HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
An Investigation of Eye Movement Dysfunctions in Children with Neurofibromatosis type 1

Today’s estimates indicate that 30-60% of Neurofibromatosis type 1 (NF1) children suffer from learning disorder, including reading disabilities, secondary to language and/or visuospatial deficits (Chia et al., 2017) with a profound impact on their academic achievement (Krav et al., 2008). Some studies suggest a delay in the maturation of low-level vision processes in children with NF1 (e.g. saccadic system, Lasker et al., 2003; magnocellular processing, Ribeiro et al., 2012). The findings from typically developing readers suggest a strong relationship between reading ability and visual processing (Leibniz, et al., 2017). The main goal of this study was to investigate the occurrence of perceptual, visuo-attentional and oculomotor deficits in NF1 children and their potential to explain reading behavior and reading problems in this population.

Method

Forty-two children with NF1 (9.8 ± 1.5 years, 26 girls) and forty-two control children (TD, 10 ± 1.1 years, 20 girls) participated in the study. Parents and children gave their informed consent prior to the experiment, approved by the local ethics committee. Reading and visual processing skills were respectively evaluated with the Alouette test (Lefavrais, 2005) and the DEM test (Garzia et al., 1990). We also recorded eye movements while a subgroup of 17 NF1 children (9.8 ± 1.4 years, 10 girls) and 21 control children (9.4 ± 0.9 years, 10 girls) performed an oculomotor lateralized bisection task on words, strings of hash marks and solid lines.

Results

- Preferred Viewing Location (PVL) for TD and NF1-nonRD between the beginning and the middle of the word
- More flattened curve for NF1-nonRD -> TD children locate their 1st fixation mostly around P2 whereas the landing positions cover a more expanded zone, P2-P3 with NF1-nonRD
- No PVL for NF1-RD who were less accurate, and more variable in saccadic programming
- NF1-RD displayed poor results in visual attention and generation of saccadic processing (e.g., less accurate, more variability, no sensibility to the discreteness of the stimuli).

Conclusions

DEM test (especially the HT) can be used clinically to distinguish NF1 with RD from NF1 without RD. Analysis of eye movement patterns represents a potential way to identify differences in the cognitive mechanisms and visuo-attentional mechanisms underlying reading in NF1 children before the occurrence of school failure. Both language and visual aspects of reading should be targeted in intervention programs.

This work has benefited from support from the French Government, managed by the French National Agency for Research (ANR), under the project DYSTAC-MAP (ANR-13-APPR-0010) and from the Association Neurofibromatoses & Recklinghausen in France.
