64 the type and multiplicity for the components attribute in InternalDependentVariable is String[1..\*]. Similarly, when encoding is base64 the type and multiplicity for the sparse grid vertexes attribute in **SparseSampling** is String[1].

#### 2.1UML Class Diagram

The schema for the CSD model, in the form of a UML class diagram [1], is shown in Fig. I. In such diagrams, each class is represented with a box that contains two compartments. The top compartment contains the name of the class, and the bottom compartment contains the attributes of the class. A composition is depicted as a binary association decorated with a filled black diamond. Inheritance is shown as a line with a hollow triangle as an arrowhead.

Each line in the bottom compartment of a box describes a single attribute of the class in the form:

name : type [multiplicity] = default {properties}

In this line name is the name of an attribute in the class, type defines the kind of object 69 that may be placed in the attribute, multiplicity indicates how many objects are assigned 70 to the attribute. The multiplicity can be a single number, e.g., "[1]", indicating that one 71 object must be assigned to the attribute. Alternatively, the multiplicity can be given as 72 a lower and upper bound for how many objects can be assigned to the attribute, e.g., 73 "[0,1]" indicates that the assignment of a single object to an attribute is optional. An 74 asterisk indicates an unlimited number of objects. For example, an attribute with a 75 multiplicity of "[1..\*]" must have no less than one object and an unlimited upper bound 76 of objects that can be assigned to it. The default is the object assigned when an 77 optional attribute is unspecified. The {properties} value at the end of the line gives additional information on the attribute. In Fig. 1 this is used to indicate whether a set 79 of objects assigned to an attribute is ordered and/or unique.

For object attribute names we adopt the "snake case" convention with all lower case characters and "camel case" for class or type names. Attribute value types used in the model are given in Table 1 along with the corresponding JSON value type used for serialization of the model. Of particular importance in the CSD model is the **ScalarQuantity** type, which is composed of a numerical value and any valid SI unit symbol or any number of accepted non-SI unit symbols. It is serialized in the JSON file as a string containing a numerical value followed by the unit symbol, for example, "3.4 m" (SI) or "2.3 bar" (non-SI). The CSD model follows the International System of Units guideline 3 for defining the physical quantities. In software usage, one must adhere to stricter conventions for unit and physical constant symbols to avoid ambiguities and symbol collisions. All unit symbols are case sensitive. For derived unit symbols, the multiplication and division of the units are represented by the *asterisk* symbol, "**\***", and the *solidus* symbol, "/", respectively. For example, a unit of speed is "m/s". Note that derived unit symbols in the CSD model require explicit use of the multiplication symbol instead of multiplication implied with spacing between symbols, e.g., use "N\*m" instead of "N m". Similarly, avoid the use of compound symbols, e.g., use "kW\*h" instead of "kWh". The *caret* symbol, "^" is used for raising unit symbols to

| Boolean                        | boolean         |

 Table 1. The relation between the CSD model attribute value types and the corresponding JSON serialized value type. In JSON serialization the attribute name is the JSON key.

a power—a unit of force is "kg\*m^2/s^2", and a unit of concentration is "g/cm^3". Operator precedence can be specified using parentheses, e.g., "J/(mol\*K)". Also, note that while both °C and °F are valid units, they are not proper thermodynamic temperature units and are discouraged due to their ambiguity. Further details on the SI system and how units are used in the CSD model are given in the supporting information.

### 2.2 CSDM object

At the root level of the CSD model is the **CSDM** object. The **CSDM** object includes a 105 required version attribute whose value is a string representing the version number of the 106 CSD model, here assigned a string value of "1.0". The optional timestamp attribute 107 indicates when the CSDM file was last serialized and holds a combined date and time 108 string representation of the Coordinated Universal Time (UTC) formatted according to 109 the ISO-8601 standard. The optional geographic coordinate attribute indicates where 110 the CSDM file was last serialized and holds a **GeographicCoordinate** object, inside 111 which are three attributes: the required latitude and longitude, and the optional altitude. 112 Positive latitude values indicate latitudes north of the equator, while negative values 113 indicate latitudes south of the equator. Longitude values are relative to the zero 114 meridian, with positive values extending east of the meridian and negative values 115 extending west of the meridian. Positive altitudes indicate above sea level while negative 116 values indicate below sea level. All three are **ScalarQuantity** types. The optional 117 boolean read only attribute is set to true for archived datasets—informing applications 118 that the dataset should not be modified or overwritten. The optional tags attribute 119 holds a set of UTF-8 allowed string values describing keywords associated with the 120 dataset. The description attribute appears in nearly every CSD model object and holds 121 a UTF-8 allowed string describing the instance of the model object. The application 122 attribute also appears in nearly every CSD model object and is a generic object that 123 can be used for storing application-specific metadata within the CSD model. Further 124 details on the expected behavior of application attributes are given in section 2.5. 125

The dependent\_variables and dimensions attributes each hold a set of **DependentVariable** and **Dimension** objects, respectively. The ordered and unique set of **Dimension** objects, indexed from k = 0 to d - 1, define the *d*-dimensional coordinate grid where discrete samples of the dependent variables are taken. **128** 

100

101

102

103

#### 2.3**Dimension** object

The mapping of grid vertexes along the  $k^{\rm th}$  dimension to an ordered set of coordinates, 131  $\mathbf{X}_k$ , are defined by one of three **Dimension** subtypes: **LabeledDimension**, **MonotonicDimension**, and **LinearDimension**. Figure 1 gives the required and optional 133 attributes along with their default values for the three subtypes. Descriptions of the 134 attributes for all three subtypes are also given in Table 2, and examples of various 135 instances are given in section 3.

#### 2.3.1LabeledDimension object

An ordered set,  $\mathbf{A}_k$ , of  $N_k$  character string labels in the labels attribute of a 138 **LabeledDimension** object are mapped to the grid vertexes along the  $k^{\text{th}}$  dimension, 139 becoming the ordered set of coordinates,  $\mathbf{X}_k$ , along the dimension, as given by 140

$$\mathbf{X}_k = \mathbf{A}_k. \tag{1}$$

130

137

143

153

154

156

157

158

159

160

161

This is a purely qualitative dimension, with no physical significance given to the spacing 141 between grid vertexes along the dimension. 142

#### 2.3.2MonotonicDimension object

An ordered set,  $\mathbf{A}_k$ , of  $N_k$  strictly ascending or descending coordinates in the 144 coordinates attribute of a MonotonicDimension object are similarly mapped to the grid 145 vertexes along the  $k^{\text{th}}$  dimension and become the ordered set of coordinates along the 146 dimension, also given by Eq. (1). 147

For the **MonotonicDimension** and **LinearDimension** objects, the CSD model allows 148 the mapping of grid vertexes along a dimension to an ordered set of absolute 149 coordinates,  $\mathbf{X}_{k}^{\text{abs}}$ , using the origin\_offset attribute according to 150

$$\mathbf{X}_{k}^{\mathrm{abs}} = \mathbf{X}_{k} + o_{k}\mathbf{1},\tag{2}$$

where  $o_k$  is the value of the origin\_offset attribute. Note, the **ScalarQuantity** objects in 151  $\mathbf{X}_k$ , and  $o_k$  must all share the same unit dimensionality. 152

#### LinearDimension object 2.3.3

The ordered set of  $N_k$  uniformly spaced coordinates along the  $k^{\text{th}}$  LinearDimension object are given by 155

$$\mathbf{X}_{k} = \Delta x_{k} \, \left( \mathbf{J}_{k} - Z_{k} \right) + b_{k} \mathbf{1},\tag{3}$$

where  $\Delta x_k$  and  $b_k$  are the **ScalarQuantity** objects in the increment and coordinates offset attributes, respectively, and  $\mathbf{J}_k$  is an ordered set of coordinate indexes along the  $k^{\text{th}}$  dimension,

$$\mathbf{J}_{k} = [0, 1, 2..., j_{k}, ..., N_{k} - 1].$$
(4)

Here,  $N_k$  is the **Integer** object in the count attribute. As before, the absolute coordinates along the  $k^{\text{th}}$  dimension are given by Eq. (2). Again, the **ScalarQuantity** objects  $\Delta x_k$ ,  $b_k$ , and  $o_k$  must all share the same unit dimensionality.

The  $Z_k$  variable in Eq. (3) is an integer with a value of  $Z_k = 0$  when the 162 LinearDimension attribute complex fft is false. The complex fft is set to true when 163 a complex fast Fourier transform (FFT) has been applied to the dataset along the  $k^{\text{th}}$ 164 dimension, and then the value of  $Z_k$  becomes  $T_k/2$ , where  $T_k = N_k$  and  $N_k - 1$  for even 165 and odd values of  $N_k$ , respectively. There are two reasons for the inclusion of the 166 attribute complex fft and the different values of  $Z_k$ . First, it provides the metadata 167 needed for determining whether a forward (false) or reverse (true) complex FFT should be performed on the dataset. Second, a value of  $Z_k = T_k/2$  in Eq. (3) when complex\_fft is true associates  $b_k$  with the zero "frequency" after a complex FFT. This definition makes  $b_k$  independent of count and the increment in the Reciprocal dimension, i.e., the dimension before the complex FFT.

#### 2.3.4 ReciprocalDimension object

An optional attribute named reciprocal can be present in both the LinearDimension and MonotonicDimension objects. This attribute holds a ReciprocalDimension object which contains metadata about the coordinate that is reciprocal to the  $X_k$  coordinate. This metadata is useful for datasets which are frequently transformed into the reciprocal dimension, such as NMR, FTIR and x-ray datasets.

### 2.4 DependentVariable object

The **DependentVariable** object can be one of two subtypes: 180 InternalDependentVariable and ExternalDependentVariable, depending on whether 181 the serialized components are stored internally with the rest of the serialized metadata or externally at a location specified by a uniform resource locator (URL) [4], 183 respectively. Descriptions of all DependentVariable attributes are given in Table [3], as well as through examples given in section [3]. See Fig. [1] for the required and optional attributes along with their default values. 186

A **DependentVariable** object holds an ordered set of p components indexed from q = 0 to p - 1,

$$[\mathbf{U}_0,\ldots,\mathbf{U}_q,\ldots,\mathbf{U}_{p-1}].$$
(5)

Each component,  $\mathbf{U}_q$ , contains an ordered array of M physical quantity values indexed from i = 0 to M - 1. These values represent samples on the coordinates grid and are ordered to follow a *column-major order* relative to the ordered set of dimensions. If  $\mathbf{U}_q$ contains a sample at every vertex of the d-dimensional grid, then

$$M = \prod_{k=0}^{d-1} N_k,\tag{6}$$

and the mapping of the values in  $\mathbf{U}_q$  to the grid vertexes follows a simple reshaping of  $\mathbf{U}_q$  to a  $N_0 \times N_1 \times \ldots \times N_{d-1}$  matrix where d is the number of **Dimension** objects. In this case, the location or memory offset of the  $i^{\text{th}}$  value in a component array maps to a grid vertex with coordinate indexes,  $(j_0, j_1, \ldots, j_{d-1})$ , given by

$$j_k = \frac{i}{\prod_{\ell=0}^{k-1} N_\ell} \mod N_k, \qquad k = 0, \dots, d-1.$$
 (7)

Conversely, the memory offset of the  $i^{\text{th}}$  value in a component array is obtained from the ordered array of coordinate indexes  $(j_0, j_1, \ldots, j_{d-1})$ , according to

$$i = \sum_{k=0}^{d-1} \left( \prod_{l=0}^{k-1} N_l \right) j_k.$$
(8)

It is also helpful to recall that the value of the empty product,  $\prod_{m=1}^{n} a_{m}$  where m > n is 1. Taken together, the *i*<sup>th</sup> values from each of the *p* components form a quantity

Taken together, the  $i^{\text{th}}$  values from each of the *p* components form a quantity specified by one of the quantity\_type attribute values given in Table 4.

201

173

179

187

| Dimension          |   |  |  |  |  |
|--------------------|---|--|--|--|--|
| attribute          | description   |  |  |  |  |
| type               | <i>Required</i> attribute for all <b>Dimension</b> objects. Holds a <b>String</b> object with one of the allowed <b>DimObjectSubtype</b> enumeration literals—linear, monotonic or labeled.   |  |  |  |  |
| labels             | <i>Required</i> attribute for LabeledDimension objects. Holds an <i>ordered and unique array</i> of String objects containing UTF-8 allowed characters. <i>Invalid</i> for LinearDimension and MonotonicDimension objects.  |  |  |  |  |
| coordinates        | <i>Required</i> attribute for <b>MonotonicDimension</b> objects. Holds an <i>ordered and unique array</i> of strictly increasing or decreasing <b>ScalarQuantity</b> objects along the dimension. The dimensionality of <b>ScalarQuantity</b> objects must be consistent with each other and other dimension attributes. <i>Invalid</i> for <b>LinearDimension</b> and <b>LabeledDimension</b> objects.   |  |  |  |  |
| count              | <i>Required</i> attribute for LinearDimension objects. Holds an Integer object specifying the number of coordinates, $N_k$ , along the dimension. <i>Invalid</i> for MonotonicDimension and LabeledDimension objects.   |  |  |  |  |
| increment          | Required attribute for LinearDimension objects. Holds a ScalarQuantity object specifying the increment, $\Delta x_k$ , along the dimension. Invalid for MonotonicDimension and LabeledDimension objects.  |  |  |  |  |
| coordinates_offset | Optional attribute for LinearDimension objects. Holds a ScalarQuantity object specifying the coordinates offset, $b_k$ , used in Eq. (3) to calculate the coordinates along the dimension. The default value is a physical quantity with a numerical value of zero. <i>Invalid</i> for MonotonicDimension and LabeledDimension objects.   |  |  |  |  |
| origin_offset      | Optional attribute for LinearDimension and MonotonicDimension objects. Holds a ScalarQuantity object specify-<br>ing the origin offset, $o_k$ , along the dimension. The default value is a physical quantity with a numerical value of<br>zero. Invalid for LabeledDimension objects.  |  |  |  |  |
| complex_fft        | Optional attribute for LinearDimension objects. Holds a Boolean specifying how the coordinate, $X_k$ , along the dimension are calculated from Eq. (3). When false, the value of $Z_k = 0$ otherwise, $Z_k = T_k/2$ where $T_k = N_k$ and $N_k - 1$ for even and odd values of $N_k$ , respectively. Invalid for MonotonicDimension and LabeledDimension objects.   |  |  |  |  |
| period             | <i>Optional</i> attribute for <b>MonotonicDimension</b> and <b>LinearDimension</b> objects. Holds a <b>ScalarQuantity</b> object speci-<br>fying the period of the dimension. The default value is a physical quantity with an infinite numerical value,<br>that is, the absence of this key indicates that the dimension is non-periodic. When present it indicates that all<br>dependent variables are periodic along the dimension. A <b>ScalarQuantity</b> object with a numerical value of zero is<br><i>invalid</i> for this attribute. <i>Invalid</i> for <b>LabeledDimension</b> objects.   |  |  |  |  |
| quantity_name      | Optional attribute for MonotonicDimension and LinearDimension objects. Holds a String object containing the quantity name associated with the dimension. This value may resolve ambiguities which may otherwise be inherent. For example, with only a unit of "J/(mol*K)", one cannot distinguish between the thermodynamic quantities 'molar entropy' and 'molar heat capacity.' Similarly, the units "1/s", "Bq", and "Hz" all have the dimensionality of inverse time, but generally "Bq" would be an acceptable unit for the quantity of radioactivity and "Hz" for frequency. If unspecified the valid quantity name is left at the end-user's discretion. A list of CSDM-accepted physical quantity names and their corresponding dimensionalities can be found in the supporting information. <i>Invalid</i> for LabeledDimension objects. |  |  |  |  |
| label              | <i>Optional</i> attribute for all <b>Dimension</b> objects. Holds a <b>String</b> object of UTF-8 allowed characters containing the label for the <b>Dimension</b> object. The default value is an empty string.  |  |  |  |  |
| description        | <i>Optional</i> attribute for all <b>Dimension</b> objects. Holds a <b>String</b> object of UTF-8 allowed characters describing an instance of the <b>Dimension</b> object. The default value is an empty string.   |  |  |  |  |
| reciprocal         | <i>Optional</i> attribute for <b>MonotonicDimension</b> and <b>LinearDimension</b> objects. Holds a <b>ReciprocalDimension</b> object. See Fig. 1 for the list of attributes in this object. These attributes follow the same definitions as described in this Table with the only difference being that these attributes describe the reciprocal dimension. <i>Invalid</i> for <b>LabeledDimension</b> objects.  |  |  |  |  |
| application        | <i>Optional</i> attribute for all <b>Dimension</b> objects. Holds a generic dictionary object. See section $2.5$ for expected behavior.   |  |  |  |  |

**Table 2.** The description of the attributes from the **Dimension** class in version 1.0 of the CSD model. There are three subtypes of this class—**LinearDimension**, **MonotonicDimension**, and **LabeledDimension**. See Fig. 1 for the list of *valid* attributes for a given subtype. If an attribute is optional, its value should only be serialized to the file if it is not the default value. As a recommendation, when descrializing a JSON file the numerical value associated with the physical quantities should be converted to a 32-bit or higher floating-point number.

| Dependent Variable  |  |  |  |  |  |
|---------------------|--|--|--|--|--|
| attribute           | description  |  |  |  |  |
| type                | <i>Required</i> attribute for all <b>DependentVariable</b> objects. Holds a <b>String</b> object with one of the two allowed <b>DVObjectSubtype</b> enumeration literals—internal or external.   |  |  |  |  |
| components          | Required attribute for InternalDependentVariable objects. Holds an ordered array of $p$ components. When the value of encoding attribute is none each component, $\mathbf{U}_q$ , is an ordered array of numerical values. When the value of the encoding attribute is base64, each component is a Base64 string. Invalid for ExternalDependentVariable objects.   |  |  |  |  |
| components_url      | Required attribute for ExternalDependentVariable objects. Holds a String object containing the Uniform Resource<br>Locator (URL) of a local or a remote file where the ordered array of numerical values $\{\mathbf{U}_0, \ldots, \mathbf{U}_q, \ldots, \mathbf{U}_p\}$<br>are stored as binary data. The CSD model utilizes the https and file schemes for locating the files. For<br>local data files, the URL is specified relative to the .csdfe file and is located either in the folder containing<br>the .csdfe file or in a subfolder of the folder containing the .csdfe file. The corresponding syntax follows<br>file:./relative/path/to/the/file. Invalid for InternalDependentVariable objects. |  |  |  |  |
| numeric_type        | Required attribute for all <b>DependentVariable</b> objects. Holds a <b>String</b> object with one of the allowed <b>NumericType</b> enumeration literals from Table <b>6</b> . This value represents the numeric type and the number of bits associated with each numerical value in Eq. (5) when the component data is stored in an external file or when Base64 encoded into a string. When numerical values are expressed as JSON numbers, this value specifies the numerical precision needed for import.   |  |  |  |  |
| quantity_type       | <i>Required</i> attribute for all <b>DependentVariable</b> objects. Holds a <b>String</b> object with any of the allowed <b>QuantityType</b> enumeration literals from Table 4. The value specifies the number, $p$ , and interpretation of the <b>DependentVariable</b> components.   |  |  |  |  |
| unit                | <i>Optional</i> attribute for all <b>DependentVariable</b> objects. Holds a <b>String</b> object representing the unit associated with the data values in Eq. (5). The default value is "", i.e., the data values are dimensionless.   |  |  |  |  |
| quantity_name       | <i>Optional</i> attribute for all <b>DependentVariable</b> objects. Holds a <b>String</b> object containing the <i>quantity name</i> associated with the physical quantity. See the description for the <b>quantity_name</b> attribute in Table 2 for further details.   |  |  |  |  |
| encoding            | <i>Optional</i> attribute for <b>InternalDependentVariable</b> objects. Holds a <b>String</b> object with one of the allowed <b>EncodingType</b> enumeration literals in Table <b>5</b> . This value specifies the encoding method used to store the data values in the <b>components</b> attribute. The default value is <b>none</b> . <i>Invalid</i> for <b>ExternalDependentVariable</b> objects.   |  |  |  |  |
| $component\_labels$ | <i>Optional</i> attribute for all <b>DependentVariable</b> objects. Holds an <i>ordered array</i> of <b>String</b> objects where the $q^{\text{th}}$ <b>String</b> is the label associated with the $q^{\text{th}}$ component. The default value is an ordered set of empty strings.   |  |  |  |  |
| name                | <i>Optional</i> attribute for all <b>DependentVariable</b> objects. Holds a <b>String</b> object of UTF-8 allowed characters containing the name associated with the dependent variable. Naming is good practice as it improves the human readability of the serialized file when multiple dependent variables might be present. The default value is an empty string.   |  |  |  |  |
| description         | <i>Optional</i> attribute for all <b>DependentVariable</b> objects. Holds a <b>String</b> object of UTF-8 allowed characters describing an instance of the <b>DependentVariable</b> . The default value is an empty string.  |  |  |  |  |
| sparse_sampling     | Optional attribute for all <b>DependentVariable</b> objects. Holds a <b>SparseSampling</b> object, which contains the attributes dimension_indexes and sparse_grid_vertexes. The attribute dimension_indexes holds an array of integers indicating which dimensions in the ordered array of dimensions are sparsely sampled and form the sparse grid. The attribute sparse_grid_vertexes holds an array of integers defining the ordered set of sampled vertexes on the sparse grid. See section 2.4.1 for further details.  |  |  |  |  |
| application         | <i>Optional</i> attribute for all <b>DependentVariable</b> objects. Holds a generic dictionary object. See section $2.5$ for expected behavior.  |  |  |  |  |

**Table 3.** The description of the attributes from the **DependentVariable** class in version 1.0 of the CSD model. If an attribute is optional, its value may only be serialized to the file if it is not the default value.

#### QuantityType

scalar

This value represents a p = 1, single-component dependent variable where the  $i^{\text{th}}$  data value is interpreted as a scalar value,  $S_i = U_{0,i}$ .

 $\texttt{vector}\_n$ 

The value represents a p = n component dependent variable where the  $i^{\text{th}}$  data value is interpreted as a vector,  $\mathcal{V}_i = [U_{0,i}, U_{1,i}, \dots U_{n-1,i}]$ .

#### matrix\_m\_n

The value represents a p = mn component dependent variable where the  $i^{\text{th}}$  data value is interpreted as a  $m \times n$  matrix, with m rows and n columns. The p components of the matrix are in column-major order.

$$\mathcal{M}_{i} = \begin{bmatrix} U_{0,i} & U_{m,i} & \dots & U_{(n-1)m,i} \\ U_{1,i} & U_{m+1,i} & \dots & U_{(n-1)m+1,i} \\ \vdots & \vdots & \vdots & \vdots \\ U_{m-1,i} & U_{2m-1,i} & \dots & U_{nm-1,i} \end{bmatrix}$$

Here, the entry at the  $r^{\text{th}}$  row and the  $c^{\text{th}}$  column is  $U_{cm+r,i}$ . symmetric\_matrix\_n

The value represents a  $p = \frac{n(n+1)}{2}$  component dependent variable. This is a special case of matrix data value where n = m and the matrix is symmetric about the leading diagonal. In this case, only the upper half of the matrix is specified. The  $n \times n$  symmetric matrix,  $\mathcal{M}_i^{(s)}$ , of the  $i^{\text{th}}$  data value is interpreted as,

$$\mathcal{M}_{i}^{(s)} = \begin{bmatrix} U_{0,i} & U_{1,i} & \dots & U_{n-1,i} \\ U_{1,i} & U_{n,i} & \dots & U_{2n-2,i} \\ \vdots & \vdots & \vdots & \vdots \\ U_{n-1,i} & U_{2n-2,i} & \dots & U_{\frac{n(n+1)}{2}-1,i} \end{bmatrix}$$

pixel\_n

The value represents a p = n component dependent variable where the  $i^{\text{th}}$  data value is interpreted as a pixel,  $[U_{0,i}, U_{1,i}, \ldots, U_{n-1,i}]$ , with the *n* components corresponding to pixel component intensities. Note this quantity type, as do all quantity types, is restricted to components that share the same physical dimensionality, i.e., can be added or subtracted, making it, for example, appropriate for holding RGB or CMYK components but not HSV components.

Table 4. The literals of the **QuantityType** enumeration allowed in version 1.0 of the CSD model along with its description. The literals are **String** objects and correspond to the value of the quantity\_type attribute of the **DependentVariable** object. In the description, the index *i* refers to the *i*<sup>th</sup> data value from the ordered array,  $U_q$ , in Eq. (5).

#### EncodingType

base64

The binary data corresponding to the ordered array of numerical values in  $U_q$  from Eq. (5) is stored as a Base64 encoded strings for the numeric\_type specified assuming 'little-endian' format. This is the recommended storage method when the type attribute of the corresponding **DependentVariable** object is internal. none

The literal denotes that the ordered array of numerical values from Eq. (5) are serialized as JSON numbers. This is the default encoding type when the encoding attribute is not present in the **DependentVariable** object.

**Table 5.** The literals of the **EncodingType** enumeration allowed in version 1.0 of the CSD model along with its description. The literals are the **String** object corresponding to the value of the **encoding** attribute of the **DependentVariable** object.

| NumericType |                                    |  |
|-------------|------------------------------------|--|
| uint8       | 8-bit unsigned integer             |  |
| uint16      | 16-bit unsigned integer            |  |
| uint32      | 32-bit unsigned integer            |  |
| uint64      | 64-bit unsigned integer            |  |
| int8        | 8-bit signed integer               |  |
| int16       | 16-bit signed integer              |  |
| int32       | 32-bit signed integer              |  |
| int64       | 64-bit signed integer              |  |
| float32     | 32-bit floating-point number       |  |
| float64     | 64-bit floating-point number       |  |
| complex64   | two 32-bit floating-points numbers |  |
| complex128  | two 64-bit floating-points numbers |  |

**Table 6.** The literals of the **NumericType** enumeration allowed in version 1.0 of the CSD model along with its description. The literal is a **String** object corresponding to the value of the **numeric** type attribute of the **DependentVariable** object.

#### **InternalDependentVariable:** The components attribute in an 202 **InternalDependentVariable** object holds an *ordered array* of p components, and each 203 component, $\mathbf{U}_q$ , is an ordered array of M numerical values associated with the $q^{\text{th}}$ 204 component. When the value of the encoding attribute is none or unspecified, a JSON 205 serialization of this object gives a human-readable list of numerical values. This 206 approach, however, is not resourceful compared to the serialization of raw binary data. 207 As JSON files are strictly text-based it is not possible to serialize raw binary data inside 208 a JSON file. A commonly used approach to reduce JSON file sizes in such situations is 209 to encode raw binary data into plain text using a binary-to-text encoding scheme. The 210 CSD model allows this approach with the raw binary data for each component encoded 211 into a Base64 string when the encoding attribute is set to base64. In this case, JSON 212 serialization of the components attribute in an **InternalDependentVariable** object holds 213 an ordered array of p Base64 strings where the $q^{\text{th}}$ string represents the array $\mathbf{U}_q$ . Out 214 of the various binary-to-text encoding schemes, we chose Base64 encoding because of its 215 widespread use and easy access to decoders across most object-oriented programming 216 languages. Base64 provides an efficiency of $\sim 75\%$ compared to the serialization of raw 217 binary data. When encoding and decoding raw binary data with Base64 we assume a 218 'little-endian' byte order for multi-byte numeric types such as 32-bit and 64-bit integers 219 or floats. Typically, data saved on Intel x86 platforms use the little-endian as the native 220 format. Also, binary floating-point standard IEEE 754 is assumed for float and complex 221 numeric types. 222

**ExternalDependentVariable:** The components url attribute is only *valid* when the 223 value of the corresponding type attribute is external. Its value is a **String** object 224 containing the address of a local or a remote file where the ordered array of numerical 225 values  $\{\mathbf{U}_0, \ldots, \mathbf{U}_q, \ldots, \mathbf{U}_p\}$  are stored as binary data. In this case we also assume 226 little-endian byte order and the binary floating-point standard IEEE 754 for float and 227 complex numeric types. The CSD model utilizes the https and file schemes of the 228 Uniform Resource Locator (URL) for locating the files. For local data files, the URL is 229 specified relative to the .csdfe file (see section 2.6) and is located either in the folder 230 containing the .csdfe file or in a subfolder of the folder containing the .csdfe file. The 231 corresponding syntax follows, file:./relative/path/to/the/file. 232

### 2.4.1 SparseSampling object

Equations (6), (7) and (8) are no longer valid when the **DependentVariable** 234 components are sparsely sampled on the d dimensional grid. In this case, additional 235 metadata is required to determine the grid vertex,  $(j_0, j_1, \ldots, j_{d-1})$ , where the  $i^{\text{th}}$ 236 sampled component value belongs. If the component is sparsely sampled along all d237 dimensions, then the additional metadata can be an ordered set of M grid vertexes. We 238 must, however, consider the general mixed case of s fully sampled dimensions and d-s239 sparsely sampled dimensions. In this case, we adopt an approach where the component 240 values are organized into a set of fully sampled s-dimensional cross-sections taken at 241 vertexes of a sub-grid formed from the sparsely sampled dimensions, which we will call 242 the sparse grid. In adopting this approach, we require that the component values along 243 the fully sampled dimensions are packed together into the array in column-major order 244 relative to the ordered set of fully sampled dimensions, i.e., excluding the sparsely 245 sampled dimensions. 246

The **SparseSampling** object provides this metadata in its two attributes dimension\_indexes and sparse\_grid\_vertexes. The dimension\_indexes attribute holds an ordered and unique set of integers indicating along which dimensions the **DependentVariable** is sparsely sampled. These dimensions form the sparse grid. The sparse\_grid\_vertexes holds an ordered set of vertexes on the sparse grid. Each sparse

grid vertex is an ordered array of d - s indexes. To make the serialization more resourceful, we flatten the ordered set of arrays intended for the sparse\_grid\_vertexes attribute into an ordered array of integers, for example,

$$[[1,0], [3,4], [5,7], [8,11], \ldots] \rightarrow [1,0,3,4,5,7,8,11,\ldots],$$

### 2.5 Generic application objects - Beyond the CSD Model

As stated earlier, the objective of the CSD model is to encapsulate the *data values* and 254 the *minimum metadata* needed to accurately represent the data in an appropriate 255 coordinate system, that is, the minimum metadata for defining the current state of the 256 dataset. Thus, the goal of the CSD model is to always remain relevant as the state of 257 the dataset changes. In our refinement of the CSD model, we identified any metadata 258 attribute as extraneous if it could become irrelevant as the state of the dataset changes. 259 Metadata attributes extraneous to the CSD model could generally be classified as 260 belonging in one of four broad and somewhat overlapping categories: acquisition, 261 process, analysis, and presentation. The design of models organizing these extraneous 262 metadata attributes tends to be scientific domain specific, although some commonalities 263 exist. The CSD model allows the inclusion of metadata models describing these other 264 categories using generic application objects. An application can place its own attribute 265 type, e.g., a dictionary object with application-specific metadata attributes inside each 266 generic application object using a reverse domain name notation string as the attribute 267 key, for example, "com.example.myApp". The use of a reverse-DNS key provides a 268 simple mechanism for reducing name-space collisions. Overall, we believe generic 269 application objects give the CSD model enough flexibility to become the native file 270 format of many applications. 271

This approach, however, creates a dilemma when CSDM files are saved and opened 272 by different applications. Specifically, what does an application from company B (e.g., 273 "com.B.process") do with generic application objects placed in a CSDM file by an 274 application from company A (e.g., "com.A.acquire")? On the one hand, company B 275 could retain the company A specific metadata (as found) in the generic application 276 object using the "com.A.acquire" key as well as serialize its own metadata using the 277 "com.B.process" key. If the company B application made any modification to the 278 dataset, however, it runs the risk that parts of the company A application-specific 279 metadata are now irrelevant or logically inconsistent with the newly saved dataset—potentially causing company A's application to crash when it tries to open this 281 newly saved dataset. On the other hand, company B could decide to discard the 282 company A specific metadata, in which case the company A application can safely open 283 the dataset saved by company B, but will have lost all of its previously saved metadata. 284 Finding a consistent solution to this dilemma is critically important as one can easily 285 envision a workflow where a dataset passes through many applications as it progresses 286 from the raw dataset to the final "product." During such a workflow there is often an 287 expectation of an audit trail, which most likely could be determined from application 288 metadata saved by each application used during the workflow. 289

One approach that could solve this dilemma is to allow the CSDM file to contain a time-ordered array of CSDM objects. In other words, company B would simply append 201

a second CSDM object with only company B metadata to the array that already 292 contains the CSDM object created by company A. No application metadata would be 293 lost, and the metadata in each CSDM object would be relevant and logically consistent 294 with its respective datasets. In this approach, the CSDM "array" file would grow as each 295 application completes its task in the overall workflow. 296

It is our opinion, however, that it is better to delegate such a task of managing a 297 time-ordered array of CSDM objects to the operating system. In this approach, we 298 envision the workflow associated with a particular dataset to result in a folder 299 containing a series of CSDM files, each a snapshot from the workflow as it progresses 300 from the raw dataset to the final "product." When each application is finished with its 301 workflow task a CSDM file is saved with the read only flag set to true, so that any 302 future work on the dataset would be performed on a copy of the CSDM dataset, leaving 303 the "read-only" file with application metadata intact. Typically, the read only flag 304 would be set to true immediately after the acquisition of raw data, after processing is 305 complete, or after analysis of a dataset. Delegating the task of managing a time-ordered 306 set of CSDM objects to the operating system also makes the workflow status involving 307 individual CSDM files more transparent to the end-user. In adopting this solution we 308 propose the general rule that while application attributes should be visible to any 309 application opening a CSDM file, only the reverse-DNS owners have permission to use 310 their respective keys to place an attribute in an application object. 311

An application could implement an additional layer of protection from application metadata loss by saving CSDM compliant files with its own application-specific file extension. Other applications could still open the CSDM compliant file but would be discouraged from saving with another application's file extension.

#### 2.6**JSON** file-serialization

A JSON file is ordinarily a UTF-8 encoded text file which is built on two structures: a 317 collection of unordered key-value pairs and an ordered list of values. The "key": value 318 pair is separated by a *colon* symbol, with the key to the left and the **value** to the right 319 of the colon. Different key-value pairs are separated using *commas*. The JSON keys are 320 always wrapped in double quotation marks, as in "key", and the value type can either 321 be (a) a string, (b) a number, (c) a JSON object, (d) an array, (e) a boolean or (d) null. 322 A string is a composition of JSON allowed characters 2 wrapped in double quotation 323 marks. A number can be integer or float. A JSON object is an unordered set of 324 key-value pairs which begins with a left curly brace, {, and ends in a right curly brace, 325 }. An array is an ordered collection of JSON values that begins with a left square 326 bracket, [, and ends in a right square bracket, ]. A boolean is true or false. In the 327 JSON serialization of the CSD model, the JSON "key" corresponds to the attribute 328 name of the various CSD model objects while the JSON value and CSD model 329 attribute value follow the relationship listed in Table 1. 330

Efforts have been made in the design of the CSD model to keep the keys intuitive 331 and self-explanatory to all scientists and engineers. To further enhance the human-readability aspect of the files, we recommend, as a general rule, that no key be 333 present in the file unless its value differs from the default value. With this in mind, the CSD model defines all boolean values as false when unspecified. In other words, the 335 only boolean keys that need to appear in the file are those set to true.

The serialization file names are designated with two possible extensions: .csdf and 337 .csdfe, the acronyms for Core Scientific Dataset Format and Core Scientific Dataset 338 Format External. When all data values are stored within the file, i.e., there are no 330 instances of an **ExternalDependentVariable** object in the serialization, then the .csdf 340 file extension is allowed, otherwise, the serialization file name must use the extension 341 .csdfe. This difference in extensions is intended to alert the end-user to a possible risk 342

#### $d\mathbf{D}\{p_0, p_1, \ldots\}$ example datasets 3

In this section we examine the CSD model in a number of illustrative examples. We use 346 a shorthand notation of  $dD\{p\}$  to indicate that a dataset has a p-component dependent 347 variable defined on a *d*-dimensional coordinate grid. In the case of correlated datasets 348 the number of components in each dependent variable is given as a list within the curly 349 braces, i.e.,  $dD\{p_0, p_1, p_2, ...\}$ . 350

of failure if the external data file is inaccessible when deserializing a file with the

Efforts have been made to include examples across disciplines, although given our 351 expertise in magnetic resonance spectroscopy, we include multiple examples from this 352 field. It is worth noting, however, that magnetic resonance datasets prove to be 353 excellent test cases for the CSD model as they are diverse and often multi-dimensional 354 in nature. We have converted a variety of datasets from various fields to the CSD model 355 format. To accomplish this, we utilize several Python packages 5,6 to import the 356 original field-specific scientific datasets as Numpy 7 array(s) and export the latter in 357 the CSD model format using the csdmpy package for Python, described in the appendix. 358

#### $1D\{1\}$ examples 3.1

.csdfe file extensions.

In this section, we examine the JSON serialization for illustrative cases of  $1D\{1\}$ datasets. These are the simplest cases, with one dimension, d = 1, and one single-component dependent variable, p = 1. The supplementary material gives further 362 1D{1} examples from FITR, UV-vis, and EPR spectroscopies.

### GMSL.csdf

An example of a JSON serialized CSD model holding a  $1D{1}$  dataset is shown in Listing 1. This dataset is a measurement of the global mean sea level 8 (GMSL) based on the satellite altimeter data from 1993-2009.

At the root level is the csdm key, an acronym for the core scientific dataset model. 368 The value of this key is a JSON object which is a serialization of the CSD model's 369 **CSDM** object and includes six keys—version, timestamp, tags, description, dimensions, 370 and dependent variables. The value of the dimensions key is an array (lines 7-14) with a 371 single JSON object defined in-between lines 8 and 13. This object is a JSON 372 serialization of the CSD model's **Dimension** object. In this example, it represents a 373 **LinearDimension** object, as indicated by the value of **linear** in the type key, and with 374 a coordinate count of 1608 as defined by the value of the key count. Furthermore, it is a 375 temporal dimension with **ScalarQuantity** values of 0.08333 yr for increment and 376 1880.0417 yr for coordinates offset. The coordinates at vertexes along this temporal 377 dimension are obtained from Eq. (3). 378

The value of the dependent variables key is an array (lines 15-31) with a single 379 JSON object describing the global mean sea level. This object is a JSON serialization of 380 an **InternalDependentVariable** object, with data values stored within the object, as 381 indicated by the value of internal for the type key. The data values are serialized as 382 JSON numbers as seen in-between lines 23-28 of Listing 1. Ellipses indicate where 383 superfluous lines were omitted from the listing. The value of float32 for the 384 numeric type key indicates that the array of JSON numbers should be converted into a 385 numerical array of data values with 32-bit floating-point precision on import. The value 386 of mm for the unit key is the unit associated with the data values. The value of the 387 component labels is an array with a single entry holding the label associated with the 388

**Listing 1.** A JSON serialized CSD model describing the global mean sea level dataset. The listing was created by the authors using data from reference 8.

Figure 2. A line plot, derived from Listing 1, depicting the global mean sea level as a function of time. The figure was created by the authors using data from reference 8.

component values. The value of scalar for the quantity\_type key indicates that the component of the dependent variable is interpreted as scalar.

A plot of the dataset is shown in Fig. 2. Note that meta-data on how a dataset is presented in a plot or otherwise is not included in the CSD model. While such presentation metadata is outside the scope of the core model, it can be included in an **application** dictionary.

#### blochDecay.csdf

Another simple example of a 1D{1} dataset is shown in Listing 2 This example corresponds to a <sup>13</sup>C free induction decay signal from a nuclear magnetic resonance spectroscopy of ethanol.

The value of the dimensions key is an array (lines 12-26) with a single JSON 309 serialized **LinearDimension** object (lines 13-25) representing a temporal dimension with 4096 coordinate positions sampled every 0.1 ms starting at -0.3 ms. The coordinate values along the dimension are evaluated using Eq. (3). This **LinearDimension** object also contains an optional JSON serialized **ReciprocalDimension** object (lines 19-24) as the value of the reciprocal key. In this example, it provides the metadata needed for describing the reciprocal time or the frequency dimension, i.e., after a Fourier transform.

The value of the dependent variables key is an array (lines 27-41) with a single 406 JSON serialized **InternalDependentVariable** object (lines 28-40) describing the signal 407 response. While the keys and values in this object are similar to the corresponding 408 object from the previous example, a key difference is that the value of the numeric type 409 key denotes a complex64 numeric type. Complex numbers are stored as an ordered 410 array of alternating real and imaginary data values, starting with the real value. In this 411 example, the first and the last complex numbers of the signal in Fig. 3 are 412 (-8899.406 - i1276.773) and (-193.923 - i67.065), respectively. Note that the length of 413 the ordered data array is 2M for complex numeric types, where M is the total number of 414 sampled data points. Figure 3 shows a line plot of the time domain NMR decay signal. 415

#### acetone.csdf

In Listing 3 is an illustration of a  $1D\{1\}$  mass spectrum dataset serialized with sparse 417 sampling. Here the InternalDependentVariable object (lines 17-43) holds a 418 **SparseSampling** object (lines 23-34) in the sparse sampling key. Inside the 419 SparseSampling object are the three keys dimensions indexes, sparse grid vertexes, 420 and unsigned integer type. The dimensions indexes key holds an array of integers 421 specifying the indexes of the dimensions along which the dependent variable is sparsely 422 sampled. In this case, it is the zeroth dimension, i.e., the only dimension in the dataset. 423 The sparse grid vertexes key holds an array of integers specifying the vertexes on the 424 one-dimensional sparsely sampled grid. Again, in this example with only one dimension, 425 the array of integers corresponds to the sampled sparse grid vertexes, i.e., the 426 coordinate indexes,  $j_0$ , along the zeroth dimension. The value uint8 for the 427 unsigned integer type key is the numeric type used when importing the JSON 428 serialized integer array from the sparse grid vertexes key. 429

**Listing 4.** JSON serialized listing of a TEM dataset containing one single-component **InternalDependentVariable** object and two **LinearDimension** objects. The listing was created by the authors using data from reference [9].

Figure 4. An intensity plot, derived from Listing 4 of a TEM dataset depicting the early larval brain of *Drosophila melanogaster*. The figure was created by the authors using data from reference 9.

given in Listing 4. This dataset has two dimensions, d=2, and one single-component 435 dependent variable, p = 1. 436

The value of the dimensions key is an array with two JSON serialized 437 LinearDimension objects, defined in-between lines 8-12 and 13-17. Both these objects 438 describe a linearly sampled spatial dimension with 512 points sampled every 4 nm. As 439 before, Eq. (3) gives the ordered list of the coordinates along the respective dimensions. 440 The value of the dependent variables key is an array containing a single JSON serialized 441 **InternalDependentVariable** object (lines 20-26). Unlike the previous examples, the 442 value of the components key is an array with a single element. This element is a Base64 443 encoded string, as indicated by the encoding key, and decodes to an array of binary data 444 values which are interpreted as an array of numerical values with a uint8 numeric type. 445 The array of numerical values is then mapped to the  $512 \times 512$  coordinate grid 446 according to Eqs. (7) and (8). 447

#### bubble.csdfe

In Fig. 5 and in Listing 5 we present a  $2D\{1\}$  astronomy dataset of the bubble nebula 449 acquired at 656 nm wavelength by the Hubble Heritage Project 10 team. In this 450 example, the value of the dimensions key is an array with two JSON serialized 451 LinearDimension objects defined in lines 8-15 and 16-23. Both these objects describe a 452 linearly sampled angular dimension. The value of the dependent variables key is an 453 array with a single JSON serialized **ExternalDependentVariable** object, described in 454 lines 26-32. In this example, the value of the type key is external, indicating that the 455 data values are stored in an external file located at the Uniform Resource Locator 456 (URL) address given by the components url key. In this case, the address corresponds 457 to a local file, designated by the **file** scheme of the URL, relative to the location of the 458 bubble.csdfe file. The external file holds an ordered array of  $11592 \times 11351$  binary 459 values, which are specified by the numeric type key as 32-bit floating-point numbers. 460

#### satRec.csdf

A monotonic dimension is employed when measurements are not uniformly spaced or 462 span several orders of magnitude along a dimension. An example of a  $2D\{1\}$  dataset 463 with a monotonic dimension is given in Listing 6. Here the dataset comes from a <sup>29</sup>Si 464 NMR magnetization recovery measurement of a highly siliceous ZSM-12 zeolite sampled 465 on a 2D rectilinear grid. Figure 6 depicts a stacked plot corresponding to the dataset 466 from Listing 6 467

The value of the dimensions key is an array with two JSON serialized **Dimension** 468 objects (lines 18-30 and 31-38). The first is a **LinearDimension** object, labeled as  $t_2$ , 469 describing a temporal dimension with 1024 points sampled at every 80  $\mu$ s with a 470 coordinates offset of -41.04 ms. Additionally, this **LinearDimension** object contains a 471 **ReciprocalDimension** object serialized as the value of the reciprocal key. The second is 472 a **MonotonicDimension** object, labeled as  $t_1$ , with the coordinates associated with grid 473 vertexes along the dimension explicitly given in the ordered set of values in the 474 coordinates key. The value of the dependent variables key is an array with a single 475 JSON serialized InternalDependentVariable object (lines 41-47) describing the signal 476 response. Here, the data values are encoded as an array with one Base64 string in the 477 components key. 478

This listing also gives an example of the use of the application key in the csdm dictionary. Here an application owning the domain name physyapps.com has placed an 480 attribute in the application dictionary using the reverse domain name key com.physyapps.rmn. Domain name owners are free to place any valid JSON object as 482 the value of their respective reverse domain name attribute inside the application 483

Listing 6. JSON serialized listing of <sup>29</sup>Si NMR magnetization saturation relaxation dataset containing one single-component **DependentVariable** object and two **Dimension** objects.

Figure 6. A stacked plot, derived from Listing 6, of an NMR dataset depicting the <sup>29</sup>Si saturation recovery measurement of a highly siliceous ZSM-12 zeolite.

dictionary. In this case, the domain name owner has used the reverse domain name key 484 com.physyapps.rmn to place a dictionary holding two keys, focus and dimension precedence. 486

An application key can also be placed in any **Dimension**, **ReciprocalDimension**, **DependentVariable**, and **SparseSampling** object. Again, according to the rule in section 2.5, only the reverse domain name owner has permission to serialize a file using their respective reverse domain name as a key in the application attribute.

### iglu 1d.csdf

Listing 7 is a 2D{1} example of an NMR signal with sparse sampling along one 492 dimension 11. Here the InternalDependentVariable object (lines 30-44) holds a 493 **SparseSampling** object (lines 37-43) in the sparse sampling key. The **SparseSampling** 494 object contains three keys dimension indexes, sparse grid vertexes, and 405 unsigned integer type. The dimension indexes key holds an array of integers specifying 496 the indexes of the dimensions along which the dependent variable is sparsely sampled, 497 in this case, the k = 1 dimension. The sparse grid vertexes key holds an array of 498 integers specifying the vertexes on the one-dimensional sparsely sampled grid. Since 499 there are two dimensions in the dataset the array of integers corresponds to the 500 coordinate indexes,  $j_1$ , along the k = 1 dimension. In this example, the dependent 501 variable values are fully sampled along the k = 0 dimension. The value of the 502 unsigned integer type key holds the numeric type used in importing the integer array 503 from sparse grid vertexes. 504

### iglu 2d.csdf

Listing [8] is a 2D{1} example of an NMR signal shown in Fig [8] with sparse sampling along two dimensions 11. As before, the sparse sampling key holds a SparseSampling object with the dimension indexes, sparse grid vertexes, and unsigned integer type attributes. The dimension indexes key holds an array of two integers, k = 0 and 1, specifying the sparse sampling dimensions. The sparse grid vertexes key holds an array of integers defining the vertexes on the two-dimensional sparsely sampled grid. As described in section 2.4.1 this array is a flattened ordered set of arrays which can be reshaped into the ordered set of sparse grid vertexes, i.e.,

 $[0, 0, 1, 0, \dots, 972, 511, 1015, 511] \longrightarrow [[0, 0], [1, 0], \dots, [972, 511], [1015, 511]].$ 

The  $i^{\rm th}$  vertex in the ordered set of sparse grid vertexes specifies the sparse grid location 506 of the  $i^{\text{th}}$  value in each component array of the dependent variable. 507

#### $2D{3}$ example 3.3

### RGB image.csdf

A simple example of a 2D dataset with multiple components is a color image, such as 510 the one shown in Fig. 9. This is a  $2D{3}$  dataset, with two **LinearDimension** objects 511 and one three-component dependent variable, p = 3. The CSDM serialization is shown 512 in Listing 9. The dimensions key holds an array with two JSON serialized 513 **LinearDimension** objects (lines 8-13 and 14-19) with 1024 and 768 points, respectively, 514

Figure 7. A plot, derived from Listing 7 of the real part 2D{1} dataset sparsely sampled in one dimension. The figure was created by the authors using data from reference 11.

and a unit sampling interval. The dependent variable key holds an array with a single 515 JSON serialized **InternalDependentVariable** object (lines 22-34) containing an image 516 dataset as indicated by the pixel\_3 value of the quantity type key. The first part, 517 pixel, indicates pixel data, and the last part, 3, gives the number of pixel components. 518 An array holding to the three components, i.e., the red, green, and blue color intensities 519 with each encoded as a Base64 string, is the value of the components key. The Base64 520 decoded binary data values are then interpreted as an array of 8-bit unsigned integer 521 (uint8), for each component, and subsequently mapped onto a  $1024 \times 768$  coordinate 522 grid. The value of the component labels key is an array of the labels ordered to match 523 the order of the components. 524

### $3.4 \quad 3D\{2\}$ example

#### wind\_velocity.csdfe

An example of a  $3D\{2\}$  dataset, i.e., with three dimensions, d = 3, and one two-component dependent variable, p = 2, is the wind velocity prediction 12 dataset as a function of latitude, longitude and time, shown in Listing 10.

The value of the dimensions key is an array with three JSON serialized **Dimension** objects. The first two **LinearDimension** objects, labeled as *longitude* and *latitudes* respectively, describe two linear dimensions sampled at every 0.5° for 49 points starting at -102.5° longitudes and 13.5° latitudes. Together, these two objects create a two-dimensional grid that spans the region around the Gulf of Mexico as depicted in Fig. 10. The third dimension is a **LabeledDimension** object as indicated by the value of the type key. The corresponding labels array lists six *date-time stamps* entries.

The value of the dependent variable key is an array with a single JSON serialized 537 **ExternalDependentVariable** object (lines 34-43) containing a two-component vector 538 dataset as identified by the quantity type key-value. This value is vector\_2 where the 530 first part, vector, indicates vector data, and the last part, 2, gives the number of vector 540 components. The two vector components are labeled as ugrd10m-eastward\_wind and 541 vgrd10m-northward\_wind, in the array assigned to the component labels key. The 542 data values are located in an external file as a binary data whose address, relative to the 543 wind\_velocity.csdfe file, is the value of the components url key. The binary data is 544 interpreted as a 32-bit floating-point numerical array. Note, because the binary data 545 does not support array indexing, unlike JSON serialization, the corresponding numerical 546 array of data values is reshaped into a matrix which includes the number of components. 547 In this case, the reshaped matrix is  $49 \times 49 \times 6 \times 2$ , where the last number is the 548 number of components, p = 2, and the remaining three is the number of points from the 549 **Dimension** objects. Table 4 contains a description of the number of components, p, for 550 each quantity type. 551

Figure 10 depicts a quiver plot of the wind velocity at three different date-time stamps. Underlaid these plots is a map of the Earth corresponding to the given range of latitudes and longitudes. These plots were generated using the Matplotlib library 14 for python in addition to the Matplotlib Basemap toolkit 13 for rendering maps.

Listing 10. JSON serialized listing of the predicted wind velocities over and around the Gulf of Mexico. The model contains one two-component **DependentVariable** object and three **Dimension** objects. Listing was created by the authors using data from the national centers for environment information/national oceanic and atmospheric administration [12].

Figure 10. A quiver plot, derived from Listing 10, of the wind velocities from the dataset in Listing 10 at three different date-time stamps. The underlaid map of the Earth corresponding to the latitudes and longitudes is rendered using the Matplotlib Basemap toolkit [13]. The figure was created by the authors using data from reference 12.

#### 3D{6} example 3.5

#### brain MRI.csdf

A 3D{6} dataset has three dimensions, d = 3, and one six-component dependent variable, p = 6. An example of such a dataset is the second rank symmetric diffusion tensor MRI dataset 15 of a brain given in Listing 11.

The value of the dimensions key is an array with three JSON serialized **Dimension** 561 objects describing the three spatial dimensions, labeled as x, y, and z respectively. Here, 562 all objects describe a linear dimension with the sampling resolution of 1 mm, and 148, 563 190 and 160 points along the respective dimension. 564

The value of the dependent variables key is an array with a single JSON serialized **InternalDependentVariable** object (lines 30-52) describing a symmetric matrix dataset 566 as indicated by the value of the quantity\_type key. The value symmetric\_matrix\_3 567 emphasizes a six-component dataset as noted in Table 4. The six components, labeled 568 as Dxx, Dxy, Dxz, Dyy, Dyz, and Dzz respectively, are stored as Base64 strings as the 569 value of the components key. Each Base64 decoded binary array is interpreted as 32-bit 570 floating-points array and subsequently reshaped to a  $148 \times 190 \times 160$  matrix. 571

The symmetric matrix data from the **brain\_MRI.csdf** file was partially processed as a second-rank symmetric diffusion tensor to determine the isotropic diffusion coefficients. The intensity plots in Fig. 11 depicts the projection of the isotropic diffusion coefficients on to the three spatial dimensions.

#### 3.6 $2D\{1,1,2,1,1\}$ example

An example of a  $2D\{1,1,2,1,1\}$  dataset using data from the US National Centers for Environment Information / National Oceanic and Atmospheric Administration [12] is given in Listing 12.

In this example, the value of the dimensions key is an array with two **LinearDimension** objects describing the two spatial dimensions, labeled as *longitude* and *latitude*, respectively. The value of the dependent variables key is an array with five **ExternalDependentVariable** objects describing the surface temperature  $(p_0 = 1)$ , the air temperature at 2 m above ground level  $(p_1 = 1)$ , the two-component wind velocity vector at 10 m above surface  $(p_2 = 2)$ , the relative humidity  $(p_3 = 1)$ , and the air

pressure at the sea level  $(p_4 = 1)$ . Figure 12 depicts the intensity and quiver plots of four dependent variables.

#### $0D\{1,1\}$ example 3.7

#### J vs s.csdf

The CSD model also allows the serialization of datasets without a coordinate grid. A 590  $0D\{1,1\}$  datasets, for example, has no dimensions, d=0, and two single-component 591 dependent variable,  $p_0 = 1$  and  $p_1 = 1$ . The listing for such a dataset 16 is given in 592 Listing 13. In this example, the two "correlated" dependent variables are the <sup>29</sup>Si-<sup>29</sup>Si 593 nuclear spin couplings,  ${}^{2}J$ , across a Si-O-Si linkage and the *s*-character product on the 594

Listing 12. JSON serialized listing of multiple dependent variables including scalar and vector on a two-dimensional grid. Listing was created by the authors using data from the US National Centers for Environment Information / National Oceanic and Atmospheric Administration [12].

Figure 12. The figure depicts (a) an intensity plot of the air temperature at 2 m above surface, (b) a quiver plot of the wind vectors at 10 m above surface, (c) an intensity plot of the relative humidity, and (d) an intensity of the air pressure at sea level corresponding to the last four dependent-variables from Listing 12. These plots are overlaid on the coastline map of the Earth corresponding to the latitude and longitudes. These coastline were rendered using the Matplotlib Basemap toolkit 13. The plots were generated using the Matplotlib library 14 for python. The figure was created by the authors using data from reference 12.

O and two Si along the Si-O bond across the Si-O-Si linkage 16. The value of the 505 dependent variables key is an array with two JSON serialized InternalDependentVariable object (lines 7-16 and 17-27). The first object, named as 597 Gaussian computed J-couplings, describes the  $^{2}J$  couplings. The data values are stored 598 as a Base64 string in the components key. The Base64 decoded binary array is 500 interpreted as a 32-bit floating-point numerical array following the value of the 600 numeric type key. The second object is named as the *product of s-characters*. Here, the 601 data values are again stored as a Base64 string, which after decoding is interpreted as a 602 32-bit floating-point numerical array. A scatter plot revealing the correlation between 603 the two dependent variables from the dataset in Listing 13 is presented in Fig. 13 604

## 4 Conclusions

We have designed the Core Scientific Dataset (CSD) Model as a lightweight, portable, 606 versatile, resourceful, and standalone data model that is capable of handling 607 multi-dimensional and correlated datasets from various spectroscopies, diffraction, 608 microscopy, and imaging techniques. A guiding principle in the design of this model was 609 to encapsulate only the minimal metadata necessary to represent the correlated datasets 610 sampled on a common orthogonal coordinate grid. The model also allows for sparse 611 sampling on this grid. Throughout the model, we make use of the **ScalarQuantity** class, 612 which is composed of a numerical value and any valid SI unit symbol or any number of 613 accepted non-SI unit symbols. This approach enables tremendous flexibility in allowing 614 the dataset model to be agnostic of the scientific domain. Historically, this may have 615 been perceived as a potential barrier to software implementation of the CSDM, however, 616 in recent years libraries capable of parsing units have become freely available for various 617 computing environments such as Matlab, Mathematica, and python. The CSD model is 618 independent of the hardware, operating system, application software, and 619 file-serialization method used for data exchange. The model provides a mechanism for 620 the inclusion of additional application-specific metadata without compromising its 621 fundamental role as a data exchange and archiving standard. When serialized using 622 JSON serialization the resulting file format is human readable and integrable with most 623 object-oriented programming languages and software. The serialization of the CSD 624 model has been adopted as an open dataset file format in NMR software development 625 under our control, i.e., SIMPSON 17,18, DMFIT 19, jsNMR 20, and RMN 21, 626 which already have a large installed user base within the solid-state NMR scientific 627 community. We envision the CSD model and its associated file format as playing an 628 important role in community accessible databases and in greater data-trail integrity and 629 compliance issues for many research laboratories. 630

Listing 13. JSON serialized listing of quantum chemistry calculation of nuclear spin-spin coupling constant between <sup>29</sup>Si nuclei across a Si-O-Si linkage in small cluster molecule. An example dataset with two **DependentVariable** objects and no **Dimension** objects. The listing was created by the authors using data from reference 16.

Figure 13. Two dependent variables 16 correlating  ${}^{2}J_{\text{Si-O-Si}}$  couplings to the corresponding product of *s*-characters on the Si, O and Si atoms along the Si-O bond across the Si-O-Si linkage. The figure was created by the authors using data from reference 16.

## Appendix

### Scaled variables

Coordinates along a dimension can also be converted into scaled quantities based on other attributes in the **Dimension** object or in application meta-data. For example, in nuclear magnetic resonance spectroscopy, the spectra are conventionally plotted as a 635 function of a dimensionless frequency ratio. In CSD model, the origin offset,  $o_k$ , is interpreted as the NMR spectrometer frequency and the coordinates offset,  $b_k$ , as the 637 reference frequency. Given the dimension coordinate,  $\mathbf{X}_k$ , from Eq. (3), the corresponding dimensionless-coordinate ratio follows,

$$\mathbf{X}_{k}^{\text{ratio}} = \frac{\mathbf{X}_{k}}{o_{k} - b_{k}}.$$
(9)

### csdmpy

The csdmpy module is the Python support for the core scientific dataset (CSD) model 641 file-exchange format. The source code is available at 642

https://github.com/DeepanshS/csdmpy and the corresponding documentation at https://csdmpy.readthedocs.io/en/stable, which includes links for downloading the CSDM compliant files used in this report.

The main objective of this python module is to facilitate the import and export of 646 the CSD model serialized files for Python users. Moreover, the module utilizes Python 647 libraries such as Numpy and therefore allowing the end-users to process or visualize the 648 imported datasets with any third-party package(s) compatible with Numpy. 649

## Supporting Information

Supporting information contains additional csdf examples and a review of SI Units and 651 constants as used in the CSD model. 652

## Author Contributions Statement

P.J.G. conceived the idea. All authors contributed to the design of the CSD model and 654 wrote codes. D.J.S. and P.J.G. prepared the figures and wrote the main manuscript 655 text. All authors reviewed the manuscript. 656
