12     **Abstract:**

14     This paper presents the dynamic modeling & simulation of a concentrating solar power (CSP)  
15    plant integrated with a thermochemical energy storage (TCES) system. The TCES material used is  
16    calcium hydroxide and the power cycle studied is a Rankine cycle driven by the CSP. Firstly,  
17    dynamics models of components written in Modelica language have been selected, developed,  
18    parametrized, connected and regulated to create the CSP plant with different TCES integration  
19    concepts. Then simulations were then performed to determine and compare the energy efficiency,  
20    water consumption and energy production/consumption of three integrations concepts for two  
21    typical days (summer and winter) and for a basic continuous production mode. After that, a  
22    feasibility study has been performed to test a peak production scenario of the CSP plant.

24     The results showed that a TCES integration could increase the overall efficiency of the CSP  
25    plant ~~efficiency~~ by more than 10%. The Turbine integration concept has the best global efficiency  
26    (31.39% for summer; 31.96% for winter). The global electricity consumption of a CSP plant with  
27    TCES represents about 12% of its total energy production for a summer day and 3% for a winter  
28    day. An increased nominal power by a factor of 10 could be reached for the peak production mode  
29    within one hour using the Turbine integration concept, but with a lower global efficiency (17.89%).

42     **1. Introduction**

43

44         Concentrating solar power (CSP) is expected to play a key role in the future energy transition  
45 scenarios towards a more electrified world with low-carbon technologies [IEA, 2018]. Meanwhile,  
46 thermal energy storage (TES) systems become indispensable to increase the dispatchability and the  
47 economic competitiveness of modern large-scale powerful CSP plants [Alva, 2018; Kuravi, 2013].  
48 Currently more than 80% of the CSP plants under construction or planned incorporate TES systems  
49 [NREL, 2018; IRENA, 2018].

50

51         Sensible storage using molten salt is the most developed and commonly used TES  
52 technology for existing CSP plants because of its simplicity, reliability and cost-effectiveness [Pelay,  
53 2017a; b]. However, the salt corrosiveness [Ding, 2019; Walczak 2018; Wang, 2019], the limited  
54 working temperature [Gimenez, 2015; Villada, 2018] and the risk of salt solidification [Vignarooban,  
55 2015; Villada, 2019] are the major drawbacks remaining to be solved. Other sensible TES systems  
56 have then been proposed and studied during the last years, as summarized in recent review papers  
57 [Mohan, 2019; Nunes, 2019]. As an alternative, latent heat storage using phase change materials  
58 (PCMs) is under intensive investigation, owing to their high density and almost constant phase  
59 change temperature during charging or discharging [Lin, 2018; Nazir, 2019]. Special attention has  
60 been focused on the improvement of their limited thermal conductivity through encapsulation as  
61 well as nanomaterials additives [Qureshi, 2018; Tao, 2018].

62

63         Another trend on the TES systems for CSP plants is the development of thermochemical  
64 energy storage (TCES) technology based on reversible endothermic/exothermic chemical reactions  
65 involving a large amount of reaction heat. TCES systems become a very attractive option because  
66 of their high energy density (up to 10 times greater than latent storage) and the long storage  
67 duration at ambient temperature [Prieto, 2016]. Latest advances on the thermochemical materials,  
68 reactors and processes are reviewed and summarized in Refs [Liu, 2018; Jarimi, 2019]. Recently,  
69 great efforts have also been devoted to investigate the appropriate coupling of the TCES system  
70 with the power generating cycle (e.g., Rankine cycle; Brayton cycle, etc.) of the CSP plant [e.g.,  
71 Alovisio, 2017; Cabeza, 2017; Ortiz, 2017; 2018; 2019; Schmidt, 2017; Pelay, 2019]. This process  
72 integration issue plays actually a key role on the adaptation of the TCES technology to the future  
73 CSP plants. Particularly in our previous study [Pelay, 2019], three TCES integration concepts using  
74 Ca(OH)<sub>2</sub>/CaO couple have been proposed. Energy and exergy analyses results indicated that  
75 compared to a reference plant without storage, the TCES integration could significantly improve  
76 the adaptability and dispatchability of the CSP plants with the increased power production [Pelay,  
77 2019].

78

79         While most of the earlier studies reported in the literature are focused on conceptual or static  
80 analysis, detailed exploration of the TCES process integration issue is still lacking. The dynamic  
81 behaviors of CSP plant with TCES integration are of particular importance because this type of  
82 installation is inherently subjected to transient boundary conditions such as the varying solar  
83 irradiation. Moreover, the dynamic simulations also make it possible to highlight the influences of

84 thermal inertia, which has usually been neglected in the static analysis but plays an important role  
85 regarding the real operations of the CSP plant.

86

87 As the following work of our previous study [Pelay, 2019], this paper makes a step forward  
88 by presenting the dynamic modeling & simulation of a CSP plant integrated with a TCES system  
89 under real conditions. Dynamic models of each component written in the Modelica language have  
90 been either adopted from the Dymola library or developed in-house. These models have then been  
91 parametrized and further interconnected to build the global model for the CSP plant with TCES  
92 integration. The main objectives of this study include: (1) to characterize, *for the first time*, the  
93 dynamic behaviors of a CSP plant coupled with a TCES unit; (2) to compare the performances of  
94 different TCES integration concepts under realistic variable environmental conditions; (3) to  
95 showcase the feasibility of the basic continuous production mode and the peak production mode by  
96 implementing advanced control strategies. The contributions of this paper are important because it  
97 will expand the limited literature and provide additional insights on the dynamic behaviors of CSP  
98 plants with TCES integration. The results obtained may be used for the large deployment of the  
99 TCES technology in CSP plants.

100

101 The rest of the paper is organized as follows. Section 2 introduces the methodology used for  
102 this study, including the proposed TCES integration concepts, the mathematic model for individual  
103 component, the operation mode, the control and the initialization parameters. Section 3 presents  
104 and compares the dynamic simulation results for the CSP with different TCES integration concepts  
105 under the continuous production mode. Section 4 reports a feasibility study on the peak production  
106 mode with the Turbine integration concept. Finally, main findings are summarized in section 5.

107

108

## 109 **2. Methodology**

110

111 In this section, the three TCES integration concepts previously proposed are briefly  
112 introduced. Then the dynamic model for each individual component used in the simulation is  
113 presented. The production scenarios, the control strategy, the simulation parameters and the  
114 initialization used for this study are also explained.

115

116

### 117 *2.1. Proposed TCES integration concepts in a CSP plant*

118

119 The reference 100 MW<sub>el</sub> CSP plant based on the Solar Power Tower (SPT) technology is  
120 schematically shown in Fig. 1. The solar tower group is mainly composed of the tower and the  
121 central solar receiver installed at the top. The power cycle in this study is a conventional  
122 regenerative Rankine cycle including a steam generator, a turbine, a condenser, an open feedwater  
123 heater and pumps. The TES group is not included in this reference SPT plant.

124

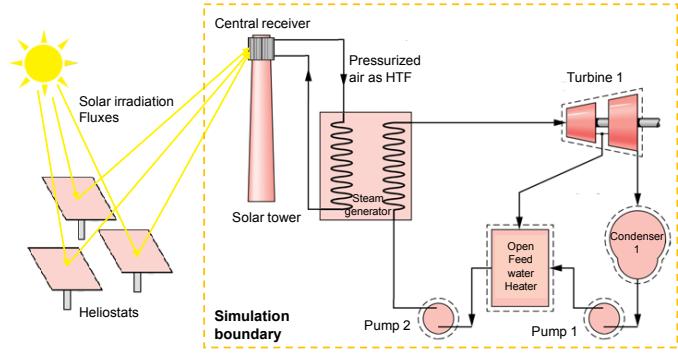

Figure 1. Schematic view of the reference SPT plant without TES. Adapted from [Pelay, 2019]

Different TCES integration concepts have been proposed for ~~a this conceptual Solar Power Tower (SPT) plant~~ [Pelay, 2019]. The ~~TCES reaction couple used is SPT plant using CaO/Ca(OH)<sub>2</sub> as the reaction couple and the power cycle studied is a Rankine cycle driven by the CSP~~. The charging stage uses solar energy for the decomposition of Ca(OH)<sub>2</sub> into CaO and the ~~water vaporsteam~~ while the discharging stage gets the CaO and the ~~water vaporsteam~~ into contact for heat release by the exothermic reaction, as shown by the reaction formula in Eq. (1). For a reaction temperature at 500 °C, the equilibrium pressure equals to 0.1 MPa (1 bar).

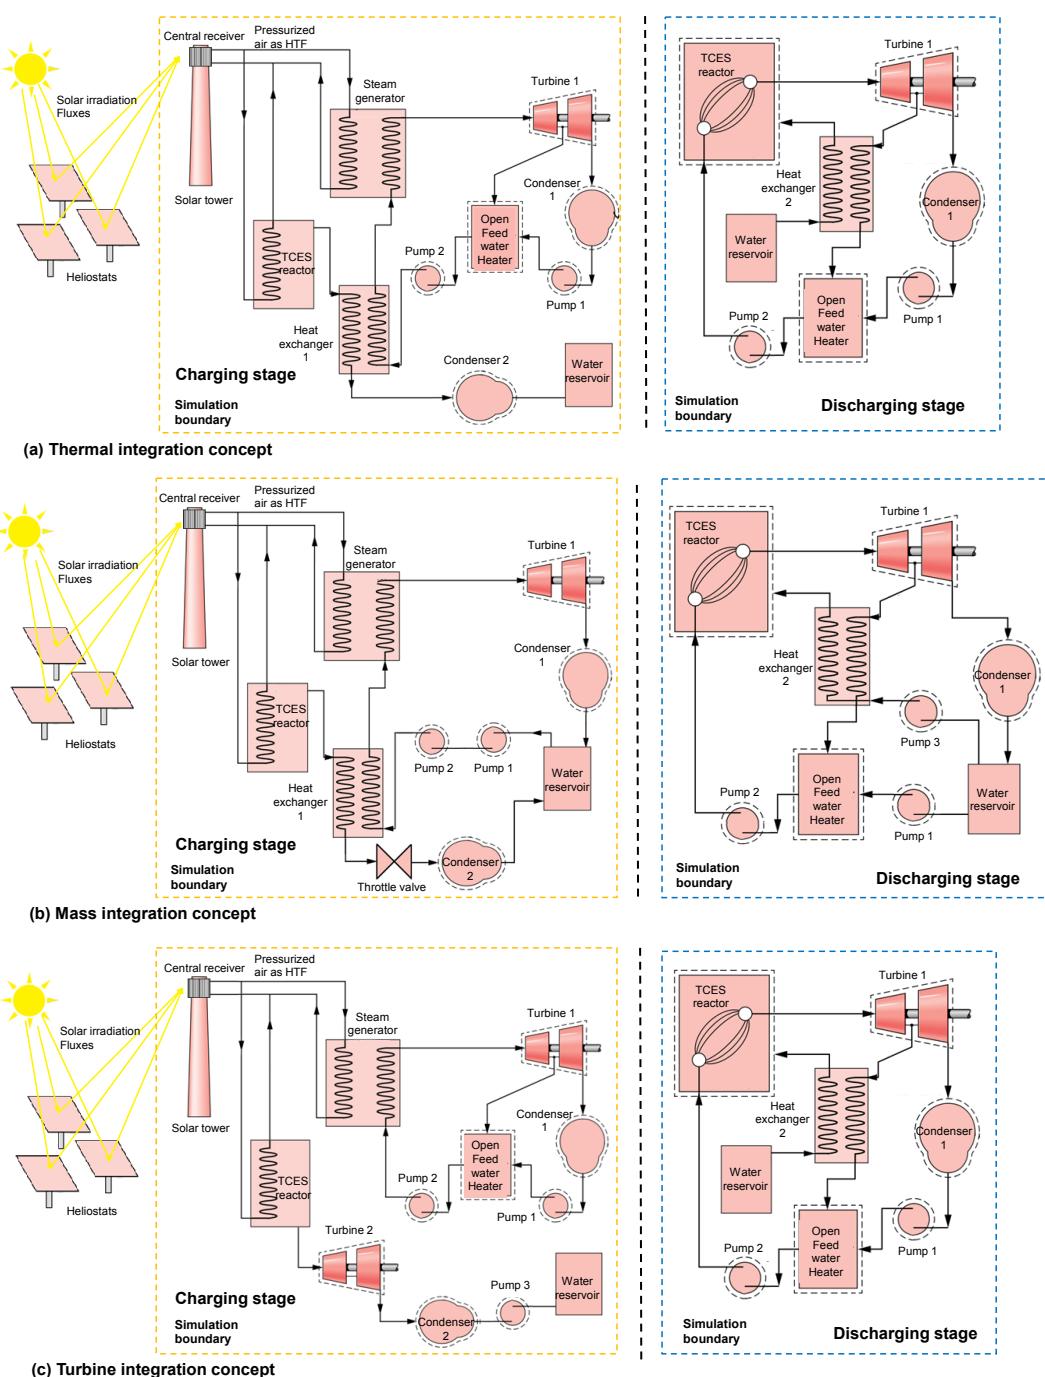

The amount of produced water is preferably to be stored in the liquid form rather than in the ~~gaseous-steam~~ form during the period between the charging and discharging, so as to largely reduce the required volume of the storage unit. The proposed TCES integration concepts then distinguish themselves by the management of the ~~water vaporsteam~~ from the TCES reactor for energy-efficient coupling between the TCES unit and the Rankine cycle, briefly described as follows.

- *Thermal integration (Thermal Int.):* during the charging stage, ~~water vaporsteam~~ (500 °C, 1 bar) released from the TCES reactor is partially condensed in a heat exchanger to preheat the working fluid of the Rankine cycle, then completely condensed by a condenser and stored as the saturated liquid (100 °C, 1 bar) in a separate water reservoir. During the discharging stage, steam extracted from the turbine of the power cycle is used to vaporize the stored liquid water to the saturated vapor (100 °C, 1 bar), which will then enter into the TCES reactor for exothermic reaction. The Rankine cycle and the TCES circuit are *thermally coupled* with each other but without direct mass contact or exchange (as shown in Fig. 3 of [Pelay, 2019] Fig. 2a).
- *Mass integration (Mass Int.):* the high temperature ~~water vaporsteam~~ generated in the TCES reactor during the charging stage is stored as the saturated water (41 °C, 0.008 MPa) in a *water reservoir shared with* the Rankine cycle. During the discharging stage, the stored liquid water is firstly pressurized by a pump and then evaporated into saturated vapor (100 °C, 0.1 MPa) by high temperature extracted steam from the Turbine. For this concept, the Rankine power cycle and the TCES circuit are *coupled and share the same working fluid with mass exchange* (as shown in Fig. 2b Fig. 4 of [Pelay, 2019]).

161

- **Turbine integration (Turbine Int.):** during the charging stage, high temperature **water-vaporsteam** ( $500\text{ }^{\circ}\text{C}$ , 1 bar) from the TCES reactor passes through *an additional turbine* to valorize a part of its thermal energy as power production. The condensed water ( $41.5\text{ }^{\circ}\text{C}$ , 0.1 MPa) is stored in a separate water reservoir. The discharging stage is the same as that of the Thermal Int. The principal Rankine circuit and the TCES circuit are completely independent of each other during the charging stage (no heat or mass exchange) and thermally coupled during the discharging stage (as shown in Fig. 2c–Fig. 5 of [Pelay, 2019]).

170

171

172       Figure 2. Schematic view of the SPT plant with TCES integration. (a) Thermal Int. concept; (b) Mass Int.  
173       concept; (c) Turbine Int. concept. Adapted from [Pelay, 2019]

174  
175       Detailed description of the three proposed Int. concepts as well as their performance  
176       modelling based on static energy and exergy analyses can be found in our earlier work [Pelay, 2019].

Table I. Component model of the CSP plant with TCES integration used for the dynamic modeling

Component (Name)	Library/Reference	Modeling assumptions	Features
Steam turbine (SteamTurbine)	ThermoCycle [Quoilin, 2017]	- No thermal inertia - Constant Isentropic efficiency	- Simple and robust - The Stodola's law with partial arc admission permits the modeling of a gas expansion without sizing the turbine [Altés Buch, 2014]
Open water tank (OpenTank)	ThermoCycle [Quoilin, 2017]  A heat exchange port with the outside is added to model the heat loss	- Dynamic energy and mass conservation model - Constant outside pressure - Inlet/outlet fluid at liquid state	- Simple and robust - Constant pressure inside the tank
Closed water tank (Tank_PL)	ThermoCycle [Quoilin, 2017]	- Dynamic energy and mass conservation model - Constant outside pressure - Saturated outlet fluid - No heat exchange with the outside	- A closed tank with a variable pressure inside - Inlet fluid can be a mixture of liquid and vapor
Pump (Pump)	ThermoCycle [Quoilin, 2017]	- Non-dynamic model - No heat loss - No thermal inertia - Constant isentropic and mechanic efficiencies - Inlet/outlet fluid at liquid state	- Simple and robust - Variable rotation speed
Compressor (Compressor)	ThermoCycle [Quoilin, 2017]	- Non-dynamic model - No heat loss - No thermal inertia - Constant isentropic and mechanic efficiencies - Inlet fluid at gaseous state	
Throttle valve (Valve)	ThermoCycle [Quoilin, 2017]	- Non-dynamic model - No heat loss - Incompressible fluid - Quadratic pressure loss for turbulent flow	- Non-linear equations generated by quadratic friction coefficient
Linear valve (LinearValve)	Modelica [Altés Buch, 2014]	- Non-dynamic model - No heat loss - Incompressible fluid - Linear pressure drop	- Simple and robust - A no-return option for fluid
Three way valve (Three-way valve)	Modelica Buildings library [MBL, 2018]	- Non-dynamic model - No heat loss - Linear pressure drop	- Relatively simple control - Presence of a dead volume preventing sudden pressure variations
TCES reactor (Reactor)	In-house  Appendix A1	- Uniform temperature in the composite - Uniform temperature in the wall - Uniform temperature in the fluid - Entering vapor is instantly at composite temperature	- Sensitive to pressure variations - Complicated to simulate several reactor in parallel
Solar receiver (Solar_Rec)	In-house  Appendix A2	- No heat loss - No thermal inertia - Gaseous entering fluid - Uniform temperature in the solar receiver	- Constant convective heat transfer coefficient - Dynamic model

Component (Name)	Library/Reference	Modeling assumptions	Features
Condenser (CrossCondenser)	[Altés Buch, 2014]	<ul style="list-style-type: none"> <li>- Constant temperature of cooling fluid</li> <li>- Fluid to be cooled is treated as a mixture of liquid and vapor</li> <li>- No sub-cooling at the outlet of condenser</li> <li>- No heat loss</li> <li>- No inertia</li> <li>- No liquid stored in the condenser</li> </ul>	<ul style="list-style-type: none"> <li>- Variable heat transfer coefficient</li> <li>- Discretized model on cold side</li> <li>- Possibility to be coupled with a tank at the exit of the hot side</li> <li>- Very sensitive to pressure variations</li> </ul>
Condenser (Tank_Condenser)	ThermoCycle [Quoilin, 2017]  Based on the Tank model, heat transfer between hot and cold fluids is added in the conservation energy equation	<ul style="list-style-type: none"> <li>- Dynamic model</li> <li>- Wall temperature equals to the hot fluid temperature</li> <li>- Uniform temperature of hot fluid</li> <li>- Fixed outlet temperature of cold fluid</li> <li>- No sub-cooling</li> <li>- Compressible hot fluid</li> <li>- No heat loss</li> <li>- Overestimated heat transfer surface area</li> </ul>	<ul style="list-style-type: none"> <li>- Very robust when coupled with a PID system</li> <li>- Condenser with an integrated tank</li> </ul>

185    2.2. *Mathematic model for individual component*

187       Object-oriented Modelica modeling language is used for this study, enabling the description  
 188       of transient behaviors by models based on differential, algebraic and discrete equations. The  
 189       conservative equations of heat and mass transfer are firstly formulated for each component of the  
 190       CSP plant. These mathematic models are then coupled together to represent the whole CSP plant  
 191       with TCES integration. The resulting system of equations is solved at each time step by the DASSL  
 192       (Differential Algebraic System Solver) integration algorithm of Dymola solver [Dassault, 2011].  
 193       Special attention is given to the initialization of simulations for such a complex system with  
 194       algebraic loops.

196       Too complex model for each individual component is difficult to be solved and coupled  
 197       together while a simpler model ignoring too many details may not be enough precise. A compromise  
 198       has thus to be reached between the accuracy and the complexity. Moreover, a global view of the  
 199       CPS plant to be simulated is also indispensable so as to identify the limiting factors (i.e. components  
 200       having the highest thermal inertia) for reasonable simplifications on les impacting components.

202       For most of the components, existing models in the Dymola library or in the literature are  
 203       adopted, with some necessary modifications. For the key components of the plant (e.g., solar  
 204       receiver, TCES reactor), their models are developed in house based on the proposed design and sizing.  
 205       Table 1 recapitulates the mathematical model used for every component, together with the modeling  
 206       assumptions of each. Note that for turbomachines (turbines, pumps and compressor), constant  
 207       coefficients (isentropic and volumetric efficiencies) were used, without taking into account the  
 208       partial load operation curves. Other components were sized for a nominal case covering all the  
 209       partial load scenarios and/or integrating variable coefficients. Detailed descriptions of the in-house  
 210       developed models can be found in [Appendix A](#) of this paper.

213    2.3. *Operational mode*

215       Two clear sunny days (one in summer and another in winter) have been selected at eastern  
 216       Pyrenees (42.497N, 1.959E) where the Themis power plant is located [Larrouturou, 2014]have been  
 217       selected. The average Direct Normal Irradiance (DNI) curves [[PVGIS](#)] during the day are shown on  
 218       Fig. 43. For the summer day, the sunrise occurs at 5h07 and sunset at 18h37 whereas for the winter  
 219       day, the sunrise occurs at 7h52 and sunset at 15h52. The solar power  $P_{sol}$  ( $\text{W}\cdot\text{m}^{-2}$ ) based on the DNI  
 220       data is described by Eqs. (2-3) and will be used as inputs for each time step  $t$  (s) of the dynamic  
 221       simulations. Note that the short DNI variation due to clouds has not been taken into account.

223       For a typical summer day:

$$224 \quad P_{sol} = \begin{cases} \text{if } t(\text{s}) < 18420 ; & 0 \\ \text{if } 18420 < t(\text{s}) < 67020 ; & -4.985809 \times 10^{-24} \times t^6 + 1.264474 \times 10^{-18} \times t^5 - 1.309668 \times 10^{-13} \times t^4 \\ & + 7.086230 \times 10^{-9} \times t^3 - 2.116637 \times 10^{-4} \times t^2 + 3.328676 \times t - 2.10949 \times 10^4 \\ \text{if } t(\text{s}) > 67020 ; & 0 \end{cases} \quad (2)$$

225       For a typical winter day:

$$P_{sol} = \begin{cases} 0 & \text{if } t(s) < 28320; \\ -2.86954539 \times 10^{-15} \times t^4 + 4.97529124 \times 10^{-10} \times t^3 - 3.28214478 \times 10^{-5} \times t^2 + 9.75426171 \times 10^{-1} \times t - 1,05104646 \times 10^4 & \text{if } 28320 < t(s) < 56220; \\ 0 & \text{if } t(s) > 57096; \end{cases} \quad (3)$$

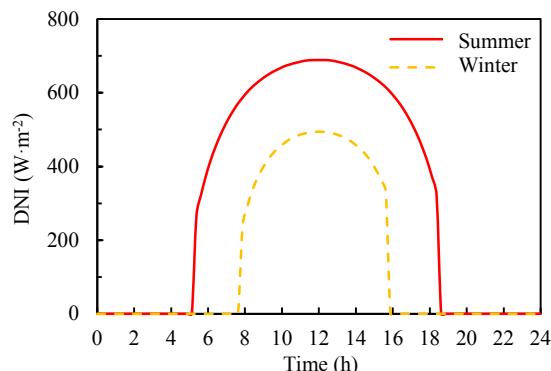

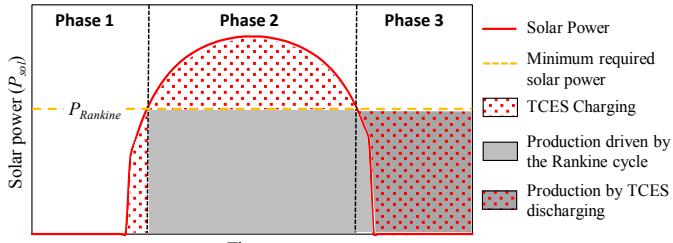

Figure 4.3. Average DNI for a typical summer and a winter day at eastern Pyrenees (42.497N, 1.959E) [PVGIS]

The basic production mode is firstly studied for three Int. concepts. The CSP plant is expected to produce electricity continuously at a constant power output over the longest possible period of time with the help of the TCES unit. Nevertheless, the continuous dynamic simulation of the CSP plant for a whole day is difficult at this stage, due to the complicated initialization and calculation instability. As a result, dynamic simulations have been performed for three separate phases of the operational mode, as shown in Fig. 2.4 and explained in detail as follows.

- ***Phase 1: plant starting.*** At the beginning of a day, the solar power ( $P_{sol}$ ) is not enough to run the Rankine power cycle at its nominal output ( $P_{Rankine}$ ). This amount of solar energy is used only for the TCES unit, i.e., to preheat the TCES reactor and to initiate the endothermic reaction when the equilibrium reaction temperature (500 °C) is reached.
- ***Phase 2: nominal production.*** Once the solar power meets the need to run the Rankine power cycle ( $P_{sol} > P_{Rankine}$ ), the nominal production of the CSP plant (phase 2) starts. The TCES system is charged simultaneously by excessive amount of solar energy for later use.
- ***Phase 3: prolonged production.*** At the end of the day when the decreased solar power becomes insufficient to run the Rankine power cycle at its nominal output ( $P_{sol} < P_{Rankine}$ ), the TCES reactor begins to discharge to compensate the deficiency. The production of CSP plant is prolonged owing to the stored solar energy in phases 1 and 2, until the TCES reactor temperature ( $T_R$ ) falls below a threshold value fixed by users (e.g., 485 °C). The cut-off temperature of the TCES reactor at the end of phase 3 is determined to equal to 485 °C, permitting still the overheated steam of the principal Rankine cycle at the outlet of the evaporator rising to 480 °C. The heat loss of the TCES reactor overnight is estimated to be negligible supposing that the TCES reactor is well-insulated.

259  
260 Figure 24. Schematic view of the operational mode divided into 3 phases for the basic continuous production  
261 mode

262  
263 At the end of each phase, all the system's variables (e.g., reactor temperature, ~~receptor~~<sub>solar</sub>  
264 ~~receiver~~ temperature, pressure in all points, chemical reaction progress) are recorded and transferred  
265 to initiate the next phase. Moreover, phase 2 is delayed from the end of phase 1 because discretized  
266 components used in the Rankine cycle are unstable to simulate at zero flowrate. Other simulations  
267 of the Rankine cycle and more precisely of the evaporator showed that the Rankine cycle needs 15  
268 minute to reach its nominal operation point.

269  
270  
271 *2.4. Control strategy*

272  
273 The proper operation of the CSP plant with TCES integration requires an adapted control  
274 strategy to perform multiple controls of the installation. The widely-used PI or PID controllers have  
275 been used owing to their robustness and high controlling efficiency. To determine the PID  
276 parameters, the manual setup was used whenever possible for simple systems. Otherwise, the  
277 Ziegler-Nichols reaction curve method was adopted [Das, 2014]. The controllers used in this study  
278 are recapitulated in [Table B1 of Appendix B2](#).

279  
280 [Table 2. List of all PID controllers](#)

Phase	Target	Controlled element	Controller type	Varied parameter
1, 2	HTF's temperature at the outlet of the solar receiver	Compressor rotation speed	PI	Variation of the HTF flowrate
2	Vapor temperature at the outlet of the evaporator	Three way valve opening/closing	PI	Variation of the HTF flowrate passing through the evaporator
3	Vapor temperature at the outlet of the evaporator	Compressor rotation speed	PI	Variation of the HTF flowrate passing through the evaporator
2, 3	Pressure at the inlet of the turbine (Rankine cycle)	Turbine's partial arc variation	PI	Variation of the fluid pressure drop in the turbine
1, 2	Pressure of the hot fluid in the condenser	Flow-rate of cooling fluid	PI	Variation of the cooling fluid flow-rate passing through the condenser
3	Pressure of the steam entering into the TCES	Withdrawal valve for the extraction from the turbine	PID	Variation of the withdrawal flow-rate between high pressure and low pressure

284 *2.5. Sizing and simulation parameters*

The solar field (heliostats) has been sized so that the TCES reactor can be almost completely charged ( $X=0.05$ ) at the end the charging stage (phase 2) for a summer day. Note that the cosine loss was not considered during the sizing, which may results in an underestimation of the required solar field areas [Peng, 2013]. The solar field surface areas for different TCES integration concepts are listed in Table 23. Details for the modeling of the solar receiver are provided in Appendix A2 of this paper.

Table 23. Sizing of the solar field for different TCES integration concepts

	Thermal Int.	Mass Int.	Turbine Int.
Solar field area (m <sup>2</sup> )	1 033 000	1 065 500	908 000

~~The cut off temperature of the TCES reactor at the end of phase 3 is determined to equal to 485 °C, permitting still the overheated steam of the principal Rankine cycle at the outlet of the evaporator rising to 480 °C. The heat loss of the TCES reactor overnight is estimated to be negligible supposing that the TCES reactor is well insulated.~~

The nomenclature, the Pparameter values and variables fixed by the user and controlled by the PID controllers for the dynamic simulation can be found in Tables B2-B5 of Appendix B4-7. Note that the power parasitic consumption is taken into account in the TCES reactor (stoichiometric reaction coefficient) and in the pumps, the turbines and the compressor (isentropic and volumetric efficiency). For other components, no power parasitic consumption is considered.

### 324 3. Results and discussion for the basic production scenario

325

326 This section shows main results of the dynamic simulation for summer and winter days.  
 327 Recall that the solar field and relevant components have been sized to offer an optimal operation  
 328 for a typical summer day and for the basic continuous production scenario.

329

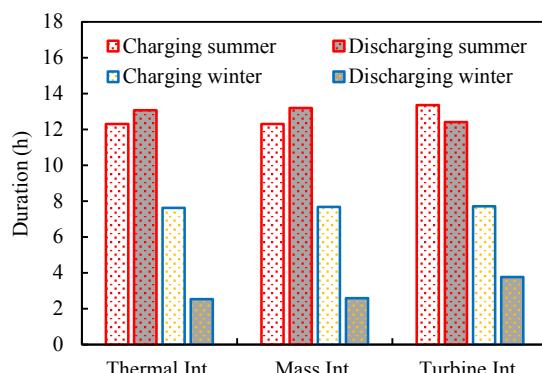

330

#### 331 3.1. Charging/discharging duration

332

333 From Fig. 3.5 one may observe that there is a slight difference on the charging/discharging  
 334 durations for different Int. concepts. Indeed, due to their conceptions, all the systems do not need  
 335 the same minimal amount of energy to operate. For example, the Turbine Int. concept would benefit  
 336 an earlier start and delayed stop, thereby rendering a relatively longer charging and a shorter  
 337 discharging in summer. In winter, these durations are significantly lower than those of summer for  
 338 all the Int. concepts studied. The CSP plant does not have the necessary solar power to decompose  
 339 all the TCES materials: the TCES reactor is largely oversized for a typical "winter" day.

340

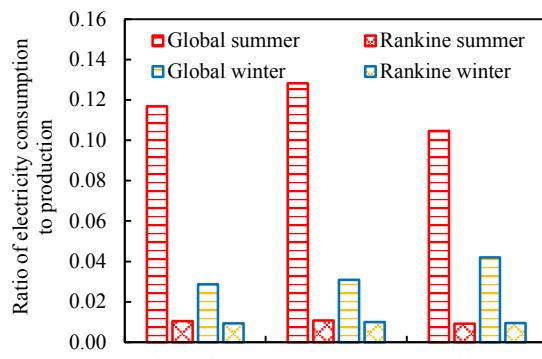

341

342

343  
344  
345 3.2. Electricity consumption/production  
346  
347

In order to make an easier comparison between the three integration concepts, the ratios of  
the electricity consumption (whole plant or Rankine cycle) to the electricity production ~~have~~  
~~been~~are represented on Fig. 46.

351 |

376 |  
377 |

Figure 46. Ratio of electricity consumption to production for the CSP plant with different TCES integration concepts ( $\text{MW.h}_{\text{el consumed}}/\text{MW.h}_{\text{el produced}}$ )

The electricity energy is mainly used to run the compressor for the HTF (pressurized air) in the solar circuit and the pumps in the Rankine cycle. In summer, the Rankine cycle electricity consumption is just about one tens of the overall electricity consumption. And in winter, the proportion is one third. It can be noticed from Fig. 4-6 that the electricity consumption for the Rankine cycle is approximately the same for all the integration concepts (about 0.01  $\text{MW.h}_{\text{consumed}}/\text{MW.h}_{\text{produced}}$  for both summer and winter). This is because the electricity consumption for running the pumps mainly depends on the mass flow-rate of the Rankine cycle's HTF, which is almost identical for all the integration concepts because of the same nominal production power of 100  $\text{MW}_{\text{el}}$ .

The global electricity consumption of the CSP plant is about 12% of the total electricity production for a typical summer day whereas for a typical winter day, the proportion is about 3%. No big difference between the three Int. concepts ~~has been is~~ observed. Meanwhile, the noticeable difference in global consumption between summer and winter is mainly due to the different mass flow-rate of HTF (pressurized air) in the solar circuit. Higher amount of solar energy available in summer needs to be transported by the HTF, resulting in higher electricity consumption in the air compressor.

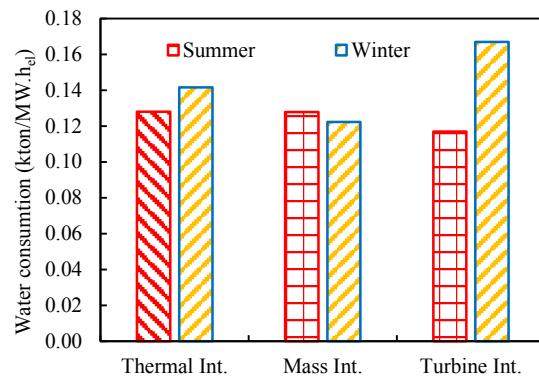

Several methods may be employed to decrease the electricity consumption of the compressor (thus the global electricity consumption). A simple way is to raise the upper temperature limit of the HTF (700 °C in the current study) so as to reduce the required HTF mass flow-rate. However, the equipment used for the solar circuit should resist to higher temperature in this case. Another way is to use a liquid HTF having a higher heat capacity (e.g., molten salts, synthetic oils) instead

378 of the pressurized air. But it will bring new problems such as the solidification of molten salts and  
 379 the higher environmental impacts [Batuecas, 2017].

### 382 3.3. Water consumption

384 The water consumption refers to the quantity of cooling water for the condensers of the CSP  
 385 plant, one for the Rankine cycle and another for the TCES unit. Note that the cooling water inlet  
 386 temperature is 15 °C and the outlet temperature is fixed at 30 °C (maximum allowable temperature  
 387 in France) [Khalanski, 1996; MTES, 1998]. Figure 5-7 shows the water consumption (kton) per  
 388 MW.h<sub>el</sub> produced for different Int. concepts of the CSP plant.

390 For a typical summer day, the Turbine Int. concept has the lowest water consumption (0.12  
 391 kton/MW.h<sub>el</sub>) because of its highest turbine bleeding at the nominal power that decreases the water  
 392 consumption for the condenser of the Rankine cycle. However, for a typical winter day, its water  
 393 consumption is the highest (0.17 kton/MW.h<sub>el</sub>) compared to the Thermal Int concept (0.14  
 394 kton/MW.h<sub>el</sub>) or the Mass Int. concept (0.12 kton/MW.h<sub>el</sub>). In winter, the charge-charging of the  
 395 TCES reactor is more important for the Turbine Int. concept, which induces a higher water  
 396 consumption. CSP plants are usually installed in desert/remote areas close to the equator (e.g., USA,  
 397 Morocco, Spain, MENA [Pelay, 2017a; b]) with summer climate in principle. The Turbine Int.  
 398 concept seems to be more beneficial regarding its lower water consumption during summer.

400  
 401 Figure 5-7. Water consumption (kton/MW.h<sub>el</sub>) of the CSP plant with different TCES integration  
 402 concepts  
 403  
 404

### 405 3.4. Energy efficiency

407 The Rankine efficiency ( $\eta_{Rankine}$ ) is defined as the efficiency of the Rankine cycle without  
 408 considering the solar circuit whereas the global efficiency ( $\eta_{Global}$ ) represents the efficiency of the  
 409 whole CSP plant. They are calculated following the Eqs. (4) and (5).

$$\eta_{Rankine} = \frac{(W_{T,C} - W_{P,C}) \cdot H_C + (W_{T,D} - W_{P,D}) \cdot H_D}{(Q_{SG} + Q_R) \cdot H_C} \quad (4)$$

$$\eta_{Global} = \frac{(W_{T,C} - W_{P,C} - W_{CP,C}).H_C + (W_{T,D} - W_{P,D} - W_{CP,D}).H_D}{(Q_{SG} + Q_R).H_C} \quad (5)$$

410 with:  $W_T$ , the energy produced by the turbines (W)  
 411  $W_P$ , the energy consumed by the pumps (W)  
 412  $Q_{SG}$ , the energy consumed by the Rankine cycle's steam generator (W)  
 413  $Q_R$ , the energy consumed by the thermochemical reactor (W)  
 414  $W_{CP}$ , the energy consumed by the compressor (W)  
 415  $H$ , the duration (h)  
 416 The indices  $C$  and  $D$  indicate the charging and the discharging stage, respectively.  
 417

418 Table 3-8 lists the simulated values of global and Rankine energy efficiencies for different  
 419 Int. concepts during typical summer and winter days. It can be easily observed that the Turbine  
 420 Int. concept has the highest global energy efficiency: 31.39% for summer and 31.96% for winter,  
 421 respectively. The option of using a second turbine to valorize the waste heat of high temperature  
 422 ~~vapor steam~~ from the TCES reactor makes it attractive. Despite that the solar field is designed for  
 423 summer operation, the winter's global efficiency is higher than that of summer for all the Int.  
 424 concepts. In fact, the heat storage in the TCES reactor has two parts: thermochemical reaction heat  
 425 and the sensible heat of the reactive salts and the reactor body. The TES by thermochemical  
 426 reaction is generally less efficient than the sensible storage due to the heat loss of the superheated  
 427 ~~vapor steam~~ extracted from the TCES reactor during its condensation. For a typical winter day, the  
 428 TCES reactor is only partially charged: approximately 20% of the  $\text{Ca(OH)}_2$  has been decomposed  
 429 whereas it is about 80% for summer. This makes the contribution of the "sensible part" more  
 430 important for the total TES, leading to the higher global energy efficiency of the CSP plant. Note  
 431 that the reference case (without TES) has a significantly lower global energy efficiency of 21.50%.  
 432 Indeed, an important amount of solar radiation received by the central solar receiver cannot be  
 433 converted into heat and is thus lost.

434  
 435 Table 38. Simulation results on energy efficiency of the CSP plant for typical summer and winter days (basic  
 436 production mode)  
 437

	Reference case	Thermal Int.		Mass Int.		Turbine Int.	
		Summer	Winter	Summer	Winter	Summer	Winter
Global efficiency (%)	21.50	28.15	30.83	27.81	30.80	31.39	31.96
Rankine efficiency (%)	21.51	31.54	31.45	31.55	31.47	34.74	33.05
Rankine efficiency (%) static study [Pelay, 2019]	42.6		30.80		30.00		33.88

438  
 439  
 440 Generally speaking, the Rankine efficiency is slightly higher than the global efficiency by  
 441 neglecting the losses in the solar circuit. The values of Rankine efficiency obtained by the dynamic  
 442 study are close to those obtained in the static study [Pelay, 2019] for all the three Int. concepts (less  
 443 than 1% difference). However, the Rankine efficiency of the reference case has halved from 42.6%  
 444 to 21.51%. This is because during the static study, the amount of solar energy was considered as  
 445 constant all along the day. While in this dynamic study, it is varied all the time. This variability  
 446 induces a large amount of lost energy.

447

448

449 **4. Peak production mode**

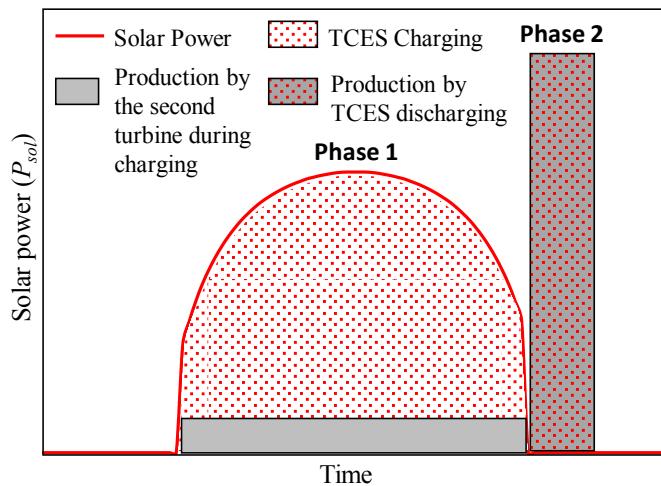

450

451 In this section, the dynamic simulation results for a peak production mode are reported.  
 452 Contrary to the basic continuous production scenario, the peak production mode aims at a massive  
 453 electricity production within one or several short periods of time when the electricity selling price is  
 454 the highest on the spot market [Tapachès, 2019]. It is thus interesting to compare the same TCES  
 455 Int. concept for two different modes of production. The Turbine Int. concept has been selected for  
 456 this purpose because it enables the waste heat recovery of overheated vapors via the second turbine  
 457 when the principal Rankine cycle is not working.

458

459 The operation mode is shown in Fig. 68. During phase 1, the Rankine cycle is at the stop  
 460 state without electricity production. The TCES reactor is charged and a part of the waste heat of  
 461 the superheated vapor-steam is valorized as electricity production via the second turbine in the  
 462 TCES circuit. During phase 2 (peak hour but insufficient sunshine), the stored heat will be all  
 463 discharged to run the Rankine cycle at about 1000 MW<sub>el</sub> (10 times of the nominal power), in order  
 464 to realize a peak power production within about 1 hour.

465

466

467

Figure 68. Schematic view of the operational mode for the peak production mode

468

469

470 Table 49 summarizes all the mains simulation results for a typical summer day under peak  
 471 and basic production modes. The charging duration of 12.7 hours corresponds to the total sunshine  
 472 duration (Fig. 48). The discharging duration (1.1 hour) is determined by the size of the TCES reactor  
 473 which is the same as that for the basic production mode. The second turbine of the TCES circuit  
 474 produces 550 MW.h<sub>el</sub> during the charging (Phase 1) while the Rankine cycle generates 1002 MW.h<sub>el</sub>  
 475 during the peak hour.

476

477

Table 49. Dynamic simulations results of Turbine Int. concept for a typical summer day in basic and peak production modes

478

479

Basic mode	Peak mode
------------	-----------

<b>Efficiency</b>		
Global efficiency (%)	28.15	17.89
Rankine efficiency (%)	31.54	27.96
<b>Storage</b>		
Charge duration (h)	12.3	12.7
Discharge duration (h)	13.06	1.1
<b>Energy produced/ consumed</b>		
Global energy produced (MW.h)	2601	1552
Global energy consumed (MW.h)	304	567
Rankine energy consumed (MW.h)	27	12
<b>Water consumption</b>		
Global water consumption (kton)	333	219

480

481

482        The Rankine cycle electricity consumption (12 MW.h<sub>el</sub>) only represents a small proportion  
 483 (2%) of the high global electricity consumption (567 MW.h<sub>el</sub>). The latter (0.37 MW.h<sub>el</sub>,  
 484 consumed/MW.h<sub>el</sub>, produced) is ~~nearly~~ four times higher than that of the basic production mode (0.09  
 485 MW.h<sub>el</sub>, consumed/MW.h<sub>el</sub>, produced). This is because the mass flow-rate of HTF has increased by a factor  
 486 of 10 (16000 kg·s<sup>-1</sup> instead of 1500 kg·s<sup>-1</sup>), resulting in much higher pressure loss in the central solar  
 487 receiver thus higher electricity consumption of the compressor. The water consumption is also more  
 488 important for the peak production mode (0.14 kton/MW.h<sub>el</sub>, produced) compared to that for the basic  
 489 production mode (0.12 kton/MW.h<sub>el</sub>, produced).

490

491        The Rankine and global energy efficiency is respectively 17.89% and 27.96%, both lower  
 492 than those for the basic production mode. Regarding the energy efficiency and environmental  
 493 impacts, the peak production mode seems less interesting than the basic mode. A techno-economic  
 494 study considering the variation of the selling electricity price on the spot market is necessary to  
 495 better evaluate its potential.

496

497

## 498        **5. Conclusion and prospects**

499

500        In this study, the dynamic simulation of a CSP plant with TCES system integration have  
 501 been performed. The Dymola environment has been used with component models existing in the  
 502 library or developed in-house. Both the basic continuous production mode and the peak production  
 503 mode have been investigated. Based on the results obtained, main conclusions can be summarized  
 504 as follows.

505

- 506        • TES integration is needed to increase the output of a CSP plant. Among the three TCES Int.  
       507 concepts proposed, the Turbine Int. concept has the best global efficiency (31.39% for  
       508 summer; 31.96% for winter).
- 509        • The TCES unit and solar field sized for a typical summer day will be largely oversized when  
       510 used for a typical winter day.

512

- The global electricity consumption of the CSP plant with TCES integration is about 12% of the total electricity production for a typical summer day and about 3% for a typical winter day.
- The water consumption of the CSP plant with TCES integration is about 0.12 kton/MW.h<sub>el</sub> for a typical summer day. For a typical winter day, the water consumption of the Turbine Int. concept is the highest (0.17 kton/MW.h<sub>el</sub>) compared to the Thermal Int concept (0.14 kton/MW.h<sub>el</sub>) or the Mass Int. concept (0.12 kton/MW.h<sub>el</sub>).
- The peak production mode is achievable by using the Turbine Int. concept. An increased nominal power by a factor of 10 could be reached by discharging the stored heat within one hour. However, a lower global efficiency (17.89%) is rendered due to the higher electricity consumption of the air compressor in the solar circuit. ~~It will then be interesting to carry out a techno-economic study for different integrations and modes of production~~

One limitation of the current study is that the simulations are based on two perfect summer and winter days while the effect of cloud passages has not been considered yet. Nevertheless, the simulations showed that the large thermal inertia of the TCES unit, owing to the great quantity of stainless steel ( $\sim 1.2 \times 10^7$  kg) and reactive salts ( $\sim 1.1 \times 10^7$  kg) involved, can allow a quick charging/discharging switch and maintain a constant output of the Rankine power cycle. A future work using real DNI curves surveyed for some typical cloudy days will provide more details on influence of the short DNI variation.

Another simplification made is that the DNI value has not been corrected with the cosine loss, which could have a non-negligible impact on the simulation results: about 5% in summer and 30% in winter based on the estimation of Peng et al., [2013]. Taking into account the cosine loss would increase the size of solar field (designed for a perfect summer day) and thereby decrease the electricity production of the winter day. This matter of concern should be addressed in the future studies.

It should be noted that this study has focused on the energy modeling and dynamic simulation of the CSP plant, under the basic and peak operation modes. The improvement of the models used for the simulations and their parameter remains an important objective. A real power parasitic consumption of the turbomachines (turbines, pumps and compressor) would be obtained with variables isentropic efficiencies. Futures experiments will also enable the use of a real stoichiometric reaction coefficient for the thermochemical reactor. Furthermore, a techno-economic assessment is also suggested in the future study to further understand the usability and the cost-effectiveness of the proposed TCES integration concepts. Recent advances on the techno-economic issue can be found in Refs [Salas, 2018; Tapachès; 2019].

563

564

565        **Nomenclature**

566

567        *Latin letters*

568         $H$             charging or discharging time, h

569         $P$             power, W

570         $Q$             heat exchange rate, W

571         $W$             work exchange rate, W

572         $T$             temperature, K

573         $t$             time, s

574         $X$             reaction progress, (-)

575

576        *Greek symbols*

577         $\eta$             energy efficiency

578         $\Delta h_R$       specific reaction heat, kJ.kg<sup>-1</sup>

579

580        *Subscripts*

581         $C$             charging stage

582         $CP$           compressor

583         $D$             discharging stage

584         $el$             electricity

585         $Global$       Whole system

586         $P$             pump

587         $R$             reactor

588         $Rankine$      Rankine circuit

589         $SG$           steam generator

590         $sol$           solar

591         $T$             turbine

592

838 **Appendix A. Detailed description of the in-house developed models**

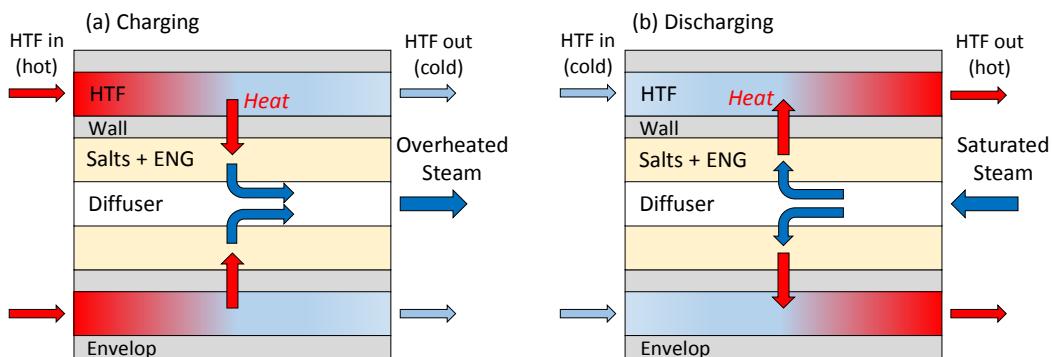

839

840 *A1. Modeling of the TCES reactor*

841

842 The TCES reactor is the most crucial element of the whole system, having the largest  
 843 thermal inertia. It is designed based on the concept of a plate heat exchanger-reactor as shown in  
 844 Fig. A1. There are four main parts that constitute the TCES reactor: (i) the mixture of salts  
 845 ( $\text{Ca(OH)}_2/\text{CaO}$ ) and the expanded natural graphite (ENG) as the reactive/storage material; (ii)  
 846 the HTF channels; (3) the metal wall separating the reactive salts and the HTF; and (iv) the dead  
 847 volume comprising the composite porosities, the diffuser and the envelop. Figure A2 shows the  
 848 schematic of the TCES reactor created in the Dymola environment. The modeling of heat and mass  
 849 transfers in this TCES reactor is presented as follows.

850

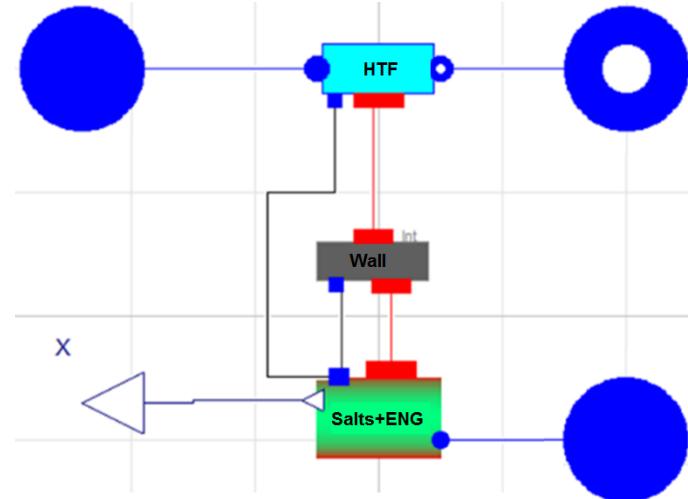

851

852 Figure A1. Schematic view of the plat-type TCES reactor. (a) charging; (b) discharging

853

854

855

856 Figure A2. Schematic diagram of the TCES reactor created in the Dymola environment

857

858

- 859 • The reactive bloc

860       The reactive bloc is composed of the composite (salts and ENG) and the dead volume. Heat  
 861 transfer occurs between the composite, the dead volume and the wall whereas mass transfer occurs  
 862 between the composite and the dead volume. A nodal model was used for the modeling of the  
 863 reactive bloc. The heat conduction between the reactive salts and the dead volume is neglected by  
 864 assuming the identical temperature. The heat absorbed or released by the reactive salts is transferred  
 865 to the wall by heat conduction and convection. During the synthesis, a certain amount of heat  
 866 (named as  $Q_{sens}$ ) released by the reaction is used to raise the steam temperature entering in the  
 867 TCES reactor up to the equilibrium temperature. The thermal balance of reactive bloc may be  
 868 written as Eqs. (A1) and (A2).

$$m_{comp} \cdot C_{p,comp} \cdot \frac{dT_{comp}}{dt} = H_{W/comp} \cdot S_{W/comp} \cdot (T_W - T_{comp}) - \Delta h_{R,comp} \cdot \frac{dn_{H_2O}}{dt} + Q_{sens} \quad (\text{A1})$$

$$Q_{sens} = \dot{m}_{H_2O} \cdot (h_{R_{ext}} - h_{R_{int}}) \quad (\text{A2})$$

869       with      $m_{comp}$ , the composite mass (kg)  
 870               $C_{p,comp}$ , the specific heat of the composite (J.kg<sup>-1</sup>.K<sup>-1</sup>)  
 871               $T_{comp}$ , the temperature of the composite (K)  
 872               $T_W$ , the wall temperature (K)  
 873               $H_{W/comp}$ , the heat transfer coefficient between the wall and the composite (W.m<sup>-2</sup>.K<sup>-1</sup>)  
 874               $S_{W/comp}$ , the contact surface area between the wall and the composite (m<sup>2</sup>)  
 875               $\Delta h_{R,comp}$ , the molar reaction heat of the Ca(OH)<sub>2</sub>/CaO couple (104 kJ·mol<sup>-1</sup>)  
 876               $n_{H_2O}$ , the mole number of H<sub>2</sub>O reacted with the CaO salt (mol)  
 877               $\dot{m}_{H_2O}$ , the vapor mass flow-rate (kg.s<sup>-1</sup>)  
 878               $h_{R_{int}}$ ,  $h_{R_{ext}}$  the enthalpy of the vapor at the interior and outside of the TCES reactor,  
 879              respectively (J.kg<sup>-1</sup>)  
 880

881       The vapor mass flow-rate ( $\dot{m}_{H_2O}$ ) entering/exiting the TCES reactor is directly dependent  
 882 on the reaction rate, calculated by Eqs. (A3) and (A4).

$$\dot{m}_{H_2O} = M_{H_2O} \cdot \frac{dn_{H_2O}}{dt} \quad (\text{A3})$$

$$\frac{dn_{H_2O}}{dt} = -\gamma_R \cdot n_{salt} \cdot \frac{dX}{dt} \quad (\text{A4})$$

883       with      $M_{H_2O}$ , the H<sub>2</sub>O molar mass (kg.mol<sup>-1</sup>)  
 884               $\gamma_R$ , the global reactor efficiency (-)  
 885               $n_{salt}$ , the salt molar quantity (mol)  
 886               $X$ , the molar reaction progress  
 887

888       The reaction progress is calculated by the kinetic model proposed by Mazet and Amouroux  
 889 [Mazet, 1991] for the decomposition (Eq. A5) and for the synthesis (Eq. A6), respectively.

$$\frac{dX}{dt} = K_{cin} \cdot X \cdot \frac{p_{op} - p_{eq}}{P_{op}} \quad (\text{A5})$$

$$\frac{dX}{dt} = K_{cin} \cdot (1 - X) \cdot \frac{p_{op} - p_{eq}}{p_{op}} \quad (\text{A6})$$

890 with  $K_{cin}$ , the reaction kinetic coefficient ( $\text{s}^{-1}$ )  
 891  $p_{op}$ , the operational pressure (Pa)  
 892  $p_{eq}$ , the equilibrium pressure (Pa)

893  
 894 The reaction kinetic coefficient ( $K_{cin}$ ) is chosen to be equal to  $5 \times 10^{-3} \text{ s}^{-1}$  at a first time,  
 895 subjected to possible modifications during the simulations [Mazet, 1991]. The equilibrium pressure  
 896  $p_{eq}$  is determined with the Clapeyron equation represented by Eq. (A7) and simplified as Eq. (A8).

$$\ln\left(\frac{p_{eq}}{p_{ref}}\right) = \frac{\Delta h_{R_{comp}}}{R} \left( \frac{1}{T_{ref}} - \frac{1}{T_{eq}} \right) \quad (\text{A7})$$

$$p_{eq} = p_{ref} \cdot e^{\frac{\Delta H_{R_{comp}}}{R} \left( \frac{1}{T_{ref}} - \frac{1}{T_{eq}} \right)} \quad (\text{A8})$$

897 With  $p_{ref}$ , the reference pressure (1 bar)  
 898  $R$ , the ideal gas constant ( $8.314 \text{ J} \cdot \text{mol}^{-1} \cdot \text{K}^{-1}$ )  
 899  $T_{ref}$ , the reference temperature (298.15 K)  
 900  $T_{eq}$ , the equilibrium temperature (773.15 K)

901  
 902 The term  $\frac{p_{op} - p_{eq}}{p_{op}}$  represents the difference between the operational and the equilibrium  
 903 conditions as the driving force for the reaction.

904  
 905 The physical properties of the composite depend on the temperature, the percentage of ENG  
 906 and the reaction rate. Three parameters were used to settle simple equations to calculate various  
 907 physical properties of the composite:

- 908 -  $m_{salt(0)}$  the anhydrous salt mass (CaO) at the initial state (kg);  
 909 -  $\tilde{\rho}_{ENG}$  the ENG apparent density ( $\text{kg} \cdot \text{m}^{-3}$ );  
 910 -  $\tau_{salt}$  the mass ratio of reactive salt in the composite, defined as Eq. (A9).

$$\tau_{salt} = \frac{m_{salt(0)}}{m_{comp(0)}} \quad (\text{A9})$$

911  $m_{comp}$  is the mass of the composite composed of reactive salts and the ENG:

$$m_{comp} = m_{salt} + m_{ENG} \quad (\text{A10})$$

$$m_{ENG} = (1 - \tau_{salt}) \times m_{comp(0)} \quad (\text{A11})$$

912  
 913 The mass of reactive salts in the TCES reactor depends on the reaction progress, shown in  
 914 Eq. (A12):

$$m_{salt} = n_{salt(0)} \cdot (X \cdot M_{Ca(OH)_2} + (1 - X) \cdot M_{CaO}) \quad (\text{A12})$$

915 with  $m_{salt}$ , the salt mass (kg)

916         $n_{salt}$ , the salt molar quantity (mol)

917         $X$ , the molar progress

918         $M_{Ca(OH)_2}$ , the Ca(OH)<sub>2</sub> molar mass (kg.mol<sup>-1</sup>)

919         $M_{CaO}$ , the CaO molar mass (kg.mol<sup>-1</sup>)

921        The specific heat of the composite varies according to its temperature and its composition,  
922        calculated by Eq. (A13):

$$Cp_{comp} = \tau_{salt} \cdot ((1 - X) \cdot Cp_{CaO} + X \cdot Cp_{Ca(OH)_2}) + (1 - \tau_{salt}) \cdot Cp_{ENG} \quad (\text{A13})$$

923        where  $Cp_{CaO}$  and  $Cp_{Ca(OH)_2}$  are determined by Eq. (A14) and Eq. (A15), respectively  
924        [Martienssen, 2005].

$$Cp_{CaO} = 0.16495 \times T + 798.647 \quad (\text{A14})$$

$$Cp_{Ca(OH)_2} = 0.38612 \times T + 1217.29416 \quad (\text{A15})$$

926        The volume of the composite used for the sizing of the TCES reactor is determined by Eq.  
927        (A16):

$$V_{comp} = \frac{(1 - \tau_{salt}) \cdot m_{salt(0)}}{\tau_{sel} \cdot \tilde{\rho}_{ENG}} \quad (\text{A16})$$

929        The porosity  $\varepsilon$  is the ratio of dead volume and composite volume, calculated by Eq. (A17):

$$\varepsilon = 1 - \frac{\tilde{\rho}_{ENG}}{\rho_{ENG}} - \tilde{\rho}_{ENG} \cdot \frac{\tau_{salt}}{1 - \tau_{salt}} \cdot \frac{X \cdot Vm_{salt(X=1)} + (1 - X) \cdot Vm_{salt(X=0)}}{M_{salt(0)}} \quad (\text{A17})$$

931        with:  $Vm_{sel(X=1)} = Vm_{Ca(OH)_2}$

932         $Vm_{sel(X=1)} = Vm_{CaO}$

933         $M_{sel(0)} = M_{CaO}$

934         $\rho_{ENG}$ , the GNE density (kg.m<sup>-3</sup>)

935         $\tilde{\rho}_{ENG}$ , the GNE apparent density (kg.m<sup>-3</sup>)

936         $V_m$ , the molar volume (m<sup>3</sup>.mol<sup>-1</sup>)

- 937        • The dead volume (DV)

940        The dead volume corresponds to all the unoccupied volume in the TCES reactor, including  
941        void volume of the composite material and the gas diffuser, calculated by Eq. (A18):

$$V_{DV} = \varepsilon \cdot V_{comp} + V_{diffuser} \quad (\text{A18})$$

942

943        The volume of diffuser depends on the reactor geometry. For a plate-type heat exchanger,  
 944 it is calculated according to the total surface area of the plates ( $S_W$ ) and the fixed diffuser thickness  
 945 ( $th_{diffuser}$ ), by Eq. (A19):

$$V_{diffuser} = \frac{S_W}{2} \cdot th_{diffuser} \quad (\text{A19})$$

946

947        The vapor flowrate variation  $d\dot{m}$  is the difference between the entering flowrate ( $\dot{m}_{in}$ ) and  
 948 the outgoing flowrate ( $\dot{m}_{out}$ ). Mass conservation equation in the DV can be written as.

$$d\dot{m} = \dot{m}_{in} - \dot{m}_{out} \quad (\text{A20})$$

$$d\dot{m} = V_{DV} \cdot \left( \frac{dh}{dt} \cdot \frac{d\rho}{dh} \Big|_p + \frac{dP}{dt} \cdot \frac{d\rho}{dp} \Big|_h \right) \quad (\text{A21})$$

949        With     $\dot{m}$ , the mass flow-rate ( $\text{kg.s}^{-1}$ )  
 950               $h$ , the mass enthalpy ( $\text{kJ.kg}^{-1}$ )  
 951               $\rho$ , the density ( $\text{kg.m}^{-3}$ )

952

953        The energy conservation in the DV is calculated with Eq. (A22):

$$\begin{aligned} & \left( \frac{V_{DV} \cdot p_{op} \cdot M_{H_2O}}{R \cdot T_{comp}} \right) \cdot \left( \left( \frac{1}{p_{op}} \cdot \frac{dp}{dt} + \frac{1}{T_{comp}} \right) \cdot \left( Cp_{H_2O} \cdot (T_{comp} - T_{ref}) - \frac{R \cdot T_{comp}}{M_{H_2O}} \right) \right. \\ & \quad \left. + \frac{dT_{comp}}{dt} \cdot \left( Cp_{H_2O} - \frac{R}{M_{H_2O}} \right) \right) = \frac{d\dot{m}}{dt} \cdot h_{comp} \end{aligned} \quad (\text{A22})$$

954        with,     $V_{DV}$ , the dead volume volume ( $\text{m}^3$ )  
 955               $T_{comp}$ , the composite temperature (K)  
 956               $p$ , the pressure (Pa)  
 957               $T_{comp}$ , the composite temperature (K)  
 958               $Cp_{H_2O}$ , the  $H_2O$  mass specific heat capacity ( $\text{J.kg}^{-1}.K^{-1}$ )

959

960

- 961        •    The wall

962

963        A nodal model was used for the wall, assuming uniform temperature and constant specific  
 964 heat. The thermal inertia of the model was however taken into account. The total exchange area  
 965 can be calculated with Eq. (A23):

$$S_W = \frac{V_{comp}}{th_{comp}} \quad (\text{A23})$$

966        The total wall mass ( $m_w$ ) can then be determined with Eq. (A24).

$$m_w = th_w \cdot S_w \cdot \rho_w \quad (\text{A24})$$

967 where  $th_w$  is the thickness of the wall fixed by the designer.  $\rho_w$  is the density of the wall  
 968 material.

969  
 970 The energy conservation is represented Eq. (A25)

$$971 \quad m_w \cdot Cp_w \cdot \frac{dT_w}{dt} = S_{ext} \cdot \varphi_{out} + S_{int} \cdot \varphi_{in} \quad (\text{A25})$$

971 with  $\varphi_e$ , the entering flux ( $\text{W.m}^{-2}$ )  
 972  $\varphi_o$ , the outgoing flux ( $\text{W.m}^{-2}$ )  
 973  $m_w$ , the wall mass (kg)  
 974  $Cp_w$ , the wall mass specific heat capacity ( $\text{J.kg}^{-1}\text{.K}^{-1}$ )  
 975  $T_w$ , the wall temperature (K)  
 976  $S_{ext}$ , the exterior surface ( $\text{m}^2$ )  
 977  $S_{int}$ , the interior surface ( $\text{m}^2$ )  
 978  
 979

980 • HTF

981  
 982 The HTF part permits the entering of HTF (pressurized air) from one side and leaving from  
 983 the other side to exchange the heat with the wall part during charging and discharge periods. Since  
 984 no phase change is occurred during the cooling/heating of the HTF, a “light non-discretized model”  
 985 was chosen for modeling the HTF part. The outlet temperature ( $T_{out}$ ) of the HTF is determined by  
 986 Eq. A26, using the NUT (Number of Unity of Transfer) method.

$$987 \quad T_{out} = T_{in} - (T_{in} - T_{out}) \cdot \left( 1 - e^{\left( -\frac{H_{HTF} \cdot S_{R/HTF}}{m_{HTF} \cdot Cp_{HTF}} \right)} \right) \quad (\text{A26})$$

988 with  $T_{out}$ , the outlet temperature (K)  
 989  $T_{in}$ , the inlet temperature (K)  
 990  $H_{HTF}$ , the HTF heat transfer coefficient ( $\text{W.m}^{-2}\text{.K}^{-1}$ )  
 991  $S_{R/HTF}$ , the exchange surface area between the HTF and the reactor ( $\text{m}^2$ )  
 992  $\dot{m}_{HTF}$ , the HTF mass flow-rate ( $\text{kg.s}^{-1}$ )  
 993  $Cp_{HTF}$ , the HTF mass specific heat capacity ( $\text{J.kg}^{-1}\text{.K}^{-1}$ )  
 994  
 995

$H_{HTF}$ , the convective heat transfer coefficient is calculated by using the plate heat exchanger  
 correlations [Vidil, 1990], shown in Eqs. (A27-A28):

$$996 \quad Nu = 0.212 \cdot Re^{0.638} \cdot Pr^{0.33} \quad (\text{A27})$$

$$997 \quad H = \frac{Nu \cdot \lambda}{L_c} \quad (\text{A28})$$

998 with  $Re$ , the Reynolds number  
 999  $Pr$ , the Prandlt number  
 1000  $Nu$ , the Nusselt number  
 1000  $H$ , the heat transfer coefficient ( $\text{W.m}^{-2}\text{.K}^{-1}$ )  
 1000  $L_c$ , the characteristic length (m)

1001            $\lambda$ , the thermal conductivity ( $\text{W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$ )

1002  
1003           The Reynold number  $Re$  and Prandt number  $Pr$  were calculated by Eq. (A29) and Eq. (A30),  
1004           respectively.

$$1005 \quad Re = \frac{u_{HTF} \cdot L_c}{\nu} \quad (\text{A29})$$

$$1006 \quad Pr = \frac{Cp_{HTF} \cdot \mu_{HTF}}{\lambda_{HTF}} \quad (\text{A30})$$

1007           with  $u_{HTF}$ , the HTF velocity ( $\text{m} \cdot \text{s}^{-1}$ )

1008            $\nu_{HTF}$  the HTF kinematic viscosity ( $\text{m}^2 \cdot \text{s}^{-1}$ )

1009            $\lambda_{HTF}$  the HTF thermal conductivity ( $\text{W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$ )

1010            $\mu_{HTF}$  the HTF dynamic viscosity ( $\text{J} \cdot \text{s} \cdot \text{m}^{-2}$ )

1011            $Cp_{HTF}$  the HTF specific heat ( $\text{J} \cdot \text{kg}^{-1} \cdot \text{K}^{-1}$ )

1012            $L_c$  the characteristic length of the HTF side plates (m)

1013           Pressure loss ( $\Delta p$ ) induced by the HTF are calculated with heat plate exchanger correlations

$$1014 \quad \Delta p = f \cdot \frac{L_p}{D_h} \cdot \rho \cdot \frac{u^2}{2} \quad (\text{A31})$$

1015           with  $f$ , the friction factor

1016            $L_p$ , the pipe length (m)

1017            $D_h$ , the hydraulic diameter (m)

1018            $\rho$ , the density ( $\text{kg} \cdot \text{m}^{-3}$ )

1019            $u$ , the fluid mean velocity ( $\text{m} \cdot \text{s}^{-1}$ )

1020           The friction factor  $f$  is a function of the  $Re$ , shown in Eq. (32) [Vidil, 1990]:

$$1021 \quad f = \left\{ \begin{array}{l} -3.0812 \cdot 10^{-6} \cdot Re^3 + 7.4857 \cdot 10^{-4} \cdot Re^2 - 6.798 \cdot 10^{-2} \cdot Re + 2.89; \text{ if } Re < 40 \\ 23.33 \cdot Re^{-0.809}; \text{ if } 40 \leq Re < 500 \\ 0.557 \cdot Re^{-0.211}; \text{ if } Re \geq 500 \end{array} \right\} \quad (\text{A32})$$

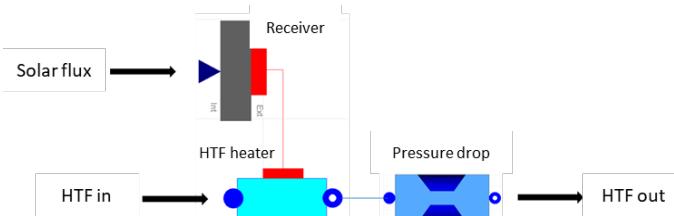

## 1022          *A2. Modeling of the solar receiver*

1023  
1024           The central solar receiver of the CSP plant absorbs and converts the sunlight into heat, and  
1025           transfers it to the HTF flowing through it. It was modeled as a volumetric receiver made of metallic  
1026           foam. Figure A3 shows the schematic view of the solar receiver model created in the Dymola  
1027           environment, composed of one receiver element absorbing the solar flux, one heater element  
1028           transmitting the solar heat to the HTF and another element representing the pressures drops. To  
1029           simplify the modeling, the following assumptions were made:

- 1030           - No thermal inertia;
- 1031           - No heat loss;
- 1032           - Gaseous entering fluid;
- 1033           - Uniform temperature in the volumetric solar receiver;

1034 - Constant convective heat transfer coefficient.

1035

1036  
1037 Figure A3. Schematic diagram of the volumetric solar receiver created in the Dymola environment

1038  
1039  
1040 The energy conservation in the solar receiver is described in Eq. (A33).

$$m_{receiver} \cdot C p_{receiver} \cdot \frac{dT_{receiver}}{dt} = \varphi_{sol} \cdot S_{sol} \cdot C + S_{receiver/HTF} \cdot H_{receiver/HTF} \cdot (T_{receiver} - T_{HTF}) \quad (\text{A33})$$

- 1041 with: -  $m_{receiver}$ , the mass of the solar receiver (kg)  
 1042 -  $C p_{receiver}$ , the specific heat of the solar receiver ( $\text{J} \cdot \text{kg}^{-1} \cdot \text{K}^{-1}$ )  
 1043 -  $T_{receiver}$ , the receiver temperature (K)  
 1044 -  $\varphi_{sol}$ , the solar flux ( $\text{W} \cdot \text{m}^{-2}$ )  
 1045 -  $S_{sol}$ , the receiver surface area ( $\text{m}^2$ )  
 1046 -  $C$ , the receiver concentration ratio  
 1047 -  $S_{receiver/HTF}$ , the receiver total exchange area between the receiver wall and the HTF ( $\text{m}^2$ )  
 1048 -  $H_{receiver/HTF}$ , the heat transfer coefficient ( $\text{W} \cdot \text{m}^{-2} \cdot \text{K}^{-1}$ )  
 1049 -  $T_{HTF}$ , the HTF mean temperature (K)

1050  
1051 Energy conservation for the HTF flow is written as Eq. (A34).

$$V_{HTF} \cdot \rho_{HTF} \cdot \frac{dh_{HTF}}{dt} + \dot{m}_{HTF} \cdot (h_{HTF_{out}} - h_{HTF_{in}}) = S \cdot h_{sw} \cdot (T_{wall} - T_{HTF}) \quad (\text{A34})$$

- 1052 with: -  $V_{HTF}$ , the volume of the HTF ( $\text{m}^3$ )  
 1053 -  $\rho_{HTF}$ , the density of the HTF ( $\text{kg} \cdot \text{m}^{-3}$ )  
 1054 -  $h_{HTF}$ , the average mass enthalpy ( $\text{kJ} \cdot \text{kg}^{-1}$ )  
 1055 -  $\dot{m}_{HTF}$ , the mass flow-rate of the HTF ( $\text{kg} \cdot \text{s}^{-1}$ )  
 1056 -  $h_{HTF_{out}}$ , the mass enthalpy of the HTF at the outlet ( $\text{kJ} \cdot \text{kg}^{-1}$ )  
 1057 -  $h_{HTF_{in}}$ , the mass enthalpy of the HTF at the inlet ( $\text{kJ} \cdot \text{kg}^{-1}$ )

1058  
1059 The heat transfer coefficient  $H$  is calculated by the Albanakis correlation [Albanakis, 2009].

$$Nu = \frac{H \cdot d_p}{\lambda} \quad (\text{A35})$$

$$Nu = 0.76 \cdot Re^{0.4} \cdot Pr^{0.37} \text{ for } Re < 40 \quad (\text{A36})$$

- 1060 with: -  $Nu$ , the Nusselt number  
 1061 -  $\lambda$ , the thermal conductivity of the metallic foam ( $\text{W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$ )  
 1062 -  $d_p$ , the average diameter of the pores (m)  
 1063 -  $Pr$ , the Prandtl number  
 1064 -  $Re$ , the Reynolds number calculated by Eq. (A37)

1065

$$Re = \frac{u_p \cdot L_c}{\nu} \quad (\text{A37})$$

1066 with -  $\nu$ , the kinematic viscosity ( $\text{m}^2 \cdot \text{s}^{-1}$ )  
1067 -  $u_p$ , the velocity in the pores ( $\text{m} \cdot \text{s}^{-1}$ )  
1068 -  $L_c$ , the characteristic length (m), calculated by Eq. (A38) [Lu, 2006].

$$L_c = (1 - e^{-(1-\varepsilon)0.04}) \cdot d_f \quad (\text{A38})$$

1069 with: -  $\varepsilon$ , the foam porosity ratio  
1070 -  $d_f$ , the fiber's diameter (m)

1071  
1072 The relation between  $d_f$ ,  $d_p$  and  $\varepsilon$  can be described by Eq. (A39) [Zhao, 2001].

$$\frac{d_f}{d_p} = 1.18 \cdot \sqrt{\frac{1-\varepsilon}{3 \cdot \pi}} \cdot \left( \frac{1}{1 - e^{-(1-\varepsilon)0.04}} \right) \quad (\text{A39})$$

1073 with  $d_p$ , the pore average diameter (m)

1074  
1075 The pressure drop  $\Delta P$  in the solar receiver was calculated by the Wu correlation [Wu, 2010],  
1076 shown in Eq. (A40).

$$\frac{\Delta P}{\Delta z} = \frac{1039 - 1002\varepsilon}{d_p^2} \cdot \mu_{HTF} \cdot u_p + \frac{0.5138 \cdot \varepsilon^{-5.739}}{d_p} \cdot \rho_{HTF} \cdot u_p^2 \quad (\text{A40})$$

1077 with -  $\Delta P$ , the pressure drop (Pa)  
1078 -  $\Delta z$ , the foam thickness (m)  
1079 -  $d_p$ , the pore mean diameter (m)  
1080 -  $\mu_{HTF}$ , the HTF dynamic viscosity ( $\text{m}^2 \cdot \text{s}^{-1}$ )  
1081 -  $u_p$ , the velocity in the pores ( $\text{m} \cdot \text{s}^{-1}$ )

1082  
1083  
1084 *A3. Modeling of the heat exchanger*

1085  
1086 The modeling of heat exchanger is based on a fixed pinch temperature: minimum  
1087 temperature difference between two fluids. Following assumptions were made.

- 1088 - Incompressible fluid  
1089 - No heat loss  
1090 - Fixed pinch temperature

1091  
1092 The indices *in*, *out*, *pinch*, *sat* indicate the inlet, the outlet, the pinch and the saturation  
1093 points; the indices *hot* and *cold* indicate the hot and the cold fluids.

1094  
1095 The energy conservation in the heat exchanger between the hot and the cold fluids can be  
1096 written in Eq. (A41).

$$h_{cold_{out}} = h_{cold_{in}} - \frac{\dot{m}_{hot}}{\dot{m}_{cold}} \cdot (h_{hot_{out}} - h_{hot_{in}}) \quad (\text{A41})$$

1097 with -  $h$ , the average mass enthalpy ( $\text{kJ} \cdot \text{kg}^{-1}$ )  
1098 -  $\dot{m}$ , the mass flow-rate ( $\text{kg} \cdot \text{s}^{-1}$ )

1099  
1100 The pinch temperature  $\Delta T_{pinch}$  between the hot and the cold fluids is calculated by:

$$\Delta T_{pinch} = T_{hot_{pinch}} - T_{cold_{pinch}} \quad (\text{A42})$$

1101 with: -  $T$ , the fluid temperature (K)

1102  
1103 The hot fluid mass enthalpy at pinch point ( $h_{hot_{pinch}}$ ) is calculated with Eq. (A43):

$$h_{hot_{pinch}} = h_{hot_{in}} - \frac{\dot{m}_{cold}}{\dot{m}_{hot}} \cdot (h_{cold_{out}} - h_{cold_{sat}}) \quad (\text{A43})$$

1104 with -  $h$ , the average mass enthalpy ( $\text{kJ} \cdot \text{kg}^{-1}$ )  
1105 -  $\dot{m}$ , the mass flow-rate ( $\text{kg} \cdot \text{s}^{-1}$ )

#### 1106 1107 1108 A4. Modeling of the evaporator

1109  
1110 The modeling of the simplified evaporator is based on a fixed-by-user outlet temperature of  
1111 the hot fluid. It allows a very robust operation and simplified pressure variations. The modeling  
1112 assumptions are as follow:

- 1113 - Incompressible fluid
- 1114 - No heat loss
- 1115 - Fixed hot fluid outlet temperature

1116  
1117 The indices *in*, *out* indicate the inlet, the outlet points; The indices *hot* and *cold* indicate the  
1118 hot and the cold fluids.

1119  
1120 The energy conservation in the evaporator between the Rankine fluid (Cold) and the HTF  
1121 (Hot) can be written as Eq. (A44):

$$h_{cold_{out}} = h_{cold_{in}} - \frac{\dot{m}_{hot}}{\dot{m}_{cold}} \cdot (h_{hot_{out}} - h_{hot_{in}}) \quad (\text{A44})$$

1122 with: -  $h$ , the fluid average mass enthalpy ( $\text{kJ} \cdot \text{kg}^{-1}$ )  
1123 -  $\dot{m}$ , the mass flow-rate ( $\text{kg} \cdot \text{s}^{-1}$ )

1124  
1125

1126 **Appendix B. Parameter values and variables fixed by the user for the dynamic simulation**

1127  
1128  
1129 **Table B1. List of all PID controllers**

Phase	Target	Controlled element	Controller type	Varied parameter
1, 2	HTF's temperature at the outlet of the solar receiver	Compressor rotation speed	Pi	Variation of the HTF flowrate
2	Vapor temperature at the outlet of the evaporator	Three-way valve opening/closing	Pi	Variation of the HTF flowrate passing through the evaporator
3	Vapor temperature at the outlet of the evaporator	Compressor rotation speed	Pi	Variation of the HTF flowrate passing through the evaporator
2, 3	Pressure at the inlet of the turbine (Rankine cycle)	Turbine's partial arc variation	Pi	Variation of the fluid pressure drop in the turbine
1, 2, 3	Pressure of the hot fluid in the condenser	Flow-rate of cooling fluid	Pi	Variation of the cooling fluid flow-rate passing through the condenser
3	Pressure of the steam entering into the TCES	Withdrawal valve for the extraction from the turbine	PID	Variation of the withdrawal flow-rate between high pressure and low pressure
2, 3	Tank's water level	Pump's rotation speed	Pi	Variation of the water flow-rate outgoing from the tank
2, 3	Fluid temperature at the outlet of the open feedwater heater	Withdrawal valve for the extraction from the turbine	Pi	Variation of the withdrawal flow-rate between high pressure and low pressure

Table B2. Parameter values for different components of the system

	Parameters	Thermal Int.	Mass Int.	Turbine Int.
<b>HTF</b>				
<b>Solar Receiver</b>	Type of fluid	Air	Air	Air
	Masse (kg)	+0000	+0000	+0000
	External surface area ( $m^2$ )	+503	+534	+396
	Internal surface area ( $m^2$ )	+8000	+8000	+8000
	Heat transfer coefficient ( $W \cdot K^{-1} \cdot m^{-2}$ )	+50	+50	+50
<b>Compressor</b>	Isentropic efficiency	0.85	0.85	0.85
	Volumetric efficiency	+	+	+
<b>TGES Reactor</b>	Masse of CaO (kg)	$1.10 \times 10^7$	$1.16 \times 10^7$	$1.11 \times 10^7$
	Length/width of CaO plate (m)	6/1	6/1	6/1
	Thickness of CaO plate (mm)	30	30	30
	Thickness of diffuser plate (mm)	5	5	5
	Thickness of wall plate (mm)	2	2	2
	Initial temperature (°C)	495	495	495
	Reaction enthalpy ( $J \cdot mol^{-1}$ )	+04000	+04000	+04000
	Heat capacity ENG ( $J \cdot K^{-1} \cdot kg^{-1}$ )	700	700	700
	Density ENG ( $kg \cdot m^{-3}$ )	2250	2250	2250
	Rate of salt (%)	90	90	90
	Kinetic reaction coefficient	$5 \times 10^{-3}$	$5 \times 10^{-3}$	$5 \times 10^{-3}$
	Stoichiometric reaction coefficient	+	+	+
	Convective heat transfer coefficient between wall and reactive salts ( $W \cdot K^{-1} \cdot m^{-2}$ )	400	400	400
<b>Turbine 2</b>	Isentropic efficiency	-	-	0.85
	Volumetric efficiency	-	-	+
<b>Pumps</b>	Isentropic efficiency	0.85	0.85	0.85
	Volumetric efficiency	+	+	+
<b>Turbine I High Pressure part</b>	Isentropic efficiency	0.85	0.85	0.85
	Volumetric efficiency	+	+	+
<b>Turbine I Low pressure part</b>	Isentropic efficiency	0.85	0.85	0.85
	Volumetric efficiency	+	+	+
<b>Evaporator</b>	Isentropic efficiency	0.85	0.85	0.85
	Volumetric efficiency	+	+	+
<b>Condenser</b>	HTF outlet temperature (°C)	250	250	250
	Volume ( $m^3$ )	+00	+00	+00
	Cold fluid exit temperature (°C)	30	30	30
	Incondensable partial pressure (bar)	0	0	0
<b>Evaporator bleeding</b>	Pinch point (°C)	+0	+0	+0
	Incondensable partial pressure (bar)	0	0	0
	Volume ( $m^3$ )	+0	+0	+0
<b>Heat exchanger I</b>	Pinch point (°C)	+0	+0	-
