Abstract

The complex transverse water proton magnetization subject to diffusion-encoding magnetic field gradient pulses in a heterogeneous medium can be modeled by the multiple compartment Bloch-Torrey partial differential equation. Under the assumption of negligible water exchange between compartments, the time-dependent apparent diffusion coefficient can be directly computed from the solution of a diffusion equation subject to a time-dependent Neumann boundary condition.

This paper describes a publicly available MATLAB toolbox called SpinDoctor that can be used 1) to solve the Bloch-Torrey partial differential equation in order to simulate the diffusion magnetic resonance imaging signal; 2) to solve a diffusion partial differential equation to obtain directly the apparent diffusion coefficient; 3) to compare the simulated apparent diffusion coefficient with a short-time approximation formula.

The partial differential equations are solved by $P1$ finite elements combined with built-in MATLAB routines for solving ordinary differential equations. The finite element mesh generation is performed using an external package called Tetgen.

SpinDoctor provides built-in options of including 1) spherical cells with a nucleus; 2) cylindrical cells with a myelin layer; 3) an extra-cellular space enclosed either a) in a box or b) in a tight wrapping around the cells; 4) deformation of canonical cells by bending and twisting; 5) permeable membranes; Built-in diffusion-encoding pulse sequences include the Pulsed Gradient Spin Echo and the Oscillating Gradient Spin Echo.

We describe in detail how to use the SpinDoctor toolbox. We validate SpinDoctor simulations using reference signals computed by the Matrix Formalism method. We compare the accuracy and computational time of SpinDoctor simulations with Monte-Carlo simulations and show significant speed-up of SpinDoctor over Monte-Carlo simulations in complex geometries. We also illustrate several extensions of SpinDoctor functionalities, including the incorporation of T_2 relaxation, the simulation of non-standard diffusion-encoding sequences, as well as the use of externally generated

geometrical meshes.

Keywords: Bloch-Torrey equation, diffusion magnetic resonance imaging, finite elements, simulation, apparent diffusion coefficient.

1. Introduction

Diffusion magnetic resonance imaging is an imaging modality that can be used to probe the tissue micro-structure by encoding the incoherent motion of water molecules with magnetic field gradient pulses. This motion during the diffusion-encoding time causes a signal attenuation from which the apparent diffusion coefficient, (and possibly higher order diffusion terms, can be calculated [1–3].

For unrestricted diffusion, the root of the mean squared displacement of molecules is given by $\bar{x} = \sqrt{2 \dim \sigma_0 t}$, where \dim is the spatial dimension, σ_0 is the intrinsic diffusion coefficient, and t is the diffusion time. In biological tissue, the diffusion is usually hindered or restricted (for example, by cell membranes) and the mean square displacement is smaller than in the case of unrestricted diffusion. This deviation from unrestricted diffusion can be used to infer information about the tissue micro-structure. The experimental parameters that can be varied include

1. the diffusion time (one can choose the parameters of the diffusion-encoding sequence, such as Pulsed Gradient Spin Echo [2] and Oscillating Gradient [4]).
2. the magnitude of the diffusion-encoding gradient (when the magnetic resonance imaging signal is acquired at low gradient magnitudes, the signal contains only information about the apparent diffusion coefficient, at higher values, Kurtosis imaging [5] becomes possible);
3. the direction of the diffusion-encoding gradient (many directions may be probed, as in high angular resolution diffusion imaging [6]).

Using diffusion magnetic resonance imaging to get tissue structural information in the mammalian brain has been the focus of much experimental and modeling work in recent years [7–14]. The predominant approach up to now has been adding the diffusion magnetic resonance imaging signal from simple geometrical components and extracting model parameters of interest. Numerous biophysical models subdivide the tissue into compartments described by spheres, ellipsoids, cylinders, and the extra-cellular space [7–9, 11, 12, 15–19]. Some model parameters of interest include axon diameter and orientation, neurite density, dendrite structure, the volume fraction and size distribution of cylinder and sphere components and the effective diffusion coefficient or tensor of the extra-cellular space.

Numerical simulations can help deepen the understanding of the relationship between the cellular structure and the diffusion magnetic resonance imaging signal and lead to the formulation of appropriate models. They can be also used to investigate the effect of different pulse sequences and tissue features on the measured signal which can be used for the development, testing, and optimization of novel diffusion magnetic resonance imaging pulse sequences [20–23].

Two main groups of approaches to the numerical simulation of diffusion magnetic resonance imaging are 1) using random walkers to mimic the diffusion process in a geometrical configuration; 2) solving

35 the Bloch-Torrey PDE , which describes the evolution of the complex transverse water proton
36 magnetization under the influence of diffusion-encoding magnetic field gradients pulses.

37 The first group is referred to as Monte-Carlo simulations in the literature and previous works include
38 [13, 24–27]. A GPU-based acceleration of Monte-Carlo simulation was proposed in [28, 29]. Some
39 software packages using this approach include

- 40 1. Camino Diffusion MRI Toolkit developed at UCL (<http://cmic.cs.ucl.ac.uk/camino/>);
- 41 2. DIFSIM developed at UC San Diego (<http://csci.ucsd.edu/projects/simulation.html>);
- 42 3. Diffusion Microscopist Simulator [25] developed at Neurospin, CEA.

43 The second group relies on solving the Bloch-Torrey PDE in a geometrical configuration. In [30–
44 32] a simplifying assumption called the narrow pulse approximation was used, where the pulse
45 duration was assumed to be much smaller than the delay between pulses. This assumption allows
46 the solution of the diffusion equation instead of the more complicated Bloch-Torrey PDE. More
47 generally, numerical methods to solve the Bloch-Torrey PDE. with arbitrary temporal profiles
48 have been proposed in [33–36]. The computational domain is discretized either by a Cartesian grid
49 [33, 34, 37] or finite elements [30–32, 35, 36]. The unstructured mesh of a finite element discretization
50 appeared to be better than a Cartesian grid in both geometry description and signal approximation
51 [35]. For time discretization, both explicit and implicit methods have been used. In [32] a second
52 order implicit time-stepping method called the generalized α -method was used to allow for high
53 frequency energy dissipation. An adaptive explicit Runge-Kutta Chebyshev method of second order
54 was used in [34, 35]. It has been theoretically proven that the Runge-Kutta Chebyshev method
55 allows for a much larger time-step compared to the standard explicit Euler method [38]. There is an
56 example showing that the Runge-Kutta Chebyshev method is faster than the implicit Euler method
57 in [35]. The Crank-Nicolson method was used in [36] to also allow for second order convergence in
58 time. The efficiency of diffusion magnetic resonance imaging simulations is also improved by either a
59 high-performance FEM computing framework [39, 40] for large-scale simulations on supercomputers
60 or a discretization on manifolds for thin-layer and thin-tube media [41].

61 In this paper, we present a MATLAB Toolbox called SpinDoctor that is a simulation pipeline going
62 from the definition of a geometrical configuration through the numerical solution of the Bloch-
63 Torrey PDE to the fitting of the apparent diffusion coefficient from the simulated signal. It also
64 includes two other modules for calculating the apparent diffusion coefficient. The first module is a
65 homogenized apparent diffusion coefficient mathematical model, which was obtained recently using
66 homogenization techniques on the Bloch-Torrey PDE. In the homogenized model, the apparent dif-
67 fusion coefficient of a geometrical configuration can be computed after solving a diffusion equation
68 subject to a time-dependent Neumann boundary condition, under the assumption of negligible wa-
69 ter exchange between compartments. The second module computes the short time approximation
70 formula for the apparent diffusion coefficient. The short time approximation implemented in Spin-
71 Doctor includes a recent generalization of this formula to account for finite pulse duration in the
72 pulsed gradient spin echo. Both of these two apparent diffusion coefficient calculations are sensitive
73 to the diffusion-encoding gradient direction, unlike many previous works where the anisotropy is
74 neglected in analytical model development.

75

76 In summary, SpinDoctor

- 77 1. solves the Bloch-Torrey PDE in three dimensions to obtain the diffusion magnetic resonance
78 imaging signal;
- 79 2. robustly fits the diffusion magnetic resonance imaging signal to obtain the apparent diffusion
80 coefficient;
- 81 3. solves the homogenized apparent diffusion coefficient model in three dimensions to obtain the
82 apparent diffusion coefficient;
- 83 4. computes the short-time approximation of the apparent diffusion coefficient;
- 84 5. computes useful geometrical quantities such as the compartment volumes and surface areas;
- 85 6. allows permeable membranes for the Bloch-Torrey PDE (the homogenized apparent diffusion
86 coefficient assumes negligible permeability).
- 87 7. displays the gradient-direction dependent apparent diffusion coefficient; in three dimensions
88 using spherical harmonics interpolation;

89 SpinDoctor provides the following built-in functionalities:

- 90 1. placement of non-overlapping spherical cells (with an optional nucleus) of different radii close
91 to each other;
- 92 2. placement of non-overlapping cylindrical cells (with an optional myelin layer) of different radii
93 close to each other in a canonical configuration where they are parallel to the z -axis;
- 94 3. inclusion of an extra-cellular space that is enclosed either
95 (a) in a tight wrapping around the cells; or
96 (b) in a rectangular box;
- 97 4. deformation of the canonical configuration by bending and twisting;

98 Built-in diffusion-encoding pulse sequences include

- 99 1. the Pulsed Gradient Spin Echo ;
- 100 2. the Oscillating Gradient Spin Echo (cos- and sin- type gradients).

101 SpinDoctor uses the following methods:

- 102 1. it generates a good quality surface triangulation of the user specified geometrical configuration
103 by calling built-in MATLAB computational geometry functions;
- 104 2. it creates a good quality tetrahedra finite elements mesh from the above surface triangulation
105 by calling Tetgen [42], an external package (executable files are included in the Toolbox
106 package);

- 107 3. it constructs finite element matrices for linear finite elements on tetrahedra (P1) using routines
 108 from [43];
- 109 4. it adds additional degrees of freedom on the compartment interfaces to allow permeability
 110 conditions for the Bloch-Torrey PDE using the formalism in [44];
- 111 5. it solves the semi-discretized FEM equations by calling built-in MATLAB routines for solving
 112 ordinary differential equations .

113 The SpinDoctor toolbox has been developed in the MATLAB R2017b and requires no additional
 114 MATLAB toolboxes. The toolbox is publicly available at:

115 <https://github.com/jingrebeccali/SpinDoctor>

116 Abbreviations frequently used in the text

- 117 MRI - magnetic resonance imaging
- 118 dMRI - diffusion magnetic resonance imaging
- 119 ADC - apparent diffusion coefficient
- 120 HADC - homogenized ADC
- 121 PGSE - pulsed gradient spin echo
- 122 OGSE - oscillating gradient
- 123 ECS - extra-cellular space
- 124 BTPDE - Bloch-Torrey partial differential equation
- 125 PDE - partial differential equation
- 126 ODE - ordinary differential equation
- 127 HARDI - high angular resolution diffusion imaging
- 128 STA - short time approximation
- 129 FE - finite elements

130 2. Theory

131 Suppose the user would like to simulate a geometrical configuration of cells with an optional myelin
 132 layer or a nucleus. If spins will be leaving the cells or if the user wants to simulate the extra-cellular
 133 space (ECS), then the ECS will enclose the geometrical shapes. Let Ω^e be the ECS, Ω_i^{in} the nucleus
 134 (or the axon) and Ω_i^{out} the cytoplasm (or the myelin layer) of the i th cell. We denote the interface
 135 between Ω_i^{in} and Ω_i^{out} by Γ_i and the interface between Ω_i^{out} and Ω^e by Σ_i , finally the outside
 136 boundary of the ECS by Ψ .

In diffusion MRI, a time-varying magnetic field gradient is applied to the tissue to encode water diffusion. Denoting the effective time profile of the diffusion-encoding magnetic field gradient by $f(t)$, and letting the vector \mathbf{g} contain the amplitude and direction information of the magnetic field gradient, the complex transverse water proton magnetization in the rotating frame satisfies the Bloch-Torrey PDE:

$$\frac{\partial}{\partial t} M_i^{in}(\mathbf{x}, t) = -I\gamma f(t)\mathbf{g} \cdot \mathbf{x} M_i^{in}(\mathbf{x}, t) + \nabla \cdot (\sigma^{in} \nabla M_i^{in}(\mathbf{x}, t)), \quad \mathbf{x} \in \Omega_i^{in}, \quad (1)$$

$$\frac{\partial}{\partial t} M_i^{out}(\mathbf{x}, t) = -I\gamma f(t)\mathbf{g} \cdot \mathbf{x} M_i^{out}(\mathbf{x}, t) + \nabla \cdot (\sigma^{out} \nabla M_i^{out}(\mathbf{x}, t)), \quad \mathbf{x} \in \Omega_i^{out}, \quad (2)$$

$$\frac{\partial}{\partial t} M^e(\mathbf{x}, t) = -I\gamma f(t)\mathbf{g} \cdot \mathbf{x} M^e(\mathbf{x}, t) + \nabla \cdot (\sigma^e \nabla M^e(\mathbf{x}, t)), \quad \mathbf{x} \in \Omega^e, \quad (3)$$

where $\gamma = 2.67513 \times 10^8 \text{ rad s}^{-1} \text{ T}^{-1}$ is the gyromagnetic ratio of the water proton, I is the imaginary unit, σ^l is the intrinsic diffusion coefficient in the compartment Ω_i^l . The magnetization is a function of position \mathbf{x} and time t , and depends on the diffusion gradient vector \mathbf{g} and the time profile $f(t)$. We denote the restriction of the magnetization in Ω_i^{in} by M_i^{in} , and similarly for M_i^{out} and M^e .

Some commonly used time profiles (diffusion-encoding sequences) are:

1. The pulsed-gradient spin echo (PGSE) [2] sequence, with two rectangular pulses of duration δ , separated by a time interval $\Delta - \delta$, for which the profile $f(t)$ is

$$f(t) = \begin{cases} 1, & t_1 \leq t \leq t_1 + \delta, \\ -1, & t_1 + \Delta < t \leq t_1 + \Delta + \delta, \\ 0, & \text{otherwise,} \end{cases} \quad (4)$$

where t_1 is the starting time of the first gradient pulse with $t_1 + \Delta > T_E/2$, T_E is the echo time at which the signal is measured.

2. The oscillating gradient spin echo (OGSE) sequence [4, 45] was introduced to reach short diffusion times. An OGSE sequence usually consists of two oscillating pulses of duration T , each containing n periods, hence the frequency is $\omega = n \frac{2\pi}{T}$, separated by a time interval $\tau - T$. For a cosine OGSE, the profile $f(t)$ is

$$f(t) = \begin{cases} \cos(n \frac{2\pi}{T} t), & t_1 < t \leq t_1 + T, \\ -\cos(n \frac{2\pi}{T} (t - \tau)), & \tau + t_1 < t \leq t_1 + \tau + T, \\ 0, & \text{otherwise,} \end{cases} \quad (5)$$

where $\tau = T_E/2$.

The BTPDE needs to be supplemented by interface conditions. We recall the interface between Ω_i^{in} and Ω_i^{out} is Γ_i , the interface between Ω_i^{out} and Ω^e is Σ_i , and the outside boundary of the ECS is Ψ . The two interface conditions on Γ_i are the flux continuity and a condition that incorporates a permeability coefficient $\kappa^{in,out}$ across Γ_i :

$$\begin{aligned} \sigma^{in} \nabla M_i^{in}(\mathbf{x}, t) \cdot \mathbf{n}_i^{in} &= -\sigma^{out} \nabla M_i^{out}(\mathbf{x}, t) \cdot \mathbf{n}_i^{out}, & \mathbf{x} \in \Gamma_i, \\ \sigma^{in} \nabla M_i^{in}(\mathbf{x}, t) \cdot \mathbf{n}_i^{in} &= \kappa^{in,out} (M_i^{out}(\mathbf{x}, t) - M_i^{in}(\mathbf{x}, t)), & \mathbf{x} \in \Gamma_i, \end{aligned}$$

where \mathbf{n} is the unit outward pointing normal vector. Similarly, between Ω_i^{out} and Ω^e we have

$$\begin{aligned}\sigma^{out}\nabla M_i^{out}(\mathbf{x}, t) \cdot \mathbf{n}_i^{out} &= -\sigma^e\nabla M^e(\mathbf{x}, t) \cdot \mathbf{n}^e, & \mathbf{x} \in \Sigma_i, \\ \sigma^{out}\nabla M_i^{out}(\mathbf{x}, t) \cdot \mathbf{n}_i^{out} &= \kappa^{out,e}\left(M^e(\mathbf{x}, t) - M_i^{out}(\mathbf{x}, t)\right), & \mathbf{x} \in \Sigma_i.\end{aligned}$$

Finally, on the outer boundary of the ECS we have

$$0 = \sigma^e\nabla M^e(\mathbf{x}, t) \cdot \mathbf{n}^e, \quad \mathbf{x} \in \Psi.$$

The BTPDE also needs initial conditions:

$$M_i^{in}(\mathbf{x}, 0) = \rho^{in}, \quad M_i^{out}(\mathbf{x}, 0) = \rho^{out}, \quad M^e(\mathbf{x}, 0) = \rho^e.$$

146 where ρ is the initial spin density.

The dMRI signal is measured at echo time $t = T_E > \Delta + \delta$ for PGSE and $T_E > 2\sigma$ for OGSE. This signal is the integral of $M(\mathbf{x}, T_E)$:

$$S := \int_{\mathbf{x} \in \cup\{\Omega_i^{in}, \Omega_i^{out}, \Omega^e\}} M(\mathbf{x}, T_E) d\mathbf{x}. \quad (6)$$

In a dMRI experiment, the pulse sequence (time profile $f(t)$) is usually fixed, while \mathbf{g} is varied in amplitude (and possibly also in direction). S is usually plotted against a quantity called the b -value. The b -value depends on \mathbf{g} and $f(t)$ and is defined as

$$b(\mathbf{g}) = \gamma^2\|\mathbf{g}\|^2 \int_0^{T_E} du \left(\int_0^u f(s)ds \right)^2.$$

For PGSE, the b -value is [2]:

$$b(\mathbf{g}, \delta, \Delta) = \gamma^2\|\mathbf{g}\|^2\delta^2(\Delta - \delta/3). \quad (7)$$

For the cosine OGSE with *integer* number of periods n in each of the two durations σ , the corresponding b -value is [33]:

$$b(\mathbf{g}, \sigma) = \gamma^2\|\mathbf{g}\|^2 \frac{\sigma^3}{4n^2\pi^2} = \gamma^2\|\mathbf{g}\|^2 \frac{\sigma}{\omega^2}. \quad (8)$$

147 The reason for these definitions is that in a homogeneous medium, the signal attenuation is $e^{-\sigma b}$,
148 where σ is the intrinsic diffusion coefficient.

149 2.2. Fitting the ADC from the dMRI signal

150 An important quantity that can be derived from the dMRI signal is the ‘‘Apparent Diffusion Co-
151 efficient’’ (ADC), which gives an indication of the root mean squared distance travelled by water
152 molecules in the gradient direction $\mathbf{g}/\|\mathbf{g}\|$, averaged over all starting positions:

$$ADC := -\frac{\partial}{\partial b} \log \frac{S(b)}{S(0)} \Big|_{b=0}. \quad (9)$$

We numerically compute ADC by a polynomial fit of

$$\log S(b) = c_0 + c_1b + \dots + c_nb^n,$$

153 increasing n from 1 onwards until we get the value of c_1 to be stable within a numerical tolerance.

154 2.3. *HADC model*

In a previous work [46], a PDE model for the time-dependent ADC was obtained starting from the Bloch-Torrey equation, using homogenization techniques. In the case of negligible water exchange between compartments (low permeability), there is no coupling between the compartments, at least to the quadratic order in \mathbf{g} , which is the ADC term. The ADC in compartment Ω is given by

$$HADC = \sigma - \frac{1}{\int_0^{TE} F(t)^2 dt} \int_0^{TE} F(t) h(t) dt, \quad (10)$$

where $F(t) = \int_0^t f(s) ds$, and

$$h(t) = \frac{1}{|\Omega|} \int_{\partial\Omega} \omega(\mathbf{x}, t) (\mathbf{u}_g \cdot \mathbf{n}) ds \quad (11)$$

is a quantity related to the directional gradient of a function ω that is the solution of the homogeneous diffusion equation with Neumann boundary condition and zero initial condition:

$$\begin{aligned} \frac{\partial}{\partial t} \omega(\mathbf{x}, t) - \nabla (\sigma \nabla \omega(\mathbf{x}, t)) &= 0, & \mathbf{x} \in \Omega, \\ \sigma \nabla \omega(\mathbf{x}, t) \cdot \mathbf{n} &= \sigma F(t) \mathbf{u}_g \cdot \mathbf{n}, & \mathbf{x} \in \partial\Omega, \\ \omega(\mathbf{x}, 0) &= 0, & \mathbf{x} \in \Omega, \end{aligned} \quad (12)$$

155 \mathbf{n} being the outward normal and $t \in [0, TE]$, \mathbf{u}_g is the unit gradient direction. The above set of
156 equations, (10)-(12), comprise the homogenized model that we call the HADC model.

157 2.4. *Short diffusion time approximation of the ADC*

A well-known formula for the ADC in the short diffusion time regime is the following short time approximation (STA) [47, 48]:

$$STA = \sigma \left(1 - \frac{4\sqrt{\sigma}}{3\sqrt{\pi}} \sqrt{\Delta} \frac{A}{\dim V} \right),$$

where $\frac{A}{V}$ is the surface to volume ratio and σ is the intrinsic diffusivity coefficient. In the above formula the pulse duration δ is assumed to be very small compared to Δ . A recent correction to the above formula [46], taking into account the finite pulse duration δ and the gradient direction \mathbf{u}_g , is the following:

$$STA = \sigma \left[1 - \frac{4\sqrt{\sigma}}{3\sqrt{\pi}} C_{\delta, \Delta} \frac{A_{\mathbf{u}_g}}{V} \right], \quad (13)$$

where

$$A_{\mathbf{u}_g} = \int_{\partial\Omega} (\mathbf{u}_g \cdot \mathbf{n})^2 ds,$$

and

$$C_{\delta, \Delta} = \frac{4}{35} \frac{(\Delta + \delta)^{7/2} + (\Delta - \delta)^{7/2} - 2(\delta^{7/2} + \Delta^{7/2})}{\delta^2 (\Delta - \delta/3)} = \sqrt{\Delta} \left(1 + \frac{1}{3} \frac{\delta}{\Delta} - \frac{8}{35} \left(\frac{\delta}{\Delta} \right)^{3/2} + \dots \right).$$

158 When $\delta \ll \Delta$, the value $C_{\delta, \Delta}$ is approximately $\sqrt{\Delta}$.

159 **3. Method**

Below is a chart describing the work flow of SpinDoctor.

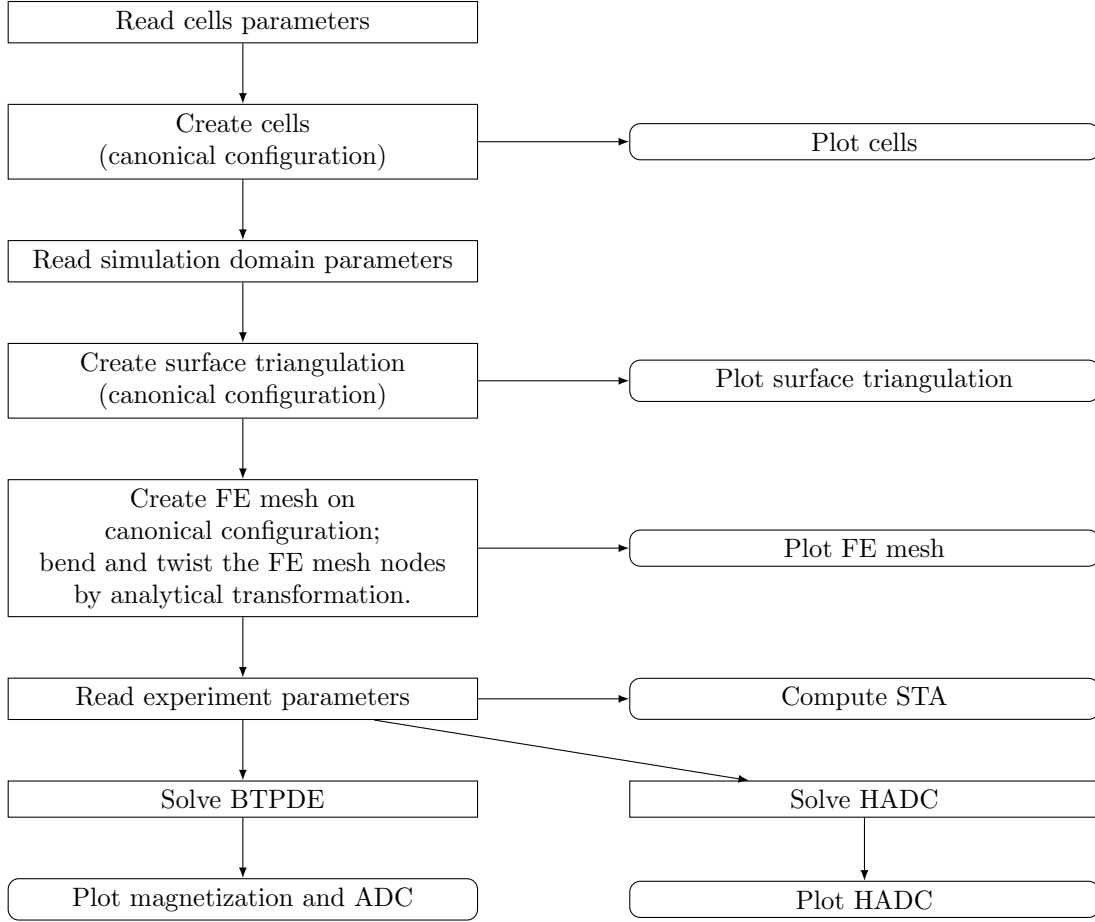

Figure 1: Flow chart describing the work flow of SpinDoctor

160

161 The physical units of the quantities in the input files for SpinDoctor are shown in Table 1, in
 162 particular, the length is in μm and the time is in μs . Below we discuss the various components of
 163 SpinDoctor in more detail.

164 *3.1. Read cells parameters*

165 The user provides an input file for the cell parameters, in the format described in Table 2.

Parameter	Unit
length	μm
time	μs
diffusion coefficient	$\mu\text{m}^2/\mu\text{s} = \text{mm}^2/\text{s}$
permeability coefficient	$\mu\text{m}/\mu\text{s} = \text{m}/\text{s}$
b-value	$\mu\text{s}/\mu\text{m}^2 = \text{s}/\text{mm}^2$
q-value	$(\mu\text{s}\mu\text{m})^{-1}$

Table 1: Physical units of the quantities in the input files for SpinDoctor.

Line	Variable name	Example	Explanation
1	cell_shape	1	1 = spheres; 2 = cylinders;
2	fname_params_cells	'current_cells'	file name to store cells description
3	ncell	10	number of cells
4	Rmin	1.5	min Radius
5	Rmax	2.5	max Radius
6	dmin	1.5	min (%) distance between cells: $dmin \times \frac{(Rmin+Rmax)}{2}$
7	dmax	2.5	max (%) distance between cells $dmax \times \frac{(Rmin+Rmax)}{2}$
8	para_deform	0.05 0.05	$[\alpha \ \beta]$; α defines the amount of bend; β defines the amount of twist
9	Hcyl	20	height of cylinders

Table 2: Input file containing cells parameters.

166 3.2. Create cells (canonical configuration)

167 SpinDoctor supports the placement of a group of non-overlapping cells in close vicinity to each
168 other. There are two proposed configurations, one composed of spheres, the other composed of
169 cylinders. The algorithm is described in Algorithm 1.

<p>Algorithm 1: Placing n_{cell} non-overlapping cells.</p> <p>Generate a large number of possible cell centers.</p> <p>Compute the minimum distance, $dist$, between the current center and previously accepted cells.</p> <p>Find the intersection of $[dist - dmax \times R_{mean}, dist - dmin \times R_{mean}]$ and $[Rmin, Rmax]$, where $R_{mean} = \frac{Rmin+Rmax}{2}$. If the intersection is not empty, then take the middle of the intersection as the new radius and accept the new center. Otherwise, reject the center.</p> <p>Loop through the possible centers until get n_{cell} accepted cells.</p>

170 *3.3. Plot cells*

171 SpinDoctor provides a routine to plot the cells to see if the configuration is acceptable (see Fig. 2).

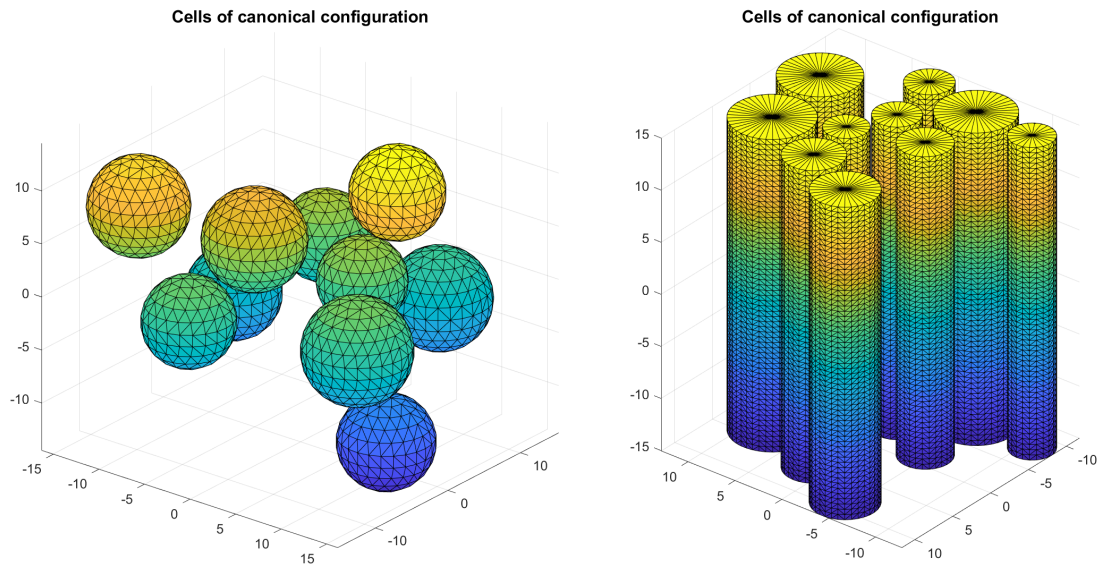

Figure 2: SpinDoctor plots cells in the canonical configuration.

172

173 *3.4. Read simulation domain parameters*

174 The user provides an input file for the simulation domain parameters, in the format described in
175 Table 3.

176 *3.5. Create surface triangulation*

177 Finite element mesh generation software requires a good surface triangulation. This means the
178 surface triangulation needs to be water-tight and does not self-intersect. How closely these require-
179 ments are met in floating point arithmetic has a direct impact on the quality of the finite element
180 mesh generated.

181 It is often difficult to produce a good surface triangulation for arbitrary geometries. Thus, we
182 restrict the allowed shapes to cylinders and spheres. Below in Algorithms 2 and 3 we describe how
183 to obtain a surface triangulation for spherical cells with nucleus, cylindrical cells with myelin layer,
184 and the ECS (box or tightly wrapped). We describe a canonical configuration where the cylinders
185 are placed parallel to the z -axis. More general shapes are obtained from the canonical configuration
186 by coordinate transformation in a later step.

Line	Variable name	Example	Explanation
1	Rratio	0.0	if Rratio is outside [0,1], it is set to 0; else $Rratio = \frac{R_{in}}{R_{out}}$;
2	include_ECS	2	0 = no ECS; 1 = box ECS; 2 = tight wrap ECS;
3	ECS_gap	0.3	ECS thickness: a. if box: as percentage of domain length; b. if tight wrap: as percentage of mean radius
4	dcoeff_IN	0.002	diffusion coefficient in IN cmpt: a. nucleus; b. axon (if there is myelin);
5	dcoeff_OUT	0.002	diffusion coefficient in OUT cmpt: a. cytoplasm; b. axon (if there is no myelin);
6	dcoeff_ECS	0.002	diffusion coefficient in ECS cmpt;
7	ic_IN	1	initial spin density in IN cmpt: a. nucleus; b. axon (if there is myelin)
8	ic_OUT	1	initial spin density in OUT cmpt: a. cytoplasm; b. axon (if there is no myelin);
9	ic_ECS	1	initial spin density in ECS cmpt:

187 *3.6. Plot surface triangulation*

188 SpinDoctor provides a routine to plot the surface triangulation (see Fig. 3).

189 *3.7. Finite element mesh generation*

190 SpinDoctor calls Tetgen [42], an external package (executable files are included in the toolbox
191 package), to create a tetrahedra finite elements mesh from the surface triangulation generated by

Algorithm 2: Surface triangulation of spherical cells and ECS.

Suppose we have n_{cell} spherical cells with nucleus. Denote a sphere with center c and radius R by $S(c, R)$, we use the built-in functions (convex hull, delaunay triangulation) in MATLAB to get its surface triangulation, $T(c, R)$. Call the radii of the nucleus r_1, \dots, r_{ncell} and the radii of the cells R_1, \dots, R_{ncell} . Then the boundaries between the cytoplasm and the nucleus are

$$\{\Gamma_i = T(c_i, r_i)\}, i = 1, \dots, ncell;$$

and between the cytoplasm and the ECS

$$\{\Sigma_i = T(c_i, R_i)\}, i = 1, \dots, ncell;$$

For the box ECS, we find the coordinate limits of the set

$$\bigcup_i S(c_i, R_i) \in [x_0, x_f] \times [y_0, y_f] \times [z_0, z_f]$$

and add a gap $k = \text{ECS_gap} \times \max\{x_f - x_0, y_f - y_0, z_f - z_0\}$ to make a box

$$B = [x_0 - k, x_f + k] \times [y_0 - k, y_f + k] \times [z_0 - k, z_f + k].$$

We put 2 triangles on each face of B to make a surface triangulation Ψ with 12 triangles. For the tight-wrap ECS, we increase the cell radius by a gap size and take the union

$$W = \bigcup_i S(c_i, R_i + \text{ECS_gap} \times R_{mean}),$$

where $R_{mean} = \frac{R_{min} + R_{max}}{2}$. We use the alphaShape function in MATLAB to find a surface triangulation Ψ that contains W .

192 Algorithms 2 and 3. The FE mesh is generated on the canonical configuration. The numbering of
 193 the compartments and boundaries used by SpinDoctor are given in Tables 4 and 5. The labels are
 194 related to the values of the intrinsic diffusion coefficient, the initial spin density, and the perme-
 195 ability requested by the user. Then the FE mesh nodes are deformed analytically by a coordinate
 196 transformation, described in Algorithm 4.

197 3.8. Plot FE mesh

198 SpinDoctor provides a routine to plot the FE mesh (see Fig. 4 for cylinders and ECS that have
 199 been bent and twisted).

200 3.9. Read experimental parameters

201 The user provides an input file for the simulation experimental parameters, in the format described
 202 in Table 6.

Algorithm 3: Surface triangulation of cylindrical cells and ECS.

Suppose we have n_{cell} cylindrical cells with a myelin layer, all with height H . Denote a disk with center c and radius R by $D(c, R)$, and the circle with the same center and radius by $C(c, R)$. Let the radii of the axons be $r_1, \dots, r_{n_{cell}}$ and the radii of the cells be $R_1, \dots, R_{n_{cell}}$, meaning the thickness of the myelin layer is $R_i - r_i$. The boundary between the axon and the myelin layer is:

$$C(c_i, r_i) \times [-H/2, H/2]$$

We discretize $C(c_i, r_i)$ as a polygon $P(c_i, r_i)$ and place one at $z = -H/2$ and one at $z = H/2$. Then we connect the corresponding vertices of $P(c_i, r_i) \times \{-H/2\}$ and $P(c_i, r_i) \times \{H/2\}$ and add a diagonal on each panel to get a surface triangulation Γ_i . Between the myelin layer and the ECS we discretize $C(c_i, R_i)$ as a polygon and place one at $z = -H/2$ and one at $z = H/2$ to get a surface triangulation Σ_i . For the box ECS, we find the coordinate limits of the union of $D(c_i, R_i)$ and add a gap to make a rectangle in two dimensions. Then we place the rectangle at $z = -H/2$ and at $z = H/2$ to get a box. Finally, the box is given a surface triangulation with 12 triangles. For tight-wrap ECS, we increase the cell radius by a gap size and take the union

$$W = \bigcup_i D(c_i, R_i + kR_{mean}).$$

We use the alphaShape function in MATLAB to find a two dimensional polygon Q that contains W . We place Q at $z = -H/2$ and at $z = H/2$ and connect corresponding vertices, adding a diagonal on each panel. Suppose Q is a polygon with n vertices, then the surface triangulation of the side of the ECS will have $2n$ triangles.

The above procedure produces a surface triangulation for the boundaries that are parallel to z -axis. We now must close the top and bottom. The top and bottom boundaries is just the interior of Q . However, the surface triangulation cannot be done on Q directly. We must cut out $D(c_i, r_i)$, the disk which touches the axon, and $A_i = D(c_i, R_i) - D(c_i, r_i)$, the annulus which touches the myelin. Then we triangulate $Q - \bigcup_i D_i - \bigcup_i A_i$ using the MATLAB built-in function that triangulates a polygon with holes to get the boundary that touches the ECS. The surface triangulation for A_i and $D(c_i, r_i)$ are straightforward.

203 **3.10. BTPDE**

204 The spatial discretization of the BTPDE is based on a finite element method where *interface (ghost)*
 205 *elements* [35] are used to impose the permeable interface conditions. The time stepping is done
 206 using the MATLAB built-in ODE routine ode23t. See Algorithm 5.

207 **3.11. HADC model**

208 Similarly, the DE of the HADC model is discretized by finite elements. See Algorithm 6.

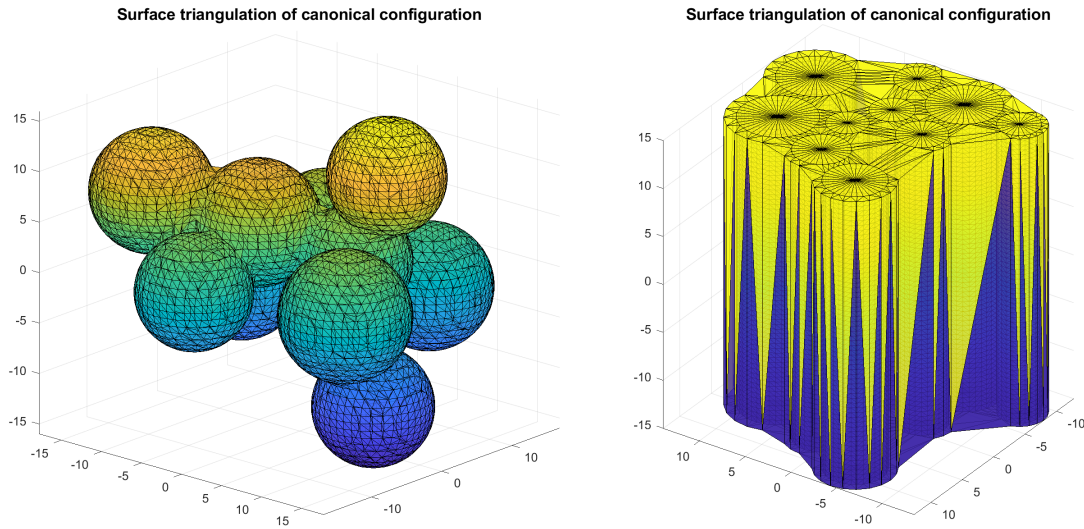

Figure 3: SpinDoctor plots the surface triangulation of the canonical configuration. Left: spherical cells with ECS; Right: cylindrical cells with ECS.

Number	$4[1 : n_{cell}] - 1$	$4[1 : n_{cell}]$	$4n_{cell} + 1$

Table 5: The labels and numbers of boundaries.

213 4. SpinDoctor examples

214 In this section we show some prototypical examples using the available functionalities of SpinDoctor.

215

216 4.1. Comparison of BTPDE and HADC with Short Time Approximation

217 In Fig. 5 we show that both BTPDE and HADC solutions match the STA values at short diffusion
218 times for cylindrical cells (compartments 1 to 5). We also show that for the ECS (compartment
219 6), the STA is too low, because it does not account for the fact that spins in the ECS can diffuse
220 around several cylinders. This also shows that when the interfaces are impermeable, the BTPDE
221 ADC and that from the HADC model are identical. The diffusion-encoding sequence here is cosine
222 OGSE with 6 periods.

223 4.2. Permeable membranes

224 In Fig. 6 we show the effect of permeability: the BTPDE model includes permeable membranes
225 ($\kappa = 1 \times 10^{-3}$ m/s) whereas the HADC has impermeable membranes. We see in the permeable case,
226 the ADC in the spheres are higher than in the impermeable case, whereas the ECS show reduced

Algorithm 4: Bending and twisting of the FE mesh of the canonical configuration.

The external package Tetgen [42] generates the finite element mesh that keeps track of the different compartments and the interfaces between them. The mesh is saved in several text files.

The connectivity matrices of the finite elements and facets are not modified by the coordinates transformation described below. The nodes are transformed by bending and twisting as described next.

The set of FE mesh nodes $\{x_i, y_i, z_i\}$ are transformed in the following ways:

Twisting around the z -axis with a user-chosen twisting parameter α_{twist} is defined by

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} \rightarrow \begin{bmatrix} \cos(\alpha_{twist}z) & -\sin(\alpha_{twist}z) & 0 \\ \sin(\alpha_{twist}z) & \cos(\alpha_{twist}z) & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}.$$

Bending on the $x - z$ plane with a user-chosen bending parameter α_{bend} is defined by

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} \rightarrow \begin{bmatrix} x + \alpha_{bend}z^2 \\ y \\ z \end{bmatrix}.$$

Given $[\alpha_{bend}, \alpha_{twist}]$, bending is performed after twisting.

227 ADC because the faster diffusing spins in the ECS are allowed to moved into the slowly diffusing
228 spherical cells. We note that in the permeable case, the ADC in each compartment is obtained by
229 using the fitting formula involving the logarithm of the dMRI signal, and we defined the "signal"
230 in a compartment as the total magnetization in that compartment at TE, which is just the integral
231 of the solution of the BTPDE in that compartment.

232 *4.3. Myelin layer*

233 In Fig. 7 we show the diffusion in cylindrical cells, the myelin layer, and the ECS. The ADC is
234 higher in the myelin layer than in the cells, because for spins in the myelin layer diffusion occurs
235 in the tangential direction (around the circle). At longer diffusion times, the ADC of both the
236 myelin layer and the cells becomes very low. The ADC is the highest in the ECS, because the
237 diffusion distance can be longer than the diameter of a cell, since the diffusing spins can move
238 around multiple cells.

239 *4.4. Twisting and bending*

240 In Fig. 8 we show the effect of bending and twising in cylindrical cells in multiple gradient directions.
241 The HADC is obtained in 20 directions uniformly distributed in the sphere. We used spherical
242 harmonics interpolation to interpolate the HADC in the entire sphere. Then we deformed the
243 radius of the unit sphere to be proportional to the interpolated HADC and plotted the 3D shape.
244 The color axis also indicates the value of the interpolated HADC.

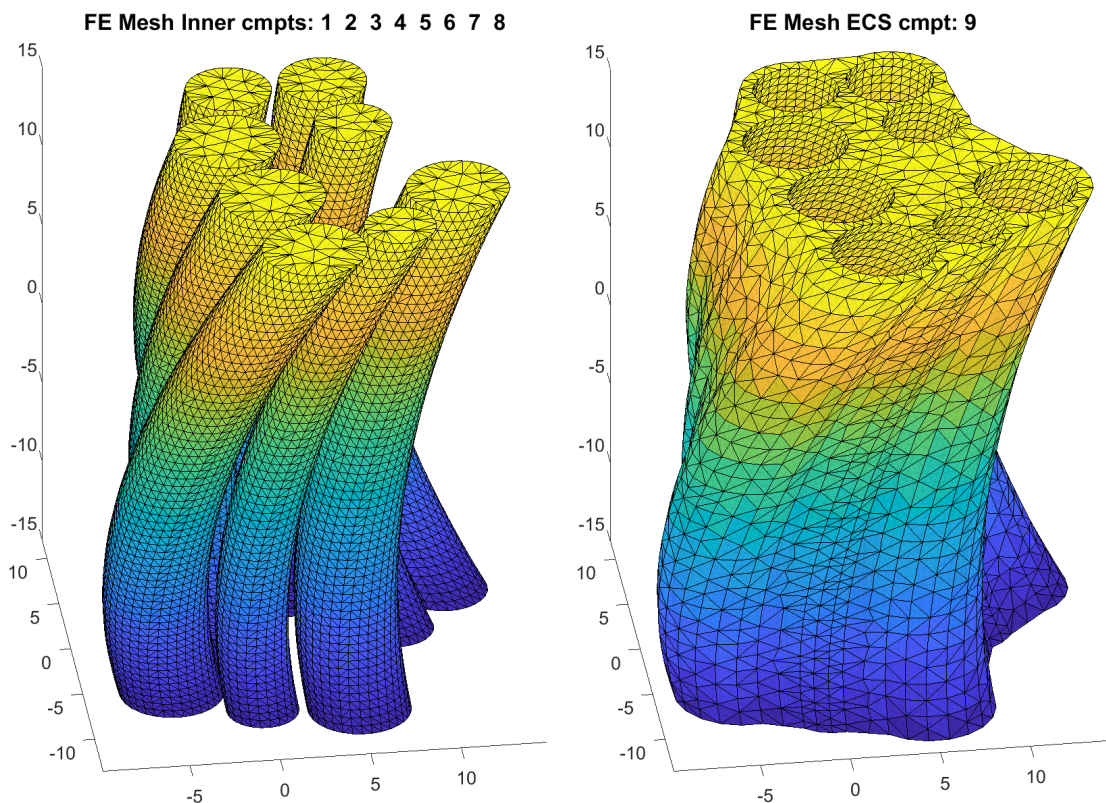

Figure 4: FE mesh of cylinders and ECS after bending and twisting. Compartment number is 1 to 8 for the cylinders and 9 for the ECS.

245 4.5. Timing

246 In Table 8 we give the average computational times for solving the BTPDE and the HADC. All
 247 simulations were performed on a laptop computer with the processor Intel(R) Core(TM) i5-4210U
 248 CPU @ 1.70 GHz 2.40 GHz, running Windows 10 (1809). The geometrical configuration includes
 249 2 axons and a tight wrap ECS, the simulated sequence is PGSE ($\delta = 2.5\text{ms}$, $\Delta = 5\text{ms}$). In
 250 the impermeable case, the compartments are uncoupled, and the computational times are given
 251 separately for each compartment. In the permeable membrane case, the compartments are coupled,
 252 and the computational time is for the coupled system (relevant to the BTPDE only).

253 5. Numerical validation of SpinDoctor

254 In this section, we validate SpinDoctor by comparing SpinDoctor with the Matrix Formalism
 255 method [49, 50] in a simple geometry. The Matrix Formalism method is a closed form representation
 256 of the dMRI signal based on the eigenfunctions of the Laplace operator subject to homogeneous
 257 Neumann boundary conditions. These eigenfunctions are available in explicit form for elementary

Line	Variable name	Example	Explanation
1	ngdir	20	number of gradient direction; if $ngdir > 1$, the gradient directions are distributed uniformly on a sphere; if $ngdir = 1$, take the gradient direction from the line below;
2	gdir	1.0 0.0 0.0	gradient direction; No need to normalize;
3	nexperi	3	number of experiments;

14	const_q	0	0: use input bvalues for all experiments; 1: take input bvalues for the first experiment and use the same q for the remaining experiments
15	bvalues	0 50 100 200	bvalues or [bmin, bmax] or [gmin, gmax]; depending on line 13;

Table 6: Input file for simulation experiment parameters.

258 geometries such as the line segment, the disk, and the sphere [51–54]. The dMRI signal obtained
259 using the Matrix Formalism method will be considered the reference solution in this section.

260 The accuracy of the SpinDoctor simulations can be tuned using three simulation parameters:

- 261 1. *Htetgen* controls the finite element mesh size;
- 262 (a) $Htetgen = -1$ means the FE mesh size is determined automatically by the internal
263 algorithm of Tetgen to ensure a good quality mesh (subject to the constraint that the
264 radius to edge ratio of tetrahedra is no larger than 2.0).
- 265 (b) $Htetgen = h$ requests a desired FE mesh tetrahedra height of $h \mu\text{m}$ (in later versions of
266 Tetgen, this parameter has been changed to the desired volume of the tetrahedra).

Algorithm 5: BTPDE.

FE matrices are generated for each compartment by the finite element method with continuous piecewise linear basis functions (known as P_1). The basis functions are denoted as φ_k for $k = 1, \dots, N_v$, where N_v denotes the number of mesh nodes (vertices). All matrices are sparse matrices. \mathbf{M} and \mathbf{S} are known in the FEM literature as mass and stiffness matrices which are defined as follows:

$$\mathbf{M}_{ij} = \int_{\Omega} \varphi_i \varphi_j \, d\mathbf{x}, \quad \mathbf{S}_{ij} = \int_{\Omega} \sigma_i \nabla \varphi_i \cdot \nabla \varphi_j \, d\mathbf{x}.$$

\mathbf{J} has a similar form as the mass matrix but it is scaled with the coefficient $\mathbf{g} \cdot \mathbf{x}$, we therefore call it the scaled-mass matrix

$$\mathbf{J}_{ij} = \int_{\Omega} \mathbf{g} \cdot \mathbf{x} \varphi_i \varphi_j \, d\mathbf{x}.$$

We construct the matrix based on the flux matrix \mathbf{Q}

$$\mathbf{Q}_{ij} = \int_{\partial\Omega} w \varphi_i \varphi_j \, ds$$

where a scalar function w is used as an interface marker. The matrices are assembled from local element matrices and the assembly process is based on vectorized routines of [43], which replace expensive loops over elements by operations with 3-dimensional arrays. All local elements matrices in the assembly of \mathbf{S} , \mathbf{M} , \mathbf{J} are evaluated at once and stored in a full matrix of size $4 \times 4 \times N_e$, where N_e denotes the number of tetrahedral elements. The assembly of \mathbf{Q} is even simpler; all local matrices are stored in a full matrix of size $3 \times 3 \times n_{be}$, where n_{be} denotes the number of boundary triangles.

Double nodes are placed at the interfaces between compartments connected by permeable membrane. $\overline{\mathbf{Q}}$ is used to impose the interface conditions and it is associated with the *interface (ghost) elements*. Specifically, assume that the double nodes are defined in a pair of indices $\{i, \tilde{i}\}$, $\overline{\mathbf{Q}}$ is defined as the following

$$\overline{\mathbf{Q}}_{ij} = \begin{cases} \mathbf{Q}_{ij}, & \text{if vertex } i \text{ and } j \text{ belong to one interface} \\ -\mathbf{Q}_{\tilde{i}\tilde{j}} & \text{if vertex } i \text{ and } j \text{ belong to two different interfaces} \end{cases}$$

The fully coupled linear system has the following form

$$\mathbf{M} \frac{\partial \xi}{\partial t} = - \left(I \gamma f(t) \mathbf{J} + \mathbf{S} + \overline{\mathbf{Q}} \right) \xi \quad (14)$$

where ξ is the approximation of the magnetization M . SpinDoctor calls MATLAB built-in ODE routine ode23t to solve the semi-discretized system of equations.

267

2. *rtol* controls the accuracy of the ODE solve. It is the relative residual tolerance at all points of the FE mesh at each time step of the ODE solve;

268

Algorithm 6: HADC model.

Eq. (12) can be discretized similarly as described for the BTPDE and has the matrix form

$$\mathbf{M} \frac{\partial \zeta}{\partial t} = -\mathbf{S} \zeta + \mathbf{Q} \bar{\zeta} \quad (15)$$

where ζ is the approximation of w and $\bar{\zeta}_i = \sigma_i F(t) \mathbf{u}_g \cdot \mathbf{n}(\mathbf{x}_i)$. We note that the matrices here are assembled and solved separately for each compartment. SpinDoctor calls MATLAB built-in ODE routine ode23t to solve the semi-discretized equation.

Variable name	Size	Explanation
TOUT	$\{\text{nexperi} \times \text{nb} \times \text{Ncmpt}\} [1 \times \text{nt}]$	ODE time discretization
YOUT	$\{\text{nexperi} \times \text{nb} \times \text{Ncmpt}\} [\text{Nnodes} \times \text{nt}]$	Magnetization
MF_cmpts	$[\text{Ncmpt} \times \text{nexperi} \times \text{nb}]$	integral of magnetization at TE in each compartment.
MF_allcmpts	$[\text{nexperi} \times \text{nb}]$	integral of magnetization at TE summed over all compartments.
ADC_cmpts	$[\text{Ncmpt} \times \text{nexperi}]$	ADC in each compartment.
ADC_allcmpts	$[\text{nexperi} \times 1]$	ADC accounting for all compartments.
ADC_cmpts_dir	$[\text{ngdir} \times \text{Ncmpt} \times \text{nexperi}]$	ADC in each compartment in each direction.
ADC_allcmpts_dir	$[\text{ngdir} \times \text{nexperi} \times 1]$	ADC accounting for all compartments in each direction.

Table 7: Some important SpinDoctor output quantities.

	FE mesh size	BTPDE $b = 50 \text{ s/mm}^2$	BTPDE $b = 1000 \text{ s/mm}^2$	HADC
Uncoupled: Axons	5865 nodes, 19087 ele	7.89 sec	9.07 sec	8.80 sec
Uncoupled: ECS	6339 nodes, 19618 ele	10.14 sec	13.95 sec	11.87 sec
Coupled: Axons+ECS	7344 nodes, 38705 ele	39.14 sec	43.24 sec	N/A

Table 8: Computational times for solving the BTPDE and the HADC. All simulations were performed on Intel(R) Core(TM) i5-4210U CPU @ 1.70 GHz 2.40 GHz, running Windows 10 (1809). The geometrical configuration includes 2 axons and a tight wrap ECS, the simulated sequence is PGSE ($\delta = 2.5\text{ms}$, $\Delta = 5\text{ms}$).

269 3. *atol* controls the accuracy of the ODE solve. It is the absolute residual tolerance at all points
270 of the FE mesh at each time step of the ODE solve;

271 We varied the finite element mesh size and the ODE solve accuracy of SpinDoctor and ran 6
272 simulations with the following simulation parameters:

273 **SpinD Simul 5-1:** $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = -1$;

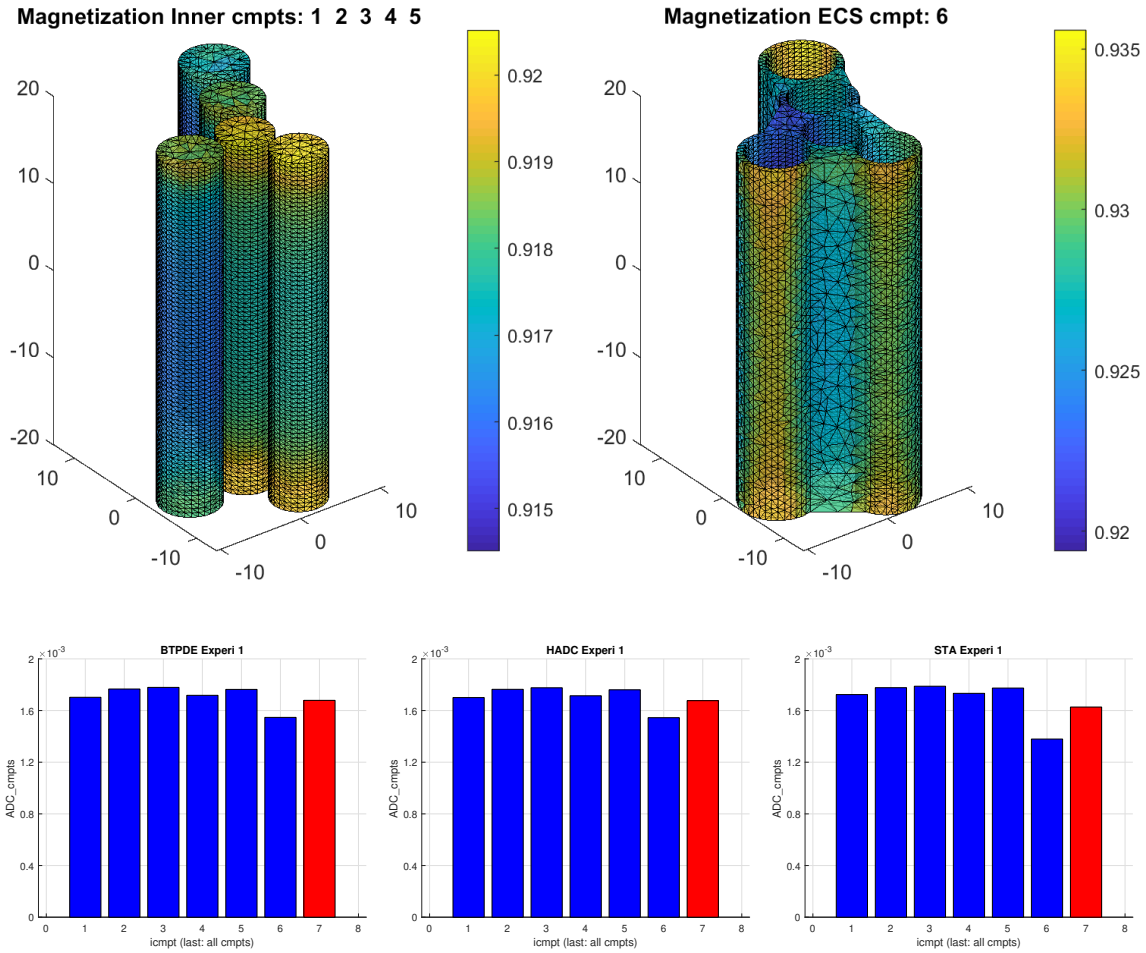

Figure 5: Geometry: 5 cylinders, tight wrap ECS, ECS gap = 0.2, $\mathbf{u}_g = [1, 1, 1]$, $\sigma^{out} = \sigma^{ecs} = 2 \times 10^{-3} \text{ mm}^2/\text{s}$, $\kappa = 0 \text{ m/s}$, OGSE cosine ($\delta = 14\text{ms}$, $\Delta = 14\text{ms}$, number of periods = 6). The vertical bars indicate the ADC in each compartment. The ADC in the rightmost position is the ADC that takes into account the diffusion in all the compartments.

274 **SpinD Simul 5-2:** $rtol = 10^{-6}$, $atol = 10^{-9}$, $Htetgen = -1$;

275 **SpinD Simul 5-3:** $rtol = 10^{-9}$, $atol = 10^{-12}$, $Htetgen = -1$;

276 **SpinD Simul 5-4:** $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = 1$;

277 **SpinD Simul 5-5:** $rtol = 10^{-6}$, $atol = 10^{-9}$, $Htetgen = 1$;

278 **SpinD Simul 5-6:** $rtol = 10^{-9}$, $atol = 10^{-12}$, $Htetgen = 1$;

279 The geometry simulated is the following:

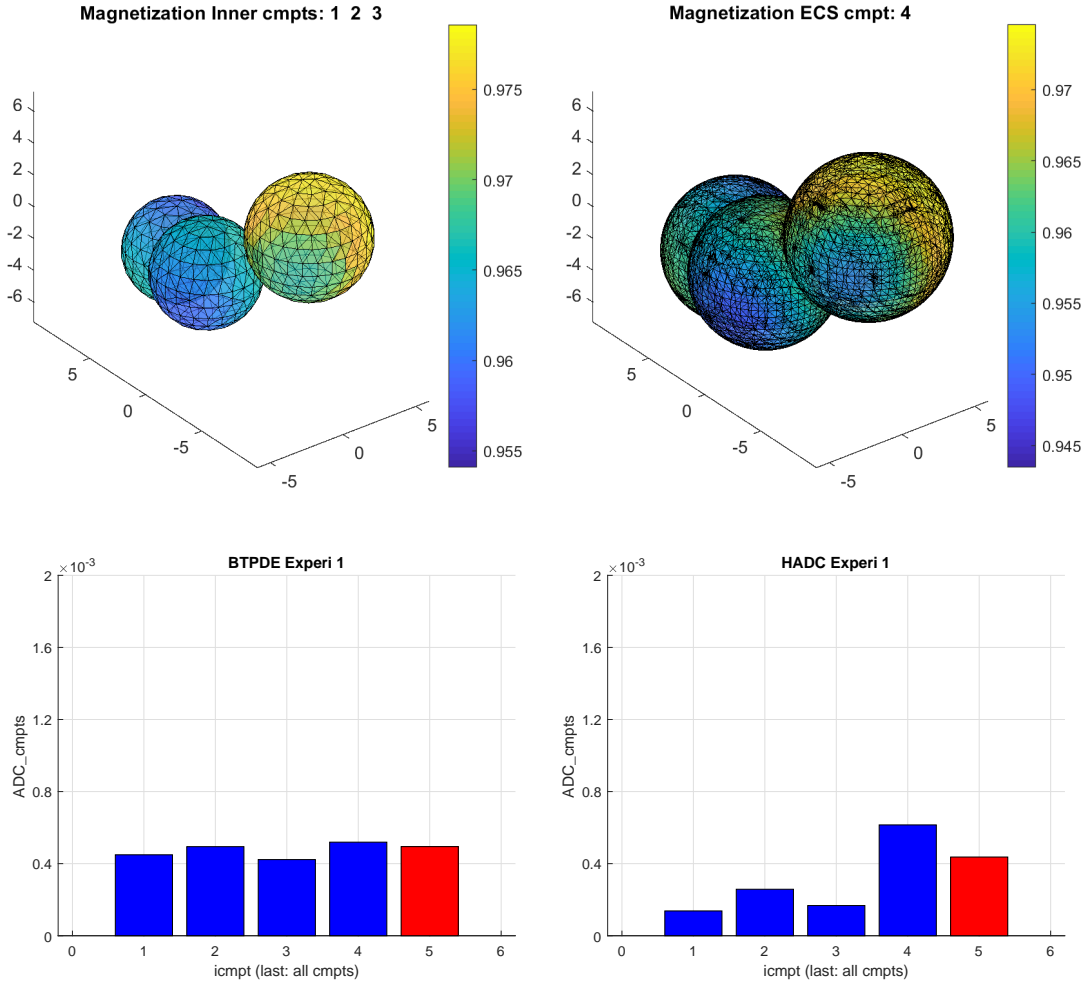

Figure 6: Geometry: 3 spheres, tight wrap ECS, ECS gap = 0.3, $\mathbf{u}_g = [1, 1, 0]$, $\sigma^{in} = \sigma^{ecs} = 2 \times 10^{-3} \text{ mm}^2/\text{s}$, $\kappa = 1 \times 10^{-3} \text{ m/s}$ (left), $\kappa = 0 \text{ m/s}$ (right). PGSE ($\delta = 5\text{ms}$, $\Delta = 5\text{ms}$). The vertical bars indicate the ADC in each compartment. The ADC in the rightmost position is the ADC that takes into account the diffusion in all the compartments.

- 280 • *3LayerCylinder* is a 3-layer cylindrical geometry of height $1\mu\text{m}$ and the layer radii, $R_1 =$
281 $2.5\mu\text{m}$, $R_2 = 5\mu\text{m}$ and $R_3 = 10\mu\text{m}$. The middle layer is subject to permeable interface
282 conditions on both the interior and the exterior interfaces, with permeability coefficient κ .
283 The exterior boundary $R = R_3$ is subject to impermeable boundary conditions. The top and
284 bottom boundaries are also subject to impermeable boundary conditions.
- 285 • For this geometry, $Htetgen = -1$ gives finite elements mesh size ($n_{nodes} = 440$, $n_{elem} = 1397$).
286 $Htetgen = 1$ gives finite elements mesh size ($n_{nodes} = 718$, $n_{elem} = 2088$).

287 The dMRI experimental parameters are the following:

- 288 • the diffusion coefficient in all compartments is $2 \times 10^{-3} \text{ mm}^2/\text{s}$;
- 289 • the diffusion-encoding sequence is PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$);
- 290 • 8 b-values: $b = \{0, 100, 500, 1000, 2000, 3000, 6000, 10000\} \text{ s/mm}^2$;
- 291 • 1 gradient direction: $[1, 1, 0]$;

In Figure 9 we show the signal differences (in percent) of the reference Matrix Formalism method and the SpinDoctor simulations, normalized by the reference signal at $b = 0$:

$$E(b) = \frac{|S^{MF}(b) - S^{SpinD}(b)|}{S^{MF}(b=0)} \times 100. \quad (16)$$

292 We see that the signal difference is less than 0.35% for $\kappa = 10^{-5} \text{ m/s}$ and it is less than 0.25% for
 293 $\kappa = 10^{-4} \text{ m/s}$ for all 6 SpinDoctor simulations. The signal difference becomes smaller when the
 294 ODE solve tolerances are changed from ($rtol = 10^{-3}$, $atol = 10^{-6}$) to ($rtol = 10^{-6}$, $atol = 10^{-9}$),
 295 but there is no change when the tolerances are further reduced to ($rtol = 10^{-9}$, $atol = 10^{-12}$). If
 296 we refine the FE mesh, but keep the ODE solve tolerances the same, the signal difference is in fact
 297 larger using the refined mesh than using the coarse mesh at the smaller b-values, though this effect
 298 disappears at higher b-values and larger permeability. This is probably due to parasitic oscillatory
 299 modes on the finer mesh that need smaller time steps to be sufficiently damped.

300 6. Computational time and comparison with Monte-Carlo simulation

301 In this section, we compare SpinDoctor with Monte-Carlo simulation using the publicly available
 302 software package Camino Diffusion MRI Toolkit [26], downloaded from <http://cmic.cs.ucl.ac.uk/camino>. All the simulations were performed on a server computer with 12 processors (Intel (R)
 303 Xeon (R) E5-2667 @2.90 GHz), 192 GB of RAM, running CentOS 7. SpinDoctor was run using
 304 MATLAB R2019a on the same computer.
 305

306 We give SpinDoctor computational times for three relatively complicated geometries. We also give
 307 Camino computational times for the first two geometries. We did not use Camino for the third
 308 geometry due to the excessive time required by Camino.

309 The number of the degrees of freedom in the SpinDoctor simulations is the finite element mesh size
 310 (the number of nodes and the number of elements). For Camino it is the number of spins. The time
 311 stepping choice of the SpinDoctor simulations is given by the ODE solve tolerances. For Camino
 312 it is given by the number of time steps. Camino has an initialization step where it places the spins
 313 and we give the time of this initialization step separately from the Camino random walk simulation
 314 time.

315 Given the interest of the dMRI community in the extra-cellular space [11] and neuron simulations,
 316 we chose the following three geometries:

- 317 1. *ECS400axons*. See Figure 10. This models the extra-cellular space outside of 400 axons. We
 318 generated 400 cylinders with height $1\mu\text{m}$ and radii ranging from $2 - 5\mu\text{m}$, randomly placed
 319 according to Algorithm 1. The small height of the cylinders means that this geometry should

320 be used only for studying transverse diffusion. We used a tight-wrap ECS: this choice means
321 we do not need to have a complicated algorithm to avoid large empty spaces as would be the
322 case when the ECS is box-shaped.

323 2. *DendriteBranch*. See Figure 11. This is a dendrite branch whose original morphological
324 reconstruction SWC file published in NeuroMorpho.Org [55]. By wrapping the geometry
325 described in the SWC file in a new watertight surface and using the external FE meshing
326 package GMSH [56], we created a FE mesh for this dendrite branch. The FE mesh was in
327 imported and used in SpinDoctor. We note this is an externally generated FE mesh and this
328 illustrate the capacity of SpinDoctor to simulate the dMRI on general geometries provided
329 by the user.

330 3. *ECS200axons*. See Figure 12. This models the extra-cellular space outside of 200 axons. To
331 study 3-dimensional diffusion, the height of the cylinders was increased to $50\mu\text{m}$. To keep the
332 finite element mesh size reasonable, we decreased the number of axons to 200, keeping the
333 range of radii between 2 – 5 microns, placed randomly as above, with a tight-wrap ECS.

334 The dMRI experimental parameters are the following:

- 335 • the diffusion coefficient is $2 \times 10^{-3} \text{ mm}^2/\text{s}$;
- 336 • the diffusion-encoding sequence is PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$);
- 337 • 8 b-values: $b = \{0, 100, 500, 1000, 2000, 3000, 6000, 10000\} \text{ s}/\text{mm}^2$;
- 338 • 1 gradient direction: $[1, 1, 0]$.

339 The SpinDoctor simulations were done using one compartment. The boundary of compartment is
340 subject to impermeable boundary conditions. We took the surface triangulations associated with
341 the finite element mesh for the SpinDoctor simulations and used them as the input PLY files for
342 Camino. Camino is called with the command `datasynth`. The options of Camino that are relevant
343 to the simulations in the above three geometries are the following:

- 344 • `-walkers $\{N\}$` : N is the number of walkers ;
- 345 • `-tmax $\{T\}$` : T is the number of time steps;
- 346 • `-p $\{P\}$` : P is the probability that a spin will step through a barrier. We set P to zero;
- 347 • `-voxels 1`: using 1 voxel for the experiment;
- 348 • `-initial intra`: random walkers are placed uniformly inside the geometry and none outside
349 of it; [In the case of the extra-cellular space, `intra` means inside the geometry, with the
350 geometry representing the extracellular space;](#)
- 351 • `-voxelsizefrac 1`: the signal is computed using all the spins inside the geometry described
352 by the PLY file, and not just in a center region;
- 353 • `-diffusivity 2E-9`: the diffusion coefficient (m^2/s);

- 354 • `-meshsep` $\{xsep\}$ $\{ysep\}$ $\{zsep\}$: specifies the separation between bounding box for
355 mesh substrates. We used a box that fully contains the geometry described by the PLY file;
- 356 • `-substrate ply`: mesh substrates are constructed using a PLY file;
- 357 • `-plyfile` $\{plyfile\}$: the name of the PLY file. We wrote a MATLAB function that outputs
358 the list of triangles that make up the boundary of the finite element mesh and formatted it
359 as a PLY file. We note these triangles form a surface triangulation;

360 6.1. ECS of 400 axons

361 SpinDoctor was run with the following 3 sets of simulation parameters:

362 **SpinD Simul 6.1-1:** $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = 0.5$;

363 **SpinD Simul 6.1-2:** $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = 1$;

364 **SpinD Simul 6.1-3:** $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = -1$;

365 For this geometry, $Htetgen = -1$ gives finite elements mesh size ($n_{nodes} = 53280$, $n_{elem} = 125798$).
366 $Htetgen = 1$ gives finite elements mesh size ($n_{nodes} = 58018$, $n_{elem} = 139582$). $Htetgen = 0.5$ gives
367 finite elements mesh size ($n_{nodes} = 70047$, $n_{elem} = 177259$).

368 Camino was run with the following 2 sets of simulation parameters:

369 **Camino Simul 6.1-1:** $N = 1000$, $T = 200$;

370 **Camino Simul 6.1-2:** $N = 4000$, $T = 800$;

371 The reference signals are **SpinD Simul 6.1-1**, the SpinDoctor signals computed on the finest FE
372 mesh ($Htetgen = 0.5$).

We computed the signal differences between the reference simulations and the 2 remaining Spin-
Doctor simulations as well as the two Camino signals:

$$E(b) = \left| \frac{S(b)}{S(0)} - \frac{S^{ref}(b)}{S^{ref}(0)} \right| \times 100. \quad (17)$$

373 In Figure 13 we see $E(b)$ for the SpinDoctor simulation on the coarsest mesh ($Htetgen = -1$) is
374 less than 0.4% for all b-values and for the SpinDoctor simulation on the mesh ($Htetgen = 1$) it
375 is less than 0.2%. The Camino simulation with ($N = 1000$, $T = 200$) has a signal difference of
376 1.9% for b-value up to 2000 s/mm^2 , and the Camino simulation with ($N = 4000$, $T = 800$) has a
377 signal difference of 0.7% for b-value up to 2000 s/mm^2 . However, for b-value $b = 3000 \text{ s/mm}^2$ and
378 greater, it seems the first Camino simulation is closer to the reference signal than the second Camino
379 simulation. It likely means that 4000 spins and 800 time steps are not enough to achieve signal
380 convergence at higher b-values. [In fact, they are below the recommended values for Monte-Carlo
381 simulations \[26\], but we chose them to keep the Camino simulations running within a reasonable
382 amount of time.](#) On the other hand, the refinement of the FE mesh for the SpinDoctor achieves
383 convergence for all b-values up to 10000 s/mm^2 . There is a significant increase of the computational

384 time of SpinDoctor as the diffusion-encoding amplitude is increased from 0.03 T/m to 0.37 T/m. At
 385 the finest mesh, the computational time increased from 35 seconds to 200 seconds. At the coarsest
 386 mesh, the computational time increased from 20 seconds to 115 seconds. This is due to the fact
 387 that at higher gradient amplitudes, the magnetization is more oscillatory, so to achieve a fixed ODE
 388 solver tolerance, smaller time steps are needed.

389 In Table 9 we show the total computational time to compute the dMRI signals at the 8 b-values
 390 for 2 SpinDoctor and 2 Camino simulations. We also include the time for Camino to place the
 391 initial spins in the geometry described by the PLY file. We include in the Table the maximum
 392 signal differences for b-values up to 2000 s/mm^2 instead of all the b-values because Camino is not
 393 convergent for b-values greater than 3000 s/mm^2 . We see that at a similar level of signal difference
 394 (0.4% for SpinDoctor versus 0.7% for Camino), the total computational time of SpinDoctor (438
 seconds) is more than 100 times faster than Camino (59147 seconds).

<i>ECS400axons</i>	SpinDoctor		Camino	
	Htet = -1	Htet = 0.5	$T = 200$	$T = 800$
Degrees of freedom	53280 nodes 125798 elements	70047 nodes 177259 elements	1000 spins	4000 spins
Max signal difference ($b \leq 2000 \text{ s/mm}^2$)	0.4%	Ref signal	1.9%	0.7%
Initialization time (sec)			69	305
Solve time (sec), 8 bvalues	438	667	3949	58842
Total time (sec)	438	667	4018	59147

Table 9: The geometry is *ECS400axons*. The total computational times (in seconds) to simulate the dMRI signal at 8 b-values using SpinDoctor and Camino. The initialization time is the time for Camino to place initial spins inside the geometry described by the PLY file. The b-values simulated are $b = \{0, 100, 500, 1000, 2000, 3000, 6000, 10000\} \text{ s/mm}^2$. The maximum signal differences are given for b-values up to 2000 s/mm^2 because Camino is not convergent for b-values greater than 3000 s/mm^2 . The diffusion coefficient is $2 \times 10^{-3} \text{ mm}^2/\text{s}$; The diffusion-encoding sequence is PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$); The gradient direction is $[1, 1, 0]$.

395

396 6.2. Dendrite branch

397 SpinDoctor was run with the following 2 sets of simulation parameters:

398 **SpinD Simul 6.2-1:** $rtol = 10^{-3}$, $atol = 10^{-6}$;

399 **SpinD Simul 6.2-2:** $rtol = 10^{-2}$, $atol = 10^{-4}$;

400 The finite elements mesh was generated by an external package and imported into SpinDoctor. The
 401 finite elements mesh size is ($n_{nodes} = 24651$, $n_{elem} = 91689$). We do not refine the FE mesh, rather,
 402 we vary the ODE solve tolerances in the SpinDoctor simulations.

403 Camino was run with the following 3 sets of simulation parameters:

404 **Camino Simul 6.2-1:** $N = 1000$, $T = 200$;

405 **Camino Simul 6.2-2:** $N = 2000, T = 400$;

406 **Camino Simul 6.2-3:** $N = 4000, T = 800$;

407 The reference signal is **SpinD Simul 6.2-1**, the SpinDoctor signal with the higher ODE solve
408 tolerances ($rtol = 10^{-3}, atol = 10^{-6}$).

409 In Figure 14 we see the signal difference $E(b)$ for the SpinDoctor simulation with the bigger ODE
410 solve tolerances ($rtol = 10^{-2}, atol = 10^{-4}$) is less than 0.6% for all b-values. The Camino simulation
411 with ($N = 1000, T = 200$) has a maximum signal difference of 6.4%, the Camino simulation with
412 ($N = 4000, T = 800$) has a maximum signal difference of 1.0%. As the gradient amplitude is
413 increased from 0.03 T/m to 0.37 T/m, at the larger ODE solve tolerances, the computational time
414 increased from 5 seconds to 17 seconds. At smaller ODE solve tolerances, the computational time
415 increased from 7 seconds to 42 seconds. Again, this increase is due to the fact that at higher gradient
416 amplitudes, the magnetization is more oscillatory, so to achieve a fixed ODE solver tolerance, smaller
417 time steps are needed. In Table 10 we see for the same level of accuracy (0.6% for SpinDoctor and
418 and 1% for Camino), SpinDoctor (109 seconds) is 400 times faster than Camino (43918 seconds).

<i>Dendrite Branch</i>	SpinDoctor		Camino		
	$rtol = 10^{-2}$	$rtol = 10^{-3}$	$T = 200$	$T = 400$	$T = 800$
Degrees of freedom	24651 nodes 91689 elements		1000 spins	2000 spins	4000 spins
Max signal difference	0.6%	Ref signal	6.4%	2.2%	1.0%
Initialization time (sec)			5897	11739	23702
Solve time (sec), 8 bvalues	109	207	1336	5138	20216
Total time (sec)	109	207	7233	16877	43918

Table 10: The geometry is *DendriteBranch*. The total computational times in seconds to simulate the dMRI signal at 8 b-values using SpinDoctor and Camino. The initialization time is the time for Camino to place initial spins inside the geometry described by the PLY file. The b-values simulated are $b = \{0, 100, 500, 1000, 2000, 3000, 6000, 10000\}$ s/mm². The diffusion coefficient is 2×10^{-3} mm²/s; The diffusion-encoding sequence is PGSE ($\delta = 10$ ms, $\Delta = 13$ ms); The gradient direction is $[1, 1, 0]$.

419 6.3. Three dimensional ECS of 200 axons

420 Due to computational time limitations, we only computed 4 b-values, $b = \{0, 100, 500, 1000\}$ s/mm²,
421 for the geometry *ECS200axons* (see Figure 12 for the finite element mesh).

422 SpinDoctor was run with the following 2 sets of simulation parameters:

423 **SpinD Simul 6.3-1:** $rtol = 10^{-3}, atol = 10^{-6}, Htetgen = -1$

424 **SpinD Simul 6.3-2:** $rtol = 10^{-3}, atol = 10^{-6}, Htetgen = 0.3$.

425 For this geometry, $Htetgen = -1$ gives finite elements mesh size ($n_{nodes} = 846298, n_{elem} =$
426 2997386). $Htetgen = 0.3$ gives finite elements mesh size ($n_{nodes} = 1017263, n_{elem} = 3950572$).

427 The difference in the signals between the two simulations is less than 0.35% (not plotted), meaning
428 the FE meshes are fine enough to produce accurate signals. In Table 11, we see that using about

429 846K nodes required 1.8 hours at $b = 100\text{s/mm}^2$, 2.7 hours at $b = 500\text{s/mm}^2$, 3.3 hours at
 430 $b = 1000\text{s/mm}^2$. We did not use Camino for *ECS200axons* due to the excessive time required by
 431 Camino.

<i>ECS200 axons</i>	SpinDoctor	
	Htet = -1	Htet = 0.3
Mesh	846298 nodes 2997386 elements	1017263 nodes 3950572 elements
Max signal difference	0.35%	Ref signal
Solve time (sec), $b = 100, 500, 1000\text{s/mm}^2$	(6611, 9620, 12107)	(16978, 23988, 32044)

Table 11: The geometry is *ECS200axons*. The computational times in seconds to simulate the dMRI signal at 3 b-values $b = \{100, 500, 1000\}\text{s/mm}^2$ using SpinDoctor. The times are listed separately for each b-value. The diffusion coefficient is $2 \times 10^{-3}\text{mm}^2/\text{s}$; The diffusion-encoding sequence is PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$); The gradient direction is $[1, 1, 0]$.

432 6.4. SpinDoctor computational time

433 We collected the computational times of the SpinDoctor simulations for *ECS400axons*, *Dendrite-*
 434 *Branch*, and *ECS200axons*, that had the ODE solve tolerances ($rtol = 10^{-3}$, $atol = 10^{-6}$). In
 435 addition, for *ECS400axons* and *DendriteBranch*, we performed simulations for another PGSE se-
 436 quence ($\delta = 10\text{ms}$, $\Delta = 23\text{ms}$).

437 Now we examine the computational time as a function of the finite element mesh size for those
 438 simulations with ODE solve tolerances ($rtol = 10^{-3}$, $atol = 10^{-6}$). There are 3 FE meshes of
 439 *ECS400axons*, 1 FE mesh of *DendriteBranch*, and 2 FE meshes of *ECS200axons*. In Figure 15 we
 440 plot the computational times to simulate the dMRI signal at two b-values ($b = 100\text{s/mm}^2$ and
 441 $b = 1000\text{s/mm}^2$) as a function of the number of FE nodes. We see at fewer than 100K finite
 442 element nodes, the SpinDoctor simulation time is less than 1 minute per b-value. At 1 million FE
 443 nodes, the SpinDoctor simulation time is about 4.7 hours for $b = 100\text{s/mm}^2$ and 8.9 hours for
 444 $b = 1000\text{s/mm}^2$.

445 7. SpinDoctor permeability and Monte-Carlo transmission probability

446 Here we illustrate the link between the membrane permeability of Spinductor and the transmission
 447 probability of crossing a membrane in the Camino simulation. The geometry is the following:

- 448 • *Permeable Sphere* involves uniformly placed initial spins inside a sphere of radius $5\mu\text{m}$, subject
 449 to permeable interface condition on the surface of the sphere, with permeability coefficient κ .
 450 No spins are initially placed outside of this sphere. In the SpinDoctor simulation, this sphere
 451 is enclosed inside a sphere of diameter $30\mu\text{m}$, subject to impermeable boundary condition on
 452 the outermost interface. In the Camino simulation, this sphere is enclosed in a box of side
 453 length $30\mu\text{m}$, subject to periodic boundary conditions. The inner sphere is far enough from
 454 the outer sphere in SpinDoctor and from the outer box in Camino so that there is no influence
 455 of the outer surface during the simulated diffusion times.

456 The dMRI experimental parameters are the following:

- 457 • the diffusion coefficient in all compartments is $2 \times 10^{-3} \text{ mm}^2/\text{s}$;
- 458 • the diffusion-encoding sequence is PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$);
- 459 • 8 b-values: $b = \{0, 100, 500, 1000, 2000, 3000, 6000, 10000\} \text{ s}/\text{mm}^2$;
- 460 • 1 gradient direction: $[1, 1, 0]$.

461 SpinDoctor was run with the following 3 sets of simulation parameters:

462 **SpinD Simul 7-1:** $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = 0.5$;

463 **SpinD Simul 7-2:** $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = 1$;

464 **SpinD Simul 7-3:** $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = -1$;

465 For this geometry, $Htetgen = -1$ gives finite elements mesh size ($n_{nodes} = 46384$, $n_{elem} = 196920$).
466 $Htetgen = 1$ gives finite elements mesh size ($n_{nodes} = 49618$, $n_{elem} = 218007$). $Htetgen = 0.5$ gives
467 finite elements mesh size ($n_{nodes} = 52803$, $n_{elem} = 237613$).

468 Camino was run with the following 2 sets of simulation parameters:

469 **Camino Simul 7-1:** $N = 4000$, $T = 800$;

470 **Camino Simul 7-2:** $N = 8000$, $T = 3200$;

471 The reference signal is **SpinD Simul 7-1**, the SpinDoctor signal on the finest FE mesh.

In [57], there is a discussion about the transmission probability of random walkers as they encounter a permeable membrane with permeability κ . The formula found in that paper is (for three dimensions)

$$P_{EX} = C_{dim} \frac{\kappa}{\sigma} \sqrt{2 dim \sigma \delta t}, \quad C_{dim} = \frac{2}{3}, \quad dim = 3, \quad (18)$$

472 σ being the intrinsic diffusion coefficient, δt is the time step.

473 In Figure 16 we show the three SpinDoctor simulations at $\kappa = 10^{-5} \text{ m/s}$ and the two Camino
474 simulations using the above formula for P_{EX} . We considered the SpinDoctor signal computed on
475 the finest FE mesh as the reference signal and we computed the signal differences between the
476 reference signal and the other two SpinDoctor signals and the Camino signals. We see that the
477 Camino signals approach the reference signal as the number of spins and times steps in Camino
478 are increased, the maximum difference decreasing from 3.8% to 2.4%. The SpinDoctor signals have
479 signal differences of less than 0.5% and 0.1%, respectively.

480 8. Extensions of SpinDoctor

481 Here we mention two extensions in the functionalities of SpinDoctor that are planned for a future
482 release.

483 *8.1. Non-standard diffusion-encoding sequences*

484 Given the interest in nonstandard diffusion sequences beyond PGSE and OGSE, such as double
 485 diffusion encoding (see [58–61]) and multidimensional diffusion encoding (see [62]), it is natural that
 486 SpinDoctor should easily support arbitrary diffusion-encoding sequences. Besides the PGSE and
 487 the sine and cosine OGSE sequences that are provided in the SpinDoctor package, new sequences
 488 can be straightforwardly implemented by changing three files in the SpinDoctor package

- 489 • SRC/DMRI/seqprofile.m defines $f(t)$
- 490 • SRC/DMRI/seqintprofile.m defines the integral $F(t) = \int_0^t f(s)ds$
- 491 • SRC/DMRI/seqbvaluenoq.m defines the associated b -value.

In the example below, we simulate the double-PGSE (Eq. 19) sequence:

$$f(t) = \begin{cases} 1, & 0 \leq t \leq \delta, \\ -1, & \Delta < t \leq \Delta + \delta, \\ 1, & \tau \leq t \leq \delta + \tau, \\ -1, & \Delta + \tau < t \leq \Delta + \delta + \tau, \\ 0, & \text{otherwise.} \end{cases} \quad (19)$$

492 Here δ is the duration of the diffusion-encoding gradient pulse, Δ is the time delay between the
 493 start of the two pulses, and τ is the distance between the two pairs of pulses ($\tau \geq \delta + \Delta$). The
 494 geometry is made of cylindrical cells, the myelin layer, and the ECS (see Figure 7). In Figure 17 we
 495 show the dMRI signals for the PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$) and dPGSE sequences ($\delta = 10\text{ms}$, $\Delta =$
 496 13ms , $\tau = \delta + \Delta$), the diffusion-encoding direction is $\mathbf{u}_g = [1, 1, 1]$.

497 *8.2. T_2 relaxation*

When T_2 -relaxation is considered, the Bloch-Torrey PDE (Eq. 1) takes the following form

$$\frac{\partial}{\partial t} M_i^{in}(\mathbf{x}, t) = -I\gamma f(t) \mathbf{g} \cdot \mathbf{x} M_i^{in}(\mathbf{x}, t) - \frac{M_i^{in}}{T_2^{in}} + \nabla \cdot (\sigma^{in} \nabla M_i^{in}(\mathbf{x}, t)), \quad \mathbf{x} \in \Omega_i^{in}, \quad (20)$$

$$\frac{\partial}{\partial t} M_i^{out}(\mathbf{x}, t) = -I\gamma f(t) \mathbf{g} \cdot \mathbf{x} M_i^{out}(\mathbf{x}, t) - \frac{M_i^{out}}{T_2^{out}} + \nabla \cdot (\sigma^{out} \nabla M_i^{out}(\mathbf{x}, t)), \quad \mathbf{x} \in \Omega_i^{out}, \quad (21)$$

$$\frac{\partial}{\partial t} M^e(\mathbf{x}, t) = -I\gamma f(t) \mathbf{g} \cdot \mathbf{x} M^e(\mathbf{x}, t) - \frac{M^e}{T_2^e} + \nabla \cdot (\sigma^e \nabla M^e(\mathbf{x}, t)), \quad \mathbf{x} \in \Omega^e, \quad (22)$$

498 We plan to incorporate T_2 relaxation effects in the next official release of SpinDoctor. In the mean-
 499 time, this additional functionality can be found in a development branch of SpinDoctor available
 500 on GitHub. The source code in this development branch allows the ability to add relaxation, with
 501 different relaxivities in the different compartments [63, 64].

T_2 relaxation is incorporated using the format $T_2 = [T_2^{in}, T_2^{out}, T_2^e]$ where $T_2^{in}, T_2^{out}, T_2^e$ are the T_2 values for the three compartments, respectively. To verify the correctness of our implementation, we check the following. Let $S_{\text{No-}T_2}(b)$ be the signal without T_2 effects. If there is no exchange between

compartments, then the T_2 effects can be cancelled from the signals in the three compartments that include T_2 effects in the following way:

$$S_{cancel}(b) = \frac{S^{in}(b)}{e^{-\frac{TE}{T_2^{in}}}} + \frac{S^{out}(b)}{e^{-\frac{TE}{T_2^{out}}}} + \frac{S^e(b)}{e^{-\frac{TE}{T_2^e}}}. \quad (23)$$

502 In Fig. 18, we compare $S_{N_0-T_2}(b)$ with $S(b)$ where $T_2 = [50\text{ms}, 20\text{ms}, 100\text{ms}]$, for the PGSE se-
 503 quences ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$) and $\mathbf{u}_g = [1, 1, 1]$. We also compute $S_{cancel}(b)$, using Eq. 23. The
 504 geometry (see Figure 7) is made of cylindrical cells, the myelin layer, and the ECS. The T_2 effects
 505 on the signal $S(b)$ are clearly seen. The T_2 effects are completely canceled out using Eq. (23).

506 9. Discussion

507 Built upon MATLAB, SpinDoctor is a software package that seeks to reduce the work required to
 508 perform numerical simulations for dMRI for prototyping purposes. There have been software pack-
 509 ages for dMRI simulation that implements the random walkers approach. A [detailed](#) comparison
 510 of the Monte-Carlo/random walkers approach with the FEM approach is beyond the scope of this
 511 paper. SpinDoctor offers an alternative, solving the same physics problem using PDEs.

512 After surveying other works on dMRI simulations, we saw a need to have a simulation toolbox that
 513 provides a way to easily define geometrical configurations. In SpinDoctor we have tried to offer
 514 useful configurations, without being overly general. Allowing too much generality in the geometrical
 515 configurations would have made code robustness very difficult to achieve due to the difficulties
 516 related to problems in computational geometry (high quality surface triangulation, robust FE mesh
 517 generation). The geometrical configuration routines provided by SpinDoctor are a helpful front
 518 end, to enable dMRI researchers to get started quickly to perform numerical simulations. Those
 519 users who already have a high quality surface triangulation can use the other parts of SpinDoctor
 520 without passing through this front end.

521 The bulk of SpinDoctor is the numerical solutions of two PDEs. When one is only interested in the
 522 ADC, then computing the HADC model is the good option. When one is interested in higher order
 523 behavior in the dMRI signal, then the BTPDE model is a good option for accessing high b-value
 524 behavior.

525 Because time stepping methods for semi-discretized linear systems arising from finite element dis-
 526 cretization is a well-studied subject in the mathematical literature, the ODE solvers implemented
 527 in MATLAB already optimize for such linear systems. For example, the mass matrix is passed into
 528 the ODE solver as an optional parameter so as to avoid explicit matrix inversion. In addition, the
 529 ODE solution is guaranteed to stay within a user-requested residual tolerance. We believe this type
 530 of optimization and error control is clearly advantageous over simulation codes that do not have it.

531 To mimic the phenomenon where the water molecules can enter and exit the computational do-
 532 main, the pseudo-periodic boundary conditions were implemented in [33–35]. At this stage, we
 533 have chosen not to implement this in SpinDoctor, instead, spins are not allowed to leave the com-
 534 putational domain. Implementing pseudo-periodic boundary conditions would make the code more
 535 complicated, and it remains to be seen if it is a desired feature among potential users. If it is, then
 536 it could be part of a future development.

537 The twisting and bending of the canonical configuration is something unique to SpinDoctor. It
538 removes many computational geometry difficulties by meshing first the canonical configuration
539 before deforming the FE mesh via an analytical coordinate transformation. This is a way to
540 simulate fibers that are not parallel, that bend, for example. For fibers that disperse, perhaps more
541 complicated analytical coordinate transformations can be performed on the canonical configuration
542 to mimic that situation. This is a possible future direction to explore.

543 SpinDoctor depends on MATLAB for the ODE solve routines as well as for the computational
544 geometry routines to produce the tight wrap ECS. To implement SpinDoctor outside of MATLAB
545 would require replacing these two sets of MATLAB routines. Other routines of SpinDoctor can be
546 easily implemented in another programming language.

547 SpinDoctor can be downloaded at <https://github.com/jingrebecali/SpinDoctor>.

548 In summary, we have validated SpinDoctor simulations using reference signals from the Matrix For-
549 malism method, in particular in the case of permeable membranes. We then compared SpinDoctor
550 with the Monte-Carlo simulations produced by the publicly available software package Camino
551 Diffusion MRI Toolkit [26]. We showed that the membrane permeability of SpinDoctor can be
552 straightforwardly linked to the transmission probability in Monte-Carlo simulations. For numerous
553 examples, it was seen that the SpinDoctor and the Camino simulations can be made close to each
554 other if one increases the degrees of freedom (the finite element mesh size for SpinDoctor and the
555 number of spins for Camino) and increase the accuracy of the time stepping (by tightening the
556 ODE solve tolerances in SpinDoctor and by increasing the number of time steps in Camino).

557 At high gradient amplitudes, the oscillatory nature of the magnetization requires the use of smaller
558 time steps to maintain accuracy. For this reason, the computational time to simulate the dMRI
559 signal at high gradient amplitudes must be longer than at low gradient amplitudes. This adaptivity
560 in the time stepping as a function of gradient amplitude is done automatically in SpinDoctor.

561 We have computed the dMRI signals on several complicated geometries on a stand-alone computer.
562 For these examples, we have shown that SpinDoctor can be more than 100 times faster than Camino.
563 *Of course, in simple configurations such as straight, parallel cylinders, it is much more efficient to*
564 *use an analytical representation of the diffusion environment rather than a triangulated mesh in*
565 *Camino. In addition, some recent implementations of random walk simulations [65, 66] should be*
566 *faster than Camino.*

567 With a finite element mesh of 100K nodes, SpinDoctor takes less than one minute per b-value. At 1
568 million finite element nodes, limited computer memory resulted in a computational time 4.7 hours
569 for $b = 100 \text{ s/mm}^2$ and 8.9 hours for $b = 1000 \text{ s/mm}^2$. This issue will be taken into account in the
570 future with high performance computing techniques in MATLAB and on other platforms. One of
571 our recent works [40] is promising for this purpose.

572 We also illustrated several extensions of SpinDoctor functionalities, including the incorporation of
573 T_2 relaxation, the simulation of non-standard diffusion-encoding sequences. We note the dendrite
574 branch example illustrates SpinDoctor's ability to import and use externally generated meshes
575 provided by the user. This capability will be very useful given the most recent developments in
576 simulating ultra-realistic virtual tissues [65, 67].

577 **10. Conclusion**

578 This paper describes a publicly available MATLAB toolbox called SpinDoctor that can be used
579 to solve the BTPDE to obtain the dMRI signal and to solve the [diffusion equation](#) of the HADC
580 model to obtain the ADC. SpinDoctor is a software package that seeks to reduce the work required
581 to perform numerical simulations for dMRI for prototyping purposes.

582 SpinDoctor provides built-in options of including spherical cells with a nucleus, cylindrical cells with
583 a myelin layer, an extra-cellular space enclosed either in a box or in a tight wrapping around the
584 cells. The deformation of canonical cells by bending and twisting is implemented via an analytical
585 coordinate transformation of the FE mesh. Permeable membranes for the BTPDE is implemented
586 using double nodes on the compartment interfaces. Built-in diffusion-encoding pulse sequences
587 include the Pulsed Gradient Spin Echo and the Oscillating Gradient Spin Echo. Error control in
588 the time stepping is done using built-in MATLAB ODE solver routines.

589 User feedback to improve SpinDoctor is welcomed.

590 **Acknowledgment**

591 The authors gratefully acknowledge the *French-Vietnam Master in Applied Mathematics* program
592 whose students (co-authors on this paper, Van-Dang Nguyen, Try Nguyen Tran, Bang Cong Trang,
593 Khieu Van Nguyen, Vu Duc Thach Son, Hoang An Tran, Hoang Trong An Tran, Thi Minh Phuong
594 Nguyen) have contributed to the SpinDoctor project during their internships in France in the past
595 several years, as well as the *Vice-Presidency for Marketing and International Relations* at Ecole
596 Polytechnique for financially supporting a part of the students' stay. Jan Valdman was supported
597 by the Czech Science Foundation (GACR), through the grant GA17-04301S. Van-Dang Nguyen
598 was supported by the Swedish Energy Agency, Sweden with the project ID P40435-1 and MSO4SC
599 with the grant number 731063.

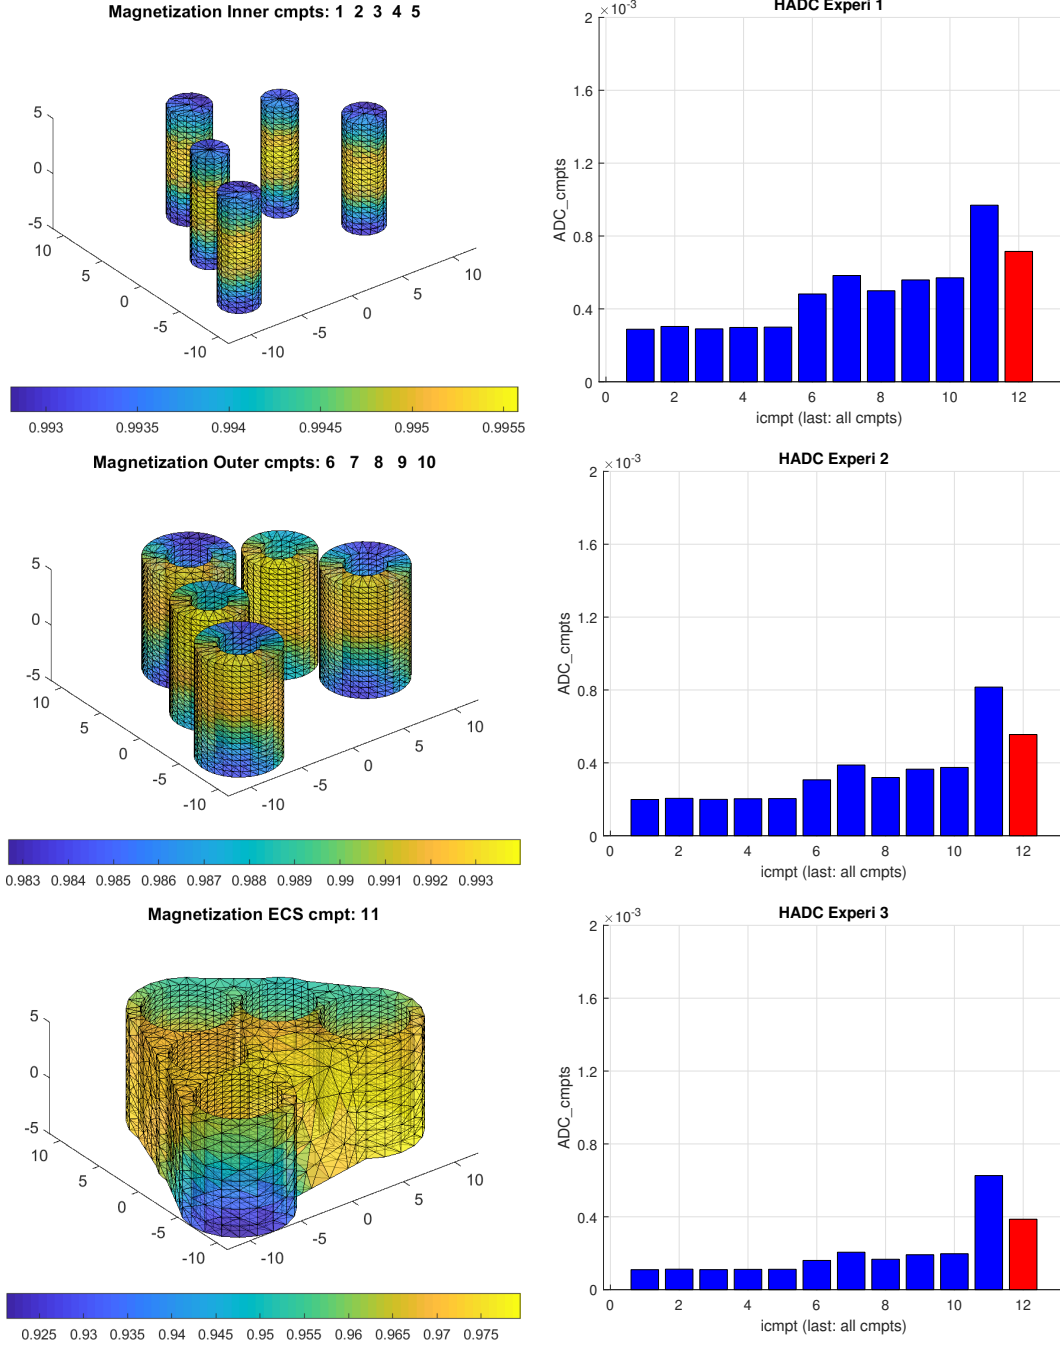

Figure 7: Geometry: 5 cylinders, myelin layer, $R_{in}/R_{out} = 0.5$, tight wrap ECS, ECS gap = 0.3, $\kappa = 0$ m/s, $\mathbf{u}_g = [1, 1, 1]$, $\sigma^{in} = \sigma^{out} = \sigma^{ecs} = 2 \times 10^{-3}$ mm²/s, 3 experiments: PGSE ($\delta = 5$ ms, $\Delta = 5, 10, 20$ ms). Left: the magnetization at $\Delta = 5$ ms. Right: the ADC values. The vertical bars indicate the ADC in each compartment. The ADC in the rightmost position is the ADC that takes into account the diffusion in all the compartments.

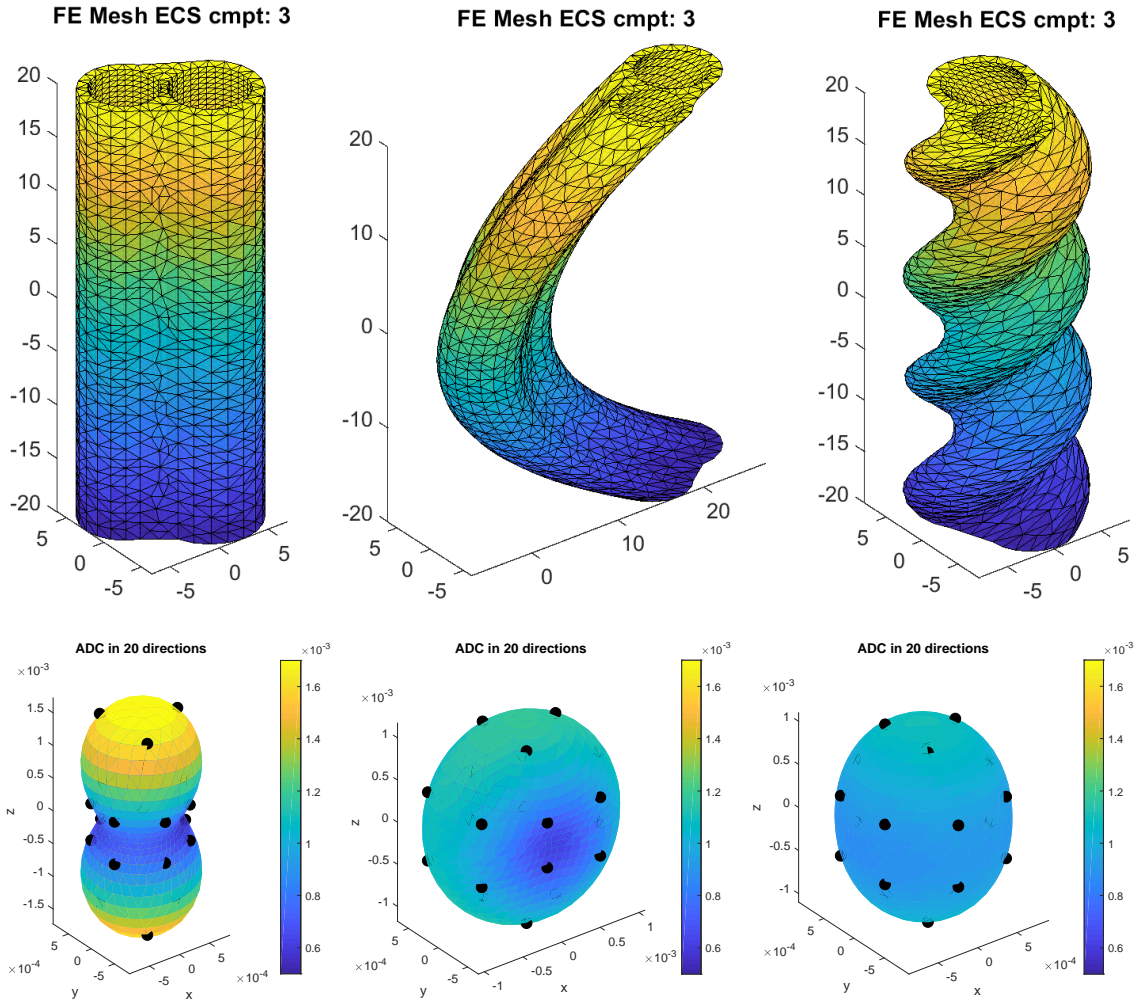

Figure 8: Geometry: 2 cylinders, no myelin layer, tight wrap ECS, ECS gap = 0.3, $\kappa = 0$ m/s, $\sigma^{out} = \sigma^{ecs} = 2 \times 10^{-3}$ mm²/s, PGSE ($\delta = 2.5$ ms, $\Delta = 5$ ms).

Left: canonical configuration. Middle: bend parameter = 0.05. Right: twist parameter = 0.30. Top: FE mesh of the ECS (the FE mesh of the axon compartments numbered 1 and 2 not shown). Bottom: interpolated values of the HADC on the unit sphere, and then the sphere was distorted to reflect the value of the HADC. The color axis also gives the value of the HADC in the various gradient directions. The black dots indicate the 20 original gradient-directions in which the HADC was simulated. The spherical harmonics interpolation takes the 20 original directions into 900 directions uniformly distributed on the sphere.

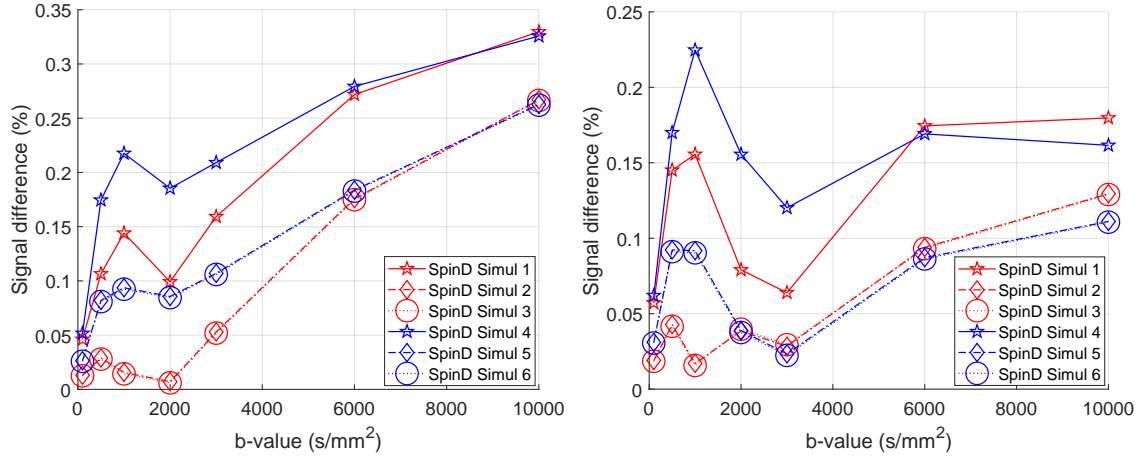

Figure 9: Signal difference between the Matrix Formalism signal (reference) and the SpinDoctor signal. Left: $\kappa = 10^{-5}$ m/s. Right: $\kappa = 10^{-4}$ m/s. The geometry is *3LayerCylinder*. The diffusion coefficient in all compartments is 2×10^{-3} mm²/s; the diffusion-encoding sequence is PGSE ($\delta = 10$ ms, $\Delta = 13$ ms); Simul 1: $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = -1$; Simul 2: $rtol = 10^{-6}$, $atol = 10^{-9}$, $Htetgen = -1$; Simul 3: $rtol = 10^{-9}$, $atol = 10^{-12}$, $Htetgen = -1$; Simul 4: $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = 1$; Simul 5: $rtol = 10^{-6}$, $atol = 10^{-9}$, $Htetgen = 1$; Simul 6: $rtol = 10^{-9}$, $atol = 10^{-12}$, $Htetgen = 1$;

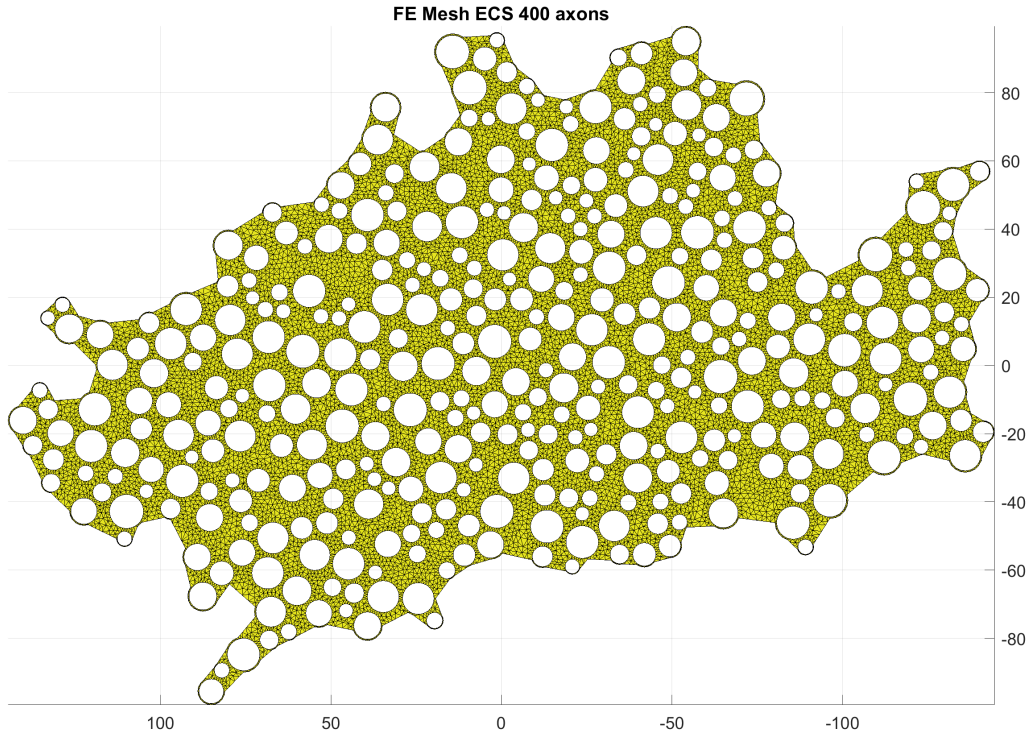

Figure 10: The geometry is *ECS400axons*. This finite elements mesh size is ($n_{nodes} = 53280, n_{elem} = 125798$).

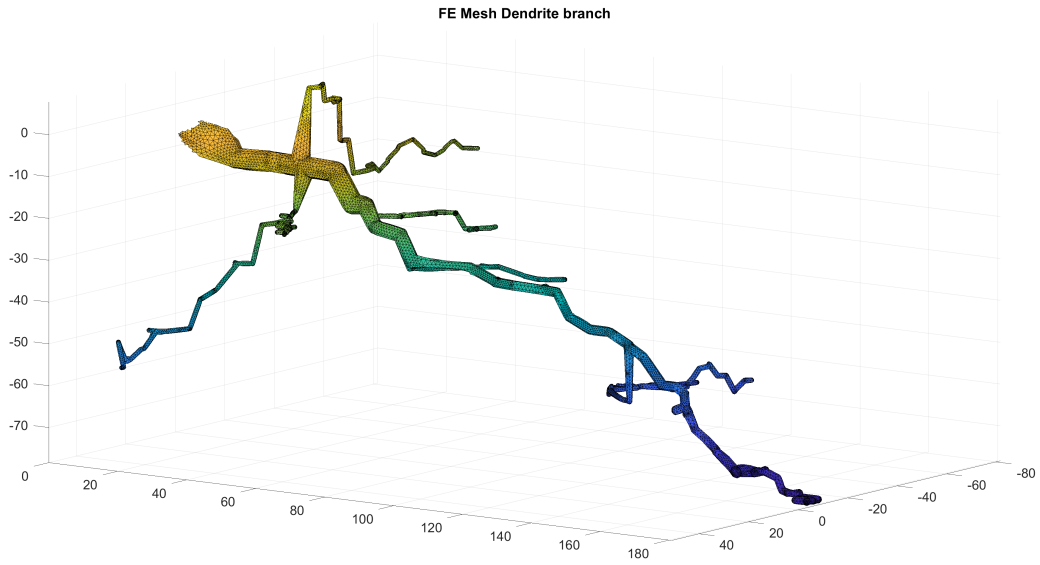

Figure 11: The geometry is *DendriteBranch*. This finite elements mesh size is ($n_{nodes} = 24651, n_{elem} = 91689$)

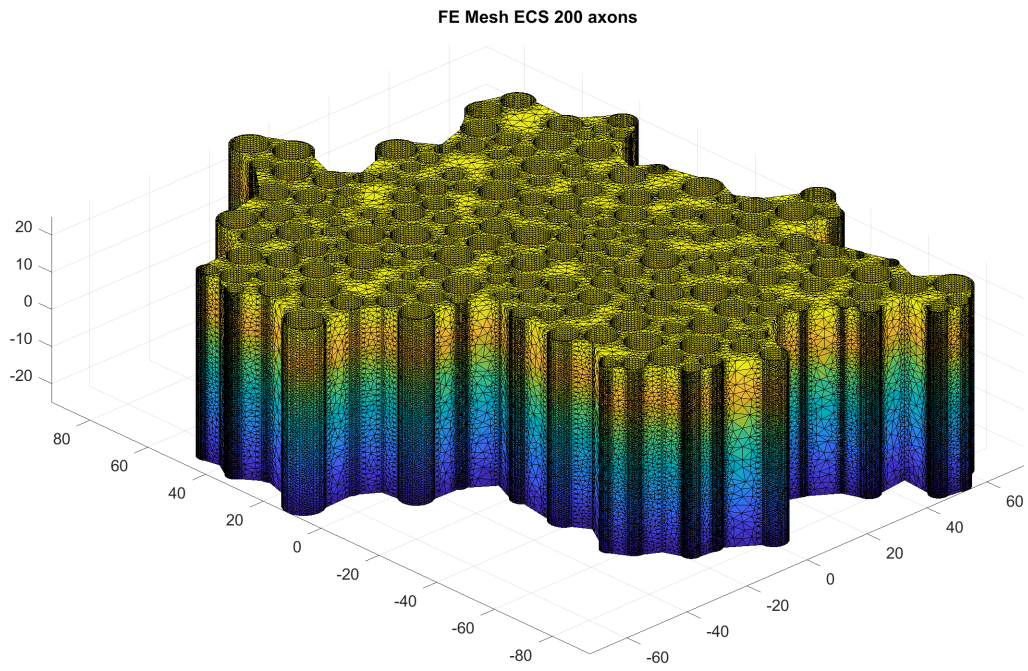

Figure 12: The geometry is *ECC200axons*. This finite elements mesh size is ($n_{nodes} = 846298, n_{elem} = 2997386$)

Figure 13: The geometry is *ECS400axons*. Top: SpinD Simul 1 is the reference signal, compared to two Camino simulations. Bottom left: the signal difference between the reference simulation and two SpinDoctor simulations and two Camino simulations. Bottom right: the computational times of SpinDoctor simulations as a function of the gradient amplitude. The diffusion coefficient is $2 \times 10^{-3} \text{ mm}^2/\text{s}$; The diffusion-encoding sequence is PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$); The gradient direction is $[1, 1, 0]$. SpinD Simul 1: $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = 0.5$; SpinD Simul 2: $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = 1$; SpinD Simul 3: $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = -1$; Camino Simul 1: $N = 1000$, $T = 200$; Camino Simul 2: $N = 4000$, $T = 800$;

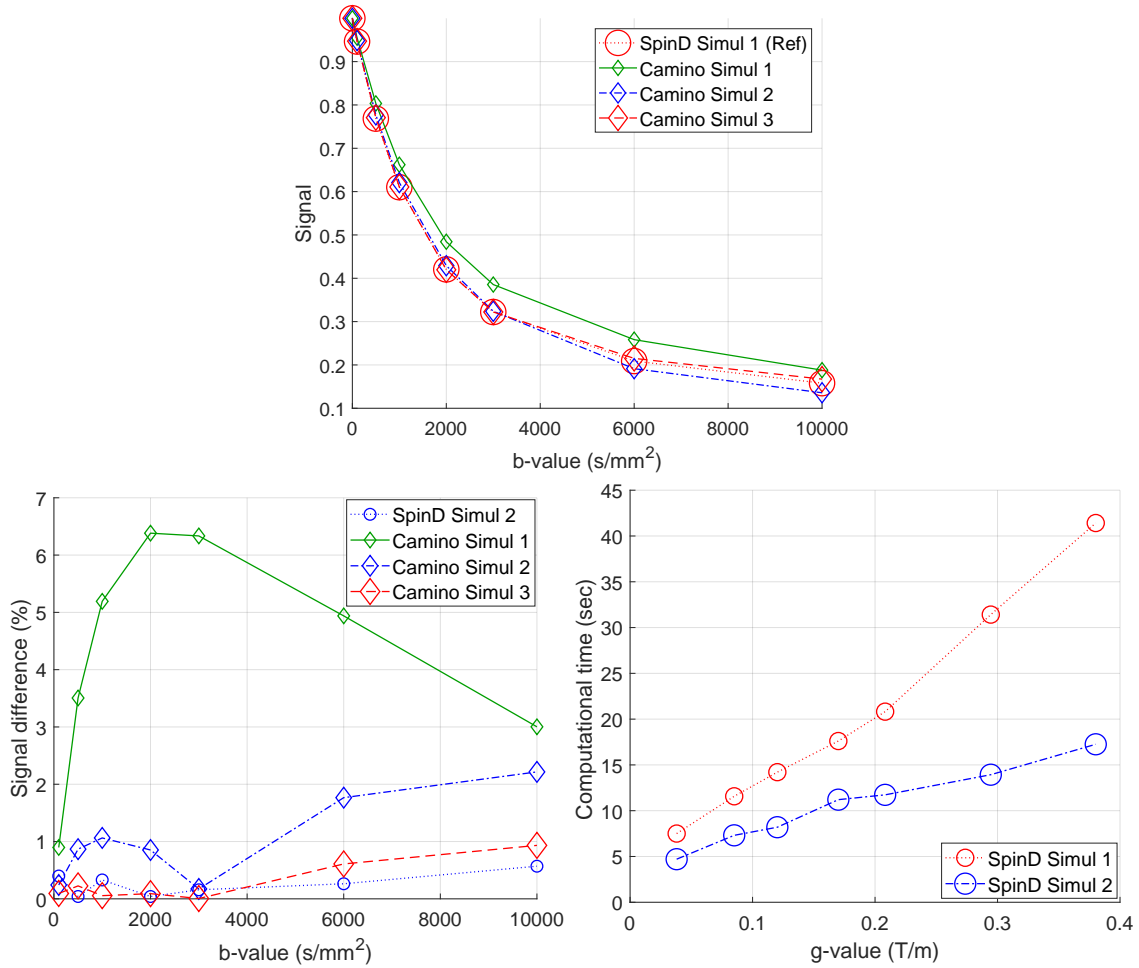

Figure 14: The geometry is *DendriteBranch*. Top: SpinD Simul 1 is the reference signal, compared to three Camino simulations. Bottom left: the signal difference between the reference simulation and a SpinDoctor simulation and three Camino simulations. Bottom right: the computational times of SpinDoctor simulations as a function of the gradient amplitudes. The diffusion coefficient is $2 \times 10^{-3} \text{ mm}^2/\text{s}$; The diffusion-encoding sequence is PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$); The gradient direction is $[1, 1, 0]$. SpinD Simul 1: $rtol = 10^{-3}$, $atol = 10^{-6}$; SpinD Simul 2: $rtol = 10^{-2}$, $atol = 10^{-4}$; Camino Simul 1: $N = 1000$, $T = 200$; Camino Simul 2: $N = 2000$, $T = 400$; Camino Simul 3: $N = 4000$, $T = 800$;

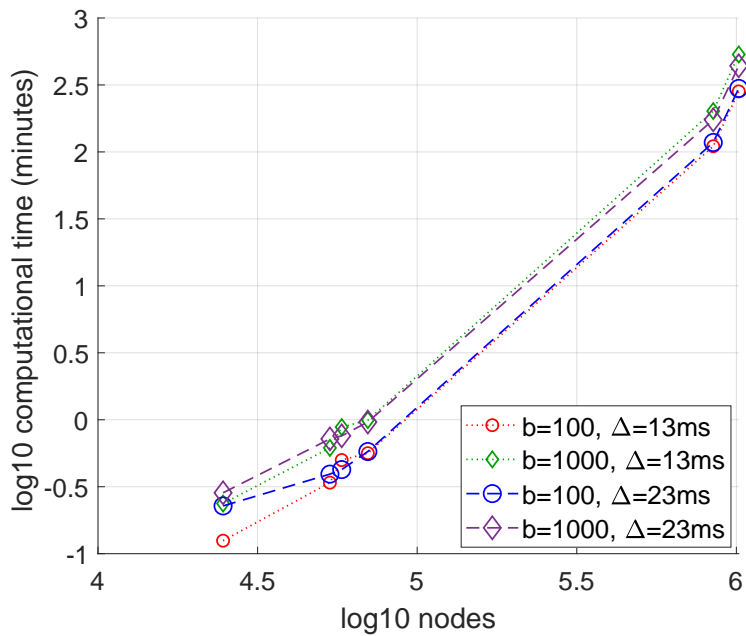

Figure 15: Computational times of SpinDoctor to simulate one b -value (either $b = 100 \text{ s/mm}^2$ or $b = 1000 \text{ s/mm}^2$). The x-axis gives log 10 of the number of finite elements nodes. The data include 3 FE meshes of *ECS400axons*, 1 FE mesh of *DendriteBranch*, and 2 FE meshes of *ECS200axons*. The y-axis gives the log 10 of the computational time in minutes. Below $y = 0$ are computational times that are less than one minute. The two sequences simulated are PGSE sequence ($\delta = 10 \text{ ms}$, $\Delta = 13 \text{ ms}$) and PGSE sequence ($\delta = 10 \text{ ms}$, $\Delta = 23 \text{ ms}$). The diffusion coefficient is $2 \times 10^{-3} \text{ mm}^2/\text{s}$; The gradient direction is $[1, 1, 0]$.

Figure 16: The *Permeable Sphere* example involves uniformly placed initial spins inside a sphere of radius $5\mu\text{m}$, subject to permeable interface condition on the surface of the sphere, with permeability coefficient $\kappa = 10^{-5}$ m/s. Left: the SpinDoctor simulation on the finest mesh as the reference signal and two Camino signals. Right: the signal difference between the reference signal and two SpinDoctor simulations and two Camino simulations. SpinD Simul 1: $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = 0.5$; SpinD Simul 2: $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = 1$; SpinD Simul 3: $rtol = 10^{-3}$, $atol = 10^{-6}$, $Htetgen = -1$; Camino Simul 1: $N = 4000$, $T = 800$; Camino Simul 2: $N = 8000$, $T = 3200$; The diffusion coefficient in all compartments is 2×10^{-3} mm²/s; The diffusion-encoding sequence is PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$); The gradient direction is $[1, 1, 0]$.

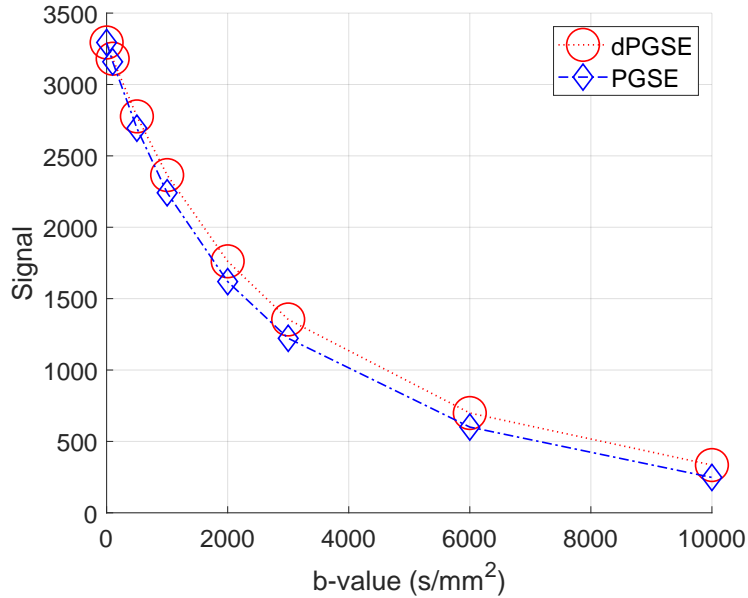

Figure 17: DMRI signals of the PGSE and the double PGSE diffusion-encoding sequences. The geometry is made of cylindrical cells, the myelin layer, and the ECS (see Figure 7). The diffusion coefficient in all compartments is 2×10^{-3} mm²/s and the compartments do not experience spin exchange, with all permeability coefficients set to zero. The diffusion-encoding sequences are PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$) and dPGSE sequences ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$, $\tau = \delta + \Delta$), the diffusion-encoding direction is $\mathbf{u}_g = [1, 1, 1]$.

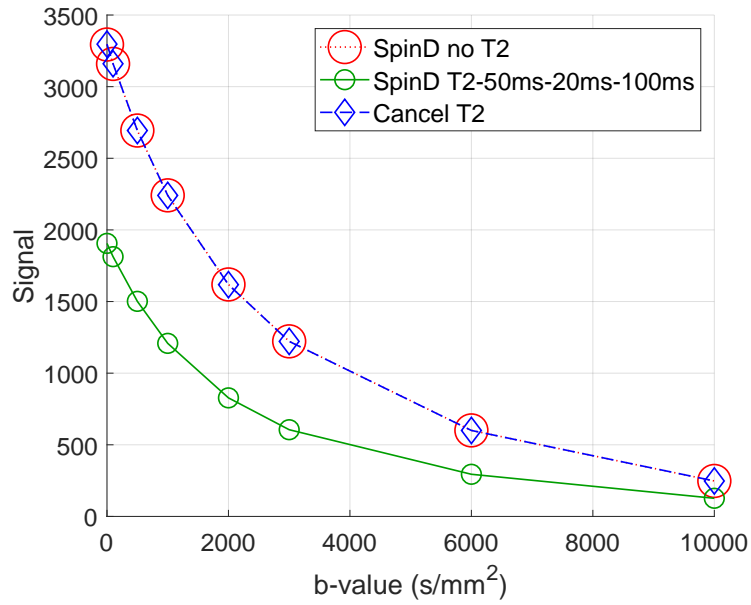

Figure 18: DMRI signal including $T_2 = [50\text{ms}, 20\text{ms}, 100\text{ms}]$ relaxation is lower than the signal without relaxation effects ("no T2"). The T_2 effects are completely canceled out using Eq. 23 so that the curve "cancel T2" coincides with the no relaxation signal. The geometry is made of cylindrical cells, the myelin layer, and the ECS (see Figure 7). The diffusion coefficient in all compartments is $2 \times 10^{-3} \text{ mm}^2/\text{s}$ and the compartments do not experience spin exchange, with all permeability coefficients set to zero. The diffusion-encoding sequence is PGSE ($\delta = 10\text{ms}$, $\Delta = 13\text{ms}$), the diffusion-encoding direction is $\mathbf{u}_g = [1, 1, 1]$.
