## 1 **Summary**

2 Autophagy facilitates the adaptation to nutritional stress. Here, we show that short-term  
3 starvation of cultured cells or mice caused the autophagy-dependent cellular release of acyl-  
4 CoA-binding protein (ACBP, also known as diazepam-binding inhibitor, DBI), and consequent  
5 ACBP-mediated feedback inhibition of autophagy. Importantly, ACBP levels were elevated in  
6 obese patients and reduced in anorexia nervosa. In mice, systemic injection of ACBP protein  
7 inhibited autophagy, induced lipogenesis, reduced glycemia and stimulated appetite, as well as  
8 weight gain. We designed three approaches to neutralize ACBP, namely, inducible whole-body  
9 knockout, systemic administration of neutralizing antibodies, and induction of antiACBP  
10 autoantibodies in mice. ACBP neutralization enhanced autophagy, stimulated fatty acid  
11 oxidation, inhibited appetite, reduced gain weight in the context of a high-fat diet or leptin  
12 deficiency, and accelerated weight loss in response to dietary changes. In conclusion,  
13 neutralization of ACBP might constitute a strategy for treating obesity and its comorbidities.

14

## 1 **Introduction**

2 Macroautophagy (in short ‘autophagy’) contributes to the maintenance of cellular and  
3 organismal homeostasis by mediating the turnover of dispensable cytoplasmic structures (Levine  
4 and Kroemer, 2019). In particular, autophagy facilitates the adaptation to nutritional stress by  
5 degrading intracellular macromolecules including proteins, lipids and glycogen into small  
6 molecules that fuel energy metabolism (Galluzzi et al., 2014).

7 Derangements of autophagy – and in particular its inhibition – play a role in all major human  
8 diseases including cancer (Amaravadi et al., 2016), cardiovascular disease (Henning and  
9 Brundel, 2017), neurodegeneration (Menzies et al., 2017), as well as obesity and its co-  
10 morbidities (Lopez-Otin et al., 2016). Thus, both genetic and pharmacological inhibition of  
11 autophagy compromise weight loss induced by starvation and develop obesity and diabetes  
12 (Fernandez et al., 2017; He et al., 2013). Circumstantial evidence indicates that obesity is  
13 associated with suppressed autophagic flux (Boudoures et al., 2017; Mizunoe et al., 2017; Potes  
14 et al., 2017), in line with the fact that its metabolic correlates including hyperglycemia (Roberts  
15 et al., 2014), hyperlipidemia (Koga et al., 2010) and hyperinsulinemia (Gulati and Thomas,  
16 2007) actually inhibit autophagy. The etiological link between excessive adiposity and  
17 accelerated manifestation of age-associated diseases might involve disabled autophagy (Lopez-  
18 Otin et al., 2016).

19 Although autophagy is mostly studied as a cell-autonomous event, there is evidence that  
20 autophagy may affect the communication between cells as well. Thus, autophagy regulates the  
21 turnover of cell surface receptors, as exemplified for EGFR (Wei et al., 2013) and cannabinoid  
22 receptors (He et al., 2013). Moreover, some factors are released from cells in an autophagy-

1 dependent fashion. This applies to adenosine triphosphate (ATP), the apoptosis-associated  
2 release of which depends on the induction of premortem autophagy, with vast consequences for  
3 the attraction of myeloid cells into the vicinity of dying cells (Qu et al., 2007; Vacchelli et al.,  
4 2015). Moreover, the cellular secretion of several leaderless proteins (which, by definition, can  
5 only be released through an unconventional pathway bypassing Golgi) is strongly associated  
6 with, and probably depends on, autophagy (Dupont et al., 2011; Ponpuak et al., 2015; Zhang and  
7 Schekman, 2013). One such leaderless protein is the phylogenetically ancient factor acyl-CoA-  
8 binding protein (ACBP), also known as diazepam binding protein (DBI) (Duran et al., 2010;  
9 Manjithaya et al., 2010). ACBP from human or mouse origin is a small protein of 87 amino acids  
10 that has two distinct functions, namely, as ACBP within cells - where it binds to long-chain acyl-  
11 CoA molecules, regulating lipid metabolism (Nees et al., 2015) - and as DBI outside cells -  
12 where the protein can interact with the benzodiazepine-binding site of the gamma-aminobutyric  
13 acid (GABA) type A receptor,  $GABA_A R$ , and modulate its activity (Bormann, 1991; Christian et  
14 al., 2013).

15 Here, we addressed the question as to whether autophagy-dependent ACBP secretion occurs in  
16 mammals and whether ACBP might participate in autophagy regulation and lipid metabolism.  
17 We show that ACBP is not only involved in the control of autophagy but that it also affects  
18 general lipid metabolism. This notion is based on the observations that ACBP levels correlate  
19 with human body mass index, that increasing ACBP levels in mice triggers lipogenesis, food  
20 intake and weight gain, and that its neutralization increases lipolysis, reduces food intake post-  
21 starvation and causes weight loss in mice.

22

## 1 **Results**

### 2 **Autophagy-dependent release of ACBP from human cells and mouse organs.**

3 We investigated whether mammalian cells would release ACBP through a similar pathway as  
4 yeast (Kinseth et al., 2007). Cells maintained in nutrient-free (NF) condition or treated with  
5 rapamycin, two potent stimulators of autophagy, underwent a *bona fide* autophagic response – as  
6 indicated by the lipidation of microtubule associated protein 1 light chain 3 beta (MAP1LC3B;  
7 best known as LC3), the redistribution of a GFP-LC3 fusion protein towards autophagosomes,  
8 and the degradation of the autophagy substrate sequestosome 1 (SQSTM1/p62) (Klionsky et al.,  
9 2016). This response was accompanied by the depletion of intracellular ACBP detectable by  
10 immunoblot analyses of cellular extracts (**Figures 1A-B** and **S1A-C**), immunofluorescence  
11 staining (**Figure S1D-G**), image cytometry (**Figure S1H-I**) or cytofluorimetric analysis (**Figure**  
12 **S1J-M**). The decrease of ACBP protein induced by short-term (4 h) starvation was not  
13 accompanied by an equivalent decrease of *ACBP* mRNA (**Figure 1C**). ACBP decrease was  
14 suppressed by the knock-down of the essential autophagy proteins ATG5, ATG7, ATG10 or  
15 Beclin 1 (BECN1), by the addition of lysosomal inhibitors like bafilomycin A1 and chloroquine,  
16 or by inhibiting phosphatidylinositol 3-kinase catalytic subunit type 3 with wortmannin (**Figures**  
17 **1A-B** and **S1A-I**). In contrast, ACBP depletion from cells was not inhibited by brefeldin A, an  
18 inhibitor of conventional protein secretion, nor by the silencing of several genes (STX3, STX4,  
19 TRIM10, SNAP29, SNAP23, TRIM16 or SECC2B) involved in the unconventional secretion of  
20 interleukin-1 $\beta$  (Kimura et al., 2017) (**Figure S1J-M**). The NF-induced, BafA1-inhibitable  
21 release of soluble ACBP into the supernatant could be detected by means of an enzyme-linked  
22 immunosorbent assay (**Figure 1D-E**) or immunoblot (**Figure S1C**) and did not require de novo  
23 protein synthesis (**Figure S1N**). This BafA1-inhibitable ACBP release was observed in primary

1 hepatocytes, peripheral blood mononuclear cells and multiple human cell lines cultured in  
2 nutrient-free media (**Figures 1D-E** and **S1H-I**).

3 The intracellular levels of ACBP decreased in several organs from autophagy-competent wild-  
4 type (WT) mice, but not in the *Atg4b*<sup>-/-</sup> mice (a well-established model of autophagy-deficiency)  
5 (Marino et al., 2010), subjected to 24 h of starvation (**Figures 1F-I** and **S2A-B**), a condition that  
6 induces autophagy in most tissues from WT mice (Mizushima et al., 2004). In parallel, starvation  
7 led to an increase in plasma ACBP levels in WT mice, but not in autophagy-deficient *Atg4b*<sup>-/-</sup>  
8 mice (**Figure 1J**). Moreover, the starvation-induced surge in plasma ACBP was inhibited by  
9 injection of dimethyl  $\alpha$ -ketoglutarate and leupeptin (**Figure S2C**), which suppress the initiation  
10 (Marino et al., 2014) and termination (Esteban-Martinez and Boya, 2015) of autophagy,  
11 respectively.

12

### 13 **Autophagy-regulatory effects of intracellular and extracellular ACBP pools.**

14 Intraperitoneal (*i.p.*) injection of an antibody that neutralizes extracellular ACBP (antiACBP)  
15 induced autophagy in the liver (**Figure 1K-L**), while the systemic intravenous (*i.v.*)  
16 administration of recombinant ACBP (recACBP) inhibited autophagy (**Figure 1M-N**). Notably,  
17 recACBP enhanced the accumulation of SQSTM1, the phosphorylation of protein kinase B (best  
18 known as AKT1) and that of the mechanistic target of rapamycin complex-I (MTORC1)  
19 substrate p70<sup>S6K</sup> in the mouse liver *in vivo* (**Figure S2D**) and in primary human hepatocytes *in*  
20 *vitro*, together with the phosphorylation of EIF4BP1, another target of MTOR (**Figure S2E-F**).  
21 AKT inhibition overcame MTORC1 activation and autophagy inhibition by recACBP (**Figure**  
22 **S2F**).

1 Depletion of ACBP by specific small-interfering RNAs inhibited NF-driven autophagy and  
2 stimulated autophagy-inhibitory MTORC1 activity in human cancer cells *in vitro* (**Figure**  
3 **S3A,C**), while transfection-enforced ACBP overexpression stimulated autophagic flux, as  
4 indicated by the redistribution of GFP-LC3 to cytoplasmic puncta and the lipidation of LC3  
5 (LC3-II) (**Figure S3B,D**). However, when ACBP was depleted (thus autophagy was inhibited)  
6 from a majority of human H4 cells that were co-cultured with a minority of ACBP-expressing  
7 cells (which are still autophagy-competent), the latter exhibited increased autophagic flux as  
8 assessed by measuring GFP-LC3 punctae in the absence or presence of BafA1 (**Figure S3E-F**),  
9 confirming the previous *in vivo* results in which we observed that extracellular ACBP inhibits  
10 autophagy. Indeed, addition of antiACBP to cultured human cells stimulated autophagy (**Figure**  
11 **S3G-H**), while addition of recACBP robustly inhibited NF-driven autophagy (**Figure S3I-J**).

12

### 13 **Metabolic impact of increasing ACBP levels.**

14 Since extracellular ACBP suppresses autophagy, we investigated whether extracellular ACBP  
15 might also affect general metabolism. To this aim, recACBP protein and an antiACBP antibody  
16 were injected into fed and starved mice, respectively, and plasma metabolomics were profiled 2  
17 h later. While recACBP reduced glycemia, ACBP neutralization reversed the starvation-induced  
18 reduction in blood glucose levels and exacerbated the increase in circulating 2-hydroxybutyric  
19 acid (**Figure 2A** and **Table S1**). We therefore decided to investigate the effects of ACBP on  
20 whole-body metabolism while focusing on energy metabolism.

21 Increasing ACBP levels, by systemic *i.v.* injection of recACBP or hydrodynamic injection of  
22 plasmids containing a cDNA-ACBP into mice, which caused hepatocytes overexpression of  
23 ACBP and increased plasma ACBP levels, stimulated food intake without affecting insulin levels

1 (**Figures 2B** and **S4A-D**). Accordingly, *i.v.* injected recACBP rapidly activated orexigenic lateral  
2 hypothalamus neurons, as indicated by the nuclear localization of the transcription factor FOS  
3 detected by immunohistochemistry (**Figures 2C** and **S4E**). Leptin and ghrelin are important  
4 endocrine regulators of energy balance and food intake (Farooqi et al., 2001; Inui, 2001).  
5 RecACBP injection reduced circulating leptin (**Figure S4F**), but did not affect ghrelin levels  
6 (**Figure S4G**). Of note, *ob/ob* mice (lacking leptin) showed an increase in circulating ACBP  
7 levels in response to starvation (**Figure S4H**). Moreover, recACBP reduced glucose levels in  
8 *ob/ob* mice (**Figure S4I**), yet failed to further enhance the constitutive hyperphagy of *ob/ob*  
9 mice, which was reduced upon leptin injection (**Figure S4J**). However, injection of a high dose  
10 of recombinant leptin (**Figure S4K**) failed to reverse the drop in glycemia (**Figure S4L**) and the  
11 hyperphagy induced by recACBP injection (**Figure S4M**), suggesting that ACBP can operate  
12 independently from the leptin system. Of note, recACBP injection caused the rapid (within 30  
13 min) increase of liver ACBP levels and glucose transporter solute carrier family 2 member 1  
14 (SLC2A1; best known as GLUT1) and also induced hepatic expression of peroxisome  
15 proliferator-activated receptor gamma (PPARG), which stimulates lipogenesis via fatty acid  
16 synthase (FASN) transactivation (**Figures 2D** and **S4N**). The upregulation of FASN and PPARG  
17 in the liver or white adipose tissue (WAT) was observed in starved mice, meaning that it is not  
18 secondary to an increased food intake (**Figure S4O-P**). In mice with ad libitum access to food,  
19 recACBP reduced fatty acid oxidation, as determined by whole-body respirometry (**Figure 2E**).  
20 Systemic injection of recACBP or transgenic expression of *Acbp*, reduced blood glucose levels  
21 (**Figures 2F** and **S4Q**) and exacerbated the ability of insulin to reduce glycemia in fed mice  
22 (**Figure S4R**), as it enhanced the incorporation of <sup>14</sup>C atoms from 2-deoxyglucose into visceral  
23 fat (**Figure S4S**). Mass spectrometric fluxomics with <sup>13</sup>C glucose confirmed the increased

1 glucose uptake into adipose tissue upon recACBP injection even in the absence of insulin  
2 injection (**Figure S4T**). The transient drop in blood glucose induced by recACBP injection was  
3 abolished by a pharmacological GLUT1 inhibitor (**Figure S4U**). Importantly, reversal of the  
4 ACBP-induced reduction in glycemia by *i.p.* injection of glucose (**Figure 2G**) prevented the  
5 increase of food intake (**Figure 2H**). Thus, ACBP stimulates glucose uptake, which may account  
6 for the blood glucose reduction that ultimately drives feeding behavior in mice and reduced the  
7 ACBP-mediated activation of orexigenic neurons (**Figure S4V**).

8

#### 9 **Effects of ACBP depletion or neutralization.**

10 To neutralize the extracellular pool of ACBP, we injected mice with suitable monoclonal or  
11 polyclonal antiACBP antibodies into the peritoneal cavity. This maneuver reduced food intake  
12 post-starvation (**Figures 3A** and **S5A**) and increased plasma glucose in fed as well as in starved  
13 mice (**Figures 3B** and **S5B**). ACBP blockade by *i.p.* injected antibodies rapidly activated  
14 neurons in the anorexigenic ventromedial nucleus, and lack of FOS expression was observed in  
15 neurons of the orexigenic lateral hypothalamic area (**Figure S5C-E**). ACBP neutralization  
16 caused reduction of the hepatic protein levels of ACBP, PPARG, FASN and the inhibitory  
17 phosphorylation of sterol regulatory element-binding transcription factor 1 (SREBF1) (**Figures**  
18 **3C** and **S5F**), and increased plasma adiponectin levels (**Figure S5G**), suggesting a global  
19 activation of lipolysis. Indeed, WAT from antiACBP antibody-injected mice generated more  
20 glycerol than WAT from isotype-injected control mice (**Figure 3D**). AntiACBP injection caused  
21 a marked raise in blood glucose levels after glycerol injection (**Figure 3E**) and a more  
22 pronounced conversion of <sup>13</sup>C-labelled glycerol into hepatic glycerol-3-phosphate, as well as into  
23 glucose in the liver and in the plasma (**Figure 3F**). ACBP neutralization enhanced whole-body

1 fatty acid oxidation in baseline (**Figure 3G**) and starved conditions (**Figure 3H**). Accordingly,  
2 ACBP neutralization also augmented the starvation-associated hepatic mobilization of lipids  
3 from adipose tissue (**Figure 3I-J**), yet did not prevent hepatic glycogen depletion (**Figure S5H-**  
4 **I**). In spite of the increase in blood glucose induced by ACBP neutralization, starved mice  
5 injected with antiACBP exhibited a decrease in plasma insulin, C-peptide and gastric inhibitory  
6 peptide (GIP) levels (**Figure S5J-L**).

7 Constitutive knockout of *Acbp* in mice results in embryonic death (Landrock et al., 2010) or  
8 multiple defects including epidermal barrier dysfunction (Bek et al., 2015), depending on the  
9 genetic background. We generated mice in which *Acbp* can be conditionally knocked-out by  
10 tamoxifen injection (based on the Tam-inducible, Cre recombinase-mediated excision of floxed  
11 *Acbp*) (**Figure S5M-N**). In contrast to starved ACBP-expressing controls, ACBP-depleted mice  
12 were able to maintain glucose levels in the normoglycemic range (**Figure 3K**) and circulating  
13 ketone bodies were increased after 24 h of starvation (**Figure S5O**). The metabolomic changes  
14 induced by the *Acbp* knockout were very similar to those induced by starvation in normal mice,  
15 both in plasma (**Figure 3L**) and in brown adipose tissue (**Figure 3M**).

16 Altogether, these results confirm that ACBP plays a critical role in regulating glucose and lipid  
17 metabolism in addition to modulating feeding behavior.

18

### 19 **ACBP levels in human and mouse obesity.**

20 In a cohort of 52 patients with anorexia nervosa, plasma ACBP concentrations were lower than  
21 in 14 age- and sex-matched controls with a normal body mass index (BMI) (**Figure 4A**),  
22 confirming a prior report on a group of 24 anorexic patients (Conti et al., 2013). More

1 importantly, ACBP concentrations were significantly elevated in obese individuals (**Figure 4B**),  
2 and ACBP levels were reduced along with weight loss 12 months after bariatric-surgery in  
3 another group of patients (**Figure 4C**). Thus, circulating ACBP levels correlated with BMI  
4 across several patient subsets (**Figure 4D**). Elevated ACBP levels in obese individuals correlated  
5 with augmented serum insulin (**Figure 4E**) and aspartate transaminase levels (**Figure 4F**), which  
6 are indicative of (pre-)diabetes and liver dysfunction, respectively. Weight loss upon 6 weeks of  
7 hypocaloric regimen (Cotillard et al., 2013) or bariatric intervention led to a temporary reduction  
8 of *ACBP* mRNA levels in the periumbilical adipose tissue from overweight/obese individuals  
9 (**Figure 4G-H**).

10 Leptin-deficient *ob/ob* mice (which are hyperphagic and become obese even on a normal diet)  
11 manifested an increase in *Acbp* mRNA expression and protein levels in liver and adipose tissue  
12 (**Figure 5A-D**), as well as an increase in circulating ACBP concentrations as compared to their  
13 lean controls (**Figure 5E**). Normal mice rendered obese by a high-fat diet (HFD) also manifested  
14 an increase in ACBP protein levels in plasma (**Figure 5F**), liver and adipose tissue (**Figure 5G-**  
15 **H**). Conversely, starvation caused a decrease in *Acbp* mRNA (**Figure 5I-J**) and ACBP protein in  
16 liver and fat (**Figure 1F-I**).

17 Altogether it appears that a long-term increase in caloric uptake and adiposity, as observed in  
18 human obesity, HFD-fed mice or *ob/ob* mice, is coupled to the transcriptional upregulation of  
19 *ACBP* gene expression and a rise in both intracellular and extracellular ACBP protein.

20

21 **Metabolic impact of modifications of ACBP levels.**

1 In the next step, we determined whether manipulation of ACBP would be sufficient to affect  
2 body mass. Hydrodynamic injection of plasmids containing a cDNA coding for ACBP into mice,  
3 caused significant weight gain. This effect was seen with an *Acbp* encoding strong short-time  
4 expression vector, pCMV6, for several days (**Figure 5K**), as well as with a weaker long-term  
5 expression vector, pLIVE, that elevates ACBP levels for several months (**Figure 5L**). Thus,  
6 experimental augmentation of ACBP triggers weight gain. Importantly, the *Acbp* knockout  
7 reduced body mass in several conditions. *Acbp* knockout increased weight loss upon starvation  
8 (**Figure 5M**) and attenuated the HFD-induced weight gain (**Figure 5N**). Moreover, mice that  
9 had been rendered obese on a HFD, lost more weight when switching to a normal diet was  
10 accompanied by *Acbp* knockout (**Figure 5O**).

11 Next, we induced the production of ACBP-neutralizing autoantibodies by repeatedly immunizing  
12 mice with ACBP coupled to keyhole limpet hemocyanine (KLH) together with a potent adjuvant  
13 (Semerano et al., 2016) (**Figure S6A-B**). Autoimmunization against ACBP lead to enhanced  
14 weight loss during starvation (**Figure 6A**). The weight gain that generally characterizes *ob/ob*  
15 mice or WT mice receiving a standard chow or HFD, respectively, was reduced upon  
16 autoimmunization against ACBP (**Figure 6B-E**). Coherently, in *ob/ob* mice treated with KLH-  
17 ACBP, we observed an increase in carnitine fatty acid esters (and a decrease of  
18 phosphatidylcholine) and free fatty acids in plasma (**Figures 6F, S6C and Table S2**). Moreover,  
19 the surge of antiACBP autoantibodies in HFD mice was accompanied by a reduction of absolute  
20 fat mass (**Figure 6G**) and the endogenous mRNA levels of *Acbp* and the lipogenic gene *Pparg* in  
21 the liver (**Figure 6H**). Additionally, HFD-fed mice subjected to ACBP-targeted  
22 autoimmunization exhibited less hepatosteatosis (**Figure 6I-J**) and reduced hepatic levels of  
23 FASN (**Figure S6D,F**). In the brown adipose tissue (BAT) of HFD-fed mice, the induction of

1 autoantibodies against ACBP was associated with increased uncoupling protein 1 (UCP1) levels,  
2 carnitine palmitoyltransferase 1A (CPT-1A, which is required for fatty acids uptake by  
3 mitochondria) (Figures S6E,G) and total protein content (Figure S6H). Of note, ACBP  
4 neutralization also reduced the median size of WAT adipocytes (Figure 6K-L), as it normalized  
5 the glucose tolerance test in HFD-fed mice (Figure 6M).

6

## 7 **Discussion**

8 The unconventional secretion of ACBP has been previously described in yeast (Kinseth et al.,  
9 2007) and mammals, more specifically in rabbit glial cells (Qian et al., 2008). However, the  
10 underlying mechanisms have remained enigmatic. Here, we provide evidence that autophagy is  
11 coupled to the release of intracellular ACBP into the extracellular space in different (non-glial)  
12 human cell lines and human peripheral blood mononuclear cells, as well as in several mouse  
13 organs. Moreover, we propose a physiological explanation to the link between autophagy  
14 induction and the release of ACBP from the intracellular compartment when energetic deficiency  
15 occurs.

16 Of note, we observed a remarkable correlation between ACBP (both intracellular and  
17 extracellular levels) and body mass in humans and mice. Thus, in adolescents with anorexia  
18 nervosa, the circulating ACBP levels are low, while restrictive dietary interventions in mice  
19 decrease intracellular *Acbp* mRNA and ACBP protein levels in fat and liver tissues. Intriguingly,  
20 deletion of *Acbp* or ACBP protein neutralization with endogenous or exogenous antibodies  
21 increased autophagy, leading to a parallel dropping of ACBP in the intracellular space and a  
22 lipolytic response in mice, enhanced fatty acid oxidation, and stimulated browning of adipose

1 tissue. In turn, these changes generated a temporary hyperglycemia, likewise due to enhanced  
2 conversion of glycerol into glucose, and a consequent anorexic response, which finally limited  
3 the weight gain, lipogenesis, adiposity and hepatosteatosis induced by HFD. Thus, antibody  
4 mediated neutralization of ACBP induced a metabolic response that mimicked that found in  
5 conditions of caloric restriction.

6 Obese patients exhibited elevated plasma levels of ACBP, while a reduction in the *ACBP* mRNA  
7 and ACBP plasma protein levels is observed in these patients after an important weight loss.  
8 Likewise, obese mice showed an increase in the expression of *Acbp* mRNA and ACBP protein  
9 levels in white adipose tissue, liver and plasma. These results agree with previous findings  
10 describing a decrease of ACBP levels in rat liver after 24 h fasting, and augmentations of hepatic  
11 ACBP after a 48 h HFD (Bhuiyan et al., 1995). Moreover, ACBP has been reported to favor the  
12 differentiation of preadipocytes into adipocytes (Hansen et al., 1991). Obesity is associated with  
13 the activation of PPAR $\gamma$  (Stienstra et al., 2007), which potently induce lipogenesis and  
14 transactivates *ACBP* (Nees et al., 2006). Thus, a long-term increase in body mass may induce an  
15 elevation in ACBP by transcriptional upregulation. Of note, in mice obesity both induced by diet  
16 (HFD) or by overeating a normal diet due to leptin-deficiency (*ob/ob*) led to similar elevations in  
17 *Acbp* mRNA and protein expression. Accordingly, the rise of ACBP levels in mice (resulting  
18 from the expression of ACBP-encoding transgenes in hepatocytes or from the injection of  
19 recACBP) stimulated a lipogenic response, an increase of glucose uptake into adipose tissue, an  
20 increase in food intake and weight gain. The regulation of food intake and energy metabolism  
21 were not depending on leptin, and the orexigenic effect of ACBP seemed to be associated with a  
22 temporary reduction in circulating blood glucose levels, as indicated by the fact that glucose  
23 injection blunted the ACBP-induced food intake.

1 Obesity is linked to autophagy inhibition (Boudoures et al., 2017; Mizunoe et al., 2017; Potes et  
2 al., 2017), meaning that altered autophagic flux may not explain the augmentation in circulating  
3 ACBP but may contribute to the increment of the intracellular ACBP levels. In addition,  
4 although we do not know the in-depth role of the extracellular protein, the experiments  
5 performed in mice suggest that the obesity-associated rise in plasma ACBP may contribute to  
6 autophagy inhibition, which in turn could counteract weight loss and promote weight gain  
7 (Fernandez et al., 2017; Marino et al., 2014). Thus, it is possible that extracellular ACBP is part  
8 of a feedback regulatory system that self-limits autophagy (Simon et al., 2017).

9 Our observation that systemic administration of recACBP has orexigenic effects contrasts with  
10 prior reports showing that stereotactic or intrathecal administration of proteolytic ACBP  
11 fragments into the brain is anxiogenic and anorexigenic (Guillebaud et al., 2017; Lanfray et al.,  
12 2013). We believe that several reasons plead in favor of a role for ACBP as a peripheral (rather  
13 than central nervous) stimulator of lipo-anabolism and that the modulation of appetite and  
14 obesity observed in this work occurs as consequence of ACBP effects on systemic metabolism.  
15 First, hepatic expression of transgenic *ACBP* reduced glucose levels and enhanced food intake.  
16 Second, peripherally (*i.v.*) administered recACBP, which does not cross the blood-brain barrier  
17 (Barmack et al., 2004), provoked rapid (within 30 min) metabolic effects leading to enhanced  
18 glucose uptake into peripheral tissues, reduced glycemia and enhanced food intake. Third, the  
19 ACBP-induced activation of orexigenic neurons and enhanced feeding was inhibited in  
20 conditions of glucose clamp, as a result of the *i.p.* injection of glucose. Fourth, neutralization of  
21 extracellular ACBP by antibodies (which cannot cross the blood-brain barrier) was able to  
22 rapidly reduce the activity of orexigenic neurons and activate anorexigenic neurons, again  
23 pleading in favor of a peripheral role for ACBP in metabolism and appetite control. Altogether, it

1 appears that ACBP may influence metabolism through systemic effects, independently from its  
2 central-nervous impact.

3 Based on these findings obtained in human and mice, we speculate that, if the long-term  
4 blockade of ACBP was exempt of detrimental side effects and constituted a desirable therapeutic  
5 goal, autoimmunization against ACBP might be useful for the prevention or treatment of obesity  
6 with its comorbidities.

7

8 **Limitations of Study:** Although the results obtained in mice clearly plead in favor of a role for  
9 ACBP in stimulating appetite and obesity, the role of ACBP in human pathophysiology remains  
10 to be corroborated by clinical trials. So far, the human data are merely correlative, indicating that  
11 ACBP plasma levels are abnormally low in anorexia nervosa and excessively high in obese  
12 patients. However, it has to be determined whether external supply of ACBP may stimulate  
13 appetite in anorexic patients. Similarly, the possibility to inhibit ACBP (or its receptor) for  
14 controlling excessive appetite and weight gain in obese patients requires further in-depth  
15 investigation.

1 **Author contributions:** GK and JMB-SP designed the study and wrote the paper with the  
2 help of CLO. JMB-SP, VS, IM, JP, FL, GA, MCM, MN-S, FA, IRP, PB, EB, RGD, JL, JD,  
3 SML and CC-G performed mammalian cell biology and mouse studies. SD, NB and FA  
4 performed metabolomics analyses. FM and NT provided phylogenetic insights. PG, NR, KC,  
5 AR, VP, FP, RC and VR provided patient samples and information on the cohorts. KC, AR, VP  
6 provided the analysis of transient reduction in *ACBP* mRNA levels in adipose tissue from obese  
7 patients. CLO, LG and MCM provided intellectual input and edited the paper. All authors  
8 reviewed the results, edited and approved the final version of the manuscript.

9

10 **Declaration of Interests:** JMBSP and GK filed a patent application dealing with targeting  
11 the *ACBP/DBI* system in anorexia, obesity and co-morbidities. GK filed additional patent  
12 applications dealing with caloric restriction mimetics (autophagy inducers) for the treatment of  
13 aging, age-related diseases, cancer, obesity and co-morbidities. GK is a scientific co-founder  
14 of Samsara Therapeutics and Therafast Bio.

## Main figures legends

### Figure 1. Autophagy-dependent release of ACBP.

(A-B) Primary mouse hepatocytes were cultured for 4 h in nutrient free (NF) condition, with or without bafilomycin A1 (BafA1). Representative immunoblots of ACBP, LC3II/I, SQSTM1 and  $\beta$ -actin (A) and densitometric quantification of 3 different experiments (B), upon normalization to the ACBP/ $\beta$ -actin ratio of untreated (Unt) condition.

(C) *Acbp* mRNA expression in primary mouse hepatocytes after 4 h in NF condition ( $n=4$  mice).

(D-E) ELISA-detectable ACBP in culture media of primary mouse hepatocytes ( $n=4$  mice per group). (D), human cancer cell lines ( $n=4$  replicates). and human peripheral blood mononuclear cells (PBMCs) ( $n=3$  individuals) (E) after the indicated treatments.

(F-J) Autophagy-dependent release of ACBP from mouse organs into the plasma. Representative pictures (F) and quantification (G) of immunofluorescence of ACBP in livers of WT or *Atg4b*<sup>-/-</sup> mice after 24 h of starvation (unfed). Representative immunoblot (3 representative lanes) (H) and quantification ( $n=3$  to 5 mice per group) (I) of ACBP levels determined in visceral fat ( $n=3$  to 5 mice per group). ELISA-detectable ACBP levels in plasma ( $n=8$  mice per group) (J).

(K-N) Effects of extracellular ACBP on autophagy *in vivo*. Immunoblots (K) and densitometric quantification (L) of LC3 lipidation in liver tissues from mice treated with an ACBP-neutralizing antibody (AntiACBP) or recombinant ACBP (RecACBP) (M-N) respectively, with or without the autophagy flux inhibitor leupeptin (leu) ( $n=3$  mice per group).

Experiments in this figure were performed three times. Results are displayed as Box and whisker plots show mean, first and third quartiles, and maximum and minimum values (C-E, J) or mean  $\pm$  SEM (B, G, I, L, N). For statistical analyses, *p* values were calculated by two-way ANOVA with Sidak (B, D, G, I-J) or two-tailed unpaired Student's *t*-test (C, E, L, N). Symbols indicate

statistical comparisons with the control condition (\* $p$ <0.05, \*\* $p$ <0.01, \*\*\* $p$ <0.001). Open circles (○) indicate values for each mouse and closed circles (●) indicate replicates from *in vitro* experiments.

See also Figures S1-S3.

**Abbreviations:** Kilodaltons (kDa); Relative units (r.u.); Sequestosome (SQSTM1).

### **Figure 2. Metabolic effects of ACBP increase in mice.**

(A) Heatmap clustered by Euclidean distance of changes in liver metabolite concentrations depicted as Log<sub>2</sub>-fold change (FC) after *i.v.* recombinant ACBP injection (RecACBP), starvation for 24 h (NF) or NF plus ACBP-neutralizing antibody (antiACBP) in relation to untreated (Unt) mice ( $n$ =3-5 mice per group). The full dataset is reported in **Table S1**.

(B-H) Metabolic effect of increasing ACBP *in vivo*. Cumulative (cum.) food intake was monitored after recACBP injection ( $n$ =10-13 mice per group) (B). Representative picture of nuclear FOS expression in neurons from lateral hypothalamus (LH) ( $n$ =3 mice per group) (C). Representative immunoblots of ACBP, peroxisome proliferator-activated receptor gamma (PPARG), fatty acid synthase (FASN), glucose transporter solute carrier family 2 member 1 (SLC2A1; best known as GLUT1), and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) in liver tissue ( $n$ =5 mice per group) (D). Fatty acid (FA) oxidation measured by respirometry over 24 h. Area under the curve (AUC) for statistical comparison ( $n$ =3 mice per group) (E). Glycemia after recACBP injection ( $n$ =5-8 mice per group) (F). Mice were injected *i.v.* with vehicle only, recACBP and/or glucose (Glu) and glycemia were measured during 2 h of treatment ( $n$ =5 mice per group) (G). Cumulative food intake monitored after 2 h of recACBP injection with or without glucose co-treatment ( $n$ =5 mice per group) (H).

Experiments in this figure were performed three times. Results are displayed as Heatmap (A) or Box and whisker plots show mean, first and third quartiles, and maximum and minimum values (B-H). Open circles (○) indicate each mouse used in each experiment. For statistical analysis, *p* values were calculated by Mann-Whitney U-test (A), two-tailed unpaired Student's *t*-test (B, E-F) or two-way ANOVA with Sidak (H). Symbols indicate statistical comparisons with controls (\**p*<0.05, \*\**p*<0.01, \*\*\**p*<0.001).

See also Figures S4 and Table S1.

**Abbreviations:** 2-hydroxybutyric acid ( $\alpha$ HB); Fornix (F); Grams (g); Kilodaltons (kDa).

### **Figure 3. Metabolic effects of ACBP neutralization in mice.**

(A-B) Cumulative food intake (A) and glycemia (B) were monitored after *i.p* antiACBP injection (*n*=5-6 mice per group).

(C) Immunoblots of ACBP, phospho-sterol regulatory element-binding transcription factor 1 (p-SREBF1), FASN, PPARG and GAPDH in the liver of mice after antiACBP injection (*n*=5 mice per group).

(D-F) Lipolysis and gluconeogenesis induced by ACBP neutralization. White adipose tissue (WAT) lipolysis activity, measured as glycerol production (*n*=5 mice per group) (D). Gluconeogenic capacity was measured by intraperitoneal glycerol tolerance tests (E) in non-fasted mice. The area under the curve (AUC) was calculated (*n*=4 mice per group without glycerol and *n*=8 to 9 mice per group with glycerol injection. Mass spectrometry analysis (F) in mice receiving <sup>13</sup>C-glycerol (gly) alone or together with antiACBP as the presence of <sup>13</sup>C-glycerol-3-P in liver and <sup>13</sup>C-glucose (glu) in liver and plasma (*n*=6 mice per group).

(G-H) Fatty acid (FA) oxidation measured by respirometry during normal feeding (G) or after 24 h of starvation (Unfed) (H); AUC for statistical comparisons ( $n=5$  to 7 mice per group).

(I-J) Representative images (I) and quantification of lipid droplet diameters (J) of Oil-red O-staining of frozen liver sections from WT mice after 24 h fasting alone or with administration of an ACBP-neutralizing antibody ( $n=3$  to 4 mice per group).

(K) Glycemia measured in WT and ACBP knockout (KO) mice after one or two days (d) of fasting (Unfed) ( $n=5$  to 6 mice per group).

(L-M) Pearson correlations in plasma (L) and brown adipose tissue (BAT) (M) between changes metabolite correlations (Log<sub>2</sub>FC) after antiACBP injection or starvation for 24 h ( $n=6$  mice per group).

Experiments in this figure were performed three times. Results are displayed as Box and whisker plots show mean, first and third quartiles, and maximum and minimum values. Open circles (○) indicate each mouse used in each experiment (A-K) or each metabolite analyzed (L-M). For statistical analysis,  $p$  values were calculated by two-tailed unpaired Student's  $t$ -test (A-H), Tukey's multiple comparisons test (J-K) and Pearson's coefficients of correlation (R) (L-M). Symbols indicate statistical comparisons with controls ( $*p<0.05$ ,  $**p<0.01$ ,  $***p<0.001$ ).

See also Figures S5.

**Abbreviations:** Fornix (F).

#### **Figure 4. ACBP levels in human anorexia and obesity.**

(A-D) Plasma ACBP concentration in individuals with normal weight ( $n=14$  (A) and 10 (B) individuals), anorexia ( $n=52$ ) or obesity ( $n=40$ ). Plasma ACBP was measured in cohorts of patients with anorexia nervosa (A), obesity (B) as compared to age- and sex-matched normal

weight controls, or in another cohort of obese patients before or one year after gastric bypass ( $n=110$ ) (C). D, Correlation between obesity, measured as body mass index (BMI) and plasma ACBP levels in humans ( $n=336$ ).

(E-F) Correlation between plasma ACBP levels and circulating insulin in fasting (E) or aspartate transaminase (AST) (F) in obese patients ( $n=40$ ).

(G-H) Transient reduction in *ACBP* mRNA levels in adipose tissue from obese patients observing a six-week-long hypocaloric diet ( $n=40$ ) (G) or after bariatric intervention ( $n=42$ ) (H). mRNA expression was measured with different oligonucleotide probes (ILMN1755926 and ILMN2305544) and values were normalized to controls.

Results are displayed as Box and whisker plots show mean, first and third quartiles, and maximum and minimum values. Circles indicate each individual used in each experiment. For statistical analysis,  $p$  values were calculated by Mann-Whitney U-test (A, B) Wilcoxon matched pairs signed rank test (C), Pearson's coefficients of correlation (R) (D-F) and false discovery rate (FDR) (G, H). Symbols indicate statistical comparisons with controls ( $*p<0.05$ ,  $**p<0.01$ ,  $***p<0.001$ ,  $****p<0.0001$ ).

**Abbreviations:** Fold change (FC).

### **Figure 5. Effect of ACBP on lipid metabolism.**

(A-B) *Acbp* mRNA expression in adipose tissue (FAT) (A) and liver (B) from lean mice (*ob/T*) and obese mice (*ob/ob*) ( $n=4$  to 8 mice per group).

(C-D) Representative immunoblot ( $n=3$  representative lanes) (C) and densitometric quantification ( $n=4$  to 5 mice per group) (D) of ACBP/ $\beta$ -actin ratio in liver and fat tissues from *ob/T* and *ob/ob* mice.

(E-F) Plasma ACBP levels from *ob/T* and *ob/ob* mice  $n=19$  (E) or WT mice feeding normal (ND) or high fat-diet (HFD) ( $n=14$  to 33 mice per group) (F).

(G-H) Representative immunoblot ( $n=3$  representative lanes) (G) and densitometric quantification ( $n=3$  to 6 mice per group) (H) of ACBP/ $\beta$ -actin ratio in liver and fat tissues from WT mice feeding ND or HFD.

(I-J) *Acbp* mRNA expression in liver ( $n=5$  mice per group) (I) and adipose tissues ( $n=4$  mice per group) (J) in mice after one or two days (d) of starvation (NF).

(K-L) Weight measurements after hydrodynamic injection of an ACBP-encoding vector pCMV6 ( $n=6$  to 8 mice per group) (K) or pLIVE ( $n=6$  mice per group) (L).

(M-O) Weight measurements of WT and ACBP knockout (KO) mice after one or two days of starvation (Unfed) (M), HFD feeding (N) and HFD plus switch to normal diet (O) ( $n=5$  to 8 mice per group).

Experiments in this figure were performed three times. Results are displayed as Box and whisker plots show mean, first and third quartiles, and maximum and minimum values.

Circles indicate each mouse used in the experiment. For statistical analyses,  $p$  values were calculated two-tailed unpaired Student's  $t$ -test (A-J) or by two-way ANOVA with Sidak (K-O).

Symbols indicate statistical comparisons with controls mice ( $*p<0.05$ ,  $**p<0.01$ ,  $***p<0.001$ ).

**Abbreviations:** Hours (h); Relative units (ru); Weeks (w).

**Figure 6. Metabolic effects of ACBP neutralization in mice undergoing KLH-based immunization.**

(A-E) Weight measurements of mice treated with keyhole limpet hemocyanin (KLH) alone or conjugated to recombinant ACBP (KLH-ACBP) after one or two days of starvation (Unfed)

(**A**), after a period of normal diet ( $n=7$  mice per group) (**B**) or in *ob/ob* mice ( $n=7$  to 9 mice per group) (**D**) or high-fat diet (HFD) (**E**). Percentage of body fat was measured in ( $n=7$  mice per group) (**C**) ( $n=9$  to 10 mice per group).

(**F**) Heatmap clustered by Euclidean distance of changes in plasma metabolite concentrations depicted as Log<sub>2</sub> fold change (FC) in obese (*ob/ob*) mice were injected with KLH alone or KLH conjugated to recombinant ACBP (KLH-ACBP) ( $n=8$  to 10 mice per group). See also Figure S6C. The full dataset is reported in Table S2.

(**G**) Representative images of the whole-body composition analysis of KLH and KLH-ACBP mice after normal diet or HFD.

(**H**) *Acbp* and *Pparg* mRNA expression in liver from mice vaccinated with KLH or KLH-ACBP and fed with HFD ( $n=5$  mice per group).

(**I-L**) Histopathological analyses of KLH or KLH-ACBP mice after a period of HFD. Pathological signs of hepatosteatosis (**I**) and their quantification (**J**). Representative images of adipocytes in KLH and KLH-ACBP treated mice (**K**) and their size distribution (**L**) ( $n=4$  to 7).

(**M**) Glucose tolerance test (GTT) of mice feeding normal diet (ND) or HFD-induced obese mice immunized with KLH alone or KLH-ACBP. Area under the curve (AUC) for statistical comparison ( $n=3$  to 9 mice per group).

Experiments in this figure were performed three times. Results are displayed as Box and whisker plots show mean, first and third quartiles, and maximum and minimum values. Circles indicate each mouse used in the experiment. For statistical analyses,  $p$  values were calculated two-tailed unpaired Student's  $t$ -test, by two-way ANOVA with Sidak (**A**, **L**) or by Mann-Whitney U-test (**F**). Symbols indicate statistical comparisons with controls KLH immunization or untreated mice (\* $p<0.05$ , \*\*  $p<0.01$ , \*\*\* $p<0.001$ ).

See also Figures S6 and Table S2.

**LEAD CONTACT AND MATERIALS AVAILABILITY**

Further information and requests for resources and reagents should be directed to and will be fulfilled by the Lead Contact, Guido Kroemer (kroemer@orange.fr).

**Materials Availability Statements:** Plasmids generated in this study will be made available upon reasonable request. These plasmids will be deposited at Addgene. The mouse line was generated by Ozgene and can be purchased from this supplier.

## EXPERIMENTAL MODEL AND SUBJECT DETAILS

**Chemicals, cell lines, culture conditions.** Unless otherwise indicated, media and supplements for cell culture were purchased from Gibco-Invitrogen (Carlsbad, CA, USA), plasticware from Corning B.V. Life Sciences (Schiphol-Rijk, The Netherlands). All cell lines were cultured at 37 °C under 5% CO<sub>2</sub>, in medium containing 10% fetal bovine serum, 100 mg/L sodium pyruvate, 10 mM HEPES buffer, 100 units/mL penicillin G sodium and 100 µg/mL streptomycin sulfate. Cell type-specific culture conditions include: (1) Dulbecco's modified Eagle's medium (DMEM) for human brain neuroglioma H4 cells (from 37-year-old Caucasian male), as well as the GFP-LC3-expressing and *ATG5*<sup>-/-</sup> derivatives, hepatocyte-derived cellular carcinoma HuH7 cells (from 57-year-old Japanese male) and hepatocyte-like CCL-13 cells (donor unknown); (2) Eagle minimum essential medium (EMEM) supplemented as above plus 2 mM glutamine and 1% non-essential amino acids (NEAA) for human hepatocellular carcinoma HepG2 cells (from 15-year-old Caucasian male), and the GFP-LC3-expressing derivative; (3) Williams' Medium E plus hepatocyte maintenance supplement pack for male mouse and human primary hepatocytes plateable (purchased by ThermoFisher Scientific). Cells were seeded in 6-, 96- or 384-well plates and grown for 24 h before treatment with 10 µM rapamycin, 50 nM bafilomycin A1, alone or in combination, 1 µg/mL Brefeldin A, 50 nM chloroquine or 50 µM cycloheximide. Nutrient-free (NF) conditions were established by culturing cells in serum-free Earle's balanced salt solution (EBSS).

**Neutralization and exogenous supply of ACBP.** The following antibodies against ACBP were used *in vivo* (5 µg/g BW, intraperitoneally, in 200 µL) or *in vitro* (1-10 µg/mL): sc-30190 (polyclonal rabbit IgG antibody, Santa Cruz Biotechnology, CA, USA), ab231910 (polyclonal rabbit IgG antibody, Abcam, Cambridge, MA, USA), mAb 7A (Fred Hutch Antibody

Technology, Seattle, WA, USA). Recombinant mouse or human ACBP (recACBP, from The Inflammation Research Center, Paris, France) was used *in vivo* at 0.5 mg/Kg body weight (intravenously, in total volumes of 50  $\mu$ L).

**Mouse experiments and tissue processing.** Wild-type C57BL/6 mice (Envigo, Gannat, France), B6.Cg-Lep<sup>ob</sup>/J *ob/ob* obese mice, S/B6.V-LEP +/*Ob* lean mice (JAX™ Mice Strain, Charles River Laboratory, Lentilly, France), B6.V-Lep *ob/ob* JRj obese mice (Janvier Labs, Saint Berthevin, France), B6.V-Lep *ob/+* JRj (Janvier labs) lean mice, *Atg4b*<sup>-/-</sup> C57BL/6 mice (gift of Dr. Carlos Lopez-Otin, University of Oviedo, Spain) were bred and maintained according to the FELASA guidelines and local guidelines from the Animal Experimental Ethics Committee (#04447.02, #2315-2015101617138161v1, #8530-2017011216394941v2, #10862-2017080217568517v3, France). Male mice were kept in SPF conditions, in standard housing conditions in a temperature-controlled environment with 12 h light/dark cycles and received normal diet (ND) or high-fat diet (HFD; SAFE, Augy, France) and water *ad libitum*. Mice were subjected to 24 h starvation or were injected intraperitoneally or intravenously and sacrificed 1 h or 6 h later. Tissues were snap-frozen in liquid nitrogen, extracted and homogenized in 2 cycles for 20 s at 5,500 rpm using a Precellys 24 tissue homogenator (Bertin Technologies, Montigny-le-Bretonneux, France) in 20 mM Tris buffer (pH 7.4) containing 150 mM NaCl, 1% Triton X-100, 10 mM EDTA and Complete® protease inhibitor cocktail (Roche Applied Science). Tissue extracts were then centrifuged at 12,000 g (4 °C) and supernatants were collected. Protein concentration in supernatants was evaluated by the bicinchoninic acid technique (BCA protein assay kit, Pierce Biotechnology, Rockford, IL, USA). Recombinant mouse leptin (50  $\mu$ g/Kg BW) was administered by *i.p.* injection. Leupeptine (15 mg/Kg BW) and dimethyl  $\alpha$ -ketoglutarate

(300 mg/Kg BW) were used *in vivo* by two *i.p.* injection, 12 h and 4 h before the end of the experiment. WZB177 (20 mg/Kg BW) was used *in vivo* at by *i.p.* administration.

**Conditional ACBP mice.** B6.Cg-Tg(UBC-cre/ERT2)1Ejb/1J mice were obtained from the Jackson Laboratory (Bar Harbor, ME, USA). *Acbp*<sup>fl/fl</sup> mice in which loxP sites flank *Acbp* exon 2 were generated by OZgene (Bentley, WA, USA). On breeding, genotype was verified by PCR using genomic DNA isolated from tail biopsies with primer pairs specific for *Cre* and *Acbp*. *Acbp* primers:

- (1) ACBP01F, CAAAGACCATCTCCCTAAACTC;
- (2) ACBP02R, TGGATAGGGAGAAAAGTCACCT;
- (3) ACBP03F, GAGCACGTACTCGGATGGAAGC;
- (4) ACBP04F, GGCTGAACTCCTGGGTGAAGCA.

PCR conditions: 95 °C (5 min); [95 °C (30 sec), 60 °C (30 sec), 72 °C (45 sec)] x 35 cycles; 72 °C (7 min); 4 °C. *Cre* primers: (1) Cre1, AGGTTCGTTCACTCATGGA; (2) Cre2, TCGACCAGTTTAGTTACCC. PCR conditions: 94 °C (3 min); [94 °C (20 s), 61.5 °C (40 s), 72 °C (3 min)] x 35 cycles; 72 °C (7 min); 4 °C. PCR products were separated by electrophoresis in 2% agarose gels and visualized using ethidium bromide.

Cre recombinase was activated by administration of Tamoxifen (*i.p.* 75mg/KG BW tamoxifen/mouse daily during 5 days). Tamoxifen was diluted in corn oil (90%) + Ethanol (10%) at a concentration of 20 mg/ml and shake overnight at 37°C.

**ACBP immunization.** Keyhole limpet haemocyanin (KLH; from Stellar Biotechnologies, Port Hueneme, CA, USA) and mouse recACBP were mixed at a 1:20 molar ratio and adjusted gradually to 0.25% (v/v) glutaraldehyde. The reaction was terminated by addition of a glycine solution. After ultrafiltration using a 100 KDa membrane (Millipore, Billerica, MA, USA), a

formaldehyde solution was added to 0.2% (v/v) final concentration. The reaction was quenched by addition of a glycine solution followed by an ultrafiltration with 70 mM phosphate buffer (pH 7.8). Male 6-8 week-old C57BL/6 mice obtained from Envigo, were immunized with intramuscular injection of 30, 30, 10, 10 µg of KLH-ACBP or KLH alone as an emulsion (1:1) with Montanide ISA-51vg (Seppic, Paris, France) on days 0, 7, 14 and 21, respectively.

***In vivo* ACBP expression by hydrodynamic injection.** Mice were injected intravenously with plasmid cDNA (10 µg) (pCMV6 or pLIVE) in saline (8% of the body weight) via the tail vein. DNA injection was completed in less than 5 s.

**ACBP detection in cell cultures and plasma samples.** ACBP levels in culture supernatants were determined using a specific ELISA kit (KA0532 ACBP (Human) ELISA; from Abnova, Taipei, Taiwan). Mouse plasma was harvested from blood collection tubes by centrifugation at 15,000 rpm for 30 min, and ACBP levels were determined by ELISA (MBS2025156; from MyBioSource, San Diego, CA, USA) as instructed by the manufacturer. Human plasma ACBP levels were measured in three different cohorts of patients, one from anorexia nervosa patients (samples from Hôpital Sainte-Anne, Paris, France) and two from obese patients (samples from Pitié-Salpêtrière Hospital, Paris, France (Cotillard et al, Nature 2013) and Genomic Institute for Diabetes, Lille, France (Lassailly et al., 2015), by means of the KA0532 ACBP (Human) ELISA kit. The subjects of the surgical cohort were participants of the ABOS study (NCT01129297), an ongoing prospective trial for the longitudinal assessment of metabolic outcomes before and after gastric banding, an exclusively restrictive weight loss intervention. The study design has been detailed elsewhere. The institutional review board approved the study protocol and patients provided written informed consent before enrolment. All patients underwent an extensive preoperative multidisciplinary evaluation according to French recommendations. Clinical and

biological features were assessed preoperatively and at 1 year after surgery. Study outcomes were weight, body mass index (BMI). Circulating insulin was measured at baseline.

**Peripheral blood mononuclear cells isolation.** To prepare peripheral blood mononuclear cells from healthy male and female volunteers, 500  $\mu$ m of total blood were diluted in 5 mL red blood cell lysis buffer (BioLegend, 420301) for 10 min at room temperature and cells were washed twice in phosphate-buffered saline (PBS; Thermo Fisher Scientific, 10010023).

**Leptin, ghrelin, insulin, C-peptide, GIP and adiponectin detection in plasma.** Plasma was harvested from blood collection tubes by centrifugation at 15,000 rpm for 30 min, and stored at  $-80$  °C until use. Leptin, ghrelin, insulin, C-peptide, GIP and adiponectin levels were measured using a mouse serum adipokine immunoassay kit following the protocol provided by the manufacturers.

**Plasmid transfection and RNA interference.** ACBP-encoding plasmids were obtained from OriGene (Rockville, MD, USA). Transient plasmid transfections were performed with the AttracteneR reagent (Qiagen, Hilden, Germany), and, unless otherwise indicated, cells were analyzed 24 h after transfection. Cells were cultured in 6- or 96-wells plates and transfected at 50-60% confluence. siRNAs were reverse-transfected with the help of the RNAi Max<sup>TM</sup> transfection reagent (Invitrogen, Eugene, USA) in the presence of 100 nM of siRNAs specific for ACBP or SMARTpool siRNAs against STX3, STX4, TRIM10, SNAP29, SNAP23, TRIM16, SEC22B, ATG5, ATG7, ATG10, and BECN1 (Qiagen) for 48-96 h. The cells were treated as described and processed for cytofluorimetric analysis to assess ACBP levels, or autophagy detection by fluorescent microscopy or western blot analysis. (Qiagen). A scrambled siRNA (SCR) was used as a control, and siRNA-mediated protein downregulation was controlled by immunoblotting.

**Cytofluorimetric assays.** Cells were collected using Accutase (StemPro™ Accutase™ Cell Dissociation Reagent, ThermoFisher, ref A1110501) and washed twice with PBS upon fixation with PBS at 2% PFA for 20 min at room temperature. Cells were permeabilized with 0.1% Triton X-100 for 10 min, then washed twice with cold blocking buffer (3% bsa, v/v in PBS), followed by overnight staining with primary antibodies at 4 °C. Cells were washed and incubated with secondary antibody AlexaFluor 647®-conjugates in blocking buffer (for 60 min) and washed prior to flow cytometer analysis (MACSQuant cytometer (Miltenyi Biotec, Bergisch Gladbach, Germany)).

**Multispectral imaging flow cytometry** was performed on an AMNIS ImageStream X Mark II equipped with 375-, 488-, 561-, and 642-nm lasers using the 60x magnification lens. Only Hoechst+ events were recorded. The analysis was done with IDEAS software v6.1. Only focused events were included in the analysis, using the gradient RMS feature of bright field images. Singlets were then gated on aspect ratio vs area of bright field and leukocyte subpopulations were gated on a pictogram indicating the intensity of PTPRC/CD45 staining versus dark field. The intensity of ACBP staining was quantified within the entire cell.

**Immunofluorescence.** Cells were fixed with 4% paraformaldehyde (PFA) for 15 min at room temperature, and permeabilized with 0.1% Triton X-100 for 10 min. Non-specific binding sites were blocked with 5% bovine serum in PBS, followed by overnight staining with primary antibodies at 4 °C. Cells were stained for the detection of ACBP with sc-30190 (Santa Cruz Biotechnology, CA, USA). Primary antibodies were revealed with appropriate AlexaFluor™ conjugates (Molecular Probes-Invitrogen, Eugene, Oregon, USA). Nuclei were counterstained with 10 μM Hoechst 33342. Standard and confocal fluorescence microscopy assessments (20X/40X) were performed on an IRE2 microscope (Leica Microsystems, Wetzlar, Germany)

equipped with a DC300F camera, an LSM 510 microscope (Carl Zeiss, Jena, Germany) or a Leica SPE confocal microscope (Leica Microsystems). Acquired images were converted to 8-bit binary files, and cytoplasmic ACBP intensity on each image was calculated by ImageJ software (NIH). Each experiment was done at least three times.

**Automated microscopy.** Cells stably expressing GFP-LC3 were seeded in 96- or 384-well imaging plates (BD Falcon, Sparks, USA) 24 h before stimulation. Cells were treated with the indicated agents for 4-6 h. Subsequently, cells were fixed with 4% PFA and counterstained with 10  $\mu$ M Hoechst 33342. Images were acquired using an ImageXpress Micro XLS Widefield High-Content Analysis System operated by the MetaXpress® Image Acquisition and Analysis Software (Molecular Devices, Sunnyvale, CA, US). Acquisition was performed by means of a 20X PlanApo objective (Nikon, Tokyo, Japan). Minimum 9 views fields per well for 96-well or 384-well plate were acquired. MetaXpress® was utilised to segment cells into nuclear area (based on Hoechst 33342 signal). GFP-LC3+ dots number per cell are counted within each cytoplasmic ROI based on differential pixel intensity of GFP-LC3 signal. Autophagy level was measured by counting the numbers of GFP-LC3+ puncta per cell. Images were also acquired using a BD pathway 855 automated microscope (BD Imaging Systems, San José, CA, USA) equipped with a 40X objective (Olympus, Center Valley, USA) coupled to a robotized Twister II plate handler (Caliper Life Sciences, Hopkinton, USA). Images were analyzed for the presence of GFP-LC3 puncta in the cytoplasm by means of the BD Attovision software (BD Imaging Systems). Cell-like objects were segmented and divided into cytoplasmic and nuclear regions as previously reported (Bravo-San Pedro et al., 2017). Rolling-bar 2x2 and Marr-Hildreth algorithms were used to recognize cytoplasmic GFP-LC3+ dots. Statistical analyses were implemented on the R bioinformatic environment (<http://www.r-project.org/>).

**Immunoblotting.** For immunoblotting, 25  $\mu$ g of proteins were separated on 4-12% Bis-Tris acrylamide precast gels (Invitrogen) or 12% Tris-Glycine SDS-PAGE precast gels (Biorad, Hercules, CA, USA) and electrotransferred to Immobilon™ membranes (Millipore). Membranes were horizontally sliced according to the molecular weight of the protein of interest to allow simultaneous detection within the same experiment. Unspecific binding sites were saturated by incubating membranes for 1 h in 0.05% Tween 20 (v:v in TBS) supplemented with 5% non-fat powdered milk (w:v in TBS), followed by overnight incubation with primary antibodies specific for human ACBP (ab16871, Abcam or sc-376853, Santa Cruz), murine ACBP (ab231910, Abcam), SQSTM1 (#H00008878-M01, clone 2C11, Abnova), MAP1LC3B (#2775, Cell Signaling Technologies), FASN (clone C20G5, #3180, Cell Signaling Technologies), phospho-p70<sup>S6K</sup> (Thr389) (clone 1A5, #9206, Cell Signaling Technologies), p70<sup>S6K</sup> (#9202, Cell Signaling Technologies), Phospho-SREBP (Ser372) (#9874, Cell Signaling Technologies), GLUT1 (PA1-46152, Thermo Scientific-Pierce), PPARG (clone 81B8, #2443, Cell Signaling Technologies), CPT-1A (ab128568), AKT1 (Cell Signaling, 9272), Phospho-AKT1 (Cell Signaling, 9271), MTOR (Cell Signaling, 2983), Phospho-MTOR (Cell Signaling, 5536), EIF4EBP1 (Cell Signaling, 9452), Phospho-EIF4EBP1 (Cell Signaling, 2855) or UCP1 (ab10983, Abcam). Revelation was performed with appropriate horseradish peroxidase (HRP)-labeled secondary antibodies (Southern Biotech, Birmingham, USA) plus SuperSignal West Pico chemoluminescent substrate (Thermo Scientific-Pierce). Antibodies specific for glyceraldehyde-3-phosphate dehydrogenase (GAPDH, #ab9484, Abcam) or  $\beta$ -actin (#Ab49900, clone AC-15, Abcam) were used to control equal loading of lanes.

**Metabolomic analysis. Sample preparation Tissue:** About 30 mg of tissues for each condition were first weighted and solubilized into 1.5 mL polypropylene microtubes with ceramic beads

with 225  $\mu\text{L}$  of MEOH. They were then homogenized three times for 20 s at 5500 rpm using Precellys 24 tissue homogenator (Bertin Technologies, Montigny-le-Bretonneux, France). 750  $\mu\text{L}$  of MTBE were added and the samples were homogenized again three times for 20 s at 5500 rpm. 188  $\mu\text{L}$  of MilliQ water were added in the samples, followed by vortex (4 min) and centrifugation (10 min at 15000 g, 4  $^{\circ}\text{C}$ ). 700  $\mu\text{L}$  of the organic upper phase of the supernatant were transferred in microtubes for further analysis, and the lower phase was supplemented with 1 ml of MEOH, followed by vortex (5 min) and centrifugation (2 min at 14000 g). The supernatant was split in two parts: the first 300  $\mu\text{L}$  used for the Gas Chromatography coupled by Mass Spectrometry (GC/MS) experiment in microtubes, the others 700  $\mu\text{L}$  used for the Ultra High Pressure Liquid Chromatography coupled by Mass Spectrometry (UHPLC/MS) experimentations. Concerning the GC-MS aliquots, 250  $\mu\text{l}$  were transferred from the microtubes to an injection vial and evaporated. The dried extract was stored at -80  $^{\circ}\text{C}$  until derivatization and analysis. Concerning the UHPLC-MS aliquots, the collected supernatant was evaporated in microtubes at 40  $^{\circ}\text{C}$  in a pneumatically-assisted concentrator (Techne DB3, Staffordshire, UK). The UHPLC-MS dried extracts were solubilized with 200  $\mu\text{L}$  of MilliQ water. One aliquot of 50  $\mu\text{L}$  was transferred in injection vial for direct analysis and the 150  $\mu\text{L}$  were aliquoted and kept as backup at -80  $^{\circ}\text{C}$ .

**Sample preparation plasma (lithium heparin):** A volume of 50  $\mu\text{L}$  of plasma were mixed with 225  $\mu\text{L}$  of MEOH into 1.5 mL microtubes, vortexed 5 minutes and centrifugated (10 min at 15000 g, 4 $^{\circ}\text{C}$ ). 750  $\mu\text{L}$  of MTBE were added and the samples were vortexed 1 min. 188  $\mu\text{L}$  of MilliQ water were added in the samples, followed by vortex (4 minutes) and centrifugation (10 min at 15000 g, 4  $^{\circ}\text{C}$ ). 700  $\mu\text{L}$  of the organic upper phase of the supernatant were transferred in microtubes for further analysis, and the lower phase was supplemented with 1 ml of MEOH

followed by vortex (5 min) and centrifugation (2 min at 14000 g). The supernatant was split in two parts: the first 300  $\mu$ L used for the GC/MS experiment in microtubes, the others 700  $\mu$ L used for the UHPLC/MS experimentations. Concerning the GC-MS aliquots, 250  $\mu$ l were transferred from the microtubes to an injection vial and evaporated. The dried extract was stored at  $-80^{\circ}\text{C}$  until derivatization and analysis. Concerning the UHPLC-MS aliquots, the collected supernatant was evaporated in microtubes at  $40^{\circ}\text{C}$  in a pneumatically-assisted concentrator (Techne DB3, Staffordshire, UK). The UHPLC-MS dried extracts were solubilized with 200  $\mu$ L of MilliQ water. One aliquot of 50  $\mu$ L was transferred in injection vial for direct analysis and the 150  $\mu$ L were aliquoted and kept as backup at  $-80^{\circ}\text{C}$ .

**Labelling experiment by targeted analysis of nucleoside phosphates and cofactors by ion pairing ultra-high performance liquid chromatography (UHPLC) coupled to a Triple Quadrupole (QQQ) mass spectrometer:** Targeted analysis was performed on a RRLC 1260 system (Agilent Technologies, Waldbronn, Germany) coupled to a Triple Quadrupole 6410 (Agilent Technologies) equipped with an electrospray source operating in negative mode. The gas temperature was set to  $350^{\circ}\text{C}$  with a gas flow of 12 L/min. The capillary voltage was set to 3.5 kV. 10  $\mu$ L of sample were injected on a Column Poroshell PhenylHexyl (100 mm x 2.1 mm particle size 2.7  $\mu$ m) from Agilent technologies, protected by a guard column XDB-C18 (5 mm x 2.1 mm particle size 1.8  $\mu$ m) and heated at  $40^{\circ}\text{C}$  by a pelletier oven. The gradient mobile phase consisted of water with 10 mM of TBA and 10 mM AA (phase A) and Methanol with 10 mM of TBA and 10mM AA (phase B). The flow rate was set to 0.2 mL/min, and gradient as follow: initial condition was 98% phase A and 2% phase B, maintained during 1 min. Molecules were then eluted using a gradient from 2% to 70% phase B over 10 min. The column was washed using 95% mobile phase B for 2 min and equilibrated using 2% mobile phase B for 4 min. The

autosampler was kept at 4°C. The collision gas was nitrogen. The scan mode used was the MRM for biological samples with the Q1 corresponding to the molecule [M-H]<sup>-</sup> and with Q3 corresponding to an expected fragment. Peak detection and integration of the isomers were performed using the Agilent Mass Hunter quantitative software (B.07.01).

**Labelling experiment by targeted analysis or by gas chromatography (GC) coupled to a Triple Quadrupole (QQQ) mass spectrometer:** Targeted analysis methods are described in Izzo et al. Cell Cycle. 2017. Briefly, derivatization of GC aliquot was carried out with 50 µL of O-ethylhydroxylamine hydrochloride stored at room temperature in the dark for 16 h followed by silylation with 80 µL of N-tert-butyldimethylsilyl-N-methyltrifluoroacetamid (MSTBFA) at 40°C for 30 min. The GC-MS/MS method was performed on a 7890B gas chromatography (Agilent Technologies, Waldbronn, Germany) coupled to a triple quadrupole 7000C (Agilent Technologies, Waldbronn, Germany) equipped with an electronic impact source (EI) operating in positive mode. The scan mode used was the MRM for biological samples with the Q1 corresponding to the maximally derivatised molecule and with Q3 corresponding to a typical fragment of silyl group (73 or 147). Peak detection and integration of the isotopomers were performed using the Agilent Mass Hunter quantitative software (B.07.01).

**Immunohistochemistry on brain tissue.** Animals were deeply anesthetized with 80 mg/kg intraperitoneally pentobarbital (Nembutal, Abbott Laboratories, Chicago, IL, USA) and perfused transcardially with 0.1 M phosphate buffer (PB), followed by 4% PFA (in 0.1 M PB). Brains were removed, post-fixed for 2 h in the same fixative, cryoprotected in 20% sucrose (in 0.1 M PB) for 48 h, and snap frozen in CO<sub>2</sub>. Coronal sections (20 µm) were cut in a CM 3050 cryostat (Leica). The hypothalamic sections were collected in three separate series and were thaw mounted on SuperFrost Plus microscopic glass slides (Faust, Schaffhausen, Switzerland). After

air-drying at room temperature and rehydrating in PBS, sections were incubated in blocking solution for 2 h (1.5% rabbit normal serum plus avidin; from Vector Laboratories, Burlingame, CA, USA). Polyclonal goat antiFOS antibodies (from Santa Cruz) was applied at 1:10000 dilution in the presence of biotin for 48 h at 4 °C. Unbound antibodies were removed by washing in PBS before the sections were incubated with secondary antibodies (biotinylated rabbit-anti-goat, 1:200; from the Vectastain-Elite ABC Kit, Vector Laboratories;) for 2 h at room temperature. After incubation in ABC solution, diaminobenzidine (DAB) was used as a chromogen [0.04% in PBS with 0.02% H<sub>2</sub>O<sub>2</sub> and 0.08% NiCl<sub>2</sub> (×6 H<sub>2</sub>O), 0.01% CoCl<sub>2</sub> (×6 H<sub>2</sub>O) for color enhancement]. Finally, sections were dehydrated in graded alcohols, cleared in xylenes, and coverslipped with Entellan (Merck, Darmstadt, Germany).

Our estimation of the orexigenic nature of cfos positive neurons as a function of their neuroanatomical location in the lateral hypothalamus (LH) is based on the comparison of images obtained in the study of Sakurai et al (Cell. 1998 Feb 20;92(4):573-85), showing the location of LH orexigenic neurons in the same region as described in our study.

**Energy expenditure and food intake analysis.** Mice were analyzed for energy expenditure (EE), oxygen consumption and carbon dioxide production ( $RQ = vCO_2/vO_2$ ), and food intake using calorimetry (Labmaster, TSE Systems GmbH, Bad Homburg, Germany). Mice were individually housed and acclimated to the chambers for 48 h before experimental measurements. Data analysis was performed using O<sub>2</sub> consumed (mL/h), CO<sub>2</sub> production (mL/h) and energy expenditure (Kcal/h) subsequently expressed as a function of whole lean body mass (LBM). LBM was acquired using an Echo Medical systems EchoMRI 100 (Whole Body Composition

Analyser, EchoMRI, Houston, TX, USA). Fatty acid oxidation rate was calculated using the following equation: Fatty acid oxidation (Kcal/h) = EE (Kcal/h)  $\times$  (1 – RQ/0.3).

**Glucose uptake measurements.** [1-<sup>14</sup>C]2-deoxyglucose (2-DG) (#NEC495A001MC, Perkin Elmer) and Glucose-D U-<sup>13</sup>C6 (CLM-1396, Eurisotop) were used to quantitate tissue glucose uptake *in vivo*. [1-<sup>14</sup>C]2-DG at 3  $\mu$ Ci was injected intraperitoneally (with or without 0.5 IU/kg insulin). Blood was drawn from the tail vein at different time points (3, 5, 10, 20, 30, 40, 60, 75 and 90 min), and glucose concentrations were measured. Twenty  $\mu$ L of blood contained in a heparinized capillary were added to a 1.5 mL tube containing 100  $\mu$ L ZnSO<sub>4</sub> (0.3 N), followed by 100  $\mu$ L Ba(OH)<sub>2</sub> (0.3 N) to precipitate proteins. At completion of the experiment (time 90 min) the samples were centrifuged at 12,000 g for 3 min and 50  $\mu$ L of supernatant were move to a counting vial and evaporated in a hood. Dry pellet was resuspended in 500  $\mu$ L water before cpm assessment. Mice were sacrificed by pentobarbital injection and tissues were processed as follows: each tissue was dissected, cleaned, weighed and transferred to a tube containing 0.5 mL NaOH (1 M), shaken on a thermo-mixer (60° C, 950-1000 rpm) for 1 h, followed by addition of 0.5 mL of HCl (1 M). Two-hundred  $\mu$ L of the homogenate were transferred to tubes containing 0.5 mL ZnSO<sub>4</sub> (0.3 N), to which 0.5 mL Ba(OH)<sub>2</sub> (0.3 N) were then added. Two-hundred  $\mu$ L of the homogenate were transferred to tubes containing 1 mL perchloric acid (6%). After vortexing and centrifuging samples for 2 min at 13000 g, 400  $\mu$ L of supernatants were transferred to counting vials and radioactivity was determined. The first series with ZnSO<sub>4</sub> and Ba(OH)<sub>2</sub> allowed for determining Xcpm (2-DG). The second series with PCA allowed for determining Ycpm (2-DG plus 2-deoxyglucose 6 phosphate, 2-DG6P). Ycpm-Xcpm = 2-DG6P synthesis reflecting cellular 2-DG uptake within the tissue.

Glucose-D U-<sup>13</sup>C6 (2.5 g/kg BW) was injected *i.p.* (with or without 0.5 μg/g BW of recACBP injected *i.v.*). At completion of the experiment (time 120 min) mice were sacrificed and tissues were collected and processed by the metabolome platform.

**Glycerol-stimulated glucose production.** Animals were fasted for 2 h and given an intraperitoneal injection of <sup>13</sup>C-glycerol labeled (1 g/KG BW). Animals were sacrificed after 1h and liver and plasma were collected. Hepatic glucose production was determined by detection of <sup>13</sup>C-glycerol-3-P or <sup>13</sup>C-glucose in liver and <sup>13</sup>C-glucose in plasma by metabolomics analysis.

**Glycerol tolerance test.** Animals were fasted for 2 h and given an intraperitoneal injection of glycerol (1 g/KG BW). Blood was collected from the lateral vein of the tail prior to and at the indicated times after the injection. Glucose was measured using a precision glucometer (Accu-Chek Performa).

**Glucose tolerance test.** Animals were fasted for 16 h and given an intraperitoneal injection of glucose (2.5 g/KG BW). Blood was collected from the lateral vein of the tail prior to and at the indicated times after the injection. Glucose was measured using a precision glucometer (Accu-Chek Performa).

**Measurement of Lipolysis.** The isolation of adipocytes from adipose tissue and measurement of lipolysis was realized following the protocol provided by the Sigma (MAK195 Sigma-Aldrich).

**Histology.** After fixation of liver and white adipose tissues, 4 μm thick paraffin sections were stained with hematoxylin-eosin-saffranin or frozen sections with Oil-Red. Each slide was examined using a Zeiss Axiophot microscope.

**Analysis of whole-body composition.** Non-invasive determination of lean tissue mass, fat mass and free fluid was performed on non-anesthetized mice using TD-NMR technology (minispec LF90II; Bruker BioSpin) at PreclinICAN. In other experiments, MRI was performed with a

dedicated small-animal 4.7 Tesla MR system (Biospec 47/40 USR Bruker) using a quadrature transmit/receive body coil with a 7 cm inner diameter (Plateforme Imageries du Vivant, INSERM UMR 970). Mice were anesthetized with air and isoflurane (4% for induction and 1% during MRI). Experiments were performed with respiratory gating to avoid movement artifact. We used a spin-echo 3D sequence of the entire mouse with the following parameters: TR/TE=750/65ms and 260 mm of resolution in the three dimensions, to bring out the signal of the fat of the mice.

**Gene expression analysis.** Total RNA from cell lines was purified using RNeasy Mini Kit (QIAGEN), total RNA from murine tissues was isolated by QIAzol (QIAGEN) trituration with a motorized micropestle, followed by column purification with RNeasy Mini Kit (QIAGEN). Following the manufacturer's instructions, Superscript III Reverse Transcriptase (Invitrogen) was used with random hexamers (Promega) for generation of cDNA. Quantitative PCR was performed on a StepOnePlus Real-Time PCR System (Applied Biosystems) using TaqMan Gene Expression Master Mix (Applied Biosystems) and the following TaqMan Gene Expression Assays: murine *Acbp* (Mm01286585\_g1), murine *Pparg* (Mm00440940\_m1) and the murine *Ppia* (Mm02342430\_g1) purchased by ThermoFisher Scientific.

## **METHOD DETAILS**

All experiments were replicated at least three times with the exception of the experiments involving human samples (that were replicated in an independent cohort) and the immunohistochemical detection of neuronal activation in mice (that was repeated once, yielding similar results). Mice were randomized into experimental groups, though without blinding of the investigators. The sample size and the statistical tests employed for each experiment are noted in the Figure Legends. There were no inclusion/exclusion criteria.

## QUANTIFICATION AND STATISTICAL ANALYSIS

Data are reported as the mean  $\pm$  SD, mean  $\pm$  SEM, or Box and whisker plots (mean, first and third quartiles, and maximum and minimum values) as specified. Sample size and exact statistical test employed for each experiment are noted in the Figure Legends. Differences were considered statistically significant when *p*-values  $\circ$  ( $p < 0.1$ ), \* ( $p < 0.05$ ), \*\* ( $p < 0.01$ ), \*\*\* ( $p < 0.001$ ) and n.s. = not significant ( $p > 0.05$ ).
