We report the synthesis and structural characterisation of new Mn₁₉ and Mn₁₈M analogues, [Mn^{III}₁₂Mn^{II}₇(μ₄-O)₈(μ₃-OCH₃)₂(μ₃-Br)₆(HL^{Me})₁₂(MeOH)₆]Br₂ (**2**) and [Mn^{III}₁₂Mn^{II}₆Sr(μ₄-O)₈(μ₃-Cl)₈(HL^{Me})₁₂(MeCN)₆]Cl₂ cluster (**3**), where H₃L^{Me} is 2,6-bis(hydroxymethyl)-p-cresol. The electrochemistry of **2** and **3** have been investigated and their activity as catalysts in the oxidation of benzyl alcohol has been evaluated. Selective oxidation of benzyl alcohol to benzaldehyde by O₂ was achieved using 1 mol% of catalyst with conversions of 74 % (**2**) and 60 % (**3**) at 140 °C using TEMPO as a co-catalyst. No partial conversion of benzaldehyde to benzoic acid was observed. The results obtained revealed that different operative parameters - such as catalyst loading, temperature, time, solvent and the presence of molecular oxygen - played an important role in the selective oxidation of benzyl alcohol.

Introduction

Manganese-based coordination clusters continue to attract intense research interest because they serve as models for various metalloenzymes,¹ and sometimes show interesting magnetic properties.^{2,3} For some time now, we have developed a variety of homo- and hetero-metallic Mn clusters using phosphonate ligands,⁴⁻⁸ and the H₃L^R ligand system based on 2,6-bis(hydroxymethyl)-4-R-phenol (where R is the substituent at the 4-position).⁹⁻¹⁴ Among others, we are particularly interested in the coordination chemistry of the H₃L^R ligand system because of the variable modes (μ₂ or μ₃) of coordination provided by this oxido-rich molecule that leads to the isolation of organic-inorganic hybrid architectures with multiple metal centres. To this end, we have successfully developed reproducible routes for the syntheses of homometallic Mn₁₉(R) (R = H, Me, I, F, OMe, SMe)⁹⁻¹² and/or heterobimetallic Mn₁₈M (M = Cd, Sr, Dy, Lu, Y) aggregates^{13,14} using this ligand system. The Mn₁₉ and Mn₁₈M systems represent a family of materials with attractive structural and magnetic properties which may open new gateways to coordination complexes exhibiting a broad range of

physicochemical properties appropriate for developing applications in data storage,¹⁵ catalysis,¹⁶ piezoelectricity,¹⁷ and superconductivity.¹⁸ Experimental and theoretical studies have revealed that the achievement of the maximum possible ground spin state of S_T = 83/2 for the mixed-valence Mn₁₉ system is insensitive to replacement of its eight μ₃-N₃ ligands of the original Mn₁₉ aggregate [Mn^{III}₁₂Mn^{II}₇(μ₄-O)₈(μ₃-N₃)₈(HL^{Me})₁₂(MeCN)₆]Cl₂ (**1**) by μ₃-Cl, μ₃-Br, μ₃-OH or μ₃-OMe, substantiating that the ferromagnetic interactions are mediated mainly by the internal (μ₄-O) ligands. Indeed, ESI-MS studies have further demonstrated the robustness of the inorganic {Mn^{III}₁₂Mn^{II}₇(μ₄-O)₈} core in the Mn₁₉ and Mn₁₈Y species as these maintain their integrity even in relatively reactive solvents (MeOH/H₂O).¹² While structural studies on these systems have focused on the modification of peripheral organic ligands, the manipulation of the face-bridging ligands as well as the selective incorporation of heterometals in view of assessing their influence on the magnetic properties of the resulting compounds,⁹⁻¹⁴ their potential as catalysts has not been explored, despite their structural (core robustness, labile apical ligands, ease of functionalization) and electronic (mixed-valence Mn) attributes. Manganese species have been shown to function as catalysts for organic and water oxidations in the presence of a variety of oxidants,¹⁹ and have also been used as electrocatalysts.^{20,21}

A variety of catalytic methods have been developed to harness molecular oxygen for the partial oxidation of alcohols to aldehydes, or for their complete oxidation to yield carboxylic acids.²² Along these lines, the partial oxidation of benzyl alcohol to benzaldehyde with molecular oxygen has been particularly well-studied, due to the role of the latter as a versatile intermediate in the pharmaceutical and agrochemical industries.²³⁻²⁶ A great many factors such as catalyst, temperature, solvent and oxidant play an important role in the reaction.²⁷⁻³³ Homometallic Mn and heterometallic Mn/M (M = Ce) complexes and many other metal-oxo complexes have also been

widely used as oxidants in chemical transformations such as the partial dehydrogenation of primary alcohols into their corresponding aldehydes.³³⁻³⁷ To this end, we have chosen the partial oxidation of benzyl alcohol as a model substrate to study the catalytic activity of new analogues of the structural robust Mn₁₉ and Mn₁₈Sr coordination clusters, namely, [Mn^{III}₁₂Mn^{II}₇(μ₄-O₈(μ₃-OCH₃)₂(μ₃-Br)₆(HL^{Me})₁₂(MeOH)₆]Br₂ (**2**) and [Mn^{III}₁₂Mn^{II}₆Sr(μ₄-O₈(μ₃-Cl)₈(HL^{Me})₁₂(MeCN)₆]Cl₂ (**3**). Compounds **2** and **3** are mixed-valent, comprising multiple Mn^{II}/Mn^{III} centres and thus have the ability to transfer (multiple) electrons. Moreover, the core features labile solvent molecules that may facilitate the coordination of incoming substrates. The electrochemical properties of **2** and **3** have been investigated, and their catalytic activity in the oxidation of benzyl alcohol has been evaluated, to test the potential of these compounds in molecular catalysis.

Experimental

Reagents and analytical methods

All chemicals and solvents were of reagent grade and purchased from Sigma-Aldrich and used without further purification. Infrared spectra were recorded on a PerkinElmer Spectrum One FT-IR spectrometer using either a universal ATR sampling accessory or a diffuse reflectance sampling accessory. Data were collected and processed using Spectrum v5.0.1 (2002 PerkinElmer Instrument LLC) software. The scan rate was 16 scans per minute with a resolution of 4 scans in the range 4000-500 cm⁻¹ (ATR measurements were performed on an ATR IRAffinity-1 instrument (Shimadzu Scientific Instruments). The analyzed samples were prepared by deposition of powder or crystals directly onto the sample plate surface). The standard abbreviations were used to describe the intensities: s, strong; m, medium; w, weak; br, broad. Elemental analyses (CHN) were performed at the School of Chemistry and Chemical Biology, University College Dublin (Ireland), using Exeter Analytical CE 440 elemental analyser. GC-MS analysis were performed on a GC System 7820A (G4320) connected to a MSD block 5977E (G7036A), using Agilent High Resolution Gas Chromatography Column: PN 19091S – 433UI, HP – 5MS UI, 28 m x 0.250 mm, 0.25 Micron, SN USD 489634H. All samples were prepared in ethyl acetate (200 μL sample volume). The analysis was carried out on a splitless 1 μL injection volume with an injection port temperature 250 °C. Column oven temperature program was as follows: 60 °C for 1 min, ramped at 30 °C/min to 310 °C with 3 min hold, with a total running time of 12.33 min. The mass spectrometer was turned on after 2 min and was operated at the electron ionization mode with quadrupole temperature of 150 °C. Data acquisition was performed in the full-scan mode (50-500). Hydrogen (99.999 % purity) was used as carrier gas at a constant flow rate of 1.5 mL/min.

Synthesis

Synthesis of [Mn^{III}₁₂Mn^{II}₇(μ₄-O)₈(μ₃-OCH₃)₂(μ₃-Br)₆(HL^{Me})₁₂(MeOH)₆]Br₂ (**2**)

MnCl₂·4H₂O (0.2 g, 1 mmol, 1.0 equiv), Et₃N (0.1 g, 1 mmol, 1.0 equiv) and 2,6-bis(hydroxymethyl)-4-methylphenol (0.17 g, 1 mmol, 1.0 equiv) were respectively added, under stirring, to a MeCN/MeOH solution (25 mL/5 mL). The resulting slurry was stirred for 1 h at RT,

before being heated at reflux for 2 h, to afford a dark brown solution, which was cooled and filtered. Dark brown crystals of **2** were obtained after 48 h slow evaporation at RT. The crystals were filtered, washed and dried. Yield: 30 % (based on Mn). Elemental analysis (%) calc. for C₁₃₇H₁₈₄Br₈Mn₁₉N₁₀O₅₃: C 36.55; H 4.12; N 3.11; found: C 36.62; H 4.23; N 3.25. Selected IR data (KBr pellet, cm⁻¹) 600 (s), 800 (s), 1050 (m), 1100 (m), 1211 (s), 1409 (s), 1610 (m), 2800 (w), 3300 (w,br).

Synthesis of [Mn^{III}₁₂Mn^{II}₆Sr(μ₄-O₈(μ₃-Cl)₈(HL^{Me})₁₂(MeCN)₆]Cl₂ (**3**)

A slurry of MnCl₂·4H₂O (0.2 g, 1 mmol, 1.0 equiv), Et₃N (0.1 g, 2 mmol, 2.0 equiv), 2,6-bis(hydroxymethyl)-4-methylphenol (0.17 g, 1 mmol, 1.0 equiv) in a solvent mixture of MeCN and MeOH (25 mL/5 mL) was stirred for 30 min at RT, and Sr(NO₃)₂ (0.11 g, 0.5 mmol, 0.5 equiv) was added. The resulting mixture was further stirred for an additional 1 h, then heated at reflux for 2 h. The dark brown mixture was cooled and filtered. After a 24 h slow evaporation at RT, dark brown crystals of **3** suitable for X-ray diffraction analysis were obtained. Yield: 40 % (based on Mn). Elemental analysis (%) calc. for C₁₂₇H₁₅₄Cl₈Mn₁₈N₆O₅₁Sr (**3**): C 38.71; H 3.94; N 2.13; found: C 38.62; H 3.63; N 2.25. FT-IR (cm⁻¹): 610 (s), 740 (s), 990 (s), 1050 (s), 1248 (s), 1495 (s), 1600 (m), 2812(w), 3300(s,br).

Single-crystal X-ray crystallographic measurements

X-ray structural analyses for crystals of **2** (TCD304) and **3** (TCD 716) were performed on at 100K on a Bruker APEX DUO CCD and Bruker D8 Quest ECO diffractometer respectively (Mo-K_α λ = 0.71073 Å). The maximum resolution for data collection was 0.77 Å with data collected using ω and φ scans for **2** and 0.80 Å using ω scans only for **3**.

The data were reduced and processed using the Bruker APEX suite of programs.³⁸ Multi-scan absorption corrections were applied using SADABS.³⁹ Using Olex2,⁴⁰ the structure was solved with the XT⁴¹ structure solution program using Intrinsic Phasing and refined with the XL⁴² refinement package using Least Squares minimisation. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions and refined with a riding model, with isotropic displacement parameters equal to either 1.2 or 1.5 times the isotropic equivalent of their carrier atoms.

The data were solved in the monoclinic space group P2₁/n (**2**) trigonal space group R $\bar{3}$ (**3**). In the structure of **2**, uncoordinated MeOH was refined with restraints (DFIX, ISOR) and modelled as half occupied. Hydroxide hydrogen atoms on all MeOH (coordinated and uncoordinated) as well as ligand OH moieties were located and refined with restraints (DFIX). Two acetonitrile solvates were also modelled with restraints (ISOR). In **3**, all MeOH molecules were modelled as half occupied with restraints (DFIX, ISOR). One MeOH (C32-O33) is on the three fold axis and the hydrogens are modelled with an occupancy of 0.16667. Large voids are present in **3** of ca. 227 Å³, with a total of 689 Å³ per unit cell. SQUEEZE⁴³ was used to verify that the void volume does not contain any electron density.

Crystal data and details of data collection and refinement of compounds **2** and **3** are summarized in Table S1. Crystallographic data, CCDC 1882361-1882362, can be obtained free of charge from

the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Electrochemistry

Electrochemical measurements were carried out in DMF containing 0.1 M Bu₄NPF₆ in a classical three-electrode cell by cyclic voltammetry (CV) and rotating-disk voltammetry (RDV). The working electrode was a glassy carbon disk (GC, 3 mm in diameter), the auxiliary electrode a Pt wire, and the pseudo reference electrode a Pt wire. The cell was connected to an Autolab PGST, AT30 potentiostat (Eco Chemie, Holland) driven by a GPSE software running on a personal computer. All potentials are given vs. Fc^{+/0}/Fc used as internal reference and are uncorrected from ohmic drop.

Chemical Oxidation

Optimization of oxidation of benzyl alcohol to benzaldehyde

All reactions were carried out in 1 mL glass vial under oxygen atmosphere, unless otherwise noted.

In a typical experiment: To a 1 mL glass vial containing a Teflon-coated magnetic stir bar was added cluster catalyst (2.3 mg, 0.60 μmol, 1.0 mol%), TEMPO (2.1 mg, 0.013 mmol, 22 mol%), benzyl alcohol (6.4 μL, 0.060 mmol, 1.0 equiv), followed by the addition of DMF (300 μL). The contents of the vial were flushed with oxygen for ca. 2 minutes. The vial was then quickly sealed and the reaction mixture magnetically stirred for 24 h in sand bath that was maintained at an internal temperature of 140 °C using an electronic thermocouple. The reaction vial was then removed from the sand bath and allowed to cool to RT. 500 μL of ethyl acetate was added to the mixture, and the solution was centrifuged until separation of the solid catalyst was achieved. A sample for GC-MS analysis was prepared by removing 10 μL of the liquid phase from the reaction, followed by dilution with ethyl acetate (190 μL).

Results and Discussion

Previously, we have demonstrated that depending on the reactants, the face-bridging ligands of the Mn₁₉ system can either be N₃, Br, Cl, OMe or OH.⁹⁻¹⁴ Herein, refluxing a mixture of H₃L^{Me} and MnBr₂·4H₂O in the presence of Et₃N in MeCN/MeOH (5/1, v/v) afforded [Mn^{III}₁₂Mn^{II}₇(μ₄-O₈(μ₃-OCH₃)₂(μ₃-Br)₆(HL^{Me})₁₂(MeOH)₆]Br₂ (**2**). When a similar reaction was carried out with MnCl₂·4H₂O as source of Mn and in the additional presence of Sr(NO₃)₂, the compound [Mn^{III}₁₂Mn^{II}₆Sr(μ₄-O₈(μ₃-Cl)₈(HL^{Me})₁₂(MeCN)₆]Cl₂ (**3**) was obtained. Single crystal X-ray analyses revealed that the compounds crystallize in the monoclinic *P*2₁/*n* (**2**) and the trigonal *R*-3 (**3**) space groups, with two and three molecules, respectively in the unit cell. The results of the X-ray structural analysis are summarized in Table S1. The crystal structure of **2** and **3** are given in Fig. 1.

Fig. 1 Symmetry unique metal/halide labelled core only diagrams of **2** (upper) and **3** (lower). All solvents, hydrogen, carbon and nitrogen atoms omitted for clarity. A full diagram of each molecule is given in the SI. Atomic displacement shown at 50% probability.

The core of **2** and **3** are isostructural to the topology of the previously reported {Mn₁₉} and {Mn₁₈M} complexes⁹⁻¹⁴ and can be considered as consisting of two supertetrahedral {Mn^{III}₆Mn^{II}₄} units sharing a common Mn^{II} vertex (**2**) or two supertetrahedral {Mn^{III}₆Mn^{II}₃Sr} units sharing a common Sr vertex (**3**). Compounds **2** and **3** slightly differ from the previously reported analogues. For instance, compound **2** differs from the original Mn₁₉ aggregate (**1**)⁹, as well as the analogous compound [Mn^{III}₁₂Mn^{II}₇(μ₄-O)₈(HL^{Me})₁₂(μ₃-Br)₇(μ₃-OH)(MeCN)₆]Br₂ (**4**)¹², in terms of their μ₃-face-bridging ligands. In **2**, the two face-bridging ligands on the molecular threefold axis are both (μ₃-OMe) unlike in compound **1** and **4** where these are made up of μ₃-N₃ (**1**) or μ₃-Br and μ₃-OH (**4**) ligands, respectively. Compound **2** also differs from **4** in the composition of the six terminal ligands on the outer Mn^{II} vertices of the supertetrahedron. In **2**, these are MeOH while in **4** these are exclusively MeCN as in compound **1**. It should be pointed out here that while similar solvent mixtures (MeCN/MeOH, 5/1, vol/vol) were employed for these reactions, the reason for the observed differences in structural composition is unclear. Moreover, all attempts to completely substitute the face-bridging ligands with μ₃-Br by using excess bromide source were unsuccessful. We have

also previously reported a Mn₁₉ aggregate, [Mn^{III}₁₂Mn^{II}₇(μ₄-O)₈(HL^{Me})₁₂(μ₃-Cl)₆(μ₃-OMe)₂(MeOH)₅(MeCN)]Cl₂ (**5**),¹² where the two face-bridging ligands on the molecular threefold axis are both μ₃-OMe as observed in **2**. In **5**, six of the face-bridging ligands are chlorides, hence compound **2** is a new analogue of the Mn₁₉ system.

Electrochemistry

Investigations of the species were carried out by cyclic voltammetry and rotating disk voltammetry (RDV) in DMF + 0.1 M Bu₄NPF₆. The electrochemical data for compound **2** and **3** are shown in Table 1.

Table 1 Electrochemical data for **2** and **3** in DMF (+ 0.1 M Bu₄NPF₆ against Fc^{+/0}/Fc).

Species	CV			RDV
	E ^o ^{a)} V/Fc ^{+/0} /Fc	ΔE _p ^{b)} mV	E _p ^{c)} V/Fc ^{+/0} /Fc	E _{1/2} ^{d)} V/Fc ^{+/0} /Fc
Mn ₁₉ (2)	-2.25	90	0.42	0.33
			-1.29	^{d)}
			-1.89	^{d)}
Mn ₁₈ Sr (3)			0.25	0.29
			-1.20	-1.20
			-1.75	-1.75
			-2.10	-2.16

^a E^o = (E_{pc} + E_{pa})/2, where E_{pc} and E_{pa} correspond to the cathodic and anodic peak potentials, respectively.

^b ΔE_p = E_{pa} - E_{pc}.

^c E_p = irreversible peak potential.

^d Due to important adsorption at the electrode, the RDV in the cathodic domain is ill defined and is not exploitable.

In oxidation, cyclic voltammetry (CV) of **2** showed two successive irreversible peaks measured at -0.12 V and 0.42 V vs. Fc^{+/0}/Fc measured without Fc after the reduction of Mn₁₉ (**2**) (Fig. 2, red curve with initial scanning direction to negative potential, explicitly reduction followed by the oxidation) while RDV presented only one wave at 0.33 V vs. Fc^{+/0}/Fc (Fig. S3, left). It should be pointed out that, the first peak detected from CV at -0.12 V was not measured in the case of the initial scanning direction to positive potential (Fig. 2, black curve), namely oxidation followed by the reduction. The potential of the only irreversible peak observed was measured at 0.27 V (measured in the absence of Fc), a value close to the potential obtained from RDV (Fig. S3). Thus, the first peak may be due to the re-oxidation of the reduced compound **2**, which might evolve after reduction to give a different oxidation potential for the Mn(III/II) redox couple. Alternatively, the first signal might be due to adsorption of the reduced compound **2** at the GC electrode, which renders the Mn atoms easier to oxidize. Because of such adsorption the coulometry is difficult to be done and give important variability of the value for the number of electron exchanged measured. The wave from CV at 0.27 V corresponds to the irreversible oxidation of the seven Mn(II) atoms to Mn(III) according the molecular structure of [Mn^{III}₁₂Mn^{II}₇(μ₄-O)₈(μ₃-OCH₃)₂(μ₃-Br)₆(HL^{Me})₁₂(MeOH)₆]Br₂ (**2**). Controlled potential coulometry under continuous argon bubbling and stirring at applied potential of 0.4 V has been conducted several times and consumes between 6.8 to 7.4 electrons *per* molecule.

Indeed, we have done two exhaustive oxidations giving 6.8, and 7.4 electrons exchanged. The fluctuation of the number of electron exchanged is probably due to the adsorption of compound (**2**) at the electrode which strongly alter the measurements.

For the Mn₁₈Sr cluster (**3**), in oxidation, cyclic voltammogram (CV) showed only one irreversible peaks at 0.25 V vs. Fc^{+/0}/Fc. RDV presented also only one wave at 0.29 V vs. Fc^{+/0}/Fc (Fig. S4). The first peak detected might be due to the oxidation of the six Mn(II) atoms to Mn(III). Such behaviour is similar to **2** compound except that the six Mn(II) are easier to be oxidized (0.25 V *versus* 0.43 V).

In the cathodic domain, CV showed three successive reductions. The first two reductions are irreversible and ill-defined at -1.29 V and -1.89 V, while the last reduction was reversible at -2.25 V (ΔE_p = 90 mV) vs. Fc^{+/0}/Fc peaks. Due to significant adsorption at the electrode, the RDV in the cathodic domain is ill-defined and is not exploitable (Fig. S3). Thus for compound **3**, the presence of the Sr atom does not affect strongly the redox behaviour in reduction. In oxidation, the oxidation of the Mn(II) are 180 mV easier to be oxidized than for **2**. The redox behaviour in reduction is also similar to **2** showing three successive steps but 90, 140 and 150 mV easier to be reduced than for **2**, respectively.

Fig. 2 Cyclic voltammetry of Mn₁₉ (**2**) at a scan rate of 0.1 V s⁻¹ in DMF 0.1 M TBAPF₆ with Fc (blue curve) and without Fc (black and red curves), c = 1 mM. The arrow as well as the color of the curves (black or red) indicate the beginning and sweep direction of the voltammetric scan. Black curve: initial scanning direction to negative potential [reduction of Mn₁₉ (**2**)] followed by a reverse sweep back in order to join the oxidation wave. Red curve: initial scanning direction to positive potential [oxidation of Mn₁₉ (**2**)].

Catalytic Oxidation

The ability of compounds **2** and **3** to act as catalysts for the partial chemical oxidation of benzyl alcohol to benzaldehyde was investigated. In analogy with previous catalytic oxidations using manganese clusters,³³ our initial investigations employed **2** (typically 1 mol%) with benzyl alcohol (1 equiv) and TEMPO (22 mol%) in DMF under an oxygen atmosphere (1 atm). GC-MS analysis of reactions carried out in a variety of solvents after 18 h at 100 °C indeed confirmed that DMF was the most efficient, likely due to the high solubility of the catalyst in that solvent (see Table S2). After optimization of temperature and time, it was found that after 24 h at 140 °C, 74% conversion to benzaldehyde was achieved without observable accompanying over-oxidation to benzoic acid (Table 2, entry 1). Further optimisation and control experiments were carried out to better understand the reaction. Catalyst **2** was indeed

required (entry 2). Lower reaction temperatures were not suitable (entries 3-4). A catalyst loading of 1 mol% was found to be optimal, with higher or lower loadings leading to poorer yields (entries 5-7). Leaving out TEMPO does not completely stop the reaction but leads to lower yields (entry 8). In the presence of TEMPO, using air instead of O₂ or even conducting the reaction under an Ar atmosphere still does not completely inhibit the reaction (entries 9-10), showing that the ultimate source of oxidant is *flexible*. However, an oxidant is nonetheless required, since omitting TEMPO and using air instead of O₂ at the same time leads to a drastic drop in yield (entry 11).

The oxidation of benzyl alcohol was also evaluated with Mn₁₈Sr (**3**) under the same conditions (Table 3). The Mn₁₈Sr catalyst gives slightly lower yields compared to Mn₁₉ and overoxidation is again not observed. No reaction occurs in the absence of **3** (entry 2). One notable observation is that the Mn₁₈Sr catalyst works best in the absence of TEMPO (entry 3), in departure from oxidation reactions catalysed by CeMn₆ clusters previously reported by Christou and co-workers.³³ In that prior report, the Ce atom was found to be the active component in the catalytic oxidation, and served to oxidize TEMPO, which in turn oxidizes the alcohol. The presence of TEMPO was thus found to be essential to catalytic oxidation. In the present work, the observation that the Mn₁₈Sr catalyst **3** is optimal in the absence of TEMPO indicates a change in mechanism, such that the catalyst itself is capable of oxidizing the alcohol with catalytic turnover. As expected, the yield drastically decreases if TEMPO, O₂ or both are removed (entries 4-6).

Table 2 Influence of conditions on the chemical oxidation of benzyl alcohol catalysed by Mn₁₉ **2**.

Entry	Deviation from standard conditions ^{a,b}	Alcohol (%)	Aldehyde (%)
1	None	26	74
2	No 2	99	1
3	120 °C instead of 140 °C	70	30
4	100 °C instead of 140 °C	95	5
5 ^c	5 mol% 2 instead of 1% mol%	80	20
6 ^c	10 mol% 2 instead of 1 mol%	100	0
7 ^c	0.1 mol% 2 instead of 1 mol%	79	21
8 ^c	No TEMPO	48	52
9	Air instead of O ₂	53	47
10	Ar instead of O ₂	54	46
11 ^c	No TEMPO and air instead of O ₂	89	11

^a Reaction conditions: oxygen (1 atm), benzyl alcohol (0.06 mmol), TEMPO (22 mol%), Mn₁₉ **2** (1 mol%) in 1 mL of DMF, at 140 °C; 48 h. ^b PhCHO was the only product; no PhCO₂H acid was detected by GC-MS. ^c Reaction run for 48 h.

Table 3. Influence of various conditions in the chemical oxidation of benzyl alcohol by Mn₁₈Sr **3**.

Entry	Deviation from standard conditions ^a	Alcohol (%)	Aldehyde (%) ^b
1	None	54	46
2	No 3	99	1
3	No TEMPO	35	65
4	Air instead of O ₂	49	51
5	Ar instead of O ₂	55	45
6	No TEMPO and air instead of O ₂	65	35

^a Reaction condition: oxygen (1 atm), benzyl alcohol (0.06 mmol), TEMPO (22 mol%), Mn₁₈Sr **3** (1 mol%) in 1 mL of DMF, at 140 °C; 24 h. ^b PhCHO was the only product; no PhCO₂H acid was detected by GC-MS.

To determine whether the catalysts employed in the present study are stable under the reaction conditions, the solid catalyst was analysed by IR spectroscopy. The IR spectra of **2** and **3** before and after the reaction show some discrepancy (Fig. S9, new bands appearing at 1300-1600 cm⁻¹), suggesting that the catalyst might have undergone some modification under the catalytic conditions. This is expected as we previously observed that the system undergoes ligand exchange and/or scrambling under certain conditions.¹²

Conclusions

We have reported new analogues of the {Mn₁₉} and {Mn₁₈Sr} aggregates, compounds **2** and **3** and demonstrated their catalytic activity in the selective oxidation of benzyl alcohol to benzaldehyde in up to 74 and 65 % yields, respectively. These values are comparable to those obtained by Christou et al for similar cluster compounds.³³ The attractiveness of the {Mn₁₉} system is that it can be further tuned to access a variety of functionalized Mn₁₉(R) aggregates, where the interplay of the electronic contribution of the substituent R can be investigated, where R = the substituent at the 4-position of the H₃L^R ligand system). Moreover {Mn₁₈M} (where M is a heterometals), are readily accessible and could be suitable candidates to explore the influence of heterometals on the redox-potential of the system and hence catalysis, even in the absence of organic co-catalysts. Linking these species to form one-, two- and three-dimensional extended arrays and evaluation of these compounds towards photo-catalytic water splitting (oxygen evolution) is also envisaged.

Acknowledgements

This project has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (grants agreements n° 639170 and n°

647719), from ANR LabEx "Chemistry of Complex Systems", and from Science Foundation Ireland (13/IA/1896).
