HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

HOMOLOGY OF CATEGORIES VIA POLYGRAPHIC RESOLUTIONS

LÉONARD GUETTA

ABSTRACT. In this paper, we extend a result of Lafont and Métayer and prove that the polygraphic homology of a small category, defined in terms of polygraphic resolutions in the category ω **Cat** of strict ω categories, is naturally isomorphic to the homology of its nerve. Along the way, we prove some results on homotopy colimits with respect to the Folk model structure and deduce a theorem which formally resembles Quillen's Theorem A.

INTRODUCTION

In [Str87], Street defines a nerve functor

 $N_{\omega}: \omega \mathbf{Cat} \to \widehat{\Delta}$

from the category of strict ω -categories (that we shall simply call ω -categories) to the category of simplicial sets. This functor can be used to pull back the homotopy theory of simplicial sets to ω -categories as it is done in the series of articles [AM14], [AM18], [Gag18], [AM20], etc. For example, we can set the following definition:

Definition. Let C be an ω -category and $k \in \mathbb{N}$. The k-th homology group $H_k(C)$ of C is the k-th homology group of its nerve $N_{\omega}(C)$.

On the other hand, in [Mét03] Métayer defines other homological invariants for ω -categories, which we call *polygraphic homology groups*. The definition of these homology groups is based on the notion of *free* ω -category on a polygraph, also known as *free* ω -category on a computad, which are ω -categories that are obtained recursively from the empty ω -category by freely adjoining cells. From now on, we will simply say *free* ω -category.

Métayer observed [Mét03, Definition 4.1 and Proposition 4.3] that every ω -category C admits a *polygraphic resolution*, that is an arrow

 $u:P\to C$

of ω **Cat**, such that P is a free ω -category and u satisfies some properties that formally resemble those of trivial fibrations of topological spaces (or of simplicial sets). Moreover, every free ω -category P can be "linearized" to a chain complex $\lambda(P)$ and Métayer proved [Mét03, Theorem 6.1] that given $P \to C$ and $P' \to C$ two polygraphic resolutions of the same ω -category, the chain complexes $\lambda(P)$ and $\lambda(P')$ have the same homology groups. This leads to the following definition:

Date: March 23, 2020.

²⁰²⁰ Mathematics Subject Classification. 18N30,18G99.

Key words and phrases. Homology, Category, Polygraph.

Definition. Let C be an ω -category and $k \in \mathbb{N}$. The k-th polygraphic homology group $H_k^{\text{pol}}(C)$ of C is the k-th homology group of $\lambda(P)$ for any polygraphic resolution $P \to C$.

In this article, we prove the following theorem:

Theorem 1. Let C be a small category. For every $k \in \mathbb{N}$, we have

$$H_k(C) \simeq H_k^{\text{pol}}(C).$$

For the statement of this theorem to make sense, we have to consider small categories as particular cases of ω -categories. Namely, a (small) category can be defined as an ω -category with only trivial cells in dimension greater than 1. Beware that this last property doesn't imply that the previous theorem is trivial: given $P \to C$, a polygraphic resolution of a small category C, P need not have only trivial cells in dimension greater than 1.

The restriction of the previous theorem to the case of monoids seen as small categories is exactly Corollary 3 of [LM09, Section 3.4]. As such, Theorem 1 is only a small generalization of Lafont and Métayer's result. However, the novelty lies in the new proof we give, which is more conceptual than the one in *loc. cit*.

Note also that the actual result we shall obtain in this article (Theorem 8.3) is more precise than Theorem 1. The first reason is that the homology of an ω -category (polygraphic or of the nerve) will be considered as a chain complex up to quasi-isomorphism and not only a sequence of abelian groups. The second and more important reason is that we will prove that the polygraphic homology and homology of the nerve of a small category are *naturally* isomorphic and even explicitly construct the natural isomorphism. This last point was not addressed at all in [LM09].

We shall now give a sketch of the proof of Theorem 1. It is slightly simpler than the proof of Theorem 8.3 but has the same key ingredients. The simplification mainly results from avoiding questions of naturality.

The first step is to give a more abstract definition of the polygraphic homology. By a variation of the Dold-Kan equivalence (see for example [Bou90]), the category $\omega Cat(Ab)$ of ω -categories internal to abelian groups is equivalent to the category $Ch_{\geq 0}$ of chain complexes in non-negative degree. Thus, we have a forgetful functor

$$\mathbf{Ch}_{\geq 0} \simeq \omega \mathbf{Cat}(\mathbf{Ab}) \rightarrow \omega \mathbf{Cat},$$

which have a left adjoint that we denote by λ . Moreover, when X is a free ω -category, $\lambda(X)$ is exactly the linearization of X considered in the definition of polygraphic homology by Métayer. Now, ω **Cat** admits a model structure, commonly referred to as the *Folk model structure* [LMW10], with equivalences of ω -categories (a generalization of the usual notion of equivalence of categories) as weak equivalences and free ω -categories as cofibrant object [Mét08]. As it turns out, if we equip ω **Cat** with the Folk model structure ture and **Ch**_{≥ 0} with the projective model structure, then λ is a left Quillen functor and hence admits a left derived functor

$$\mathbb{L}\lambda : \operatorname{Ho}(\omega \operatorname{\mathbf{Cat}}) \to \operatorname{Ho}(\operatorname{\mathbf{Ch}}_{>0}).$$

The polygraphic homology groups of an ω -category X are exactly the homology groups of $\mathbb{L}\lambda(X)$.¹ We shall now simply write $H^{\text{pol}}(X) := \mathbb{L}\lambda(X)$.

Recall now that for every (small) category C, we have a canonical isomorphism

$$\operatorname{colim}_{c \in C} C/c \simeq C,$$

where C/c is the slice over c. The keystone idea at the origin of this paper was to remark that this colimit was a homotopy colimit with respect to the weak equivalences of the Folk model structure (Theorem 7.10). Since $\mathbb{L}\lambda$ is the left derived functor of a Left Quillen functor, it commutes with homotopy colimits. In particular, we have:

$$H^{\mathrm{pol}}(C) \simeq \operatorname*{hocolim}_{c \in C} H^{\mathrm{pol}}(C/c).$$

Then we can show that the polygraphic homology of a small category with a final object is isomorphic to (the homology of) \mathbb{Z} concentrated in degree 0 (Proposition 6.6). Hence, we have

$$H^{\mathrm{pol}}(C) \simeq \operatorname{hocolim}_{c \in C} \mathbb{Z}.$$

We conclude by remarking that the right-hand side of the previous equation is nothing but the homology of the nerve of C (see for example [GZ67, Appendix II, Proposition 3.3] or [Qui73, Section 1]). Note that when Cis a monoid M, the category of functors $M \to \mathbf{Ch}_{\geq 0}$ is isomorphic to the category $\mathbf{Ch}_{\geq 0}(M)$ of chain complexes of left $\mathbb{Z}M$ -modules and the colim_M functor can be identified with the functor

$$-\bigotimes_{\mathbb{Z}M}\mathbb{Z}:\mathbf{Ch}_{\geq 0}(M)\to\mathbf{Ch}_{\geq 0}.$$

Hence, in that case we also recover the definition of homology of a monoid in terms of Tor functors.

Let us end this introduction by mentioning that this paper is part of an ongoing program carried out by the author which aims at understanding which are the ω -categories C such that

$$H_k^{\mathrm{pol}}(C) \simeq H_k(C).$$

Theorem 1 may lead us to think that all ω -categories satisfy this property but a folkloric counter-example discovered by Ara and Maltsiniotis shows that it is not the case: Let C be the commutative monoid $(\mathbb{N}, +)$ considered as a 2-category with no non-trivial cells in dimension 0 and 1. This 2category is free (as an ω -category) and a quick computation shows that

$$H_k^{\text{pol}}(C) \simeq \begin{cases} \mathbb{Z} \text{ for } k=0, 2\\ 0 \text{ otherwise.} \end{cases}$$

But, as proved in [Ara19, Theorem 4.9 and Example 4.10], the nerve of C is a $K(\mathbb{Z}, 2)$ -space which has non-trivial homology groups in arbitrarily high even dimension.

¹The description of polygraphic homology as a left derived functor has been around in the folklore for quite some time and I claim no originality for this result. For example, it will appear in [ABG⁺].

Acknowledgment

I am infinitely grateful to Georges Maltsiniotis for explaining homotopy colimits to me. His point of view on the subject has infused into me, and into this article.

1. Generalities on homotopy colimits

1.1. A *localizer* is a pair $(\mathcal{C}, \mathcal{W})$ where \mathcal{C} is a category and \mathcal{W} is a class of arrows of \mathcal{C} , which we usually refer to as the weak equivalences. We denote by Ho (\mathcal{C}) , the localization of \mathcal{C} with respect to \mathcal{W} and by

$$\gamma: \mathcal{C} \to \operatorname{Ho}(\mathcal{C})$$

the localization functor [GZ67, 1.1]. Recall the universal property of the localization: for any category \mathcal{D} , the functor induced by pre-composition

$$\gamma^* : \underline{\operatorname{Hom}}(\operatorname{Ho}(\mathcal{C}), \mathcal{D}) \to \underline{\operatorname{Hom}}(\mathcal{C}, \mathcal{D})$$

is fully faithful and its essential image consists of functors $F : \mathcal{C} \to \mathcal{D}$ that sends morphism of \mathcal{W} to isomorphisms of \mathcal{D} .

We shall always consider that C and Ho(C) have the same class of objects and implicitly use the equality

$$\gamma(X) = X$$

for any object X of \mathcal{C} .

1.2. Let $(\mathcal{C}, \mathcal{W})$ and $(\mathcal{C}', \mathcal{W}')$ be two localizers and $F : \mathcal{C} \to \mathcal{C}'$ a functor. If F preserves weak equivalences, i.e. $F(\mathcal{W}) \subseteq \mathcal{W}'$, then the universal property of the localization implies that there is a canonical functor

$$\overline{F}: \operatorname{Ho}(\mathcal{C}) \to \operatorname{Ho}(\mathcal{C}')$$

such that the square

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{F} & \mathcal{C}' \\ \downarrow^{\gamma} & & \downarrow^{\gamma'} \\ \operatorname{Ho}(\mathcal{C}) & \xrightarrow{\overline{F}} & \operatorname{Ho}(\mathcal{C}') \end{array}$$

is commutative.

1.3. Let $(\mathcal{C}, \mathcal{W})$ and $(\mathcal{C}', \mathcal{W}')$ be two localizers. A functor $F : \mathcal{C} \to \mathcal{C}'$ is *totally left derivable* when there exists a functor

$$\mathbb{L}F: \mathrm{Ho}(\mathcal{C}) \to \mathrm{Ho}(\mathcal{C}')$$

and a natural transformation

$$\alpha: \mathbb{L}F \circ \gamma \Rightarrow \gamma' \circ F$$

that makes $\mathbb{L}F$ the *right* Kan extension of $\gamma' \circ F$ along γ :

$$\begin{array}{c} \mathcal{C} & \xrightarrow{F} & \mathcal{C}' \\ \downarrow^{\gamma} & \stackrel{\alpha}{\longrightarrow} & \downarrow^{\gamma'} \\ \operatorname{Ho}(\mathcal{C}) & \xrightarrow{\mathbb{L}F} & \operatorname{Ho}(\mathcal{C}'). \end{array}$$

When this right Kan extension is *absolute*, we say that F is *absolutely totally left derivable*.

Note that when a functor F is totally left derivable, the pair $(\mathbb{L}F, \alpha)$ is unique up to a unique natural isomorphism and thus we shall refer to $\mathbb{L}F$ as *the* total left derived functor of F.

The notion of (absolute) total right derivable functor is defined dually.

Remark 1.3.1. If $F : \mathcal{C} \to \mathcal{C}'$ preserves weak equivalences then it follows from the universal property of the localization that F is absolutely totally left derivable and $\mathbb{L}F \simeq \overline{F}$.

1.4. Let $(\mathcal{C}, \mathcal{W})$ be a localizer and A a small category. We denote by \mathcal{C}^A the category of functors from A to \mathcal{C} and natural transformations between them. An arrow $\alpha : d \to d'$ is a *pointwise weak equivalences* when $\alpha_a : d(a) \to d'(a)$ belongs to \mathcal{W} for every $a \in \mathcal{A}$. We denote by \mathcal{W}_A the class of pointwise weak equivalences. This defines a localizer $(\mathcal{C}^A, \mathcal{W}_A)$.

Let

$$k: \mathcal{C} \to \mathcal{C}^A$$

be the diagonal functor, i.e. for an object X of \mathcal{C} , $k(X) : A \to \mathcal{C}$ is the constant functor with value X. This functor preserves weak equivalences, whence a functor

$$\overline{k} : \operatorname{Ho}(\mathcal{C}) \to \operatorname{Ho}(\mathcal{C}^A).$$

Definition 1.5. A localizer $(\mathcal{C}, \mathcal{W})$ has homotopy colimits when for every small category A, the functor

$$\overline{k}: \operatorname{Ho}(\mathcal{C}) \to \operatorname{Ho}(\mathcal{C}^A)$$

has a left adjoint.

1.6. When a localizer $(\mathcal{C}, \mathcal{W})$ has homotopy colimits, we denote by

hocolim :
$$\operatorname{Ho}(\mathcal{C}) \to \operatorname{Ho}(\mathcal{C}^A)$$

the left adjoint of \overline{k} : Ho(\mathcal{C}) \rightarrow Ho(\mathcal{C}^A). For an object d of \mathcal{C}^A , the object

$$\operatorname{hocolim}_{A}(d)$$

of $\operatorname{Ho}(\mathcal{C})$ is the *homotopy colimit* of *d*. For consistency, we also use the notation

$$\operatorname{hocolim}_{a \in A} d(a).$$

Note that when \mathcal{C} has colimits and $(\mathcal{C}, \mathcal{W})$ has homotopy colimits, it follows from Remark 1.3.1 and the dual of [Gon12, Theorem 3.4] that hocolim_A is the left derived functor of colim_A. In particular, for any functor $d : A \to \mathcal{C}$, there is a canonical arrow of Ho(\mathcal{C})

$$\operatorname{hocolim}_{A}(d) \to \operatorname{colim}_{A}(d).$$

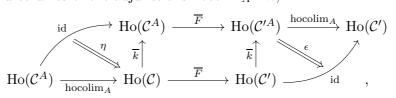

1.7. Let $(\mathcal{C}, \mathcal{W})$ and $(\mathcal{C}', \mathcal{W}')$ be two localizers and $F : \mathcal{C} \to \mathcal{C}'$ that preserves weak equivalences. For any small category A, the functor induced by post-composition, which we abusively denote by

$$F: \mathcal{C}^A \to \mathcal{C}'^A,$$

again preserves weak equivalences and we have a commutative square

$$\begin{array}{c} \operatorname{Ho}(\mathcal{C}^{A}) & \xrightarrow{\overline{F}} & \operatorname{Ho}(\mathcal{C}'^{A}) \\ \hline \overline{k} & & \overline{k} \\ \operatorname{Ho}(\mathcal{C}) & \xrightarrow{\overline{F}} & \operatorname{Ho}(\mathcal{C}'). \end{array}$$

Suppose now that $(\mathcal{C}, \mathcal{W})$ and $(\mathcal{C}', \mathcal{W}')$ have homotopy colimits. Using the unit and co-units of the adjunctions $\operatorname{hocolim}_A \dashv \overline{k}$,

we obtain a natural transformation

$$\operatorname{hocolim}_{A} \circ \overline{F} \Rightarrow \overline{F} \circ \operatorname{hocolim}_{A}$$
.

Hence, for every object $d: A \to C$ of C^A , a canonical map

$$\operatorname{hocolim}_{A}(F(d)) \to F(\operatorname{hocolim}_{A}(d)).$$

2. Homotopy colimits in combinatorial model categories

We suppose that the reader is familiar with the basics of model category theory. Recall that a combinatorial model category is a cofibrantly generated model category such that the underlying category is locally presentable.

2.1. Let $(\mathcal{C}, \mathcal{W}, \text{Cof}, \text{Fib})$ and $(\mathcal{C}', \mathcal{W}', \text{Cof}', \text{Fib}')$ be two model categories and $F : \mathcal{C} \to \mathcal{C}'$. Recall that if F is a left Quillen functor (i.e. the left adjoint in a Quillen adjunction), then F is absolutely totally left derivable and for any cofibrant object X of \mathcal{C} , the canonical arrow

$$\mathbb{L}F(X) \to F(X)$$

is an isomorphism of $\operatorname{Ho}(\mathcal{C}')$.

Remark 2.1.1. Note that the definition of totally left derivable functor only depends on weak equivalences. In particular, if there are several model structures for which a functor F is left Quillen, then for any cofibrant object X of any such model structure, the canonical map

$$\mathbb{L}F(X) \to F(X)$$

is an isomorphism.

Proposition 2.2. Let (C, W, Cof, Fib) be a combinatorial model category. For any small category A, there exists:

- (1) A model structure on C^A , called the projective model structure, with pointwise weak equivalences and pointwise fibrations as weak equivalences and fibrations respectively.
- (2) A model structure on C^A , called the injective model structure, with pointwise weak equivalences and pointwise cofibrations as weak equivalences and cofibrations respectively.

Proof. See [Lur09, Proposition A.2.8.2]

Proposition 2.3. Let $(\mathcal{C}, \mathcal{W}, \text{Cof}, \text{Fib})$ be a combinatorial model category and A a small category. The adjunction

$$\operatorname{colim}_A : \mathcal{C}^A \longleftrightarrow \mathcal{C} : k$$

is a Quillen adjunction with respect to the projective model structure on \mathcal{C}^A .

Proof. By definition of the projective model structure, k preserve weak equivalences and fibrations.

2.4. We deduce from the previous proposition that if a localizer $(\mathcal{C}, \mathcal{W})$ can be extended to a combinatorial model category $(\mathcal{C}, \mathcal{W}, \text{Cof}, \text{Fib})$, then it has homotopy colimits and

$$\operatorname{hocolim}_A \simeq \mathbb{L}\operatorname{colim}_A.$$

Since colim_A is left Quillen with respect to the projective model structure, it is particularly interesting to detect the cofibrant objects of this model structure in order to compute homotopy colimits. This is the goal of the paragraph below and the lemma that follows.

2.5. Let C be a category with coproducts and A a small category. For any object X of C and any object a of A, we define $X \otimes a$ as the functor

$$X \otimes a : A \to \mathcal{C}$$
$$b \mapsto \coprod_{\operatorname{Hom}_{A}(a,b)} X.$$

For any object a of A, this gives rise to a functor

$$b \otimes a : \mathcal{C} \to \mathcal{C}^A$$

 $X \mapsto X \otimes a.$

Lemma 2.6. Let C = (C, W, Cof, Fib) be a combinatorial model category and A a small category. For any object a of A and any cofibration $f : X \to Y$ of C, the arrow

$$f \otimes a : X \otimes a \to Y \otimes a$$

is a cofibration of the projective model structure on \mathcal{C}^A .

Proof. We leave it to the reader to check that the functor $-\otimes a$ is left adjoint to

$$\operatorname{ev}_a : \mathcal{C}^A \to \mathcal{C}$$

 $F \mapsto F(a).$

Let α be a fibration of the projective model structure on \mathcal{C}^A . By definition, f has the left lifting property with respect to $\operatorname{ev}_a(\alpha)$. Hence, by adjunction, $f \otimes a$ has the left lifting property with respect to α , which is what we needed to prove.

2.7. Let $(\mathcal{C}, \mathcal{W}, \operatorname{Cof}, \operatorname{Fib})$ and $(\mathcal{C}', \mathcal{W}', \operatorname{Cof}', \operatorname{Fib}')$ be two combinatorial model categories and $F : \mathcal{C} \to \mathcal{C}'$ a left Quillen functor. For any small category A, the functor induced by post-composition

$$F: \mathcal{C}^A \to \mathcal{C}'^A$$

is left Quillen both with respect to the projective model structure *and* the injective model structure. In particular, all arrows of the commutative square

$$\begin{array}{ccc} \mathcal{C}^A & \stackrel{F}{\longrightarrow} & \mathcal{C}'^A \\ k & \uparrow & & k \\ \mathcal{C} & \stackrel{F}{\longrightarrow} & \mathcal{C}'. \end{array}$$

are left Quillen functors when \mathcal{C}^A and \mathcal{C}'^A are equipped with the injective model structure. Hence, by composition of left Quillen functors, we obtain a commutative square up to a canonical isomorphism

$$\begin{array}{ccc} \operatorname{Ho}(\mathcal{C}^{A}) & \stackrel{\mathbb{L}F}{\longrightarrow} & \operatorname{Ho}(\mathcal{C}'^{A}) \\ \hline \overline{k} & & & & \\ \hline \overline{k} & & & & \\ \operatorname{Ho}(\mathcal{C}) & \stackrel{\mathbb{L}F}{\longrightarrow} & \operatorname{Ho}(\mathcal{C}'). \end{array}$$

In a similar fashion as in Paragraph 1.7, we obtain a natural transformation

$$\operatorname{hocolim}_{A} \circ \mathbb{L}F \Rightarrow \mathbb{L}F \circ \operatorname{hocolim}_{A}$$

The next proposition tells us that left Quillen functors are "homotopy cocontinuous".

Proposition 2.8. Let $(\mathcal{C}, \mathcal{W}, \text{Cof}, \text{Fib})$ and $(\mathcal{C}', \mathcal{W}', \text{Cof}', \text{Fib}')$ be two combinatorial model categories, $F : \mathcal{C} \to \mathcal{C}'$ a left Quillen functor and A a small category. For any object $d : A \to \mathcal{C}$ of \mathcal{C}^A , the canonical map

$$\operatorname{hocolim}_{A}(\mathbb{L}F(d)) \to \mathbb{L}F(\operatorname{hocolim}_{A}(d))$$

is an isomorphism of $\operatorname{Ho}(\mathcal{C}')$.

Proof. We use here the projective model structures on \mathcal{C}^A and \mathcal{C}'^A . Since every object d of \mathcal{C}^A is isomorphic in $\operatorname{Ho}(\mathcal{C}^A)$ to a cofibrant one, it suffices to show that the map

$$\operatorname{hocolim}_{A}(\mathbb{L}F(d)) \to \mathbb{L}F(\operatorname{hocolim}_{A}(d))$$

is an isomorphism when d is cofibrant. But in this case, the previous map can be identified with the image of the map

$$\operatorname{colim}_{A}(F(d)) \to F(\operatorname{colim}_{A}(d))$$

in the localization of $\mathcal{C}^{\prime A}$. Since F is a left adjoint, this map is indeed an isomorphism.

3. ω -categories

3.1. We denote by ω **Cat** the category of (small) *strict* ω -categories and *strict* ω -functors. Since we shall never deal with non-strict ω -categories, we omit the word "strict" and simply say ω -categories and ω -functors. For an ω -category C, we denote by C_n the set of n-cells of C. For $x \in C_n$, we refer to the integer n as the dimension of x.

For an *n*-cell x with n > 0, s(x) and t(x) are respectively the source and target of x (which are (n-1)-cells). More generally, for any k < n, $s_k(x)$ and $t_k(x)$ are respectively the k-dimensional source of x and the k-dimensional

target of x, which are obtained by iteration. We say that two n-cells x and y are parallel if either n = 0 or n > 0 and

$$s(x) = s(y)$$
 and $t(x) = t(y)$.

Let $k < n \in \mathbb{N}$. Two *n*-cells x and y are k-composable if $s_k(x) = t_k(y)$, in which case we denote their k-composition by $x *_k y$.

For an *n*-cell x, 1_x is the unit on x, which is a (n+1)-cell. More generally, for any k > n we denote by $1_x^{(k)}$ the k-dimensional unit on n obtained by iteration. (Note that the superscript denotes the dimension and not the number of iterations.) For consistency, we also define $1_x^{(n)} := x$ for any *n*-cell x. A *n*-cell x is degenerate if there exists a cell y of dimension strictly lower than n and such that $x = 1_y^{(n)}$.

We extend the notion of k-composition for cells of different dimension in the following way. Let x be a n-cell, y be a m-cell and $k < \min\{m, n\}$. The cells x and y are k-composable if $s_k(x) = t_k(y)$, in which case we define $x *_k y$ as the cell of dimension $l := \max\{m, n\}$ as

$$x *_k y := 1_x^{(l)} *_k 1_y^{(l)}.$$

Finally, we use the convention that for n < m the operation $*_n$ has priority over $*_m$, which means that

$$x *_n y *_m z = (x *_n y) *_m z$$
 and $x *_m y *_n z = x *_m (y *_n z)$

whenever these equations make sense.

3.2. Let $n \in \mathbb{N}$. An *n*-category is an ω -category such that all cells of dimension strictly greater than n are degenerate. An *n*-functor is an ω -functor between *n*-categories. We denote by $n\mathbf{Cat}$ the category of *n*-categories and *n*-functors. For an ω -category C, we denote by $C_{\leq n}$ the *n*-category obtained from C by removing all non-degenerate cells of dimension strictly greater than n. The functor

$$\omega \mathbf{Cat} \to n\mathbf{Cat}$$
$$C \mapsto C_{\leq n}$$

is right adjoint to the canonical inclusion functor

$$n\mathbf{Cat} \hookrightarrow \omega\mathbf{Cat}.$$

For an ω -category C, we define $C_{\leq -1}$ to be the empty ω -category (which is a (-1)-category).

Remark 3.3. When n = 1, we have a canonical functor

 $1\mathbf{Cat} \to \mathbf{Cat}$

from the category of 1-categories to the category of small categories, which simply forgets the k-cells for k > 1. Since this functor is an isomorphism of categories, we usually identify the categories **Cat** and 1**Cat** and consider that the terms "1-category" and "(small) category" are synonyms.

3.4. Let $n \in \mathbb{N}$. The functor

$$\omega \mathbf{Cat} \to \mathbf{Set}$$
$$C \mapsto C_n$$

is representable and we define the *n*-globe \mathbb{D}_n as the ω -category representing this functor. (\mathbb{D}_n is in fact an *n*-category). For an *n*-cell *x* of an ω -category *C*, we denote by

$$\langle x \rangle : \mathbb{D}_n \to C$$

the associated morphism of $\omega \mathbf{Cat}$. Here are some pictures of \mathbb{D}_n in low dimension:

$$\mathbb{D}_{0} = \bullet ,$$
$$\mathbb{D}_{1} = \bullet \longrightarrow \bullet ,$$
$$\mathbb{D}_{2} = \bullet \bigoplus^{\prime} \bullet ,$$
$$\mathbb{D}_{3} = \bullet \bigoplus^{\prime} \bullet .$$

For an ω -category C, let us denote by $\operatorname{Par}_n(C)$ the set of pair of parallel *n*-cells of C. The functor

$$\omega \mathbf{Cat} \to \mathbf{Set}$$
$$C \mapsto \mathrm{Par}_n(C)$$

is representable and we define the *n*-sphere \mathbb{S}_n as the ω -category representing this functor. (\mathbb{S}_n is in fact an *n*-category). If x and y are parallel *n*-cells of C, we denote by

$$\langle x, y \rangle : \mathbb{S}_n \to C$$

the associated morphism of $\omega \mathbf{Cat}$. Here are some pictures of \mathbb{S}_n in low dimension:

$$S_0 = \bullet ,$$

$$S_1 = \bullet ,$$

$$S_2 = \bullet () + \bullet ,$$

Suppose now that n > 0, and let C be an ω -category. The canonical morphism

$$C_n \to \operatorname{Par}_{n-1}(C)$$

 $x \mapsto (s(x), t(x))$

is natural in C. Hence, a canonical morphism

$$i_n: \mathbb{S}_{n-1} \to \mathbb{D}_n$$

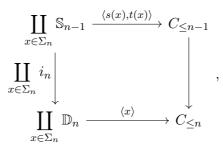

We also define \mathbb{S}_{-1} to be the empty ω -category (which is the initial object of $\omega \mathbf{Cat}$), and i_0 to be the unique morphism

$$i_0: \mathbb{S}_{-1} \to \mathbb{D}_0.$$

3.5. A basis of an ω -category C is a graded set of cells of C

$$\Sigma = (\Sigma_n \subseteq C_n)_{n \in \mathbb{N}}$$

such that for every $n \in \mathbb{N}$, the commutative square

where the anonymous arrow is the canonical inclusion, is a pushout square. That is, $C_{\leq n}$ is obtained from $C_{\leq n-1}$ by freely adjoining the *n*-cells that belongs to Σ_n . An ω -category is *free* when it has a basis. Note that a free ω -category has a *unique* basis (see [Mak05, Section 4, Proposition 8.3]). This allows us to speak of *the* basis of a free ω -category. Cells that belong to Σ_n are referred to as *generating n-cells* of *C*.

Recall from [Gue18] the following definition:

Definition 3.6. An ω -functor $f : C \to D$ is a discrete Conduché ω -functor if for every *n*-cell *x* of *C*, every k < n and every pair (y_1, y_2) of *k*-composable *n*-cells of *D* such that

$$f(x) = y_1 *_k y_2$$

there exists a *unique* pair (x_1, x_2) of k-composable n-cells of C such that

(1) $x = x_1 *_k x_2$

(2)
$$f(x_1) = y_1$$
 and $f(x_2) = y_2$.

Lemma 3.7. Let

$$\begin{array}{ccc} C' & \stackrel{u}{\longrightarrow} & C \\ & \downarrow^{f'} & & \downarrow^{f} \\ D' & \stackrel{v}{\longrightarrow} & D \end{array}$$

be a pullback square in ω **Cat**. If f is a discrete Conduché ω -functor then so is f'.

Proof. Left to the reader. See [Gue18, remark 4.5].

Proposition 3.8. Let $f : C \to D$ be a discrete Conduché ω -functor. If D is a free ω -category then so is C.

More precisely, if we denote by Σ_n^D the set of generating n-cells of D, then the set of generating n-cells of C is

$$\Sigma_n^C = \{ x \in C_n | f(x) \in \Sigma_n^D \}$$

Proof. This is Theorem 5.12(1) from [Gue18].

3.9. Let C be an ω -category. We define the equivalence relation \sim_{ω} on the set C_n by co-induction on $n \in \mathbb{N}$. Let $x, y \in C_n$, then $x \sim_{\omega} y$ when:

- x and y are parallel,

11

- there exist $r, s \in C_{n+1}$ such that $r: x \to y, s: y \to x$,

$$r *_n s \sim_\omega 1_y$$

and

$$s *_n r \sim_\omega 1_x$$

For details on this definition and the proof that it is an equivalence relation, see [LMW10, section 4.2].

3.10. An ω -functor $f: C \to D$ is an equivalence of ω -categories when:

- for every $y \in D_0$, there exists a $x \in C_0$ such that

 $f(x) \sim_{\omega} y,$

- for every $x, y \in C_n$ that are *parallel* and every $\beta \in D_{n+1}$ such that

 $\beta: f(x) \to f(y),$

there exists $\alpha \in C_{n+1}$ such that

$$\alpha: x \to y$$

and

$$f(\alpha) \sim_{\omega} \beta$$

Theorem 3.11. There exists a combinatorial model structure on ω **Cat** such that the weak equivalences are the equivalences of ω -categories, and the set $\{i_n : \mathbb{S}_{n-1} \to \mathbb{D}_n | n \in \mathbb{N}\}$ is a set of generating cofibrations.

Proof. This is the main result of [LMW10].

3.12. We refer to the model structure of the previous theorem as the *Folk* model structure on ω **Cat**. Data of this model structure will often be referred to by using the adjective folk, *e.g. folk cofibration*. From now on, unless otherwise explicitly specified, we will always consider that ω **Cat** is equipped with this model structure. In particular, Ho(ω **Cat**) will always be the localization of ω **Cat** with respect to the class of equivalence of ω -categories.

Proposition 3.13. An ω -category is cofibrant for the Folk model structure if and only if it is free.

Proof. The fact that every free ω -category is cofibrant follows immediately from the fact that the $i_n : \mathbb{S}_{n-1} \to \mathbb{D}_n$ are cofibrations and that every ω -category C is the colimit of the canonical diagram

$$\emptyset = C_{\leq -1} \to C_{\leq 0} \to \dots \to C_{\leq n} \to C_{\leq n+1} \dots$$

For the converse, see [Mét08].

4. Polygraphic homology

4.1. Let C be an ω -category. We define a chain complex in non-negative degree $\lambda(C)$ in the following way:

- for $n \in \mathbb{N}$, $\lambda(C)_n$ is the abelian group obtained by quotienting the free abelian group $\mathbb{Z}C_n$ by the congruence generated by the relations

$$x *_k y \sim x + y$$

for any $x, y \in C_n$ that are k-composable,

- the differential $\partial: \lambda(C)_n \to \lambda(C)_{n-1}$ is induced by the map

$$\mathbb{Z}C_n \to \mathbb{Z}C_{n-1}$$
$$x \in C_n \mapsto t(x) - s(x).$$

The axioms of ω -categories imply that $\partial \circ \partial = 0$. Now let $f : C \to D$ be an ω -functor. The map

$$\mathbb{Z}C_n \to \mathbb{Z}D_n$$
$$x \in C_n \mapsto f(x)$$

induces a map

$$\lambda(f)_n : \lambda(C)_n \to \lambda(D)_n.$$

Since f commutes with source and targets, we obtain a morphism of chain complexes $(\lambda(f)_n)_{n \in \mathbb{N}}$. This defines a functor

$$\lambda: \omega \mathbf{Cat} \to \mathbf{Ch}_{\geq 0},$$

where $\mathbf{Ch}_{\geq 0}$ is the category of chain complexes in non-negative degree, which we call the *abelianization functor*.

Lemma 4.2. Let C be a free ω -category and let $\Sigma = (\Sigma_n)_{n\mathbb{N}}$ be its basis. Then for every $n \in \mathbb{N}$, $\lambda(C)_n$ is isomorphic to the free abelian group $\mathbb{Z}\Sigma_n$.

Proof. Let G be an abelian group. For any $n \in \mathbb{N}$, we define an n-category $B^n G$ with:

- $(B^n G)_k$ is a singleton set for every k < n,
- $(B^n G)_n = G$
- for all x and y in G and i < n,

$$x *_i y := x + y.$$

It it straightforward to check that this defines an *n*-category. Note that when n = 1, the previous definition would still make sense without the hypothesis that G be abelian, but for $n \ge 2$ this hypothesis is necessary because of the Eckmann-Hilton argument. For n = 0, we only needed that G was a set.

This defines a functor

$$B^n : \mathbf{Ab} \to n\mathbf{Cat}$$
$$G \mapsto B^n G,$$

which is easily seen to be right adjoint to the functor

$$n\mathbf{Cat} \to \mathbf{Ab}$$
$$C \mapsto \lambda(C)_n.$$

Now, if C is an ω -category then $\lambda(C_{\leq n})_n = \lambda(C)_n$ and if C is free with basis $\Sigma = (\Sigma_n)_{n \in \mathbb{N}}$, then for any abelian group G there is a natural isomorphism

$$\operatorname{Hom}_{n\mathbf{Cat}}(C_{\leq n}, B^n G) \simeq \operatorname{Hom}_{\mathbf{Set}}(\Sigma_n, |G|),$$

where |G| is the underlying set of G. Altogether, we have

$$\operatorname{Hom}_{\mathbf{Ab}}(\lambda(C)_n, G) \simeq \operatorname{Hom}_{\mathbf{Ab}}(\lambda(C_{\leq n})_n, G)$$
$$\simeq \operatorname{Hom}_{n\mathbf{Cat}}(C_{\leq n}, B^n G)$$
$$\simeq \operatorname{Hom}_{\mathbf{Set}}(\Sigma_n, |G|)$$
$$\simeq \operatorname{Hom}_{\mathbf{Ab}}(\mathbb{Z}\Sigma_n, G).$$

Lemma 4.3. The functor λ is a left adjoint.

Proof. The category of chain complexes is equivalent to the category $\omega \mathbf{Cat}(\mathbf{Ab})$ of ω -categories internal to abelian groups (see [Bou90, Theorem 3.3]) and with this identification, the functor $\lambda : \omega \mathbf{Cat} \to \omega \mathbf{Cat}(\mathbf{Ab})$ is nothing but the left adjoint of the canonical forgetful functor $\omega \mathbf{Cat}(\mathbf{Ab}) \to \omega \mathbf{Cat}$. \Box

4.4. Let $u, v : C \to D$ be two ω -functors. An *oplax transformation* α from u to v consists of the following data:

- for every 0-cell x of C, a 1-cell of D

$$\alpha_x: u(x) \to v(x)$$

- for every *n*-cell of x of C with n > 0, an (n + 1)-cell of D

$$\alpha_x : \alpha_{t_{n-1}(x)} *_{n-1} \cdots *_1 \alpha_{t_0(x)} *_0 u(x) \to v(x) *_0 \alpha_{s_0(x)} *_1 \cdots *_{n-1} \alpha_{s_{n-1}(x)}$$

subject to the following axioms:

(1) for every *n*-cell x,

$$\alpha_{1_x} = 1_{\alpha_x},$$

(2) for all $0 \le k < n$, for all *n*-cells x and y that are k-composable,

$$\alpha_{x*_{k}y} = \left(v(t_{k+1}(x)) *_{0} \alpha_{s_{0}(x)} *_{1} \cdots *_{n-1} \alpha_{s_{n-1}(x)} *_{k} \alpha_{y} \right) \\ *_{k+1} \left(\alpha_{t_{n-1}(x)} *_{n-1} \cdots *_{1} \alpha_{t_{0}(x)} *_{0} u(s_{k+1}(y)) \right).$$

We use the notation $\alpha : u \Rightarrow v$ to say that α is an oplax transformation from u to v.

4.5. Let

$$B \xrightarrow{f} C \xrightarrow{u} D \xrightarrow{g} E$$

be a diagram in $\omega \mathbf{Cat}$ and $\alpha : u \Rightarrow v$ an oplax transformation. The data of

$$(g \star \alpha)_x := g(\alpha_x)$$

for each cell x of C (resp.

$$(\alpha \star f)_x := \alpha_{f(x)}$$

for each cell x of B) defines an oplax transformation from gu to gv (resp. uf to ug) that we denote $g \star \alpha$ (resp. $\alpha \star f$).

Lemma 4.6. Let $u, v : C \to D$ be two ω -functors. If there is an oplax transformation $\alpha : u \Rightarrow v$, then there is a homotopy of chain complexes from $\lambda(u)$ to $\lambda(v)$.

Proof. For any *n*-cell x of C (resp. D), let us use the notation [x] for the image of x in $\lambda(C)_n$ (resp. $\lambda(D)_n$).

Let h_n be the map

$$h_n : \lambda(C)_n \to \lambda(D)_{n+1}$$

 $[x] \mapsto [\alpha_x].$

The definition of oplax transformations implies that h_n is linear and that for every *n*-cell x of C,

$$\partial(h_n(x)) + h_{n-1}(\partial(x)) = [v(x)] - [u(x)].$$

Details are left to the reader.

4.7. Recall that the category of chain complexes in non-negative degree $\mathbf{Ch}_{>0}$ has a cofibrantly model structure where:

- the weak equivalences are the quasi-isomorphisms, i.e. morphisms of chain complexes that induce an isomorphism on homology groups,
- the cofibrations are the morphisms of chain complexes $f: X \to Y$ such that for every $n \ge 0$, $f_n: X_n \to Y_n$ is a monomorphism with projective cokernel,
- the fibrations are the morphisms of chain complexes $f: X \to Y$ such that for every n > 0, $f_n: X_n \to Y_n$ is an epimorphism.

(See for example [DS95, Section 7].) From now on, we will implicitly consider that the category $\mathbf{Ch}_{>0}$ is equipped with this model structure.

Proposition 4.8. The functor $\lambda : \omega \mathbf{Cat} \to \mathbf{Ch}_{\geq 0}$ is left Quillen.

Proof. The fact that λ is a left adjoint is Lemma 4.3.

A simple computation using Lemma 4.2 shows that for every $n \in \mathbb{N}$,

$$\lambda(i_n):\lambda(\mathbb{S}_{n-1})\to\lambda(\mathbb{D}_n)$$

is a monomorphism with projective cokernel. This shows that λ preserves cofibrations.

Then, we know from [LMW10, Sections 4.6 and 4.7] and [AM16, Remarque B.1.16] (see also [AL19, Paragraph 3.11]) that there exists a set of generating trivial cofibrations J of the Folk model structure on ω **Cat** such that any $j: X \to Y$ in J satisfies the following conditions:

- there exists $r: Y \to X$ such that $r \circ j = 1_X$,

- there exists an oplax transformation $\alpha : j \circ r \Rightarrow 1_Y$.

From Lemma 4.6, we conclude that λ preserves trivial cofibrations.

The previous proposition leads the following definition:

Definition 4.9. We define the *polygraphic homology functor*

 $\mathbb{H}^{\mathrm{pol}}:\mathrm{Ho}(\omega\mathbf{Cat})\to\mathrm{Ho}(\mathbf{Ch}_{>0})$

as the left derived functor of $\lambda : \omega \mathbf{Cat} \to \mathbf{Ch}_{\geq 0}$.

5. Nerve of ω -categories and the comparison map

5.1. We denote by Δ the category whose objects are the finite non-empty totally ordered sets $[n] = \{0 < \cdots < n\}$ and whose morphisms are the non-decreasing maps. For $n \in \mathbb{N}$ and $0 \leq i \leq n$, we denote by

$$\delta^i: [n-1] \to [n]$$

the only injective increasing map whose image does not contain i.

The category Δ of simplicial sets is the category of presheaves on Δ . For a simplicial set X, we use the notations

$$X_n := X([n])$$

$$\partial_i := X(\delta^i) : X_n \to X_{n-1}$$

Elements of X_n are referred to as *n*-simplices of X.

5.2. From now on, we will consider that the category $\widehat{\Delta}$ is equipped with the model structure defined by Quillen in [Qui67]. A weak equivalence of *simplicial sets* is a weak equivalence for this model structure.

5.3. We denote by $\mathcal{O}: \Delta \to \omega \mathbf{Cat}$ the cosimplicial object introduced by Street in [Str87]. The ω -category \mathcal{O}_n is the *n*-oriental. For a definition and basic properties of this cosimplicial object we refer to op. cit., [Ste04] and [AM16, Chapitre 7].

For every $n \in \mathbb{N}$, the ω -category \mathcal{O}_n is free and the set of generating k-cells is canonically isomorphic to the set of increasing sequence

$$0 \le i_0 < i_1 < \dots < i_k \le n.$$

We will denote such a generating cell by $\langle i_0 i_1 \cdots i_k \rangle$. In particular, \mathcal{O}_n is an *n*-category and it has a unique generating *n*-cell, namely $\langle 012 \cdots n \rangle$, which we call the *principal cell* of \mathcal{O}_n .

Here are some pictures in low dimension:

$$\mathcal{O}_{0} = \langle 0 \rangle,$$

$$\mathcal{O}_{1} = \langle 0 \rangle \xrightarrow{\langle 01 \rangle} \langle 1 \rangle,$$

$$\mathcal{O}_{2} = \begin{array}{c} \langle 01 \rangle & \stackrel{\langle 1 \rangle}{\swarrow} & \stackrel{\langle 12 \rangle}{\swarrow} \\ \langle 0 \rangle & \stackrel{\langle 01 \rangle}{\longrightarrow} & \langle 2 \rangle \end{array}$$

5.4. For every ω -category X, the nerve of X is the simplicial set $N_{\omega}(X)$ defined as $N_{\cdot}(X) \cdot \Lambda^{op}$

$$\mathcal{N}_{\omega}(X): \Delta^{op} \to \mathbf{Set}$$

$$[n] \mapsto \operatorname{Hom}_{\omega \operatorname{Cat}}(\mathcal{O}_n, X).$$

By post-composition, this yields a functor

$$N_{\omega}: \omega \mathbf{Cat} \to \widehat{\Delta}$$
$$X \mapsto N_{\omega}(X)$$

Note that when X is a 1-category, $N_{\omega}(X)$ is canonically isomorphic to the usual nerve of X, that is, the simplicial set

$$\Delta^{op} \to \mathbf{Set}$$

 $[n] \mapsto \operatorname{Hom}_{\mathbf{Cat}}([n], X),$

where [n] is seen as a 1-category.

By the usual Kan extension technique, $\mathcal{O}: \Delta \to \omega \mathbf{Cat}$ can be extended to a functor

$$c_{\omega}: \Delta \to \omega \mathbf{Cat},$$

which is left adjoint to the nerve functor N_{ω} .

Lemma 5.5. The nerve functor $N_{\omega} : \omega \mathbf{Cat} \to \widehat{\Delta}$ sends equivalences of ω -categories to weak equivalences of simplicial sets.

In particular, this means that the nerve functor induces a functor

 \overline{N}_{ω} : Ho(ω **Cat**) \rightarrow Ho($\widehat{\Delta}$).

Proof. Since every ω -category is fibrant for the Folk model structure [LMW10, Proposition 9], it follows from Ken Brown's Lemma [Hov07, Lemma 1.1.12] that it suffices to show that the nerve sends folk trivial fibrations to weak equivalences of simplicial sets. In particular, it suffices to show the stronger condition that the nerve sends folk trivial fibrations to trivial fibrations of simplicial sets.

By adjunction, this is equivalent to showing that the functor $c_{\omega} : \Delta \to \omega \mathbf{Cat}$ sends cofibrations of simplicial sets to folk cofibrations. Since c_{ω} is cocontinuous and the cofibrations of simplicial sets are generated by the canonical inclusions

$$\partial \Delta_n \to \Delta_n$$

for $n \in \mathbb{N}$, it suffices to show that c_{ω} sends these inclusions to folk cofibrations.

Now, it follows from any reference on orientals previously cited that the image of the inclusion $\partial \Delta_n \to \Delta_n$ by c_{ω} can be identified with the canonical inclusion

$$(\mathcal{O}_n)_{\leq n-1} \to \mathcal{O}_n.$$

Since \mathcal{O}_n is free, this last morphism is by definition a push-out of a coproduct of folk cofibrations, hence a folk cofibration.

5.6. Let X be a simplicial set. We denote by $K_n(X)$ the abelian group of *n*-chains of X, that is the free abelian group on X_n , and by $\partial : K_n(X) \to K_{n-1}(X)$ the linear map defined for $x \in X_n$ by

$$\partial(x) = \sum_{0 \le i \le n} (-1)^i \partial_i(x).$$

It can be shown that $\partial \circ \partial = 0$ and thus, the previous data defines a chain complex K(X). This actually yields a functor

$$K: \Delta \to \mathbf{Ch}_{>0}.$$

5.7. Recall that an *n*-simplex x of a simplicial set X is degenerate if there exists a surjective non-decreasing map $\varphi : [n] \to [k]$ with k < n and a k-simplex x' of X such that $X(\varphi)(x') = x$. For every $n \in \mathbb{N}$, we define $D_n(X)$ as the subgroup of $K_n(X)$ spanned by the degenerate *n*-simplices.

We denote by $\kappa_n(X)$ the abelian group of normalized chain complex,

$$\kappa_n(X) = K_n(X) / D_n(X).$$

It can be shown that $\partial(D_n(X)) \subseteq D_{n-1}(X)$ and we denote by

$$\partial: \kappa_n(X) \to \kappa_{n-1}(X)$$

the map induced by the differential of K(X). This data defines a chain complex $\kappa(X)$ that we call the *normalized chain complex of* X. This yields a functor

$$\kappa : \Delta \to \mathbf{Ch}_{>0}.$$

Lemma 5.8. The functor $\kappa : \widehat{\Delta} \to \mathbf{Ch}_{\geq 0}$ is left Quillen and sends weak equivalences of simplicial sets to quasi-isomorphisms.

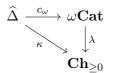

Proof. From the Dold-Kan equivalence, we know that $\mathbf{Ch}_{\geq 0}$ is equivalent to the category $\mathbf{Ab}(\Delta)$ of simplicial abelian groups. With this identification the functor $\kappa : \widehat{\Delta} \to \mathbf{Ch}_{\geq 0}$ is left adjoint of the canonical forgetful functor

$$U: \mathbf{Ch}_{>0} \simeq \mathbf{Ab}(\Delta) \to \widehat{\Delta}$$

induced by the forgetful functor from abelian groups to sets. It follows from [GJ09, Lemma 2.9 and Corollary 2.10] that U is right Quillen, hence κ is left Quillen.

The fact that κ preserves weak equivalences follows from Ken Brown's Lemma [Hov07, Lemma 1.1.12] and the fact that all simplicial sets are cofibrant.

Lemma 5.9. The triangle of functors

is commutative (up to a canonical isomorphism).

Proof. Since all the functors involved are cocontinuous, it suffices to show that the triangle is commutative when we pre-compose it by the Yoneda embedding $\Delta \rightarrow \hat{\Delta}$. This property follows straightforwardly from the description of the orientals in [Ste04].

5.10. From Lemma 5.9, the co-unit of the adjunction $c_{\omega} \dashv N_{\omega}$ induces a natural transformation

$$\kappa N_{\omega} \simeq \lambda c_{\omega} N_{\omega} \Rightarrow \lambda.$$

From Lemma 5.5, Lemma 5.8, Remark 1.3.1 and the universal property of left derivable functors, we obtain a natural transformation

$$\overline{\kappa}\overline{N}_{\omega} \Rightarrow \mathbb{H}^{\mathrm{pol}}$$

that we refer to as the *canonical comparison map*.

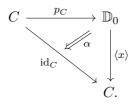

6. The case of contractible ω -categories

6.1. For any ω -category C, we denote by

$$p_C: C \to \mathbb{D}_0$$

the unique morphism from C to \mathbb{D}_0 (which is a terminal object of $\omega \mathbf{Cat}$).

Definition 6.2. An ω -category *C* is *contractible* if there exists a 0-cell *x* of *C* and an oplax transformation

6.3. An immediate computation using Lemma 4.2 shows that $\lambda(\mathbb{D}_0)$ is canonically isomorphic to \mathbb{Z} considered as a chain complex concentrated in degree 0.

Lemma 6.4. Let C be a contractible ω -category. The morphism of chain complexes

$$\lambda(p_C):\lambda(C)\to\lambda(\mathbb{D}_0)\simeq\mathbb{Z}$$

is a quasi-isomorphism.

Proof. This follows immediately from Lemma 4.6.

Lemma 6.5. Let

$$\begin{array}{ccc} C' & \stackrel{f'_{\epsilon}}{\longrightarrow} & D' \\ \downarrow u & & \downarrow v \\ C & \stackrel{f_{\epsilon}}{\longrightarrow} & D \end{array}$$

be commutative squares in ω **Cat** for $\epsilon \in \{0, 1\}$.

If C' is a free ω -category and v is a trivial fibration for the Folk model structure on ω **Cat**, then for any oplax transformation

$$\alpha: f_0 \Rightarrow f_1,$$

there is an oplax transformation

$$\alpha': f_0' \Rightarrow f_1'$$

such that

$$v \star \alpha' = \alpha \star u.$$

Proof. We denote by \otimes the *Gray monoidal product* (see for example [AM16, Appendice A]) on the category ω **Cat**. Recall that the unit of this monoidal product is the ω -category \mathbb{D}_0 .

From [AM16, Appendice B], we know that given $u, v : C \to D$ two ω -functors, the set of oplax transformations from u to v is in bijection with the set of functors $\alpha : \mathbb{D}_1 \otimes C \to D$ such that the diagram

$$(\mathbb{D}_0 \amalg \mathbb{D}_0) \otimes C \simeq C \amalg C$$
$$\stackrel{i_1 \otimes C}{\longrightarrow} D_1 \otimes C \xrightarrow{\langle u, v \rangle} D,$$

where $i_1 : \mathbb{D}_0 \amalg \mathbb{D}_0 \simeq \mathbb{S}_0 \to \mathbb{D}_1$ is the morphism introduced in 3.4, is commutative. We use the same letter to denote an oplax transformation and the functor $\mathbb{D}_1 \otimes C \to D$ associated to it.

Moreover, for an ω -functor $f: B \to C$, the oplax transformation $\alpha \star f$ is represented by the functor

$$\mathbb{D}_1 \otimes B \xrightarrow{\mathbb{D}_1 \otimes f} \mathbb{D}_1 \otimes C \xrightarrow{\alpha} D$$

and for an ω -functor $g: D \to E$, the oplax transformation $g \star \alpha$ is represented by the functor

$$\mathbb{D}_1 \otimes C \xrightarrow{\alpha} D \xrightarrow{g} E.$$

Using this way of representing oplax transformations, the hypotheses of the present lemma yield the following commutative square

$$\begin{array}{ccc} (\mathbb{D}_0 \amalg \mathbb{D}_0) \otimes C' & \xrightarrow{\langle f_0', f_1' \rangle} & D' \\ & & i_1 \otimes C' \\ & & & \downarrow^v \\ \mathbb{D}_1 \otimes C' & \xrightarrow{\mathbb{D}_1 \otimes u} & \mathbb{D}_1 \otimes C & \xrightarrow{\alpha} & D. \end{array}$$

.

Since i_1 is a folk cofibration and C' is cofibrant, it follows that the left vertical morphism of the previous square is a folk cofibration (see [Luc17, Proposition 5.1.2.7] or [AL19]). By hypothesis, v is a folk trivial fibration, the above square admits a lift

$$\alpha': \mathbb{D}_1 \otimes C' \to D'.$$

The commutativity of the two induced triangle shows what we needed to prove. $\hfill \Box$

Proposition 6.6. Let C be an ω -category. If C is contractible, then the canonical comparison map

$$\kappa N_{\omega}(C) \to \mathbb{H}^{\mathrm{pol}}(C)$$

is an isomorphism of $\operatorname{Ho}(\mathbf{Ch}_{\geq 0})$. More precisely, this morphism can be identified with the identity morphism $\operatorname{id}_{\mathbb{Z}} : \mathbb{Z} \to \mathbb{Z}$ (where \mathbb{Z} is seen as an object of $\operatorname{Ho}(\mathbf{Ch}_{\geq 0})$ concentrated in degree 0).

Proof. Consider first the case when C is cofibrant for the Folk model structure. It follows respectively from Lemma 6.4 and [AM20, Corollaire A.13] that the morphisms

$$\mathbb{H}^{\mathrm{pol}}(C) \to \mathbb{H}^{\mathrm{pol}}(\mathbb{D}_0)$$

and

$$\kappa N_{\omega}(C) \to \kappa N_{\omega}(\mathbb{D}_0),$$

induced by the canonical morphism $p_C : C \to \mathbb{D}_0$, are isomorphisms of $\operatorname{Ho}(\mathbf{Ch}_{\geq 0})$. Moreover, it is straightforward to check that the canonical comparison map

$$\kappa N_{\omega}(\mathbb{D}_0) \to \mathbb{H}^{\mathrm{pol}}(\mathbb{D}_0)$$

is an isomorphism $\operatorname{Ho}(\mathbf{Ch}_{\geq 0})$ (and can be identified with the identity morphism $id_{\mathbb{Z}} : \mathbb{Z} \to \mathbb{Z}$, where \mathbb{Z} is seen as a chain complex concentrated in degree 0). From the naturality square

$$\kappa N_{\omega}(C) \longrightarrow \mathbb{H}^{\mathrm{pol}}(C)$$

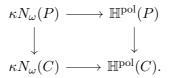

$$\downarrow \qquad \qquad \downarrow$$

$$\kappa N_{\omega}(\mathbb{D}_{0}) \longrightarrow \mathbb{H}^{\mathrm{pol}}(\mathbb{D}_{0})$$

we deduce that the top arrow is an isomorphism of $Ho(Ch_{\geq 0})$.

In the general case, let us choose an equivalence of ω -categories $u: P \to C$ with P cofibrant for the Folk model structure and consider the naturality

square

From Lemma 6.5, we deduce that P is also contractible, hence the top arrow is an isomorphism. Since u is a weak equivalence for the Folk model structure, both vertical arrows are isomorphisms and thus the bottom arrow is also an isomorphism.

7. The folk homotopy colimit theorem

7.1. For every object *a* of a (small) category *A*, we denote by A/a the slice category over *a*. That is, an object of A/a is a pair $(b, p : b \to a)$ where *b* is an object of *A* and *p* is an arrow of *A*, and an arrow $(b, p) \to (b', p')$ of A/a is an arrow $q : b \to b'$ of *A* such that $p' \circ q = p$.

We denote by

$$\pi_a: A/a \to A$$
$$(b,p) \mapsto b$$

the canonical forgetful functor.

Definition 7.2. Let A be a small category, a an object of A, X an ω -category and $f: X \to A$ be an ω -functor.

We define the ω -category X/a and the ω -functor

$$f/a: X/a \to A/a$$

as the following pullback

7.3. More explicitly, a *n*-arrow of X/a is a pair (x, p) where x is a *n*-arrow of X and p is an arrow of A of the form $p: f(t_0(x)) \to a$.

The source and target of a *n*-arrow of X/a (when n > 1) are given by

$$s((x,p)) = (s(x),p)$$
 and $t((x,p)) = (t(x),p)$.

For (x, p) a *n*-arrow of X/a, we have

$$(f/a)(x,p) = (f(x),p),$$

and the canonical arrow $X/a \to X$ is simply expressed as

$$(x,p) \mapsto x.$$

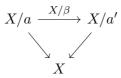

7.4. Let $f : X \to A$ be an ω -functor with A a 1-category. Any arrow $\beta : a \to a'$ of A induces an ω -functor

$$X/\beta: X/a \to X/a'$$
$$(x,p) \mapsto (x,\beta \circ p).$$

This defines a functor

$$\begin{array}{l} X/\text{-}: A \to \omega \mathbf{Cat} \\ a \mapsto X/a. \end{array}$$

Moreover, for every arrow $\beta: a \to a'$ of A, the triangle

is commutative. By universal property, this induces a canonical arrow

$$\operatorname{colim}_{a \in A} (X/a) \to X.$$

Now, let

be a commutative triangle in ω **Cat** with A a 1-category. For every $a \in Ob(A)$, we define the ω -functor g/a as

$$X/a \to X'/a$$
$$(x,p) \mapsto (g(x),p)$$

This induces an ω -functor

$$\operatorname{colim}_{a \in A}(X/a) \to \operatorname{colim}_{a \in A}(X'/a)$$

and the square

$$\begin{array}{c} \operatornamewithlimits{colim}_{a \in A}(X/a) \longrightarrow X \\ \downarrow & \qquad \downarrow^g \\ \operatornamewithlimits{colim}_{a \in A}(X'/a) \longrightarrow X' \end{array}$$

is commutative.

Lemma 7.5. Let $f : X \to A$ be an ω -functor such that A is a 1-category. The canonical arrow

$$\operatorname{colim}_{a \in A} (X/a) \to X$$

is an isomorphism.

Proof. We have to show that the cocone

$$(X/a \to X)_{a \in \mathrm{Ob}(A)}$$

is colimiting. Let

$$(g_a: (X/a) \to C)_{a \in \mathrm{Ob}(A)}$$

be another cocone and let x be a n-arrow of X. Notice that the pair

 $(x, 1_{f(t_0(x))})$

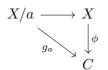

is a *n*-arrow of $X/f(t_0(x))$. We leave it to the reader to prove that the formula $\phi: X \to C$

$$: \Lambda \to C$$

$$x \mapsto g_{f(t_0(x))}(x, \mathbf{1}_{f(t_0(x))}).$$

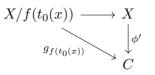

defines an ω -functor. This proves the existence part of the universal property.

It is straightforward to check that for every $a \in Ob(A)$ the triangle

23

is commutative. Now let $\phi': X \to C$ be another ω -functor that makes the previous triangles commute and let x be a n-arrow of X. Since the triangle

is commutative, we necessarily have

$$\phi'(x) = g_{f(t_0(x))}(x, 1_{f(t_0(x))})$$

which proves that $\phi' = \phi$.

Lemma 7.6. If X is free, then for any $a \in Ob(A)$ the ω -category X/a is free.

More precisely, if we denote by Σ_n^X the set of generating n-cells of X, then the set of generating n-cells of X/a is

$$\Sigma_n^{X/a} = \{(x,p) \in (X/a)_n | x \in \Sigma_n^X\}.$$

Proof. Remark first that for any $a \in Ob(A)$, the map

$$\pi_c: A/a \to A$$

is a discrete Conduché ω -functor (Definition 3.6). Hence, from Lemma 3.7, we deduce that the canonical map

$$X/a \to X$$

is a discrete Conduché ω -functor. We conclude with Proposition 3.8.

7.7. Let $f: X \to A$ be as before and suppose that X is free. Any arrow $\beta: a \to a'$ of A induces a map:

$$\begin{split} \Sigma_n^{X/a'} &\to \Sigma_n^{X/a} \\ (x,p) &\mapsto (x,\beta \circ p) \end{split}$$

This defines a functor

$$\begin{split} \Sigma_n^{X/-} &: A \to \mathbf{Set} \\ a &\mapsto \Sigma_n^{X/a} \end{split}$$

Lemma 7.8. If X is free, then there is a natural isomorphism

$$\Sigma_n^{X/-} \simeq \coprod_{x \in \Sigma_n^X} \operatorname{Hom}_A \left(f(t_0(x)), - \right).$$

Proof. Let a be an object of A. For each $x \in \Sigma_n^X$, there is a canonical map

$$\operatorname{Hom}_{A}\left(f(t_{0}(x)), a\right) \to \Sigma_{n}^{X/a}$$
$$p \mapsto (x, p)$$

that induces by universal property a map

$$\coprod_{x \in \Sigma_n^X} \operatorname{Hom}_A \left(f(t_0(x)), a \right) \to \Sigma_n^{X/a}.$$

The naturality in a and the fact that this map is an isomorphism are obvious. $\hfill \Box$

Proposition 7.9. Let $f: X \to A$ be an ω -functor with A a 1-category and X a free ω -category. The functor

$$X/-: A \to \omega \mathbf{Cat}$$
$$a \mapsto X/a.$$

is a cofibrant object for the projective model structure on $\omega \mathbf{Cat}^A$ induced by the Folk model structure on $\omega \mathbf{Cat}$.

Proof. Recall that the set

$$\{i_n: \mathbb{S}_{n-1} \to \mathbb{D}_n | n \in \mathbb{N}\}$$

is a set a generating cofibrations for the Folk model structure on ω **Cat**. From Lemmas 7.6 and 7.8 we deduce that for any $a \in Ob(A)$ and $n \in \mathbb{N}$, the canonical square

is a pushout square. It is straightforward to check that this square is natural in a in an obvious sense. The result follows from Lemma 2.6.

Theorem 7.10. Let X be an ω -category, A a 1-category and $f : X \to A$ an ω -functor. The canonical arrow of Ho(ω Cat)

$$\underset{a \in A}{\operatorname{hocolim}}(X/a) \to \underset{a \in A}{\operatorname{colim}}(X/a)$$

is an isomorphism.

NB. Note that in the previous theorem, we did *not* suppose that X was cofibrant for the Folk model structure.

Proof of Theorem 7.10. Let P be a free ω -category and $g: P \to X$ a trivial fibration for the Folk model structure. We have a commutative diagram in

 $Ho(\omega Cat)$

where the vertical arrows are induced by the arrows

$$g/a: P/a \to X/a.$$

Since trivial fibrations are stable by pullback, g/a is a trivial fibration. This proves that the left vertical arrow of square (1) is an isomorphism.

Moreover, from paragraph 7.4 and Lemma 7.5, we deduce that the right vertical arrow of (1) can be identified with the image of $g : P \to X$ in $Ho(\omega Cat)$ and hence is an isomorphism.

Finally, from Proposition 7.9, we deduce that the top horizontal arrow of (1) is an isomorphism.

This proves the theorem.

8. Homology of 1-categories

8.1. For a functor $d : A \to \mathbf{Cat}$ with A a small category, we denote by $\int_A d$ the *Grothendieck construction for d*. We refer to [Mal05, Section 3.1] for a definition and basic properties of this construction. Recall that there is a canonical morphism $\int_A d \to A$ as well a canonical morphism $\int_A d \to \operatorname{colim}_A(d)$, and that if d is the functor $a \mapsto A/a$ then these two morphisms can be identified via the isomorphism $\operatorname{colim}_A A/a \simeq A$.

Lemma 8.2. Let A be a small category and consider the functor

$$A \to \omega \mathbf{Cat}$$
$$a \mapsto A/a.$$

The canonical map

$$\operatorname{hocolim}_{a \in A} N_{\omega}(A/a) \to N_{\omega}(\operatorname{hocolim}_{a \in A} A/a)$$

is an isomorphism of $Ho(\Delta)$.

Proof. The proof is long and we divide it in several parts. Recall that we consider **Cat** as a full subcategory of ω **Cat** (see Remark 3.3). Given a functor $d : A \rightarrow$ **Cat**, we still denote d the functor obtained by post-composition

$$A \xrightarrow{d} \mathbf{Cat} \longleftrightarrow \omega \mathbf{Cat}.$$

Preliminaries: We say that a morphism of $\omega \mathbf{Cat}$, $f: X \to Y$, is a Thomason weak equivalence when $N_{\omega}(f)$ is a weak equivalence of simplicial sets. We denote by $\mathcal{W}_{\omega}^{\mathrm{Th}}$ the class of Thomason weak equivalences. In order to avoid any confusion, we use the notation $\mathrm{Ho}^{\mathrm{Th}}(\omega \mathbf{Cat})$ for the localization of $\omega \mathbf{Cat}$ with respect to Thomason weak equivalences and the notation $\mathrm{Ho}^{\mathrm{folk}}(\omega \mathbf{Cat})$ the localization of $\omega \mathbf{Cat}$ with respect to $\mathcal{W}_{\omega}^{\mathrm{folk}}$, the weak equivalences of the folk model structure (3.12).

Similarly, we denote by $\mathcal{W}_1^{\text{Th}}$ the class of arrows of **Cat** whose elements are Thomason weak equivalences (seen as arrows of ω **Cat**) and by HoTh(**Cat**) the localization of **Cat** with respect to $\mathcal{W}_1^{\text{Th}}$. Note that $\mathcal{W}_1^{\text{Th}}$ is indeed the class of weak equivalences of the model structure on **Cat** considered by Thomason in [Tho80].

Thus, we have defined three localizers: $(\mathbf{Cat}, \mathcal{W}_1^{\mathrm{Th}})$, $(\omega \mathbf{Cat}, \mathcal{W}_{\omega}^{\mathrm{Th}})$ and $(\omega \mathbf{Cat}, \mathcal{W}_{\omega}^{\mathrm{folk}})$. We have already seen that $(\omega \mathbf{Cat}, \mathcal{W}_{\omega}^{\mathrm{folk}})$ has homotopy colimits and from the existence of the Thomason model structure on \mathbf{Cat} [Tho80], we deduce that $(\mathbf{Cat}, \mathcal{W}_1^{\mathrm{Th}})$ has homotopy colimits. Although the existence of a model structure on $\omega \mathbf{Cat}$ with the Thomason weak equivalences as weak equivalences is not established (see [AM14] though), we will see later in this proof that $(\omega \mathbf{Cat}, \mathcal{W}_{\omega}^{\mathrm{Th}})$ has homotopy colimits. In order to explicitly distinguish the homotopy colimits in these three localizers, we use the self-explanatory notations:

Similarly, we use the notations

$$\begin{array}{cc} \mathbf{Cat} & \omega \mathbf{Cat} \\ \operatorname{colim}_{A} & \operatorname{and} & \operatorname{colim}_{A} \end{array}$$

to distinguish colimits in **Cat** and ω **Cat**.

Thomason's homotopy colimit theorem: From [Mal05, Section 3.1], we know that the functor $\int_A : \mathbf{Cat}^A \to \mathbf{Cat}$ preserves Thomason weak equivalences and that the induced functor

$$\overline{\int_A} : \operatorname{Ho}^{\operatorname{Th}}(\mathbf{Cat}^A) \to \operatorname{Ho}^{\operatorname{Th}}(\mathbf{Cat})$$

is a left adjoint to the diagonal functor (1.4)

 $\overline{k} : \operatorname{Ho}^{\operatorname{Th}}(\operatorname{\mathbf{Cat}}) \to \operatorname{Ho}^{\operatorname{Th}}(\operatorname{\mathbf{Cat}}^A).$

Hence, there is a canonical isomorphism of functors

$$\overline{\int_A} \simeq \underset{A}{\overset{\mathbf{Cat},\mathrm{Th}}{\underset{A}{\overset{\mathrm{Cat},\mathrm{Th}}}}}.$$

Since for any object a of A, the category A/a has a terminal object, it follows from [Qui73, Section 1, Corollary 2] that the canonical morphism

$$p_{A/a}: A/a \to \mathbb{D}_0$$

to the terminal category is a Thomason weak equivalence. In particular, if $d: A \to \mathbf{Cat}$ is the functor $a \mapsto A/a$, the induced map

(2)
$$\int_{A} d \to \int_{A} k(\mathbb{D}_{0}),$$

where $k(\mathbb{D}_0)$ is the constant diagram with value \mathbb{D}_0 , is an isomorphism of HoTh(**Cat**). A quick computation left to the reader shows

that $\int_A k(\mathbb{D}_0) \simeq A$ and that the map (2) can be identified with the canonical map

$$\operatorname{Cat,Th}_{a \in A} A/a \to \operatorname{colim}_{a \in A} A/a,$$

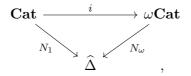

which is an isomorphism of $Ho^{Th}(Cat)$.

Preservation of Thomason homotopy colimits: From [Gag18, Theorem 2.4 and 6.9], it follows that $N_{\omega} : \omega \operatorname{Cat} \to \widehat{\Delta}$ induces an equivalence of prederivators (here $\omega \operatorname{Cat}$ is equipped with Thomason weak equivalences). Concretely to us, this implies that $(\omega \operatorname{Cat}, \mathcal{W}_{\omega}^{\mathrm{Th}})$ has homotopy colimits and that for any functor $d : A \to \omega \operatorname{Cat}$, the canonical map

$$\widehat{\Delta}_{\substack{A \\ \text{hocolim}(N_{\omega}(d)) \to N_{\omega}(\underset{A}{\overset{\omega \mathbf{Cat}, \mathrm{Th}}{\operatorname{hocolim}}(d))}}$$

is an isomorphism of $\operatorname{Ho}(\widehat{\Delta})$.

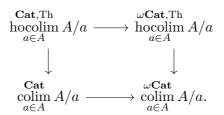

Similarly, the usual nerve functor for 1-categories $N_1 : \mathbf{Cat} \to \Delta$ induces an equivalence of prederivators and from the commutativity of the triangle

and the fact that *i* preserve Thomason weak equivalences (by definition), we deduce that *i* also induces an equivalence of prederivators. Hence, for any functor $d: A \to \mathbf{Cat}$, the canonical map

$$\overset{\omega \mathbf{Cat},\mathrm{Th}}{\operatorname{hocolim}(d)} \xrightarrow{\mathbf{Cat},\mathrm{Th}}{\operatorname{hocolim}(d)}$$

is an isomorphism of HoTh(ω **Cat**). Consider now the commutative square in HoTh(ω **Cat**):

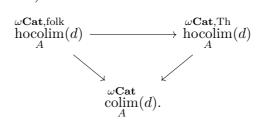

So far we have proved that the top horizontal arrow and the left vertical arrows are isomorphisms. Since the inclusion functor $Cat \rightarrow \omega Cat$ preserves colimits, the bottom horizontal arrow is also an isomorphism. This implies that the right vertical arrow is an isomorphism.

Comparing Folk and Thomason homotopy colimits: From Lemma 5.5, we have that $\mathcal{W}^{\text{folk}}_{\omega} \subseteq \mathcal{W}^{\text{Th}}_{\omega}$. In particular, the identity functor $\omega \text{Cat} \to \omega \text{Cat}$ induces a functor

$$\operatorname{Ho}^{\operatorname{folk}}(\omega \operatorname{\mathbf{Cat}}) \to \operatorname{Ho}^{\operatorname{Th}}(\omega \operatorname{\mathbf{Cat}}),$$

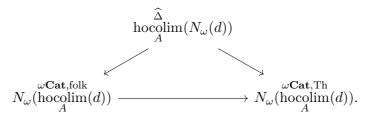

and for any functor $d: A \to \omega \mathbf{Cat}$, we have a commutative triangle in HoTh($\omega \mathbf{Cat}$):

In the case d is the functor $a \mapsto A/a$, we have already proved that the two slanted arrows of the previous triangle were isomorphisms. Hence, the canonical map

$$\substack{ \omega \mathbf{Cat}, \mathrm{folk} \\ \mathrm{hocolim} \ A/a \to \operatorname{hocolim} A/a \\ a \in A} \xrightarrow{\omega \mathbf{Cat}, \mathrm{Th}} A/a$$

is an isomorphism. Consider now the commutative triangle induced by the nerve functor:

We have already seen that the slanted arrow on the right is an isomorphism. In the case that d is the functor $a \mapsto A/a$, it follows from what we have proved that the horizontal arrow is an isomorphism. Hence, the canonical map

is an isomorphism.

We can now prove the main theorem of this paper.

Theorem 8.3. Let A be a small category seen as an object of ω **Cat**. The canonical comparison map

$$\kappa N_{\omega}(A) \to \mathbb{H}^{\mathrm{pol}}(A)$$

is an isomorphism of $Ho(Ch_{\geq 0})$.

Proof. We have a commutative diagram

$$\begin{split} \underset{a \in A}{\operatorname{hocolim}} & \kappa N_{\omega}(A/a) \longrightarrow \kappa N_{\omega}(\operatorname{hocolim} A/a) \longrightarrow \kappa N_{\omega}(\operatorname{colim} A/a) \longrightarrow \kappa N_{\omega}(A) \\ & \downarrow \qquad (A) \qquad \downarrow \qquad (B) \qquad \downarrow \qquad (C) \qquad \downarrow \\ \operatorname{hocolim}_{a \in A} & \mathbb{H}^{\operatorname{pol}}(A/a) \longrightarrow & \mathbb{H}^{\operatorname{pol}}(\operatorname{hocolim}_{a \in A} A/a) \longrightarrow & \mathbb{H}^{\operatorname{pol}}(\operatorname{colim}_{a \in A} A/a) \longrightarrow & \mathbb{H}^{\operatorname{pol}}(A), \end{split}$$

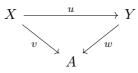

where the vertical arrows are induced by the canonical comparison map. The goal is to show that the right vertical map of square (C) is an isomorphism.

By Lemma 7.5 the horizontal arrows of square (C) are isomorphisms. By Theorem 7.10, the horizontal arrows of square (B) are isomorphisms. By Lemma 8.2, the top horizontal arrow of square (A) is an isomorphim, and by 2.8 the bottom horizontal arrow of the same square is an isomorphism. Finally, by Proposition 6.6, the left vertical arrow of square (A) is an isomorphism. By 2-out-of-3 property for isomorphisms, this shows what we wanted.

9. Complement : a folk Theorem A

9.1. As a corollary of Theorem 7.10, we obtain Proposition 9.2 below. It is to be compare with Theorem A of Quillen [Qui73, Theorem A] and its generalization for ω -categories by Ara and Maltsiniotis [AM18] and [AM20]. However, note that in the pre-cited references, the weak equivalences considered are the ones induced by the nerve (5.4), whereas in the proposition below we work with the weak equivalences of the Folk model structure (3.10).

Proposition 9.2. Let

be a commutative triangle in ω **Cat** and suppose that A is a 1-category. If for every $a \in Ob(A)$, the induced arrow

$$u/a: X/a \to Y/a$$

is an equivalence of ω -categories, then u is also an equivalence of ω -categories.

Proof. Consider the commutative square in Ho(ω **Cat**):

$$\begin{array}{c} \operatorname{hocolim}(X/a) \longrightarrow \operatorname{colim}(X/a) \\ \downarrow \qquad \qquad \downarrow \\ \operatorname{hocolim}(Y/a) \longrightarrow \operatorname{colim}(Y/a) \end{array}$$

where the vertical arrows are induced by the arrows

$$u/a: X/a \to Y/a.$$

Since we supposed that these arrows were weak equivalences of the Folk model structure, it follows that the left vertical arrow of the previous square is an isomorphism. From Theorem 7.10, the horizontal arrows are isomorphisms.

This proves that the right vertical arrow is also an isomorphism but it follows from 7.4 and Lemma 7.5 that this arrow can be identified with the image of $u: X \to Y$ in Ho(ω **Cat**).
