28 Abstract

29 Grasp55 is a ubiquitous Golgi stacking protein involved in autophagy, protein trafficking and glucose deprivation sensing. The function of Grasp55 in protein trafficking has been 30 attributed to its PDZ-mediated interaction with the c-terminal "PDZ binding motifs" of 31 protein cargos. We have recently shown that such an interaction occurs between Grasp55 and 32 the adhesion molecule Jam-C which plays a central role in stemness maintenance of 33 34 hematopoietic and spermatogenic cells. Accordingly, we have found that Grasp55-deficient mice suffer from spermatogenesis defects similar to Jam-C knock-out mice. However, 35 whether Grasp55 is involved in the maintenance of immuno-hematopoietic homeostasis 36 37 through regulation of protein transport and Jam-C expression remains unknown. Here, we show that Grasp55 deficiency does not affect hematopoietic stem cell differentiation, 38 engraftment or mobilization, which are known to depend on expression of Grasp55-dependent 39 40 protein cargos. In contrast, using a Myc-dependent leukemic model addicted to autophagy, we show that knock-down of Grasp55 in leukemic cells reduces spleen and bone marrow tumor 41 42 burden upon intravenous leukemic engraftment. This is not due to reduced homing of 43 Grasp55-deficient cells to these organs but to increased spontaneous apoptosis of Grasp55-44 deficient leukemic cells correlated with increased sensitivity of the cells to glucose 45 deprivation. These results show that Grasp55 plays a role in Myc-transformed hematopoietic 46 cells but not in normal hematopoietic cells in vivo.

47

48 Key points:

- 49 Golgi morphology and *Grasp55* expression are regulated during hematopoiesis
- 50 Hematopoiesis is not affected in *Grasp55*-deficient mice
- 51 Grasp55 regulates Myc-transformed leukemic cell survival
- 52

54

55 Introduction

56 Hematopoiesis and spermatogenesis are two differentiation processes in which adult stem cells produce their progeny in a sequentially ordered manner. It has been shown previously 57 58 that JAM-C is expressed by hematopoietic stem cells (HSC) and by male germ cells (1-3). In both biological models, JAM-C plays a role in the maintenance of tissue homeostasis through 59 adhesion regulation between developing cells and surrounding stromal cells expressing JAM-60 B, the high affinity ligand of JAM-C (4, 5). During spermatogenesis, JAM-C regulates 61 62 polarization of developing spermatids, a critical step in spermatozoa development (3). During hematopoiesis, JAM-C interaction with JAM-B plays a critical role in maintenance of 63 64 hematopoietic stem cells (HSC) which are at the apex of hematopoietic hierarchy (6). HSC 65 differentiate into more mature multipotent progenitors (MPPs) which have decreased selfrenewal capacity and progressively engage in megakaryocyte (MPP2), myeloid biased 66 67 (MPP3) or lymphoid biased (MPP4) multipotent progenitors (7). In agreement with its function in HSC maintenance, JAM-C is downregulated in MPPs during steady state 68 69 hematopoiesis (2). JAM-C expression by HSC is also rapidly downregulated after HSC 70 mobilization using Cyclophosphamide and G-CSF (8), suggesting that JAM-C may play a 71 role in the switch from steady state to emergency hematopoiesis. However, down-regulation 72 of JAM-C is not unique to G-CSF-induced mobilization since down-regulation of other bone 73 marrow retention signals such as VCAM-1/VLA-4, CXCL12/CXCR4 or SCF/Kit have also 74 been documented (9-11).

We have recently identified the Golgi-reassembly stacking protein of 55kDa (Grasp55) as a PDZ-domain containing protein interacting with the C-terminal PDZ-binding motif of Jam-B and Jam-C in mouse (12). Grasp55, and the related protein Grasp65, are highly conserved throughout evolution and play complementary roles in Golgi cisternal stacking through oligomerization and PDZ-mediated interactions with proteins of the golgin family such as

Golgin45, GM130 or p24 (13-17). In addition, GRASP55 depletion results in accelerated 80 81 protein trafficking through the Golgi apparatus and has striking negative effects on protein glycosylation and sorting (18). More recently, O-GlcNAcylation has been shown to restrict 82 the function of GRASP55 to Golgi stacking, while de-O-GlcNAcylation switches its function 83 84 as an autophagosome-lysosome tethering molecule (19). However, the function of GRASP55 85 is not limited to Golgi stacking and autophagy regulation since several studies have shown 86 that GRASP55 is involved in protein trafficking through an unconventional secretory pathway triggered by cellular stress or unfolded protein response (UPR) (20-23). TGF-B, MT1-MMP, 87 88 membrane bound SCF, CD8a, Frizzled4, CD83 and IL1β have been shown to be transported 89 in a GRASP55-dependent manner (24-28). In addition, GRASP55 has been involved in MT1-MMP activation which is necessary for various biological processes, including HSC 90 mobilization (29). We have thus explored the function of GRASP55 in adult mammalian 91 92 normal and pathological hematopoiesis. To this end, we have generated constitutive and inducible knock-out mouse models of Gorasp2 (encoding Grasp55) and studied HSC self-93 94 renewal, engraftment, mobilization and differentiation. To test whether Grasp55 may be 95 involved in pathological hematopoiesis, we also questioned whether Grasp55 controls 96 leukemic development. To this end, we used the Eµ-Myc lymphoma model known to be 97 addicted to autophagy activation (30, 31).

98 Our results show that Grasp55 is not involved in the regulation of JAM-C expression in HSC. 99 In addition, Grasp55-deficiency does not affect HSC maintenance or differentiation at steady 100 state or upon hematopoietic stress. We further show that this is not due to compensatory 101 mechanisms since acute depletion of Grasp55 expression using Mx1-Cre inducible system 102 does not result in hematopoietic abnormalities. This is likely due to the inversely regulated 103 expression of Grasp55 and Jam-C during hematopoietic cell differentiation. Indeed, Grasp55 104 transcript and protein are expressed at low levels in the most immature hematopoietic cells (HSC-MPP1) and are upregulated in the following differentiation steps (MPP2 and MPP3-4)
in which JAM-C expression is lost. We thus tested whether Myc-induced B cell lymphoid
leukemia would depend on Grasp55 expression for their growth. Our results show that
Grasp55 is necessary for Myc-dependent lymphoid leukemic development *in vivo*, opening
the way for specific Grasp55 targeting in Myc-addicted hematological malignancies.

111 Material and Methods

112 Mice

Generation and genotyping of Gorasp2 constitutive deficient mice were previously described 113 114 (Cartier-Michaud et al.). Because Gorasp2 deficient male are sterile, the colony is maintained by interbreeding of heterozygote mice. The colony was backcross on C57/BL6J mice more 115 than 10 generation. Floxed Gorasp2 lines, obtained before CMV-Cre deleter mice mating 116 117 during Gorasp2 knockout generation, are maintained by intercrossing and backcrossing on C57/BL6 background more than 7 generation. Conditional inducible Grasp55 (Gorasp2) 118 deficient mice were obtained by two successive mating: in a first time Grasp55^{-/-} female were 119 mated with Mx1-cre^{Pos} male mice to obtained Grasp55^{+/-} Mx1-Cre^{Pos} mice, in a second time 120 Grasp55^{+/-} Mx1-Cre^{Pos} mice are mated with Grasp55^{fl/fl} mice. Grasp55^{fl/-} Mx1-Cre^{Neg} and 121 Grasp55^{fl/-} Mx1-Cre^{Pos} mice were used for experimentation. Same strategy was used to obtain 122 hematopoietic-specific constitutive Grasp55^{fl/-} Vav-Cre mice, Gorasp2^{fl/-} Vav-Cre^{Neg} 123 $(Grasp55^{WT} \text{ and } Gorasp2^{fl-} \text{ Vav-Cre}^{Pos} (Grasp55^{\Delta Hem}) \text{ mice were used for experimentation.}$ 124

125 CD45.1/2 mice used as competitor in competitive assay were obtained by interbreeding of 126 CD45.1 with CD45.2 mice (purchased from JANVIER LABS). Mice were used at age more 127 than 8 weeks old. All animal experiments were performed according to French Guidelines for 128 Animal Handling in CRCM animal facility (Agreement D13 055 04). Experimental protocols 129 were approved by the Ethical Committee #14 under the declaration number #02294.01.

130

131 Genotyping

Genotyping of *floxed Grasp55* line was achieved by PCR of genomic DNA extracted from
mouse tails using the same primers and conditions as constitutive *Gorasp2* mice. But resulting
in an amplification of 544-bp fragment for the WT allele and 700-bp fragment for the floxed
allele were both obtained using heterozygous mice. Genotyping of Mx1-cre and Vav-cre mice

136 was achieved using the generic Cre and the iVav-Cre genotyping protocols from The Jackson137 Laboratory.

138

139 HSC exhaustion after 5-FU treatment

Grasp55^{WT} and Grasp55^{AHem} mice were injected intraperitoneally once a week with 5-Fluorouracil (5-FU) at 120 mg/kg during 5 weeks. One day after 5-FU injection, blood paramaters
were tested using IDEXX ProCyte Dx® Hematology Analyzer (IDEXX Laboratories). Mice
were sacrificed at D35 after the first injection.

144

145 Inducible deletion with polyI:C and analysis of Grasp55 deletion

146 Gorasp2 gene deletion in Gorasp2^{fl/-} Mx1-Cre mice was induced by three intraperitoneal injection of 200µg poly(I:C) (Invivogen) on day D0, D2 and D4. Gorasp2 gene deletion in 147 white blood cells (WBC) was confirmed on day 15 by PCR. Briefly, WBC isolated from 148 149 100µL of peripheral blood by Ficoll and genomic DNA was extracted by digestion in 250µl 150 lysis buffer (50mM KCl, 10mM Tris pH 8,8, 2,5mM MgCl2, 0,45% NP40, 0,45% Tween) 151 with 0.4mg/ml Proteinase K (Invitrogen) for 30min at 56°C, then PCR was achieved using 152 same protocol as genotyping. Mice were sacrificed for analysis one month after the first 153 poly(I:C) injection.

154

155 BM Mobilization Assays

Mobilization was induced using cyclophosphamide (CY, 4 mg i.p. d0) and rhG-CSF (5 mg
s.c. at d1, 2, and 3) injections as previously described (8). Mice were sacrificed on day 5 for
analysis.

160 Colony-Forming Assay

Peripheral blood and BM white blood cells were isolated by Ficoll. 200.000 blood cells were
seeded per well in methylcellulose medium following the manufacturer's instructions (Stem
Cell Technologies, Grenoble, France, www.stemcell.com, ref 3434).

164

165 Competitive Bone Marrow Transplantation

Lethally irradiated (8 grays) CD45.1 mice were transplanted with 2.10⁶ of total bone marrow cell from donors (*Gorasp2*^{+/+} or *Gorasp2*^{-/-} CD45.2) and competitor (CD45.1/2) cells in a 1:1 ratio by retroorbital sinus injection. Mice chimerism was assessed monthly by monitoring of host (CD45.1), competitor (CD45.1/2) and donor (CD45.2) cells in peripheral blood by flow cytometry. Chimerism and hematopoietic phenotype in bone marrow were evaluated 18 weeks after transplantation.

172

173 Thioglycollate induced-peritonitis in chimeric mice

Lethally irradiated (8 grays) CD45.1 mice were transplanted with 2.10⁶ of total bone marrow cell from donors (*Gorasp2*^{+/+} or *Gorasp2*^{-/-} CD45.2) by retro-orbital sinus injection. 18 weeks after transplantation, chimeric mice were injected intraperitoneally with 3ml of thioglycollate 3% (w/v; Sigma). 18 hours after injection, mice were sacrificed and peritoneal exudates were collected by three successive peritoneal washes with 10 ml cold phosphate buffer saline (PBS). Cells were counted and analyzed using IDEXX ProCyte Dx® Hematology Analyzer (IDEXX Laboratories).

181

182 EµMyc cells engraftment in mice

Mouse primary Eµ-Myc lymphoma cells were isolated as previously described (32) and
 expanded through passaging in irradiated recipient mice. 500.000 GRASP55^{KD} or Grasp55^{WT}

Eµ-Myc cells are injected into caudal tail vein of Ly5.1 mice. Mice were sacrificed at D9
after injection. Tumoral invasion in blood, spleen and bone marrow was assessed by flow
cytometry.

188

189 Cytometry and cell sorting

190 Single cells suspensions were prepared from bone marrow (one leg: femur and tibia) and red 191 blood cells were lysed with ACK (ammonium-chloride-potassium) buffer (Gibco). Cells were 192 incubated with mAbs in PBS-0,5% BSA for 30 min at 4°C. For blood samples, RBC lysis was done after staining with BD FACS Lysing buffer (BD Bioscience). For hematopoietic 193 194 cells identification, following antibodies were used: biotin anti-CD3, CD4, CD8, CD19, CD11c, DX5, Ter119, CD11b, B220, Gr1 (Lineage cocktail, Biolegend), CD16-32-PE (clone 195 196 2.4G2, BD Pharmingen), CD45.1-PECF594 (clone A20, BD Horizon), CD45.2-eF450 197 (clone104, eBioscience), CD48-PE-Cy7 (clone HM48-1, Biolegend), CD150-eF647 (clone TC15-12F12.2, Biolegend), CD117-APC-e780 (clone 2B8, eBioscience), CD127-PE-Cy5 198 199 (clone A7R34, eBioscience), CD135-PECF594 (clone A2F10.1, BD Horizon), Sca-1-BV421 200 (clone D7, BD Horizon) CD4-FITC (clone RAM4-5, eBioscience), CD8-PE (clone 53-6.7, eBioscience), B220-AF700 (clone RA3-6B2, eBiosciences), CD11b-APC (M1/70, 201 202 eBioscience) and BV510-Streptavidin (BD Horizon). EµMyc cells were phenotyped using : 203 CD19-BV500 (clone 1D3, BD Biosciences), CD23-BV711 (clone B3B4, BD Biosciences), CD25-PE-Cy5 (clone PC61, eBioscience), CD45.2-PE-Cy5.5 (clone 104, eBioscience), 204 B220-APC-Cy7 (clone RA3-6B2, BD Biosciences), CD71-BV605 (clone C2, BD 205 206 Biosciences), CD93-PE-Cy7 (clone AA4.1, eBioscience), BP1-biotin (clone BP1, BD 207 Biosciences), streptavidin-AF594 (Biolegend). In all experiments a viability marker was used 208 depending of the panels: SYTOX Green nucleic acid stain (Life Technologies), Fixable Viability Dye eF506 (eBioscience), DRAQ7 (Biostatus). JAM-B and JAM-C staining were 209

done using staining polyclonal rabbit anti-mouse JAM-B (pAb829) and JAM-C (pAb 501)
produced in laboratory and R-Phycoerythrin conjugated goat-anti-rabbit IgG(H+L) antibody
(1/200, Jackson Immunoresearch Laboratories) as secondary antibody. Grasp55 intracellular
staining was done using anti-Grasp55 antibody (Protein-tech) and BD Cytofix/Cytoperm
solution following the manufacture's instruction.

For hematopoietic stem and progenitor cells sorting, bone marrow cells were depleted using
Lineage cell depletion Kit from Miltenyi and AutoMACS Pro. The Lin- cells were stained as
described in preceding paragraph.

For Annexin-PI staining cells were stained with APC-AnnexinV (BD Bioscience) and
propidium iodide solution (Sigma Aldrich) in Annexin binding buffer (Life Technologies) for
15 minutes at room temperature.

Stained cells were analyzed by a BD LSR-II FACS (lasers 405, 488, 561, and 633nm) and
sorted by Aria III SORP sorter (BDBiosciences). Results were analyzed with BD-Diva
version 8.0.1 software or FlowJo version 10.0.7 software (Treestar).

224

225 Cell culture

226 Eµ-Myc clone 504 cells were provided JE. Ricci. EµMyc cells were cultured in DMEM 227 Glutamax, supplemented with 10% FBS, 1% non-essential amino acids, 1% L-glutamin, 1% 228 Hepes 1mM, 1%PS, 0,1% β-mercaptoethanol (all cell culture products were purchased from 229 Gibco). For cell proliferation, cells were plated at a density of 10.000 cells/well into 96-wells 230 plate and cell numbers were quantified after 24, 48, 72, 96 hours using Cell Titer Glow Assay (Promega). Grasp55^{+/+} and Grasp55^{-/-} mouse embryonic fibroblasts (MEFs) were obtained as 231 232 previously described (12). Chloroquine treatment was performed at a concentration of half IC50 (5µM for EµMyc cells and 17.5µM for MEFs) during 24 hours. For EµMyc glucose 233

starvation, cells were washed twice in PBS, incubated in DMEM without glucose (Gibco),
10% FCS, 1%PS and cells were quantified 24 hours later using Cell Titer Glow (Promega).

236

237 Lentiviral transduction

For lentiviral transduction, 1.10⁶ cells were plated in 96-wells plates in 190µL complete 238 239 medium with 8µg/ml polybrene and 10µl of lentiviral particles expressing Grasp55 shRNA-GFP (GRASP55^{KD}) or Control GFP (GRASP55^{WT}) vectors (TRIPdU3 vector). Cells were 240 241 centrifuged at 3000 rpm without brake during 2h at 32°C and incubated overnight. Next day 242 medium was replaced by complete medium and cell fluorescence was checked by microscopy 243 (AMG EVOS LED fluorescence microscope). One week after transduction, transduced cells 244 were sorted by flow cytometry based on GFP expression. Correct GRASP55 silencing was 245 tested by Western blot.

246

247 Gene expression analysis

248 500 for each population (HSC-MPP1, MPP2, and MPP3-4) from WT CD45.1 mice were 249 sorted using the autoclone module on an Aria III SORP sorter (BD Biosciences) into 96-well plates in the RT-STA Master Mix Solution. Cell lysis, cDNA synthesis, and amplification 250 251 were performed according to Fluidigm protocols. Selected TaqMan Gene Expression assays 252 (original magnification $\times 20$) were pooled and diluted with water 100-fold so that each assay is at a final concentration of $0.2 \times$ in the pooled assay mix. Five microliters of CellsDirect $2 \times$ 253 254 Reaction Mix (Invitrogen), 2.5 µl pooled assay mix, 0.2 µl SuperScript III RT/Platinum 255 Taqmax mix, and 2.3 µl water were combined to a final volume of 10 µl in 1 well of a 96-well 256 qPCR plate for the sort. cDNA samples were amplified using the following program (1): 257 50°C, 10 min (2); 95°C, 2 min (3); 95°C, 15 s (4); 60°C, 4 min; repeat steps (3) and (4) 18 times. Preamplified products were diluted 5-fold before analysis with Universal PCR Master 258

259 Mix and inventoried TaqMan gene expression assays in 96.96 Dynamic Arrays on a BioMark 260 System (Fluidigm). For each gene, the relative expression was defined as the mean value of 40 minus cycle threshold for the gene of interest divided by 40 minus cycle threshold for 261 262 represented as an heat map using actin. Results were Morpheus software (https://software.broadinstitute.org/morpheus/). 263

264

265 Western blot

GRASP-55 expression by hematopoietic cells was tested using a total of 10000-sorted cells 266 267 for each population (HSC-MPP1, MPP2, MPP3-4) re-suspended in 50µl of RIPA buffer 268 (50mM Tris HCl pH7.5, 150mM NaCl, 1% Triton, 0.1% SDS, 1% Na desoxylate) and 10µl of 6x sample buffer. Western blots for LC3 were performed on 20µg of proteins. Whole protein 269 270 extracts were separated by SDS-PAGE and transfered onto nitrocellulose membrane. 271 Saturated membranes were exposed to rabbit anti-GRASP55 antibody (1/500e ProteinTech), 272 rabbit anti-LC3 antibody (1/1000e, MBL international corporation), mouse anti-α-tubulin 273 antibody (1/1000, T6074 Sigma) in PBS-1% non-fat milk, 0,1% tween at 4°C overnight. 274 Membranes were incubated with HRP-conjugated goat anti-rabbit IgG or HRP-conjugated 275 goat anti-mouse IgG antibody (1/5000, Jackson Immunoresearch Laboratories) at RT one 276 hour. Signal was revealed using SuperSignal West Pico Chemiluminescent substrate 277 (ThermoFischer Scientific).

278

279 Immunofluorescence

1000 sorted cells were incubated in a 50µl PBS-0,5% BSA drop on poly L-lysine-coated slide
in a humidified chamber at 37°C during 2 hours, buffer was carefully removed by aspiration
and replaced by saturation mix (PBS-2%BSA).

Primary antibody anti-GRASP55 (ProteinTech, 1/250) was incubated overnight at 4°C in
PBS-0,5% BSA. After soft washes, samples were incubated one hour at room temperature
with donkey anti-rabbit-eF594-conjugated secondary probe purchased from Jackson
Immunoresearch. DAPI nuclear staining was done with the second final wash. Coverslip was
mounted using prolong gold antifade reagent (Invitrogen).

Images were obtained using a Zeiss LMS880 Meta confocal. Images were analyzed using
Image J. Three dimensions Golgi volume quantification was performed as previously
described (12).

291

292 Caspase activity assay

Cells were plated at a density of 10.000 cells/wells into a white walled 96-wells plate.
Caspase activity was determined using the Caspase-Glo® 3/7 kit following the
manufacturer's instructions (G811A from Promega®). Luminescence was measured using a
POLARstar omega from BMG LABTECH.

297

298 In vivo homing

Eµ-myc GRASP55^{KD} were labeled with calcein violet (violet) and GFP (green) was used for
Eµ-myc GRASP55^{WT} and injected at 1:1 ratio into mice (5.10⁶ cells/200µL NaCl per mice).
Cells in each organ were analyzed for expression of green or violet fluorescence by flow
cytometry. Stained cells were analyzed by an LSRII FACS (lasers 405, 488, 561, and 633nm
BDBiosciences). Results were analyzed with BD-Diva version 8.0.1 software.

304

305 Statistical Analysis

All experiments were performed at least 3 times. Statistical significance was performed using
non-parametric Mann-Whitney U-test, Student t-Test or Two way ANOVA with Bonferroni
post-test in Prism software. P-value less than 0.05 was considered as statistically significant.

310

311 **Results**

312 Regulated expression of GRASP55 during HSC differentiation

313 We first tested if Gorasp2, the gene encoding Grasp55, was expressed in hematopoietic stem 314 and progenitor cells (HSPCs) using RT-qPCR on sorted cells from mouse bone marrow 315 according to the gating strategy shown in Figure 1A. Although Jam3, the gene encoding Jam-C, was highly expressed on the most immature compartment (HSC-MPP1) and 316 317 downregulated in more mature cells, Gorasp2 presented an inverted pattern of expression and 318 was barely detectable in HSC-MPP1 and MPP2 cells (Fig. 1B). Other genes encoding 319 proteins involved in Golgi stacking such as *Blzf1* (encoding Golgin45) or *Golgb1* (encoding 320 Giantin) followed the same pattern of expression as compared to Gorasp2, while expression 321 of Golga2 (encoding GM130) remained stable. Of note, and consistent with publicly available 322 datasets from Immgen consortium (immgen.org), we failed to detect Gorasp1, the gene 323 encoding Grasp65 in HSPC (not shown). Grasp55 upregulation between the most immature 324 compartment (HSC-MPP1) and more differentiated multipotent progenitors (MPP2 and 325 MPP3-4) was further confirmed at the protein level by flow cytometry and western-blotting 326 (Fig. 1C-D). Immunostaining for Grasp55 performed on HSC-MPP1, MPP2 and MPP3-4 isolated from wild type or Grasp55-/- mice confirmed that Grasp55 expression and 327 328 localization changed during hematopoietic cell differentiation (Fig. 1E). We found that 329 Grasp55 signal was barely detectable in wild type HSC-MPP1 and was increased in MPP2 and MPP3-4, as confirmed by staining intensity quantification of confocal Z-stacked pictures 330 331 (Fig. 1F). In addition, three dimensional quantification of Grasp55 staining revealed that the 332 volume of Grasp55 vesiculo-tubular objects was not significantly different between HSC-333 MPP1 and MPP2 cells, while there was a significant increase in MPP3-4 cells (Fig. 1G). This 334 indicates that Grasp55 is upregulated and recruited to large Golgi stacks at the transition between MPP2 and MPP3-4 stages of differentiation, suggesting that structural Golgiremodeling occurs during hematopoietic differentiation.

337

338 Lack of hematopoietic and inflammatory defects in *Grasp55^{-/-}* mice

We thus analyzed early hematopoietic differentiation in Grasp55^{-/-} mice and compared to 339 control littermate animals. Total number of bone marrow cells and percentages of 340 Lin^{Neg}Sca^{Pos}Kit^{Pos} (LSK) were identical between *Grasp55^{+/+}* and *Grasp55^{-/-}* (Fig. 2A-B). 341 342 Results were thus expressed as percentage of the LSK compartment (Fig. 2C) or percentage of total bone marrow (Fig. 2D). Within the LSK compartment, HSC-MPP1, MPP2 or MPP3-4 343 344 were not affected by the loss of Grasp55 expression (Fig. 2C), nor the more mature common myeloid progenitors (CMPs) or granulocyte/monocyte progenitors (GMP) (Fig. 2D). In 345 346 addition, downregulation of JAM-C expression during hematopoietic differentiation was not 347 affected suggesting that LT-HSC maintenance remained unaffected in absence of Grasp55 expression at steady state (Fig. 2E). We thus tested if Grasp55 may be involved in emergency 348 349 hematopoiesis using constitutive hematopoietic specific Grasp55 deficient mice (Grasp55 Δ^{Hem}) obtained by crossing *Grasp55*^{fl/-} mice with Vav-Cre transgenic mice. 350 Repeated injection of 5-Fluoro-Uracil (5-FU) resulted in similar decrease in hematocrit values 351 between $Grasp55^{WT}$ and $Grasp55\Delta^{Hem}$ animals (Supplementary Fig. 1A-B). The day 35 was 352 353 defined as the endpoint for analysis of bone marrow composition to avoid death of the animals because of sustained anemia. No difference in absolute cell numbers or frequencies of 354 early hematopoietic subsets was found between $Grasp55^{\Delta Hem}$ and $Grasp55^{wt}$ control animals 355 356 after 4 injections of 5-FU (Supplementary Fig. 1C-F). Although only three mice were 357 analyzed in this pilot experiment, power calculation shows that a tremendous number of mice 358 would have been necessary to get a chance to reach statistical significance. We thus decided to move to another model in which deletion of Grasp55 is induced in an acute manner to not 359

allow for compensatory mechanism to take place. To this end, Grasp55^{fl/-} animals crossed 360 361 with Mx1-cre transgenic mice were injected with poly(I:C) resulting in floxed allele deletion fifteen days upon poly(I:C) treatment (Supplementary Fig. 2A). Analysis of absolute bone 362 363 marrow cell numbers and frequencies of LSK cells showed no differences between controls and conditional induced knock-out mice poly(I:C)-treated Grasp55^{fl/-} Mx1-Cre mice 364 365 (Supplementary Fig. 2B-C); nor did the analysis of different LSK (HSC-MPP1, MPP2, 366 MPP3-4) and progenitor subsets (CMP, GMP) reveals difference between experimental 367 groups (Supplementary Fig. 2D-E). Finally, since Grasp55 has also been involved in 368 inflammatory response in vitro (23), we also tested whether inflammatory recruitment of 369 leukocytes at effector sites would be affected by Grasp55 deficiency. Here again, we did not find significant differences in acute inflammatory recruitment of leukocytes to the peritoneal 370 371 cavity upon thioglycollate challenge (Supplementary Fig. 3). This indicates that Grasp55 is 372 dispensable for emergency hematopoiesis and inflammatory recruitment in vivo.

373

374 HSC mobilization and engraftment are not affected by *Grasp55* deficiency

375 Because Grasp55 has been involved in the regulation of retention signals for HSC in the bone 376 marrow, we next performed HSC mobilization assays using Cyclophosphamide and G-CSF. 377 This experimental setting induces dramatic changes in molecular mechanisms involved in 378 HSC retention within BM niches and results in myeloid biased expansion of HSPCs (33). As expected, increase of LSK cells frequencies was found in mouse bone marrow and blood 379 upon mobilization (Fig. 3A-B). However, such increase was independent of GRASP55 380 381 expression. When Colony Forming Unit-Cells (CFU-C) assays were performed as a read-out of hematopoietic cell progenitor activity, no differences were found between Grasp55^{-/-} mice 382 383 and control littermate animals (Fig. 3C). To get further insights into the function of GRASP55 in controlling cellular crosstalks upon hematopoietic stress, we performed competitive bone 384

385 marrow engraftment assays. To avoid bias due to the difference in CD45.1; CD45.2 and 386 CD45.1/2 allele expression (34), we designed two experimental groups using CD45.2 Grasp55^{+/+} or CD45.2 Grasp55^{-/-} BM cells admixed at 1:1 ratios with wild-type CD45.1/2 387 388 bone marrow cells as competitors (Supplementary Fig. 4A). Engraftment was performed in CD45.1 lethally irradiated recipients (Fig. 4A). Such experiments are highly sensitive and 389 390 have been widely used to highlight subtle defects in hematopoiesis which are not revealed in 391 other experimental settings. Using chimerism measurement in the peripheral blood as follow-392 up, we found significant decrease in Grasp55^{-/-} hematopoietic engraftment as compared to $Grasp55^{+/+}$ cells before 12 weeks, while differences disappeared at 16 weeks (Fig. 4B). This 393 394 was mostly due to a reduction of Grasp55-deficient lymphoid cells in the blood circulation 395 during the first four months after engraftment (Fig 4C-F). Such difference was abolished after 18 weeks, suggesting that this transient difference revealed subtle changes in the early steps 396 of Grasp55-deficient cells commitment toward lymphoid versus myeloid lineage after 397 engraftment. This is consistent with the high expression of Grasp55 found in MPP3-MPP4s 398 399 myeloid and lymphoid biased progenitors (Fig.1). When chimerism in the bone marrow was 400 analyzed after 18 weeks, overt engraftment advantage for wild-type competitor cells (CD45.1/2) against donor cells (CD45.2) was found in the LSK compartment irrespective of 401 Grasp55 genotype (Fig. 4G). No change in bone marrow cellularity was observed 402 403 (Supplementary Fig. 4B). More interestingly, specific significant decrease in CMP frequencies was observed in mixed chimeric mice engrafted with *Grasp55^{-/-}* and wild-type 404 competitor cells as compared to Grasp55^{+/+}/wild-type chimeras while no change in GMP 405 406 frequencies was detected (Fig. 4H). This was due to a significant decrease in competitor cell 407 frequencies suggesting that loss of Grasp55 expression in hematopoietic cells may alter 408 indirectly the maintenance of wild-type CMP.

410

411

412 GRASP55 plays a role in Myc-addicted leukemic growth in vivo

413 Since we failed to detect Grasp55-dependent alterations of the hematopoietic system at steady state or upon stress, we asked the question whether GRASP55 may contribute to development 414 415 of Myc-addicted lymphoma/leukemia known to depend on autophagy pathway activation (30, 416 31, 35). One leukemic primary cell clone obtained from Eµ-Myc mice harbored a pre-B cell 417 phenotype as demonstrated by positivity for CD19, CD25, CD43, BP1, CD93 (Fig. 5A). In addition, the selected clone expressed JAM-B, a known interacting partner of GRASP55 (Fig. 418 419 5B & (12)). Two cell lines in which GRASP55 expression was depleted or not were derived upon lentiviral transfection with shRNA directed against GRASP55 or empty vector 420 421 containing the GFP only (Fig. 5C). Silencing GRASP55 did not affect JAM-B expression (not 422 shown) nor cell proliferation (Fig. 5D). Upon engraftment in C57BL/6 animals, control Eµ-423 Myc cells invaded spleen and bone marrow within nine days, while invasion by Eµ-Myc GRASP55 knock-down cells (Eµ-Myc GRASP55^{KD}) was greatly reduced (Fig. 5E-F). This 424 425 was accompanied by a three-fold decrease in peripheral leukemic cell load for Eµ-Myc GRASP55^{KD} leukemic cells as compared to control (Fig. 5G). Since such differences may 426 427 rely on changes in homing or engraftment properties, we tested the tissue homing properties 428 of the two cell lines. To this end, tissue homing was analyzed upon intra-vascular injection of mixed Eµ-Myc GRASP55^{WT} and Eµ-Myc GRASP55^{KD} cells, respectively labeled by GFP 429 and GFP/Calcein violet reporters (Fig. 6A, left panel). Frequencies of Eµ-Myc GRASP55^{WT} 430 cells were significantly increased as compared to Eµ-Myc GRASP55^{KD} cells in spleen, bone 431 marrow and blood sixteen hours after injection (Fig 6B). This last result was surprising since 432 reduced short term tissue homing is usually accompanied by increased number of cells 433 remaining in the blood (36). 434

435

436

437 GRASP55 regulates cell survival in an autophagy independent manner

We thus hypothesized that Eµ-Myc GRASP55^{KD} cells may present reduced survival during 438 early steps of homing experiments. Spontaneous apoptosis of Eµ-Myc GRASP55^{KD} cells was 439 thus compared to Eµ-Myc GRASP55^{WT} cells. To this end, caspase activity was measured 440 441 twelve hours after viable cell replating in fresh medium. A significant increase of caspase 3/7 activity was observed in Eµ-Myc GRASP55^{KD} cell culture as compared to control (Fig. 7A). 442 Accordingly, we observed an increase in early and late apoptotic cells in Eµ-Myc 443 GRASP55^{KD} cell culture as compared to Eµ-Myc GRASP55^{WT} (Fig. 7B-C). However, the 444 effect was only marginal and would not totally explain results from in vivo homing 445 446 experiments. Since normal value of glucose level in mouse serum is by far lower than in 447 culture medium (1,4g/l versus 4g/l) and because GRASP55 has been involved in glucose 448 sensing (37), we then reasoned that glucose starvation may be needed to reveal a more 449 pronounced difference. We thus cultured Eµ-Myc leukemic cells for 96 hours in complete medium or in absence of glucose. Although more than 67% of Eµ-Myc GRASP55^{WT} cells 450 survived glucose starvation, less than 55% of Eµ-Myc GRASP55^{KD} cells were still alive as 451 452 compared to control culture condition in complete medium (Fig 7D). This result is consistent 453 with a recent study showing that GRASP55 sense glucose deprivation to promote autophagosome-lysosome fusion (19). We then questioned whether such a pathway 454 455 contributes to the better survival of Eµ-Myc proficient cells. To this end, we treated cells with 456 chloroquine which is known to induce Eµ-Myc cell death through inhibition of lysosome 457 function and autophagosome accumulation (38). We found no differences in cytotoxicity with 458 respect to Grasp55 expression in Eµ-Myc cells or in mouse embryonic fibroblasts (MEFs) isolated from *Grasp55*^{+/+} or *Grasp55*^{-/-} mice (Fig. 8A). We confirmed that Myc transformed 459

460 cells were more sensitive to chloroquine than MEFs as previously reported (Fig. 8B & (38)).

461 However, we found no difference in LC3-II accumulation between Grasp55 proficient and

462 deficient cells at the steady state or upon chloroquine treatment (Fig. 8C-D). Altogether, these

463 results argue for an increased sensitivity to glucose starvation of Eμ-Myc Grasp55-deficient

464 cells without dramatic changes in autophagic fluxes.

466

467 Discussion

468 In the present study, we have addressed the physiological function of Grasp55 in normal, 469 emergency and pathological hematopoiesis using Grasp55-deficient mice for which we have previously reported spermatogenesis defects (12). Surprisingly, we found no difference in 470 471 normal and emergency hematopoiesis between Grasp55-deficient and proficient mice, even 472 though Grasp55 has been involved in the regulation of number of molecules known to be essential for hematopoietic homeostasis. We rule out that this was due to incomplete deletion 473 of the gene since mice presented overt phenotypes reminiscent of $Jam-c^{-/-}$ mice such as male 474 475 infertility (3, 12, 39) which has been confirmed in another Grasp55-deficient strain (23). Although the absence of JAM-C deregulation in *Grasp55^{-/-}* hematopoietic cells may be easily 476 477 explained by the inverted expression pattern of JAM-C and GRASP55 during early 478 hematopoietic cell differentiation (Fig. 1), the lack of overt immuno-hematopoietic phenotype remains puzzling. Indeed, given the roles of GRASP55 in Golgi structure, protein expression 479 480 and autophagy (19, 23, 40, 41), one could expect dramatic effects due to the loss of GRASP55 481 expression when the hematopoietic system is challenged.

482 Several key regulators of hematopoietic homeostasis such as TGF-β, membrane bound SCF, 483 or MT1-MMP have been shown to interact with GRASP55 (25, 29). TGF-β and membrane bound SCF interact with GRASP55 through canonical c-terminal PDZ binding motifs (25). 484 Interaction of GRASP55 with transmembrane TGF- β was directly correlated to cell surface 485 486 levels since mutation of the last two hydrophobic amino-acid (aa) reduced surface expression 487 and GRASP55 interaction, while truncation of the last eight aa abolished interaction and 488 expression. However, the reverse experiment consisting in silencing expression of GRASP55 489 and measuring TGF- β or membrane bound SCF expression were not performed in these studies. Thus, we cannot exclude that bone marrow stromal cells use alternative trafficking 490

machinery to express these niche factors. Our results are more difficult to reconcile with the 491 492 described function of GRASP55 in regulating MT1-MMP activation or IL1ß secretion (23, 493 27, 29). Indeed, MT1-MMP activation by furin has been shown to depend on GRASP55 using 494 dominant negative approaches and overexpression of GRASP55 in HT1080 human fibrosarcoma cell line (29). MT1-MMP plays a central role in maintenance of hematopoietic 495 496 homeostasis through the control of HIF1 α and MMP2 activation (42, 43). The latter has been 497 shown to activate MMP9 which releases membrane-bound SCF upon HSC mobilization with G-CSF (9). We failed to detect hematopoietic alterations at steady state homeostasis or upon 498 G-CSF-induced HSC mobilization in *Grasp55^{-/-}* mice indicating that alternative pathways 499 500 regulating MT1-MMP activation must exist in bone marrow stromal cells. Same is true for IL1ß secretion. Indeed a first study has shown that silencing Grasp55 expression in bone 501 502 marrow derived macrophages (BMDM) reduces IL1ß secretion induced by nigericin and 503 starvation (27). A more recent study has demonstrated that IL1ß secretion is reduced in BMDM isolated from Grasp55-deficient mice due to impaired unfolded protein response 504 505 signaling (23). However, we found no differences in hematopoietic response upon 5-FU 506 treatment which is known to involve IL1 β secretion by myeloid cells (44). This discrepancy 507 may be due to differences in the pathways involved in IL1 β secretion by BMDM as compared 508 to $IL1\beta$ secretion by the whole organism in response to hematopoietic stress. This raises the 509 question as to whether silencing Grasp55 in isolated cellular models reflects its physiological 510 function. Alternatively, it may well be that redundant unconventional secretory pathways are 511 present in higher eukaryotes and that compensatory mechanisms take place in absence of 512 Grasp55. Indeed, a single GRASP isoform is present in Saccharomyces cerevisiae and has 513 been involved in autophagic mediated secretion of Acb1 which lacks a signal sequence 514 similar to IL1 β (45). This Grasp homologue represents the unique PDZ-containing protein of yeast. This is in sharp contrast with the situation in mammals in which more than 250 PDZ 515

domains are present in more than 150 proteins (46). Therefore, it would be interesting to
perform a shRNA screening against genes encoding PDZ containing proteins that could
compensate *Gorasp2* deficiency for maintenance of hematopoietic stem cell homeostasis.

519 More interestingly, our results demonstrate that Eµ-Myc transformed hematopoietic cells become addict to Grasp55 pathway. Myc-dependent transformation is well known to induce 520 521 unfolded protein response (UPR) which results in endoplasmic reticulum stress-induced 522 autophagy (31). Autophagy promotes survival of tumor cells through processing cellular 523 contents destined for degradation in order to support bioenergetics (30). Since Grasp55 has 524 been involved in autophagy-driven pathways of unconventional secretion and in 525 autophagosome-lysosome fusion upon glucose deprivation (19, 27, 45, 47), it may well be that the Eu-Myc Grasp55^{KD} cells lose their ability to use autophagy as rescue mechanism and 526 527 become sensitized to apoptosis. This would be consistent with previous findings showing that 528 caloric restriction sensitizes Eµ-Myc cells to inhibitors of the antiapoptotic Bcl-2 protein 529 family (48). It would therefore be interesting to explore effects of combined drug inhibition of 530 Grasp55 and antiapoptotic proteins in additional cancer models known to involve UPR 531 response and autophagy.

533 Acknowledgements

We are grateful to the flow cytometry, microscopy and animal core facilities for providing
supportive help. We thank C. Bagnis and JE. Ricci who provided lentiviral stocks and
primary lymphoma cells from Eμ-Myc mice, respectively.

537

538 Author contributions

ALB and JMPG designed and performed experiments, analyzed results, and wrote the
manuscript. ACM, FB, MDG, MB and AG performed experiments. JCL performed lentiviral
transductions. SJCM designed the flow cytometry panels and wrote the manuscript. AS
performed imaging analysis. MAL supervised the study, analyzed results, discussed data and
wrote the manuscript. All authors provided valuable inputs on the manuscript.

712 Legend to Figures

713 Figure 1: Regulated expression of GRASP55 during early mouse hematopoietic cell differentiation. (A) Flow-cytometry gating strategy used to define hematopoietic stem and 714 715 progenitor cells (HSPC). Representative dot-plot for wild-type mouse is shown. 716 Hematopoietic Stem Cells and Multi-Potent Progenitor 1 (HSC-MPP1) are defined as LSK 717 (Lin⁻ Sca-1⁺ c-Kit⁺) CD150⁺ CD48⁻, Multi-Potent Progenitor 2 MPP2 as LSK CD150⁺ CD48⁺, MMP3-4 as LSK CD150⁻ CD48⁺. Common Myeloid Progenitors (CMP) and 718 719 Granulocyte Macrophage Progenitor (GMP) are respectively defined as LK (Lin⁻ Sca-1⁻ c-Kit⁺) CD127⁻CD16/32⁻ and LK CD127⁻CD16/32⁺. (B) Heat-map representation of relative 720 721 mRNA expression as detected by RT-qPCR on 500 sorted cells. Actin expression levels were used for normalization. (C) Histogram showing changes in GRASP55 expression as measured 722 723 by flow-cytometry. Results are expressed as fold changes relative to mean fluorescence 724 intensity signals obtained for HSC-MPP1 subset. n=4 mice, * p< 0.05, ** p< 0.01. (D) 725 Representative western-blot against GRASP55 on cell lysates obtained from 20 000 sorted 726 cells. Ponceau red staining is shown as loading control. (E) Representative pictures of 727 GRASP55 immunostaining on indicated cells isolated by flow-cytometry cell sorting. Cells isolated from $Grasp55^{-/-}$ mice were used as control. n= 3 mice. (F) Summed pixel intensities 728 729 of individual objects found in individual confocal planes of Z stacks acquired on five HSC-730 MPP1, eight MPP2 and six MPP3-4 cells. *** p < 0.001. (G) Three dimensional quantification expressed as the volume of the largest vesiculo-tubular structures found in 731 HSC-MPP1, MPP2 and MPP3-4 cells analyzed in (E). A significant enlargement of 732 GRASP55 stained structures was found in MPP3-4. * p < 0.05, ** p < 0.01. 733

734

Figure 2: Early hematopoietic differentiation in *Grasp55^{-/-}* mice. (A) Absolute numbers of
bone marrow cells isolated from *Grasp55^{-/-}* and control littermate mice. Results are expressed

as mean +/- SEM of cell numbers isolated from two legs per mice (n=6 per group). (B-D) 737 Relative frequencies of LSK (Lin^{Neg}Sca^{Pos}Kit^{Pos}) cells (B), HSC-MPP1, MPP2 and MPP3-4 738 cells (C) and CMP and GMP (D) found in the bone marrow of Grasp55-/- and control 739 littermate mice. Flow-cytometry gating strategy used to define HSPC in control and Grasp-55 740 741 deficient mouse is described in Fig. 1A. (E) Graph showing the relative Median Fluorescence Intensity (MFI) detected by flow cytometry for JAM-C staining on HSC-MMP1, MPP2, 742 MPP3-4 cells isolated from *Grasp55^{-/-}* and control littermate mice. Results are expressed as 743 744 mean +/- SEM. Data are representative of six independent experiments.

745

746 Figure 3 : HSC mobilization is not affected by *Grasp55* deficiency.

(A) Relative frequencies of LSK (Lin^{Neg}Sca^{Pos}Kit^{Pos}) cells found in the bone marrow of 747 Grasp55^{-/-} and control littermate mice after HSC mobilization by CY/G-CSF. NaCl treated 748 749 mice are used as control. (B) Relative frequencies of LSK cells found in blood of CY/G-CSF or NaCl injected *Grasp55^{-/-}* and Grasp+/+ mice. (C) Number of CFU-C mobilized into blood 750 from Grasp55-/- and control littermate mice after CY/G-CSF. Each symbol represents the 751 average of colony numbers obtained per mice (2.10^5 cells/well, two wells per mice). * p< 752 0.05, ** p< 0.01, *** p< 0.001. Results from a single experiment with n=3 to 4 mice are 753 <mark>shown.</mark> 754

755

Figure 4 : Competitive engraftment of *Grasp55* deficient bone marrow cells.

(A) Experimental design of competitive bone marrow transplantation. The same number of *Grasp55*^{+/+} or *Grasp55*^{-/-} donor (CD45.2) cells were mixed in 1:1 ratio with competitor
(CD45.1/2) bone marrow cells (See Sup Fig. 4A) and injected into CD45.1 lethally irradiated
recipients. (B) Graph showing the frequency of CD45.2 donor cells in the blood of recipient
mice engrafted either with *Grasp55*^{+/+} (white dots) or *Grasp55*^{-/-} (filled black dots) donor

cells. *p< 0.05 (C-F) Donor specific CD4⁺ T cells (C), CD8⁺ T cells (D), B220⁺ B cells (E)
and CD11b⁺ myeloid cells (F) frequencies in the blood of mice transplanted with *Grasp55^{+/+}*(white dots) or *Grasp55^{-/-}* (filled black dots) bone marrow. (G-H) Relative frequencies of
donor and competitor LSK (Lin^{Neg}Sca^{Pos}Kit^{Pos}), HSC-MPP1, MPP2, MPP3-4 (G), CMP and
GMP (H) cells found in the bone marrow of mixed chimera engrafted with *Grasp55^{+/+}* or *Grasp55^{-/-}* donor cells 18 weeks after cell injection. Results are expressed as mean +/- SEM.
Data show results of one representative experiment from two independent experiments.

769

770

Figure 5 : *Grasp55* silencing inhibits Eµ-myc leukemic engraftment

772 (A) Phenotype of primary Eµ-myc clone assessed by flow cytometry and showing the pre-B 773 cell nature of leukemic cells. (B) JAM-B expression by the primary Eµ-myc clone shown in 774 (A). (C) Western-blot analysis of Eµ-myc cells one week after transfection with Ctl-GFP or shGRASP-55 lentivirus using GRASPP55 (upper panel) or actin (lower panel) antibodies. (D) 775 Proliferation of Eµ-Myc GRASP55^{WT} and Eµ-Myc GRASP55^{KD} in complete medium was 776 777 determined using ATPmetry (Cell Titer Glow, Promega). Results are expressed as mean RLU values +/- SEM obtained from four replicates. Doubling times are 16.20+/-1.468 hours 778 for Eµ-Myc GRASP55^{WT} and 20.10+/-3.869 hours for Eµ-Myc GRASP55^{KD}. (E-G) Tumor 779 780 invasion of Eµ-myc cells in the indicated organ nine days after injection of 50.000 GRASP55^{WT} or GRASP55^{KD} Eµ-myc cells in CD45.1 mice. Tumor invasion in spleen is 781 revealed by spleen weight and percentage of CD45.2⁺GFP⁺ cells (E). Percentages of CD45.2⁺ 782 783 GFP⁺ cells in bone (F) and blood (G) are shown. Results are expressed as mean \pm SEM. n = 6 mice per group. One representative experiment from two independent experiments is 784 shown. ** p<0.01. 785

787 Figure 6 : *Grasp55* silencing decreases leukemic cell survival

(A) Left panel: dot plot showing the indicated fluorescence of the mix of GRASP55^{WT} 788 (GFP⁺Calcein violet⁻) and GRASP55^{KD} (GFP⁺Calcein violet⁺) Eµ-myc cells before injection. 789 Right panels: dot plots showing the GFP and Calcein violet fluorescence signals 16 hours 790 after injection in the indicated organs. Relative proportions of GRASP55^{WT} (Calcein violet⁻) 791 and $GRASP55^{KD}$ (Calcein violet+) cells within the GFP+ compartments are indicated. (B) 792 Absolute number of GRASP55^{WT} and GRASP55^{KD} Eµ-myc cells in the indicated organs 793 794 sixteen hours after injection. Each symbol represents an individual mouse. n = 6 mice per group. Results obtained in a single experiment are expressed as mean +/- SD. *** p<0.001. 795

796

797 Figure 7: Grasp55 silencing increases apoptosis

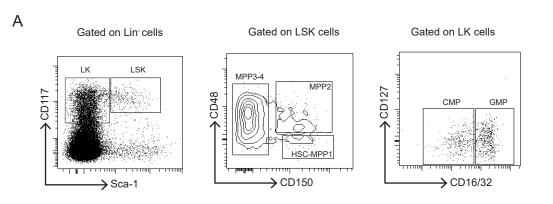

(A) Histograms showing Caspase 3/7 activity of GRASP55^{WT} (white bar) and GRASP55^{KD} 798 799 Eµ-myc cells (black bar) twelve hours after plating and expressed as fold increase over time 800 0. (B) Dot plots showing representative results of AnnexinV and iodinium propide (PI) or cytometry staining of GRASP55^{WT} and GRASP55^{KD} Eµ-myc cells twelve hours after plating 801 802 in fresh medium. (C) Quantification of results shown in (B) showing significant decrease survival of GRASP55^{KD} as compared to GRASP55^{WT} Eµ-myc cells twelve hours after plating. 803 Conversely, significant increases in early and late apoptosis are observed * p<0.05, *** 804 805 p < 0.001. (**D**) Graph showing Eµ-myc cell survival upon glucose starvation after 96 hours. Results are expressed as percentage of survival obtained in complete medium. * p<0.05. One 806

807 representative experiment from three independent experiments is shown.

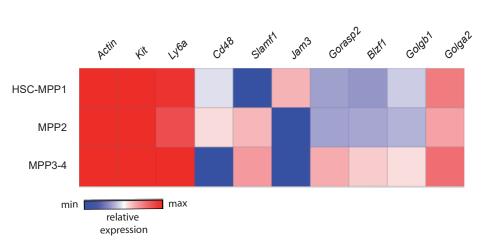

808

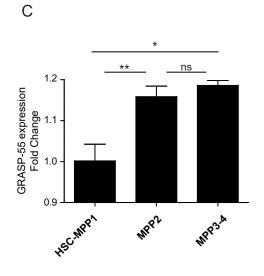

Figure 8: GRASP55 is not required for autophagy. (A) Cytotoxicity of chloroquine on
 GRASP55^{WT} and GRASP55^{KO} EµMyc and Grasp55^{+/+} and Grasp55^{-/-} MEFs at 24 hours using
 Cell Titer Glo assay. (B) IC50 of chloroquine on GRASP55^{WT} and GRASP55^{KO} EµMyc and

- 812 Grasp55^{+/+} and Grasp55^{-/-} MEFs at 24hours. Results of one representative experiment from
- 813 three independent experiments are shown. (C-D) Western blot against GRASP55 and LC3 on
- 814 GRASP55^{WT} and GRASP55^{KO} EμMyc (C) and Grasp55^{+/+} and Grasp55^{-/-} MEFs (D) after 24
- 815 hours chloroquine treatment. Tubulin was used as loading control. One representative
- 816 experiment from three independent experiments is shown.

Supplementary Figure 1: Hematopoietic stress response of *Grasp55^{-/-}* **mice. (A)** Experimental design for HSC exhaustion after 5-fluoro-uracil (5-FU) treatment: *Grasp55*^{fl/-} Vav-cre^{Neg} and *Grasp55*^{fl/-}Vav-cre^{Pos} mice were injected weekly with 120mg/kg 5-FU and bled one day later over five weeks. Mice were sacrificed at D35 after first injection. **(B)** Hematocrit levels of Grasp55^{fl/-}Vav-cre^{Neg} and Grasp55^{fl/-}Vav-cre^{Pos} mice at indicated time points. (n=3 per group). * p< 0.05, ** p< 0.01, *** p<0.0001. **(C)** Absolute numbers of bone marrow cells isolated from *Grasp55*^{fl/-}Vav-cre^{Neg} and *Grasp55*^{fl/-}Vav-cre^{Pos} animals at sacrifice. **(D-F)** Relative frequencies of LSK (D), HSC-MPP1, MPP2, MPP3-4 (E), CMP and GMP (F) found in the bone marrow of from *Grasp55*^{fl/-}Vav-cre^{Neg} and *Grasp55*^{fl/-}Vav-cre^{Pos}

Supplementary Figure 2: Induced deletion of Grasp55 in adult hematopoietic cells does not result in impaired hematopoiesis. (A) Agarose gel of the PCR-amplified products obtained from white blood cells isolated from Grasp55fl/- Mx1-CreNeg and Grasp55fl/- Mx1-CrePos fifteen days after injection with polyI:C or NaCl. (B-E) Absolute numbers of bone marrow cells (B) and relative frequencies of LSK (C) HSC-MPP1, MPP2, MPP3-4 (D) CMP and GMP (E) found in the bone marrow of from Grasp55fl/- Mx1-CreNeg and Grasp55fl/- Mx1-CrePos one month after Mx1-cre induction with polyI:C. NaCl injected animals and mice lacking Mx1-Cre expression are used as control. No significant difference between experimental groups is observed. Results represent the pool of two independent experiments with n=3 to 5 mice per group.

Supplementary Figure 3: GRASP-55 is dispensable for inflammatory cells recruitment in thioglycollate-induced peritonitis. Absolute number of total cells (left panel) and leukocytes frequencies (right panel) in peritoneal lavage fluids of Grasp55^{-/-} and Grasp55^{+/+} chimeric mice 18 hours after thioglycollate i.p. injection. One representative experiment is shown (from three independent experiments).

Supplementary Figure 4: Competitive bone marrow transplantation

(A) Representative dot plots showing the 1:1 ratio of donor and competitor cells for the indicated experimental group used in Figure 4 (Grasp55-/-, left panel and Grasp55+/+, right panel). (B) Absolute number of bone marrow cells in recipient mice 18 weeks after engraftment with $Grasp55^{+/+}$ and $Grasp55^{-/-}$ donor cells.
