HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

GENERALIZED CURIE-WEISS POTTS MODELS AND QUADRATIC PRESSURE IN ERGODIC THEORY

RENAUD LEPLAIDEUR AND FRÉDÉRIQUE WATBLED

ABSTRACT. We extend results on quadratic pressure and convergence of Gibbs mesures from [14] to the Curie-Weiss-Potts model. We define the notion of equilibrium state for the quadratic pressure and show that under some conditions on the maxima for some auxiliary function, the Gibbs measure converges to a convex combination of eigen-measures for the Transfer Operator. This extension works for dynamical systems defined by infinite-to-one maps. As an example, we compute the equilibrium for the mean-field XY model as the number of particles goes to $+\infty$.

1. INTRODUCTION

1.1. Background, main motivations, open questions. In a recent work ([14]) the authors defined the notion of quadratic pressure associated to some potential ψ for the symbolic dynamics $\{0, 1\}^{\mathbb{N}}$ (with the shift map). The motivation for that was to study similarities and differences between phase transitions in Ergodic Theory on the one hand and in Probability and Statistical Mechanics on the other hand.

The authors pointed out that the Curie-Weiss model in Probability theory can be linked to Ergodic Theory with the quadratic equilibriums. More precisely, it was shown that *Probability Gibbs Measures* (PGM for short) converge as the number of sites goes to $+\infty$ to a convex combination of *Dynamical Conformal Measures* associated to the invariant measures which maximize the quadratic pressure.

In the present paper, Theorem 2 and 3 extend results of [14] to the Curie-Weiss-Potts model. This is a natural question as the Curie-Weiss-Potts model is a kind of generalization of Curie-Weiss model. In view to give an application to the XY-model (see Section 5), the statement is done for dynamical systems which are not necessarily finite-to-one.

RENAUD LEPLAIDEUR AND FRÉDÉRIQUE WATBLED

For that goal, the notion of entropy needs to be made precise. This notion has already been investigated and we mention e.g. a series of works [6, 5, 1, 15] and more recently [9]. We re-employ the idea to define the entropy as the Fenchel-Legendre transform of the pressure function and to link it to a min-max problem. The main assumption in [9] is the existence of the spectral gap for the transfer operator and the purpose of Theorem 1 is thus to state this spectral gap.

Some version of the transfer operator with infinite-to-one map has already been studied in [15]. We point out that in our case we have a more flexible operator as the transition depends on the two first coordinates (see below). Actually, we believe that it can easily be extended to the case where transitions only depend on finitely many coordinates, which is what should be a natural extension of the notion of subshift of finite type with infinite (and uncountable) alphabet. In other words, the transfer operator in [15] is the one for a full-shift of finite type whereas our is the one for more general irreducible subshift of finite type. Furthermore, we study here the regularity of the spectral radius^{*}, in particular for the multi-dimensional case, and we did not find any reference of that problem in [15].

Theorem 2 is where we make the link between equilibrium states for the linear pressure and the equilibrium states for the quadratic pressure. This result goes in the same direction as [14] and more recently [4]. Equilibrium states for quadratic pressure are equilibrium states for the linear pressure but with a change of the parameter.

Theorem 3 is where we make links between Dynamical Gibbs Measures and Probabilistic Gibbs Measures. It deals with convergence of the PGM to a convex combination of eigen-measures for the Transfer Operator. One of the key points is the Laplace method. We point out here a big difference between the 1d case and the multi-dimensional case. In the 1d-case, the Laplace method can be applied even if the Hessian at maximal points is degenerated.

We remind that Laplace method deals with integrals of the form $\int_a^b f(t)e^{n\phi(t)}dt$ and gives an equivalent of this quantity as n goes to $+\infty$. This equivalent only involves values c_i where ϕ is maximal. For each c_i one gets an expression in n depending on how flat ϕ is closed to c_i and also on how f behaves closed to c_i .

The crucial point is that in dimension 1, we get an expression at each c_i and we can compare them. We remind that roughly speaking, it was shown in [14] that only the maxima where ϕ is the flattest yield a positive contribution for the limit of the PGM.

On the contrary, this comparison between maxima does not seem to be (easily) possible if we deal with an integral in higher dimension, unless all the maxima have a non-degenerated Hessian. The consequence in our problem is that we can precisely

^{*}This is one key point in our work.

determine what is the convex combination for the limit of the PGM, only if all the maxima are non-degenerated.

This naturally leads to ask for which $\overrightarrow{\psi}$ the Hessian is non-degenerated. We have no idea for the answer yet. As we will see below, the mean-field XY model has degenerate Hessian but it reduces to a one dimensional problem and we can deal with it.

1.2. Settings and results.

1.2.1. Shift with (possibly) infinite alphabet. Let (E, d) be a compact metric space, let ρ be a Borel probability measure on E with full support. We assume that ρ satisfies the following assumption

(H): for any sufficiently small $\varepsilon > 0, x \mapsto \rho(B(x, \varepsilon))$ is continuous.

We consider a map $A: E \times E \to [0, 1]$ called the transition function, which satisfies the following properties:

- (A1): A is continuous with values in $\{0, 1\}$.
- (A2): A is Lipschitz continuous with respect to the second variable with Lipschitz constant $\operatorname{Lip}(A)$.

(A3): A generates some mixing in the following sense.

(1)
$$\exists N \in \mathbb{N}, \forall n \ge N, \forall a, b \in E, \exists z_1, \dots, z_{n-1} \in E$$

such that $A(a, z_1)A(z_1, z_2) \dots A(z_{n-1}, b) = 1$.

Remark 1. The assumption (A1) yields that A is constant with value 0 or 1 on each connected component of $E \times E$. The assumption (A3) implies in particular that A is not identically null.

We define $\Omega \subset E^{\mathbb{N}}$ in the following way:

$$\Omega := \left\{ x = x_0 x_1 x_2 \dots \in E^{\mathbb{N}}; \ \forall \, i \in \mathbb{N}, \ A(x_i, x_{i+1}) > 0 \right\}.$$

The shift map $\sigma: \Omega \to \Omega$ is defined by

$$\sigma(x_0 x_1 x_2 \ldots) = x_1 x_2 \ldots$$

Note that if E is connected, e.g. E = [0, 1], then $A \equiv 1$. If E is a finite set $\{1, \ldots, k\}$, then Ω is the subshift of finite type with transition matrix having entries A(i, j).

For $n \geq 1$, let Ω_n be the set of words $z_1 \dots z_n$ with $\prod_{i=1}^{n-1} A(z_i, z_{i+1}) = 1$. For aand b in E, let $\Omega_{n-1}(a, b)$ be the set of words $z_1 \dots z_{n-1}$ in Ω_{n-1} with $A(a, z_1) = A(z_{n-1}, b) = 1$. Assumption (A3) on A means that for every a, b in E, for every $n \geq N$, $\Omega_{n-1}(a, b) \neq \emptyset$. It implies in particular that for every a in E, there always exist u, v in E such that A(a, u) = 1 and A(v, a) = 1. We denote by $\Omega_n(b)$ the set of words $z_0 \ldots z_{n-1}$ in Ω_n with $A(z_{n-1}, b) = 1$.

We set $\mathbb{P} = \rho^{\otimes \mathbb{N}}$. The distance over Ω is defined by

$$d_{\Omega}(x,y) = \sum_{n=0}^{+\infty} \frac{d(x_n, y_n)}{2^{n+1}}.$$

We notice that for any a in Ω_n ,

$$d_{\Omega}(ax, ay) = \frac{1}{2^n} d_{\Omega}(x, y)$$

and that

$$d_{\Omega}(\sigma^n x, \sigma^n y) = 2^n \left(d_{\Omega}(x, y) - \sum_{k=0}^{n-1} \frac{d(x_k, y_k)}{2^{k+1}} \right).$$

We denote by $\mathcal{C}^{0}(\Omega)$, respectively $\mathcal{C}^{+1}(\Omega)$, the set of continuous, respectively Lipschitz continuous, functions from Ω to \mathbb{R} , equipped respectively with the norms

$$\|\phi\|_{\infty} = \max_{x \in \Omega} |\phi(x)|, \qquad \|\phi\|_{L} = \|\phi\|_{\infty} + \operatorname{Lip}(\phi).$$

where $\operatorname{Lip}(\phi)$ stands for the Lipschitz constant of ϕ . We recall that the spaces $(\mathcal{C}^0(\Omega), \|\cdot\|_{\infty})$ and $(\mathcal{C}^{+1}(\Omega), \|\cdot\|_L)$ are Banach spaces. We set $M(\Omega)$ the space of probability measures on Ω and recall that by the Riesz representation theorem, the map $\mu \mapsto (f \mapsto \int f d\mu)$ is a bijection between $M(\Omega)$ and

$$\{l \in \mathcal{C}^0(\Omega)^*; l(\mathbb{I}) = 1 \text{ and } l(f) \ge 0 \text{ whenever } f \ge 0\}.$$

A measure μ is σ -invariant if $\mu(\sigma^{-1}(B)) = \mu(B)$ for all Borel sets B. The set $M_{\sigma}(\Omega)$ is the space of σ -invariant probability measures on Ω . Both $M(\Omega)$ and $M_{\sigma}(\Omega)$ are convex and compact for the weak star topology.

The transfer operator associated to $\phi : \Omega \to \mathbb{R}$ (Lipschitz continuous) is the linear operator defined by

$$\mathcal{L}_{\phi}(f)(\omega) = \int_{E} e^{\phi(t\omega)} A(t,\omega_0) f(t\omega) \, d\rho(t).$$

Theorem 1 states several properties on the spectrum of the transfer operator. To properly state the theorem we need to introduce some more quantities.

The operator \mathcal{L}_{ϕ} acts on $\mathcal{C}^{0}(\Omega)$ and on $\mathcal{C}^{+1}(\Omega)$. The spectral radius of \mathcal{L}_{ϕ} on $\mathcal{C}^{0}(\Omega)$, denoted by r_{ϕ} , is a simple eigenvalue of the adjoint operator $\mathcal{L}_{\phi}^{\star}$ acting on the space of Radon measures on Ω , and the conformal measure ν_{ϕ} is the unique probability eigen-measure associated to the eigenvalue r_{ϕ} . It is also a simple eigenvalue of \mathcal{L}_{ϕ} acting on $\mathcal{C}^{+1}(\Omega)$, with a positive eigenfunction G_{ϕ} such that the measure $\mu_{\phi} = G_{\phi}\nu_{\phi}$ is a probability measure. We call μ_{ϕ} the dynamical Gibbs measure (DGM for short) associated to ϕ . If \boldsymbol{z} belongs to \mathbb{R}^q and ψ_i , $i = 1, \ldots q$ are in $\mathcal{C}^{+1}(\Omega)$ one sets $\overrightarrow{\boldsymbol{\psi}} := (\psi_1, \ldots, \psi_q)$ and $\boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}} := \sum_{i=1}^q z_i \psi_i$. We note $||\boldsymbol{z}||$ the Euclidean norm of \boldsymbol{z}

$$||\boldsymbol{z}||^2 = \sum_{i=1}^q z_i^2.$$

Definition 1.1. For fixed $\overrightarrow{\psi}$ and $z \in \mathbb{R}^q$, one sets

$$\mathcal{H}(oldsymbol{z}, \overrightarrow{oldsymbol{\psi}}) := \inf_{oldsymbol{t} \in \mathbb{R}^q} \left\{ \log r_{oldsymbol{t} \cdot \overrightarrow{oldsymbol{\psi}}} - oldsymbol{t} \cdot oldsymbol{z}
ight\}.$$

and

$$I(\overrightarrow{\psi}) := \left\{ \int \overrightarrow{\psi} \, d\mu, \ \mu \in M_{\sigma}(\Omega) \right\}.$$

Note that $I(\vec{\psi})$ is a closed convex subset of \mathbb{R}^q . Moreover, $\mathbf{z} \mapsto \mathcal{H}(\mathbf{z}, \vec{\psi})$ is upper semi-continuous, as it is an infimum of affine functions.

Theorem 1. For any $\phi \in C^{+1}(\Omega)$, r_{ϕ} is a simple single dominating eigenvalue. Moreover, for any $\overrightarrow{\psi}$ with $\psi_i \in C^{+1}(\Omega)$, the map $\mathcal{P} : \mathbf{t} \mapsto \log r_{\mathbf{t} \cdot \overrightarrow{\psi}}$ is infinitely differentiable.

Furthermore,

(1)
$$\mathcal{H}(\boldsymbol{z}, \overrightarrow{\boldsymbol{\psi}}) = -\infty \text{ if } \boldsymbol{z} \notin I(\overrightarrow{\boldsymbol{\psi}}),$$

(2) $\mathcal{H}(\boldsymbol{z}, \overrightarrow{\boldsymbol{\psi}}) \text{ is finite if } \boldsymbol{z} \in \nabla \mathcal{P}(\mathbb{R}^q)$

We call *pressure function* for $\overrightarrow{\psi}$ the map $t \mapsto \mathcal{P}(t)$.

1.2.2. Quadratic Pressure. For fixed $\overrightarrow{\psi} \in \mathcal{C}^{+1}(\Omega)^q$ and for $\beta \ge 0$, $\boldsymbol{t}, \boldsymbol{z}$ in \mathbb{R}^q , we set $\varphi_{\beta}(\boldsymbol{t}) := -\frac{\beta}{2} ||\boldsymbol{t}||^2 + \log r_{\beta \boldsymbol{t} \cdot \overrightarrow{\psi}}$ and $\overline{\varphi}_{\beta}(\boldsymbol{z}) := \mathcal{H}(\boldsymbol{z}, \overrightarrow{\psi}) + \frac{\beta}{2} ||\boldsymbol{z}||^2$.

Notation 1. We set $\mathcal{H}_{top} := \log r_0$.

Definition 1.2. For μ in $M_{\sigma}(\Omega)$, the entropy is the quantity

$$\widehat{\mathcal{H}}(\mu) := \inf_{\overrightarrow{\psi} \in \mathcal{C}^{+1}(\Omega)^q} \mathcal{H}\left(\int \overrightarrow{\psi} \, d\mu, \overrightarrow{\psi}\right).$$

Let $\overrightarrow{\psi} \in \mathcal{C}^{+1}(\Omega)^q$ be fixed. The quantity

$$\mathcal{P}_{2}(\beta) = \sup_{\mu} \left\{ \widehat{\mathcal{H}}(\mu) + \frac{\beta}{2} \left\| \int \overrightarrow{\psi} \, d\mu \right\|^{2} \right\}$$

is referred to as the quadratic pressure function for $\overline{\psi}$.

Remark 2. In [9] the authors define the entropy by setting

$$h_{\mathcal{X}}(\mu) := \inf_{A \in \mathcal{X}(\Omega)} \left(\log r_A - \int A \, d\mu \right) \text{ for } \mu \in M_{\sigma}(\Omega)$$

and the pressure by setting

$$\Pr(\mathbf{B}) := \sup_{\mu \in \mathcal{M}_{\sigma}(\Omega)} \left(\mathbf{h}_{\mathcal{X}}(\mu) + \int \mathbf{B} \, \mathrm{d}\mu \right) \text{ for } \mathbf{B} \in \mathcal{X}(\Omega),$$

where $\mathcal{X}(\Omega)$ is a suitable space of potentials $\Omega \to \mathbb{R}$. We notice that our definition of entropy is the same as theirs with $\mathcal{X}(\Omega) = \mathcal{C}^{+1}(\Omega)$, whereas our definition of pressure is linked to theirs by $\mathcal{P}(\mathbf{t}) = \Pr(\mathbf{t} \cdot \vec{\psi})$, where $\vec{\psi}$ is fixed in $\mathcal{C}^{+1}(\Omega)^q$. We point out that $\mu \mapsto \widehat{\mathcal{H}}(\mu)$ is upper semi-continuous as the infimum over a family of upper semi-continuous functions.

From Theorem 1 we can use the work of Giulietti and *al* in [9, th.F]. We emphasize that the key point in their work is the spectral decomposition of the transfer operator, which is stated in Theorem 1. Then, we deduce the existence of the DGM which is the unique equilibrium state for ϕ .

Stated with our settings, we get that for any $\overrightarrow{\psi} \in \mathcal{C}^{+1}(\Omega)^q$ and for any t there is a unique invariant measure $\mu_{t,\overrightarrow{\psi}}$ which maximizes $\widehat{\mathcal{H}}(\mu) + \int t \cdot \overrightarrow{\psi} d\mu$. Moreover,

(2)
$$\mathcal{P}(\boldsymbol{t}) = \widehat{\mathcal{H}}(\mu_{\boldsymbol{t}\cdot\vec{\boldsymbol{\psi}}}) + \int \boldsymbol{t}\cdot\vec{\boldsymbol{\psi}} \, d\mu_{\boldsymbol{t}\cdot\vec{\boldsymbol{\psi}}}$$

Convexity for the multi-dimensional pressure function $\mathbf{t} \mapsto \mathcal{P}(\mathbf{t}) = \sup_{\mu} \{\widehat{\mathcal{H}}(\mu) + \int \mathbf{t} \cdot \overrightarrow{\psi} \, d\mu\}$ and differentiability obtained from Theorem 1 yield that for every \mathbf{t} and every i, $\frac{\partial \log r_{\mathbf{t} \cdot \overrightarrow{\psi}}}{\partial t_i} = \int \psi_i \, d\mu_{\beta \mathbf{t} \cdot \overrightarrow{\psi}}$.

Theorem 2. Equilibrium states for the quadratic pressure. For any $\overrightarrow{\psi} \in C^{+1}(\Omega)^q$ and for any $\beta \geq 0$ the invariant probability measures which maximize $\mathcal{P}_2(\beta)$ are the dynamical Gibbs measures $\mu_{\beta t} \overrightarrow{\psi}$ where the **t**'s are the maxima for φ_{β} .

This result goes in the same direction as the ones from [14] and [4]. However, we point out some interesting difference here: in the higher-dimensional case, there may be infinitely many measures which maximize the quadratic pressure. This is actually the case for XY-model (see below Remark 6).

1.2.3. Generalized Curie-Weiss-Potts Hamiltonian. For $\phi \in \mathcal{C}^{+1}(\Omega)$, we remind that $S_n(\phi)$ stands for $\phi + \ldots + \phi \circ \sigma^{n-1}$. With previous notations, $S_n(\overrightarrow{\psi})$ is the vector with coordinates $S_n(\psi_i)$. Then, the Generalized Curie-Weiss-Potts Hamiltonian is defined for $\omega \in \Omega$ by

$$H_n(\omega) := -\frac{1}{2n} \|S_n(\overrightarrow{\psi})(\omega)\|^2.$$

We define the probabilistic Gibbs measure (PGM for short) $\mu_{n,\beta}$ on Ω by

(3)
$$\mu_{n,\beta}(d\omega) := \frac{e^{-\beta H_n(\omega)}}{Z_{n,\beta}} \mathbb{P}(d\omega) = \frac{e^{\frac{\beta}{2n} \|S_n(\overline{\psi})(\omega)\|^2}}{Z_{n,\beta}} \mathbb{P}(d\omega),$$

where $Z_{n,\beta}$ is the suitable normalization factor.

If P_n , P are probability measures in $M(\Omega)$, we say that P_n converges weakly to Pif $\int_{\Omega} f \, dP_n \to \int_{\Omega} f \, dP$ for each f in $\mathcal{C}^0(\Omega)$. As $\mathcal{C}^{+1}(\Omega)$ is dense in $\mathcal{C}^0(\Omega)$, this is equivalent to $\int_{\Omega} f \, dP_n \to \int_{\Omega} f \, dP$ for each f in $\mathcal{C}^{+1}(\Omega)$.

Theorem 3. Generalized Curie-Weiss-Potts model.

One dimensional case: if q = 1, then the PGM $\mu_{n,\beta}$ converges weakly to a convex combination of the conformal measures $\nu_{\beta t\psi}$ associated to the $\mu_{\beta t\psi}$'s from Theorem 2 as n goes to $+\infty$.

Higher dimensional case: for q > 1, if φ_{β} attains its maximum only on nondegenerated points (i.e., $d^2\varphi_{\beta}$ is invertible), then they are finitely many and the PGM $\mu_{n,\beta}$ converges weakly to a convex combination of the conformal measures $\nu_{\beta t:\vec{v}}$ associated to the $\mu_{\beta t:\vec{v}}$'s, where the **t**'s are the maxima for φ_{β} .

Remark 3. The "classical" Curie-Weiss-Potts model (see Theorem 2.1 of [8]) is obtained by taking $E = \{1, \ldots, q\}, \psi_i = \mathbb{I}_{[i]}$ and A(i, j) = 1 for every pair (i, j).

We point out that the mean-field XY model (see Section 5) is an example where φ_{β} atteins its maximum on a infinite set of points, and for all of them the Hessian is degenerated.

1.3. **Plan of the paper.** In Section 2 we prove Theorem 1. As we said above, the main ingredient is to define and study the spectrum of the Transfer Operator. We prove this operator has a spectral gap and that the spectral radius is a simple isolated dominating eigenvalue. This allows to define the notion of conformal measure.

In Section 3 we prove Theorem 2. The main ingredient is to define two auxiliary functions, φ_{β} and $\overline{\varphi}_{\beta}$, to show that one is always bigger than the other one, but both have the same maxima (arising for the same points). Maximal value for $\overline{\varphi}_{\beta}$ equals the quadratic pressure but maxima for φ_{β} are easier to detect. Part of the difficulty in this section comes from our way to define the entropy for measure, as we want to deal with possibly infinite-to-one maps.

In Section 4 we prove Theorem 3. The main trick is the Hubbard-Stratonovich formula and then the Laplace method, as in [14].

In Section 5 we discuss an application to the mean-field XY model.

2. Proof of Theorem 1

2.1. Properties for the Transfer Operator with infinite alphabet.

2.1.1. First spectral properties: \mathcal{L}_{ϕ} is quasi-compact. The function A is continuous thus uniformly continuous (since $E \times E$ is compact) and with values in $\{0, 1\}$. Therefore, there exists $\varepsilon_A \in]0, 1[$ such that for any u, u', t and t' in E satisfying $d(u, u') < \varepsilon_A$ and $d(t, t') < \varepsilon_A$,

$$A(t, u) = A(t', u').$$

Lemma 2.1. \mathcal{L}_{ϕ} acts on $\mathcal{C}^{0}(\Omega)$ and on $\mathcal{C}^{+1}(\Omega)$.

Proof. Let f be in $\mathcal{C}^0(\Omega)$. The function $x \mapsto e^{\phi(tx)}A(t, x_0)f(tx)$ is continuous on Ω and

$$|e^{\phi(tx)}A(t,x_0)f(tx)| \le e^{\|\phi\|_{\infty}} \|f\|_{\infty},$$

thus by the dominated convergence theorem $\mathcal{L}_{\phi}(f)$ is continuous on Ω . Moreover \mathcal{L}_{ϕ} acts continuously on $\mathcal{C}^{0}(\Omega)$ with operator norm

$$\|\mathcal{L}_{\phi}\|_{\infty} \le e^{\|\phi\|_{\infty}}.$$

Now let f be in $\mathcal{C}^{+1}(\Omega)$. Notice that for any t in E and x, y in Ω ,

$$d_{\Omega}(tx, ty) = \frac{1}{2}d_{\Omega}(x, y)$$

so that the function $f_t : x \mapsto f(tx)$ is Lipschitz with $\operatorname{Lip}(f_t) \leq \frac{1}{2}\operatorname{Lip}(f)$. It is easy to show that if ϕ is Lipschitz, then e^{ϕ} is Lipschitz with

$$\operatorname{Lip}(e^{\phi}) \le e^{\|\phi\|_{\infty}} \operatorname{Lip}(\phi).$$

Notice also that for any t in E, the map $A_t : x \mapsto A(t, x_0)$ is Lipschitz with

$$\operatorname{Lip}(A_t) \le 2\operatorname{Lip}(A)$$

As the product of two Lipschitz functions f and g is Lipschitz with

$$\operatorname{Lip}(fg) \le \|f\|_{\infty} \operatorname{Lip}(g) + \|g\|_{\infty} \operatorname{Lip}(f),$$

we easily deduce that $\mathcal{L}_{\phi}(f)$ is Lipschitz and that \mathcal{L}_{ϕ} acts continuously on $\mathcal{C}^{+1}(\Omega)$.

Lemma 2.2. The spectral radius on $\mathcal{C}^0(\Omega)$ satisfies $\log r_{\phi} = \lim_{n \to +\infty} \frac{1}{n} \log ||\mathcal{L}^n_{\phi}(\mathbb{I})||_{\infty}$.

Proof. We recall that $r_{\phi} := \lim_{n \to +\infty} \|\mathcal{L}_{\phi}^{n}\|_{\infty}^{1/n} = \inf_{n \ge 1} \|\mathcal{L}_{\phi}^{n}\|_{\infty}^{1/n}$. For any f in $\mathcal{C}^{0}(\Omega), x \in \Omega$,

$$|\mathcal{L}_{\phi}(f)(x)| \leq \int_{E} e^{\phi(tx)} A(t, x_{0}) |f(tx)| \, d\rho(t) \leq ||f||_{\infty} \mathcal{L}_{\phi}(\mathbb{I})(x) \leq ||f||_{\infty} ||\mathcal{L}_{\phi}(\mathbb{I})||_{\infty}$$

hence $\|\mathcal{L}_{\phi}\|_{\infty} = \|\mathcal{L}_{\phi}(\mathbb{I})\|_{\infty}$. For $n \in \mathbb{N}$,

$$\mathcal{L}^{n}_{\phi}(f)(x) = \int_{\Omega_{n}(x_{0})} e^{S_{n}(\phi)(tx)} f(tx) \rho^{\otimes n}(dt),$$

where t inside the integral stands for $t = t_0 \cdots t_{n-1}$ and $\rho^{\otimes n}(dt) = \prod_{i=0}^{n-1} \rho(dt_i)$. Then $\|\mathcal{L}_{\phi}^n\|_{\infty} = \|\mathcal{L}_{\phi}^n(\mathbb{1})\|_{\infty}$ for the same reason as for n = 1, hence $r_{\phi} = \lim_{n \to +\infty} \|\mathcal{L}_{\phi}^n(\mathbb{1})\|_{\infty}^{1/n}$.

As the measure ρ is of full support and A satisfies the hypothesis (A3) it is easy to show that for any x in Ω , $\mathcal{L}_{\phi}(\mathbb{I})(x)$ is strictly positive. One then has that

$$\widehat{\mathcal{L}}_{\phi}^{*}(\mu) := rac{\mathcal{L}_{\phi}^{*}(\mu)}{\mathcal{L}_{\phi}^{*}(\mu)(\mathbb{I})}$$

is a probability measure for any $\mu \in M(\Omega)$. The map $\widehat{\mathcal{L}}_{\phi}^* : M(\Omega) \to M(\Omega)$ is continuous on the compact (for the weak*-topology) convex space $M(\Omega)$ therefore by the Schauder-Tychonoff theorem, there exists a probability measure ν_{ϕ} such that

$$\widehat{\mathcal{L}}^*_{\phi}(\nu_{\phi}) = \nu_{\phi}$$

This measure is either called the *conformal measure* or the *eigen-measure*. In the following we set $\lambda_{\phi} := \mathcal{L}_{\phi}^*(\nu_{\phi})(\mathbb{1}) = \int \mathcal{L}_{\phi}(\mathbb{1}) d\nu_{\phi}$.

Proposition 2.3. With previous notations $r_{\phi} = \lambda_{\phi}$. Moreover for any $x \in \Omega$,

(4)
$$\log r_{\phi} = \lim_{n \to +\infty} \frac{1}{n} \log \mathcal{L}_{\phi}^{n}(\mathbb{I})(x).$$

Proof. Lipschitz regularity for ϕ yields that the Bowen condition holds: for any n, for any x and y satisfying $x_i = y_i$ for $i = 0, \ldots n - 1$,

(5)
$$|S_n(\phi)(x) - S_n(\phi)(y)| \le D \operatorname{Lip}(\phi),$$

where $D = \text{Diam}(\Omega) = \max\{d_{\Omega}(x, y); x, y \in \Omega\}$. Indeed if $x_i = y_i$ for $i = 0, \ldots n - 1$ then $d_{\Omega}(\sigma^k x, \sigma^k y) = 2^k d_{\Omega}(x, y)$ for $0 \le k \le n$, so that

$$\begin{aligned} |S_n(\phi)(x) - S_n(\phi)(y)| &\leq \sum_{k=0}^{n-1} \operatorname{Lip}(\phi) 2^k d_\Omega(x, y) \leq 2^n \operatorname{Lip}(\phi) d_\Omega(x, y) \\ &= \operatorname{Lip}(\phi) d_\Omega(\sigma^n(x), \sigma^n(y)). \end{aligned}$$

Lemma 2.4. For any x, y in Ω such that $d_{\Omega}(x, y) < \frac{\varepsilon_A}{2}$, for any $n \geq 2$,

(6)
$$e^{-DLip(\phi)} \le \frac{\mathcal{L}^n_{\phi}(\mathbb{I})(x)}{\mathcal{L}^n_{\phi}(\mathbb{I})(y)} \le e^{DLip(\phi)}.$$

Proof. If $d_{\Omega}(x,y) < \frac{\varepsilon_A}{2}$ then $d(x_0,y_0) < \varepsilon_A$ so that $\Omega_n(x_0) = \Omega_n(y_0)$. For any $a \in \Omega_n(x_0)$, (5) implies that

$$|S_n(\phi)(ax) - S_n(\phi)(ay)| \le D \operatorname{Lip}(\phi),$$

therefore

$$e^{S_n(\phi)(ay)}e^{-D\operatorname{Lip}(\phi)} \le e^{S_n(\phi)(ax)} \le e^{S_n(\phi)(ay)}e^{D\operatorname{Lip}(\phi)}$$

and by integrating over $\Omega_n(x_0)$ one gets

$$\mathcal{L}^{n}_{\phi}(\mathbb{I})(y)e^{-D\operatorname{Lip}(\phi)} \leq \mathcal{L}^{n}_{\phi}(\mathbb{I})(x) \leq \mathcal{L}^{n}_{\phi}(\mathbb{I})(y)e^{D\operatorname{Lip}(\phi)}.$$

We pick N_1 sufficiently big such that Assumption (A3) holds, that is

$$\forall a, b \in E, \ \Omega_{N_1-1}(a, b) \neq \emptyset.$$

Then, we choose N_2 sufficiently big such that $2^{-N_2} < \frac{\varepsilon_A}{2\text{Diam}(\Omega)}$.

Claim 1. There exists $C = C(\phi) > 0$ such that for every $n > N_1 + N_2$, for every x and y in Ω ,

(7)
$$e^{-C} \le \frac{\mathcal{L}^n_{\phi}(\mathbb{I})(x)}{\mathcal{L}^n_{\phi}(\mathbb{I})(y)} \le e^C.$$

Proof of the Claim. We pick x and y in Ω . We denote by **t** an element (t_1, \ldots, t_{N_2}) of Ω_{N_2} and by **u** and **v** some elements of Ω_{N_1} . We set $N := N_2 + N_1$ and m := n - N.

$$\begin{aligned} \mathcal{L}_{\phi}^{n}(\mathbb{I})(x) &= \mathcal{L}_{\phi}^{N} \circ \mathcal{L}_{\phi}^{m}(\mathbb{I})(x) \\ &= \iint e^{S_{N}(\phi)(\mathbf{t}\mathbf{u}x)} A(t_{N_{2}}, u_{1}) A(u_{N_{1}}, x_{0}) \mathcal{L}_{\phi}^{m}(\mathbb{I})(\mathbf{t}\mathbf{u}x) \, d\rho^{\otimes N_{2}}(\mathbf{t}) d\rho^{\otimes N_{1}}(\mathbf{u}) \\ &= \iint e^{S_{N_{2}}(\phi)(\mathbf{t}\mathbf{u}x)} e^{S_{N_{1}}(\phi)(\mathbf{u}x)} A(t_{N_{2}}, u_{1}) A(u_{N_{1}}, x_{0}) \mathcal{L}_{\phi}^{m}(\mathbb{I})(\mathbf{t}\mathbf{u}x) \, d\rho^{\otimes N_{2}}(\mathbf{t}) d\rho^{\otimes N_{1}}(\mathbf{u}) \end{aligned}$$

where we used the identity

$$S_{N_1+N_2}(\phi) = S_{N_2}(\phi) + S_{N_1}(\phi) \circ \sigma^{N_2}$$

Let us set $m_A = \inf_{t \in E} \rho(B(t, \varepsilon_A))$, which is positive thanks to hypothesis **(H)**. As $\Omega_{N_1-1}(u_1, y_0) \neq \emptyset$ we can pick \underline{u} in it. If $\mathbf{v} \in \Omega_{N_1}$ is such that $d(v_1, u_1) < \varepsilon_A$ and $d(v_i, \underline{u}_{i-1}) < \varepsilon_A$ for every $2 \leq i \leq N_1$, then $A(v_{N_1}, y_0) = 1$, that is $\mathbf{v} \in \Omega_{N_1}(y_0)$. We deduce that

$$\int_{\Omega_{N_1}} A(v_{N_1}, y_0) \mathbb{1}_{B(u_1, \varepsilon_A)}(v_1) d\rho^{\otimes N_1}(\mathbf{v}) \ge m_A^{N_1}$$

Therefore

$$\mathcal{L}_{\phi}^{n}(\mathbb{I})(x) \leq \frac{1}{m_{A}^{N_{1}}} \iiint e^{S_{N_{2}}(\phi)(\mathbf{tu}x)} e^{S_{N_{1}}(\phi)(\mathbf{u}x)} A(t_{N_{2}}, u_{1}) A(u_{N_{1}}, x_{0}) \mathcal{L}_{\phi}^{m}(\mathbb{I})(\mathbf{tu}x) A(v_{N_{1}}, y_{0}) \mathbb{I}_{B(u_{1}, \varepsilon_{A})}(v_{1}) d\rho^{\otimes N_{1}}(\mathbf{v}) d\rho^{\otimes N_{2}}(\mathbf{t}) d\rho^{\otimes N_{1}}(\mathbf{u}) A(v_{N_{1}}, y_{0}) \mathbb{I}_{B(u_{1}, \varepsilon_{A})}(v_{1}) d\rho^{\otimes N_{1}}(\mathbf{v}) d\rho^{\otimes N_{2}}(\mathbf{t}) d\rho^{\otimes N_{1}}(\mathbf{u}) A(v_{N_{1}}, y_{0}) \mathbb{I}_{B(u_{1}, \varepsilon_{A})}(v_{1}) d\rho^{\otimes N_{1}}(\mathbf{v}) d\rho^{\otimes N_{2}}(\mathbf{t}) d\rho^{\otimes N_{1}}(\mathbf{u}) A(v_{N_{1}}, y_{0}) \mathbb{I}_{B(u_{1}, \varepsilon_{A})}(v_{1}) d\rho^{\otimes N_{1}}(\mathbf{v}) d\rho^{\otimes N_{1$$

From (5) we deduce that

$$e^{S_{N_2}(\phi)(\mathbf{t}\mathbf{u}x)} \leq e^{D\mathrm{Lip}(\phi)}e^{S_{N_2}(\phi)(\mathbf{t}\mathbf{v}y)}.$$

As $d_{\Omega}(\mathbf{t}\mathbf{u}x,\mathbf{t}\mathbf{v}y) = 2^{-N_2}d_{\Omega}(\mathbf{u}x,\mathbf{v}y) < \frac{\varepsilon_A}{2}$ we know from (6) that
 $\mathcal{L}_{\phi}^m(\mathbb{I})(\mathbf{t}\mathbf{u}x) \leq e^{D\mathrm{Lip}(\phi)}\mathcal{L}_{\phi}^m(\mathbb{I})(\mathbf{t}\mathbf{v}y).$

As $e^{S_{N_1}(\phi)(\mathbf{u}x)} \leq e^{2N_1 \|\phi\|_{\infty}} e^{S_{N_1}(\phi)(\mathbf{v}y)}$ we deduce eventually that

$$\begin{split} \mathcal{L}_{\phi}^{n}(\mathbb{I})(x) &\leq \frac{e^{2D\operatorname{Lip}(\phi)+2N_{1}\|\phi\|_{\infty}}}{m_{A}^{N_{1}}} \iiint e^{S_{N_{2}}(\phi)(\mathbf{t}\mathbf{v}y)} e^{S_{N_{1}}(\phi)(\mathbf{v}y)} \mathcal{L}_{\phi}^{m}(\mathbb{I})(\mathbf{t}\mathbf{v}y) A(t_{N_{2}},u_{1}) \\ &\quad A(u_{N_{1}},x_{0})A(v_{N_{1}},y_{0})\mathbb{I}_{B(u_{1},\varepsilon_{A})}(v_{1}) d\rho^{\otimes N_{1}}(\mathbf{v}) d\rho^{\otimes N_{2}}(\mathbf{t}) d\rho^{\otimes N_{1}}(\mathbf{u}) \\ &\leq \frac{e^{2D\operatorname{Lip}(\phi)+2N_{1}\|\phi\|_{\infty}}}{m_{A}^{N_{1}}} \iint e^{S_{N}(\phi)(\mathbf{t}\mathbf{v}y)} \mathcal{L}_{\phi}^{m}(\mathbb{I})(\mathbf{t}\mathbf{v}y) \\ &\quad A(t_{N_{2}},v_{1})A(v_{N_{1}},y_{0}) d\rho^{\otimes N_{2}}(\mathbf{t}) d\rho^{\otimes N_{1}}(\mathbf{v}) \\ &\quad \text{where we use } A(t_{N_{2}},v_{1}) = A(t_{N_{2}},u_{1}), \\ &\leq \frac{e^{2D\operatorname{Lip}(\phi)+2N_{1}\|\phi\|_{\infty}}}{m_{A}^{N_{1}}} \mathcal{L}_{\phi}^{n}(\mathbb{I})(y). \end{split}$$

Exchanging x and y we get the reverse inequality.

We can now finish the proof of Proposition 2.3. First we recall that according to Lemma 2.2, $\log r_{\phi} = \lim_{n \to +\infty} \frac{1}{n} \log ||\mathcal{L}_{\phi}^{n}(\mathbb{I})||_{\infty}$. As Ω is compact there exists $x_{n} \in \Omega$ such that $||\mathcal{L}_{\phi}^{n}(\mathbb{I})||_{\infty} = \mathcal{L}_{\phi}^{n}(\mathbb{I})(x_{n})$. For any x in Ω and $n > N_{1} + N_{2}$ we get from (7) that

(8)
$$e^{-C}\mathcal{L}^{n}_{\phi}(\mathbb{I})(x_{n}) \leq \mathcal{L}^{n}_{\phi}(\mathbb{I})(x) \leq e^{C}\mathcal{L}^{n}_{\phi}(\mathbb{I})(x_{n}),$$

therefore

$$-\frac{C}{n} + \frac{1}{n}\log\mathcal{L}_{\phi}^{n}(\mathbb{I})(x_{n}) \leq \frac{1}{n}\log\mathcal{L}_{\phi}^{n}(\mathbb{I})(x) \leq \frac{C}{n} + \frac{1}{n}\log\mathcal{L}_{\phi}^{n}(\mathbb{I})(x_{n}),$$

and taking the limit we get (4). Now integrating (8) we get

$$e^{-C}\mathcal{L}^{n}_{\phi}(\mathbb{I})(x_{n}) \leq \int \mathcal{L}^{n}_{\phi}(\mathbb{I})(x) \, d\nu_{\phi}(x) \leq e^{C}\mathcal{L}^{n}_{\phi}(\mathbb{I})(x_{n}),$$

and since $\lambda_{\phi}^{n} = \int \mathcal{L}_{\phi}^{n}(\mathbb{I})(x) d\nu_{\phi}(x)$ we get $\log \lambda_{\phi} = \log r_{\phi}$.

We claim that we can apply the Ionescu-Tulcea & Marinescu Theorem^{\dagger} (see [12], see also [3], Theorem 4.2 or [16], Theorem 2.1) to get a spectral decomposition of the operator $\widetilde{\mathcal{L}}_{\phi} := \frac{1}{r_{\phi}} \mathcal{L}_{\phi}$. Indeed the spaces $\mathcal{C}^{0}(\Omega)$, $\mathcal{C}^{+1}(\Omega)$ satisfy the first hypothesis of ITM Theorem, which is

(1) if $f_n \in \mathcal{C}^{+1}(\Omega)$, $f \in \mathcal{C}^0(\Omega)$, $\lim_{n \to \infty} ||f_n - f||_{\infty} = 0$, and $||f_n||_L \leq C$ for all n, then $f \in \mathcal{C}^{+1}(\Omega)$ and $||f||_L \leq C$,

and $\widetilde{\mathcal{L}}_{\phi}$ satisfies the three following hypothesis:

- (2) $\sup_{n\in\mathbb{N}}\{\|\widetilde{\mathcal{L}}_{\phi}^{n}(f)\|_{\infty}, f\in\mathcal{C}^{+1}(\Omega), \|f\|_{L}\leq 1\}<+\infty,$ (3) there exists $a\in]0,1[, b>0$ and $n_{0}\geq 1$ such that for any $f\in\mathcal{C}^{+1}(\Omega),$

$$\|\mathcal{L}_{\phi}^{n_{0}}(f)\|_{L} \le a\|f\|_{L} + b\|f\|_{\infty},$$

(4) if V is a bounded subset of $(\mathcal{C}^{+1}(\Omega), \|\cdot\|_L)$, then $\widetilde{\mathcal{L}}_{\phi}^{n_0}(V)$ has compact closure in $(\mathcal{C}^0(\Omega), \|\cdot\|_\infty)$.

We sketch the proof of (3) and let the reader check the other conditions.

Proof of (3). A direct computation yields that for f Lipschitz continuous

$$\begin{aligned} \left| \mathcal{L}_{\phi}^{n}(f)(x) - \mathcal{L}_{\phi}^{n}(f)(y) \right| &\leq \operatorname{Lip}(f) \frac{d_{\Omega}(x,y)}{2^{n}} \mathcal{L}_{\phi}^{n}(\mathbb{I})(x) \\ &+ e^{n \|\phi\|_{\infty}} \|f\|_{\infty}(\operatorname{Lip}(\phi) + 2\operatorname{Lip}(A)) d_{\Omega}(x,y). \end{aligned}$$

From (7) we know that for any $n > N_1 + N_2$, for any x in Ω ,

$$e^{-C} \leq \frac{\mathcal{L}^n_{\phi}(\mathbb{I})(x)}{\lambda^n_{\phi}} \leq e^C,$$

hence as $r_{\phi} = \lambda_{\phi}$ we have

$$\begin{split} \left| \widetilde{\mathcal{L}}_{\phi}^{n}(f)(x) - \widetilde{\mathcal{L}}_{\phi}^{n}(f)(y) \right| &\leq \operatorname{Lip}(f) \frac{d_{\Omega}(x,y)}{2^{n}} e^{C} \\ &+ \frac{e^{n \|\phi\|_{\infty}}}{r_{\phi}^{n}} \|f\|_{\infty} (\operatorname{Lip}(\phi) + 2\operatorname{Lip}(A)) d_{\Omega}(x,y). \end{split}$$

Therefore

 $\|\widetilde{\mathcal{L}}^n_{\phi}(f)\|_L = \operatorname{Lip}(\widetilde{\mathcal{L}}^n_{\phi}(f)) + \|\widetilde{\mathcal{L}}^n_{\phi}(f)\|_{\infty} \le A_n \operatorname{Lip}(f) + B_n \|f\|_{\infty} \le A_n \|f\|_L + B_n \|f\|_{\infty}$ where $A_n = \frac{e^C}{2^n}$ and $B_n = \frac{e^{n\|\phi\|_{\infty}}}{r_{\alpha}^n}(\operatorname{Lip}(\phi) + 2\operatorname{Lip}(A) + 1)$. Picking any a in]0,1[and adjusting n such that $2^{-n}e^C \stackrel{\checkmark}{<} a$ one gets the result.

[†]ITM Theorem in short.

13

In particular, and considering \mathcal{L}_{ϕ} as an operator on $\mathcal{C}^{+1}(\Omega)$, the proof of the ITM Theorem shows (see [3, Lem. 4.7], or [16, Lemma 2.4]) that r_{ϕ} is an eigenvalue for \mathcal{L}_{ϕ} associated to the function in $\mathcal{C}^{+1}(\Omega)$ defined by

$$G_{\phi} := \lim_{n \to +\infty} \frac{1}{n} \sum_{k=0}^{n-1} \widetilde{\mathcal{L}}_{\phi}^{k}(\mathbb{I}).$$

Furthermore, we have the following decomposition

$$\widetilde{\mathcal{L}}_{\phi} := \sum e^{i\theta_j} \Pi_j + \Psi$$

where the Π_j 's are (finitely many) projectors with finite rank, the θ_j 's are real numbers and Ψ has spectral radius strictly smaller than 1. Moreover,

$$\Pi_k \Pi_j = 0$$
 if $j \neq k$ and $\Psi \Pi_j = \Pi_j \Psi = 0$.

2.1.2. Second decomposition of the spectrum: r_{ϕ} is the unique eigenvalue with maximal modulus and its eigenspace is of dimension one. For simplicity we set $\theta_0 = 0$. We shall see that mixing yields more precise results on the spectral decomposition of \mathcal{L}_{ϕ} .

Lemma 2.5. For any $x \in \Omega$, $\bigcup_{n \ge 0} \sigma^{-n}(\{x\})$ is dense in Ω .

Proof. Let x and y be in Ω , let $\varepsilon > 0$. Let $n \in \mathbb{N}$ be such that $2^{-n}\operatorname{Diam}(\Omega) < \varepsilon$, and let $z_i = y_i$ for every i in [0, n-1], so that $d_{\Omega}(y, z) \leq \varepsilon$. According to assumption (A3) there exist u_n, \dots, u_{n+N-2} in E such that $z := y_0 \dots y_{n-1} u_n \dots u_{n+N-2} x$ belongs to Ω . Then z belongs to $\sigma^{-(n+N-1)}(\{x\}) \cap B(y, \varepsilon)$. \Box

Remark 4. Actually, we have proved a better result: for any ε , there exists $N' = N'(\varepsilon)$ such that for any y and x, $B(y,\varepsilon) \cap \sigma^{-N'}(\{x\}) \neq \emptyset$.

Proposition 2.6. The spectral radius r_{ϕ} is a simple single dominating eigenvalue. The rest of the spectrum for \mathcal{L}_{ϕ} is a compact set strictly inside the disk $\mathbb{D}(0, r_{\phi})$.

Proof. Because of the first result on the spectrum of \mathcal{L}_{ϕ} , it remains to prove that r_{ϕ} is simple and that any other eigenvalue has modulus strictly lower than r_{ϕ} . For that we use spectral properties of positive operators exposed in [13, chap. 1& 2]. We claim that the set K of non-negative Lipschitz functions is a *solid and reproducing cone*. Solid means it has non-empty interior and reproducing means

$$\mathcal{C}^{+1}(\Omega) = K - K.$$

It is easy to see that any positive Lipschitz function is in K.

• Step one. We prove that for any $f \neq 0 \in K$, there exists p such that $\mathcal{L}^p_{\phi}(f)$ belongs to $\overset{\circ}{K}$.

Let y be such that f(y) > 0. Let $\varepsilon > 0$ be such that $d_{\Omega}(y, y') \leq \varepsilon \Longrightarrow f(y') > 0$. According to Remark 4, there exists $p \in \mathbb{N}$ such that for any $x \in \Omega$, $B(y, \varepsilon) \cap \sigma^{-p}(\{x\}) \neq \emptyset$. Then $\mathcal{L}^{p}_{\phi}(f)$ is positive. Indeed let $x \in \Omega$, and z in $B(y, \varepsilon) \cap \sigma^{-p}(\{x\})$. Let $\eta := \min(\varepsilon_{A}, \frac{\varepsilon}{2})$. The definition of ε_{A} yields that every t in $\prod_{i=0}^{p-1} B(z_{i}, \eta)$ belongs to $\Omega_{p}(x_{0})$, therefore

$$\mathcal{L}^{p}_{\phi}(f)(x) = \int_{\Omega_{p}(x_{0})} e^{S_{p}(\phi)(tx)} f(tx) \rho^{\otimes p}(dt) \ge \int_{\prod_{i=0}^{p-1} B(z_{i},\eta)} e^{S_{p}(\phi)(tx)} f(tx) \rho^{\otimes p}(dt)$$

But if $t \in \prod_{i=0}^{p-1} B(z_i, \eta)$ then

$$d_{\Omega}(tx,y) \le d_{\Omega}(tx,z) + d_{\Omega}(z,y) \le \eta + \frac{\varepsilon}{2} \le \varepsilon$$

hence f(tx) > 0. As any non-empty ball in E has positive ρ -measure we deduce that $\mathcal{L}^{p}_{\phi}(f)(x) > 0$.

• Step two. End of the proof. We deduce from step one that \mathcal{L}_{ϕ} is strongly positive (see [13, Definitions 2.1.1]). Therefore it is *u*-positive for any $u \in \overset{\circ}{K}$. From Th. 2.10, 2.11 and 2.13 we deduce that r_{ϕ} is a simple eigenvalue and that every other eigenvalue λ of \mathcal{L}_{ϕ} satisfies the inequality $|\lambda| < r_{\phi}$.

To re-employ notation from above, there is only one Π_0 , no other Π_i 's. Furthermore, using the fact that ν_{ϕ} is an eigenmeasure, one easily gets that for any $f \in \mathcal{C}^{+1}(\Omega)$,

(9)
$$\mathcal{L}_{\phi}(f) = r_{\phi} \underbrace{\int f \, d\nu_{\phi} \cdot G_{\phi}}_{=\Pi_{0}(f)} + r_{\phi} \Psi(f).$$

2.2. Gibbs measure and ergodic properties.

2.2.1. The Gibbs measure and its main properties. Let μ_{ϕ} be the measure defined by $d\mu_{\phi} := G_{\phi} d\nu_{\phi}$. We emphasize that by construction μ_{ϕ} is a probability measure. We shall use the following fact: for every $n \in \mathbb{N}$,

(10)
$$\mathcal{L}^n_{\phi}(f \cdot g \circ \sigma^n) = g \cdot \mathcal{L}^n_{\phi}(f).$$

Lemma 2.7. The measure μ_{ϕ} is σ -invariant. It is called the Dynamical Gibbs Measure (DGM in short) associated to ϕ .

Proof. For f continuous

$$\int f \circ \sigma \, d\mu_{\phi} = \int f \circ \sigma \cdot G_{\phi} \, d\nu_{\phi}$$
$$= \frac{1}{r_{\phi}} \int \mathcal{L}_{\phi}(f \circ \sigma \cdot G_{\phi}) \, d\nu_{\phi}$$
$$= \frac{1}{r_{\phi}} \int f \cdot \mathcal{L}_{\phi}(G_{\phi}) \, d\nu_{\phi} = \int f \, d\mu_{\phi}.$$

Proposition 2.8. The measure μ_{ϕ} is mixing thus ergodic.

Proof. Let f and g be two functions in $\mathcal{C}^{+1}(\Omega)$. Then

$$\int f \cdot g \circ \sigma^n d\mu_{\phi} = \int f \cdot g \circ \sigma^n \cdot G_{\phi} d\nu_{\phi}$$
$$= \frac{1}{r_{\phi}^n} \int \mathcal{L}_{\phi}^n (fG_{\phi}.g \circ \sigma^n) d\nu_{\phi}$$
$$= \frac{1}{r_{\phi}^n} \int \mathcal{L}_{\phi}^n (fG_{\phi}).g d\nu_{\phi}$$
$$= \int \left(\int fG_{\phi} d\nu_{\phi} \cdot G_{\phi} + \Psi^n (fG_{\phi}) \right) \cdot g d\nu_{\phi}$$

We have seen that the spectral radius of Ψ is strictly lower than 1. Therefore $\Psi^n(fG_{\phi})$ goes to 0 for the Lipschitz norm, thus for the continuous norm. This yields

$$\int f \cdot g \circ \sigma^n \, d\mu_\phi \to_{n \to +\infty} \int f \, d\mu_\phi \int g \, d\mu_\phi,$$

and the proposition is proved.

2.2.2. Furthermore properties.

Lemma 2.9. There exists $C(\phi)$ such that for every x, $e^{-C(\phi)} \leq G_{\phi}(x) \leq e^{C(\phi)}$.

Proof. By definition, $G_{\phi} \geq 0$. Let us prove by contradiction it is positive. Assume that $G_{\phi}(x) = 0$. Then, $\mathcal{L}_{\phi}(G_{\phi}) = r_{\phi}G_{\phi}$ shows that $G_{\phi}(tx) = 0$ for ρ -a.e. t in E such that $A(t, x_0) > 0$. As A and G_{ϕ} are continuous and ρ has full support, this yields that for every t such that $A(t, x_0) > 0$ $G_{\phi}(tx) = 0$. In other words, for every y in $\sigma^{-1}(\{x\}), G_{\phi}(y) = 0$. By induction we deduce that for every $n \in \mathbb{N}$, for every z in $\sigma^{-n}(\{x\}), G_{\phi}(z) = 0$. Now, the set $\bigcup_{n\geq 0}\sigma^{-n}(\{x\})$ is dense, and G_{ϕ} is continuous everywhere and null on a dense set. It is thus null everywhere which is impossible because $\int G_{\phi} d\nu_{\phi} = 1$. This shows that G_{ϕ} is positive, thus bounded from below by some constant of the form $e^{-C(\phi)}$. Furthermore, Ω is compact and then G_{ϕ} is bounded from above. \Box

15

Lemma 2.9 immediately yields

Corollary 2.10. Both measures μ_{ϕ} and ν_{ϕ} are equivalent.

2.2.3. Regularity of the spectral radius.

Proposition 2.11. The map $P: \phi \mapsto \log r_{\phi}$ is convex on $\mathcal{C}^{+1}(\Omega)$.

Proof. Let us pick ϕ_1 , ϕ_2 in $\mathcal{C}^{+1}(\Omega)$, and $\alpha \in [0,1]$. Set $\phi := \alpha \phi_1 + (1-\alpha)\phi_2$. For $n \in \mathbb{N}, x \in \Omega$,

$$\begin{aligned} \mathcal{L}_{\phi}^{n}(\mathbf{1})(x) &= \int_{E^{n}} e^{S_{n}(\phi)(tx)} \mathbf{1}_{\Omega_{n}(x_{0})}(t) \rho^{\otimes n}(dt) \\ &= \int_{E^{n}} e^{\alpha S_{n}(\phi_{1})(tx)} \mathbf{1}_{\Omega_{n}(x_{0})}^{\alpha}(t) e^{(1-\alpha)S_{n}(\phi_{2})(tx)} \mathbf{1}_{\Omega_{n}(x_{0})}^{1-\alpha}(t) \rho^{\otimes n}(dt) \\ &\leq \left(\int_{E^{n}} e^{S_{n}(\phi_{1})(tx)} \mathbf{1}_{\Omega_{n}(x_{0})}(t) \rho^{\otimes n}(dt)\right)^{\alpha} \left(\int_{E^{n}} e^{S_{n}(\phi_{2})(tx)} \mathbf{1}_{\Omega_{n}(x_{0})}(t) \rho^{\otimes n}(dt)\right)^{1-\alpha} \end{aligned}$$

therefore

$$\frac{1}{n}\log\left(\mathcal{L}_{\phi}^{n}(\mathbb{I})(x)\right) \leq \alpha \frac{1}{n}\log\left(\mathcal{L}_{\phi_{1}}^{n}(\mathbb{I})(x)\right) + (1-\alpha)\frac{1}{n}\log\left(\mathcal{L}_{\phi_{2}}^{n}(\mathbb{I})(x)\right).$$

We deduce from (4) that

$$\log r_{\alpha\phi_1+(1-\alpha)\phi_2} \le \alpha \log r_{\phi_1} + (1-\alpha) \log r_{\phi_2}$$

which proves the convexity of P.

Let $\overrightarrow{\psi}$ be as above. We recall the definition

$$I(\overrightarrow{\psi}) := \left\{ \int \overrightarrow{\psi} \, d\mu, \ \mu \in M_{\sigma}(\Omega) \right\}.$$

By definition $I(\vec{\psi})$ is a convex and closed set.

Proposition 2.12. The map $\mathcal{P}: \mathbf{t} \mapsto \log r_{\mathbf{t} \cdot \vec{\psi}}$ is convex and infinitely differentiable on \mathbb{R}^q with

(11)
$$\nabla \mathcal{P}(\boldsymbol{t}) = \int \overrightarrow{\boldsymbol{\psi}} \, d\mu_{\boldsymbol{t} \cdot \overrightarrow{\boldsymbol{\psi}}}$$

For any $\boldsymbol{z} = \nabla \mathcal{P}(\boldsymbol{t})$ in $\nabla \mathcal{P}(\mathbb{R}^q)$, $\mathcal{H}(z, \vec{\psi})$ is finite with

(12)
$$\mathcal{H}(\nabla \mathcal{P}(t), \overrightarrow{\psi}) = \mathcal{P}(t) - t \cdot \nabla \mathcal{P}(t) = \log r_{t \cdot \overrightarrow{\psi}} - \int t \cdot \overrightarrow{\psi} \, d\mu_{t \cdot \overrightarrow{\psi}}.$$

If \boldsymbol{z} does not belong to the closure $\overline{\nabla \mathcal{P}(\mathbb{R}^q)}$ of $\nabla \mathcal{P}(\mathbb{R}^q)$, in particular when $z \notin I(\overrightarrow{\boldsymbol{\psi}})$, then $\mathcal{H}(\boldsymbol{z}, \overrightarrow{\boldsymbol{\psi}}) = -\infty$.

16

Proof. The convexity of \mathcal{P} follow from Proposition 2.11. The map Q with values in $\mathcal{L}(\mathcal{C}^{+1}(\Omega))$ defined on \mathbb{R}^q by

$$Q(t) = \mathcal{L}_{t \cdot \overrightarrow{\psi}}$$

is infinitely differentiable with

$$\frac{\partial Q}{\partial t_k}(t)(g) = Q(t)(\psi_k g).$$

Adapting the proof of Thm. III.8 and Corollary III.11. of [11] we see that the map $t \mapsto r_{t \cdot \overrightarrow{v}}$ is infinitely differentiable with

$$\frac{\partial r_{\boldsymbol{t}\cdot\overrightarrow{\boldsymbol{\psi}}}}{\partial t_k}(\boldsymbol{t}) = r_{\boldsymbol{t}\cdot\overrightarrow{\boldsymbol{\psi}}} \int \psi_k \, d\mu_{\boldsymbol{t}\cdot\overrightarrow{\boldsymbol{\psi}}},$$

from which we deduce (11).

The conjugate function \mathcal{P}^* of \mathcal{P} , defined by

$$\mathcal{P}^*(oldsymbol{z}) = \sup_{oldsymbol{t} \in \mathbb{R}^q} (oldsymbol{t} \cdot oldsymbol{z} - \mathcal{P}(oldsymbol{t})),$$

is convex on \mathbb{R}^q with values in $]-\infty, +\infty]$. We refer for instance to [17], section 26, for the theory of conjugates of convex functions. In particular it is known that

$$\nabla \mathcal{P}(\mathbb{R}^q) \subset \mathrm{dom} \mathcal{P}^* \subset \overline{\nabla \mathcal{P}(\mathbb{R}^q)},$$

where dom $\mathcal{P}^* = \{ \boldsymbol{z} \in \mathbb{R}^q, \, \mathcal{P}^*(\boldsymbol{z}) < +\infty \}$, with

$$\mathcal{P}^*(
abla \mathcal{P}(oldsymbol{t})) = oldsymbol{t} \cdot
abla \mathcal{P}(oldsymbol{t}) - \mathcal{P}(oldsymbol{t}).$$

As $\mathcal{H}(\cdot, \overrightarrow{\psi}) = -\mathcal{P}^*$ the proof is finished.

3. Proof of Theorem 2

3.1. Auxiliary functions φ and $\overline{\varphi}_{\beta}$. We recall the definitions of φ_{β} and $\overline{\varphi}_{\beta}$ defined on \mathbb{R}^{q} :

(13)
$$\varphi_{\beta}(\boldsymbol{t}) = -\frac{\beta}{2} \|\boldsymbol{t}\|^2 + \log r_{\beta \boldsymbol{t} \cdot \overrightarrow{\boldsymbol{\psi}}}, \quad \overline{\varphi}_{\beta}(\boldsymbol{z}) := \mathcal{H}(\boldsymbol{z}, \overrightarrow{\boldsymbol{\psi}}) + \frac{\beta}{2} \|\boldsymbol{z}\|^2.$$

3.1.1. The function φ_{β} .

Lemma 3.1. For every $\beta > 0$ and every t satisfying $||t|| > 4 ||\vec{\psi}||_{\infty}$,

$$arphi_eta(oldsymbol{t}) < \mathcal{H}_{top} - rac{eta}{4} ||oldsymbol{t}||^2.$$

Proof. Let us set $g(x) := \log r_{x\beta t \cdot \vec{\psi}}$ with $x \in [0, 1]$. It is differentiable and Prop. 2.12 yields that for every x,

$$g'(x) = \beta t \cdot \int \overrightarrow{\psi} d\mu_{x\beta t \cdot \overrightarrow{\psi}}$$

Then, we use the mean value theorem. There exists $\theta \in [0, 1]$ such that

$$\log r_{\beta t \cdot \vec{\psi}} = g(1) = \mathcal{H}_{top} + g'(\theta) = \mathcal{H}_{top} + \beta t \cdot \int \vec{\psi} \, d\mu_{\theta \beta t \cdot \vec{\psi}}$$

This yields

$$\varphi_{\beta}(\boldsymbol{t}) = \log r_{\beta \boldsymbol{t} \cdot \overrightarrow{\boldsymbol{\psi}}} - \frac{\beta}{2} ||\boldsymbol{t}||^2 \leq \mathcal{H}_{top} + \beta ||\boldsymbol{t}|| ||\overrightarrow{\boldsymbol{\psi}}||_{\infty} - \frac{\beta}{2} ||\boldsymbol{t}||^2.$$

Now

$$\beta \|\boldsymbol{t}\| \| \overrightarrow{\boldsymbol{\psi}} \|_{\infty} - \frac{\beta}{2} ||\boldsymbol{t}||^2 - \left(-\frac{\beta}{4} ||\boldsymbol{t}||^2\right) = -\frac{\beta \|\boldsymbol{t}\|}{4} \left(\|\boldsymbol{t}\| - 4\| \overrightarrow{\boldsymbol{\psi}} \|_{\infty} \right)$$

and we get the result.

We emphasize an immediate consequence of Lemma 3.1: all the maxima for φ_{β} are reached at critical points and inside the hypercube $[-K, K]^q$ if K is chosen greater than $4 \| \overrightarrow{\psi} \|_{\infty}$. Indeed $\varphi_{\beta}(\mathbf{0}) = \mathcal{H}_{top}$ and if \mathbf{t} is outside the hypercube $[-K, K]^q$ with $K \ge 4 \| \overrightarrow{\psi} \|_{\infty}$ then $\||\mathbf{t}\|| > 4 \| \overrightarrow{\psi} \|_{\infty}$, which implies $\varphi_{\beta}(\mathbf{t}) < \mathcal{H}_{top}$.

3.1.2. The function $\overline{\varphi}_{\beta}$. We also recall the definition

(14)
$$\mathcal{H}(\boldsymbol{z}, \overrightarrow{\boldsymbol{\psi}}) := \inf_{\boldsymbol{t} \in \mathbb{R}^q} \left\{ \log r_{\boldsymbol{t} \cdot \overrightarrow{\boldsymbol{\psi}}} - \boldsymbol{t} \cdot \boldsymbol{z} \right\} = -\mathcal{P}^*(\boldsymbol{z}), \text{ where } \mathcal{P}(\boldsymbol{t}) = \log r_{\boldsymbol{t} \cdot \overrightarrow{\boldsymbol{\psi}}}.$$

From the theory of conjugate functions we know that $\mathcal{H}(\cdot, \vec{\psi})$ is concave and upper semi-continuous, with values in $[-\infty, +\infty]$.

We emphasize that Proposition 2.12 yields that $\overline{\varphi}_{\beta} = -\infty$ outside $\mathcal{I}(\overrightarrow{\psi})$, and $\overline{\varphi}_{\beta}$ is finite on $\nabla \mathcal{P}(\mathbb{R}^q)$. Consequently all the maxima for $\overline{\varphi}_{\beta}$ are reached inside the hypercube $[-\|\overrightarrow{\psi}\|_{\infty}, \|\overrightarrow{\psi}\|_{\infty}]^q$, which contains $\mathcal{I}(\overrightarrow{\psi})$.

Moreover, in our setting the equality $\mathcal{P}^{**} = \mathcal{P}$ holds true, hence we know that

(15)
$$\log r_{t \cdot \vec{\psi}} = \mathcal{P}(t) = \sup_{z} \{ \mathcal{H}(z, \vec{\psi}) + t \cdot z \}.$$

Let us set

$$\widetilde{\mathcal{H}}(\boldsymbol{z}) := \begin{cases} \sup_{\boldsymbol{\mu}} \left\{ \widehat{\mathcal{H}}(\boldsymbol{\mu}), \ \int \overrightarrow{\boldsymbol{\psi}} \ d\boldsymbol{\mu} = \boldsymbol{z} \right\} \ \text{if } \boldsymbol{z} \in I(\overrightarrow{\boldsymbol{\psi}}), \\ -\infty \text{ if } \boldsymbol{z} \notin I(\overrightarrow{\boldsymbol{\psi}}). \end{cases}$$

Then,

Proposition 3.2. For every z in \mathbb{R}^q , $\widetilde{\mathcal{H}}(z) = \mathcal{H}(z, \overrightarrow{\psi})$.

Proof. For any $t \in \mathbb{R}^q$ we have

$$\begin{aligned} \mathcal{P}(\boldsymbol{t}) &= \sup_{\mu} \left(\widehat{\mathcal{H}}(\mu) + \boldsymbol{t} \cdot \int \overrightarrow{\boldsymbol{\psi}} \, d\mu \right) \\ &= \sup_{\boldsymbol{z} \in \mathbb{R}^q} \sup_{\mu, \int \overrightarrow{\boldsymbol{\psi}} \, d\mu = z} \left(\widehat{\mathcal{H}}(\mu) + \boldsymbol{t} \cdot \boldsymbol{z} \right) \\ &= \sup_{\boldsymbol{z} \in \mathbb{R}^q} \left(\widetilde{\mathcal{H}}(\boldsymbol{z}) + \boldsymbol{t} \cdot \boldsymbol{z} \right). \end{aligned}$$

In other words $(-\widetilde{\mathcal{H}})^* = \mathcal{P}$. It is easily seen that $\widetilde{\mathcal{H}}$ is concave. By Theorem 12.2 of [17] the biconjugate $(-\widetilde{\mathcal{H}})^{**}$ of $-\widetilde{\mathcal{H}}$ is equal to its closure. The following lemma shows that $-\widetilde{\mathcal{H}}$ is closed convex therefore $-\widetilde{\mathcal{H}} = \mathcal{P}^*$. As by definition $\mathcal{P}^* = -\mathcal{H}(\cdot, \overrightarrow{\psi})$, we deduce that $\widetilde{\mathcal{H}} = \mathcal{H}(\cdot, \overrightarrow{\psi})$.

Lemma 3.3. The function $\widetilde{\mathcal{H}}$ is upper semi continuous on \mathbb{R}^q .

Proof. Let \boldsymbol{z} be fixed in \mathbb{R}^q , let (\boldsymbol{z}_n) be a sequence in \mathbb{R}^q converging to \boldsymbol{z} . If \boldsymbol{z} is not in $\mathcal{I}(\overrightarrow{\boldsymbol{\psi}})$ then neither is \boldsymbol{z}_n for n big enough hence

$$\limsup_{n \to +\infty} \widetilde{\mathcal{H}}(\boldsymbol{z}_n) = -\infty = \widetilde{\mathcal{H}}(\boldsymbol{z}).$$

Let us thus assume that \boldsymbol{z} is in $\mathcal{I}(\vec{\psi})$. If only a finite number of $\boldsymbol{z}'_n s$ belong to $\mathcal{I}(\vec{\psi})$ then

$$\limsup_{n \to +\infty} \widetilde{\mathcal{H}}(\boldsymbol{z}_n) = -\infty \leq \widetilde{\mathcal{H}}(\boldsymbol{z}).$$

If an infinite number of $\mathbf{z}'_n s$ belong to $\mathcal{I}(\vec{\psi})$ then to compute the limsup we can assume without loss of generality that every \mathbf{z}_n is in $\mathcal{I}(\vec{\psi})$. Let μ_n be an invariant measure such that $\int \vec{\psi} d\mu_n = \mathbf{z}_n$ and

(16)
$$\widehat{\mathcal{H}}(\mu_n) \ge \widetilde{\mathcal{H}}(\boldsymbol{z}_n) - \frac{1}{n}.$$

Let μ be any accumulation point for (μ_n) for the weak* topology. For simplicity we shall write $\mu = \lim_{n \to +\infty} \mu_n$.

Then, $\int \vec{\psi} d\mu = \lim_{n \to +\infty} \int \vec{\psi} d\mu_n = \lim_{n \to +\infty} \boldsymbol{z}_n = \boldsymbol{z}$ and as the metric entropy is upper semi-continuous we get

$$\widetilde{\mathcal{H}}(\boldsymbol{z}) \geq \widehat{\mathcal{H}}(\mu) \geq \limsup_{n \to +\infty} \widehat{\mathcal{H}}(\mu_n) \geq \limsup_{n \to +\infty} \left(\widetilde{\mathcal{H}}(\boldsymbol{z}_n) - \frac{1}{n} \right) = \limsup_{n \to +\infty} \widetilde{\mathcal{H}}(\boldsymbol{z}_n).$$

Finally we have:

Corollary 3.4. For every $\boldsymbol{z} \in \mathbb{R}^q$, $\overline{\varphi}_{\beta}(\boldsymbol{z}) = \widetilde{\mathcal{H}}(\boldsymbol{z}) + \frac{\beta}{2} ||\boldsymbol{z}||^2$.

3.1.3. Maxima for φ_{β} and $\overline{\varphi}_{\beta}$. The main result of this Subsection is

Proposition 3.5. Inequality $\varphi_{\beta}(z) \geq \overline{\varphi}_{\beta}(z)$ holds for any z in \mathbb{R}^{q} . Moreover $\varphi_{\beta}(z)$ is maximum if and only if $\overline{\varphi}_{\beta}(z)$ is maximum. Furthermore, if $\varphi_{\beta}(z)$ is maximum then $\varphi_{\beta}(z) = \overline{\varphi}_{\beta}(z)$.

Proof. • Step 1. $\varphi_{\beta} \geq \overline{\varphi}_{\beta}$. We use Equality (14) with $\boldsymbol{t} = \beta \boldsymbol{z}$. This yields

$$\overline{\varphi}_{\beta}(\boldsymbol{z}) = \mathcal{H}(\boldsymbol{z}, \overrightarrow{\boldsymbol{\psi}}) + \frac{\beta}{2} \|\boldsymbol{z}\|^2 \le \log r_{\boldsymbol{t} \cdot \overrightarrow{\boldsymbol{\psi}}} - \boldsymbol{t} \cdot \boldsymbol{z} + \frac{\beta}{2} ||\boldsymbol{z}||^2 = \log r_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}} - \frac{\beta}{2} ||\boldsymbol{z}||^2 = \varphi_{\beta}(\boldsymbol{z}) \cdot \boldsymbol{z}$$

• Step 2. $\overline{\varphi}_{\beta}(\boldsymbol{z})$ is maximal if and only if $\varphi_{\beta}(\boldsymbol{z})$ is maximal and maximal values do coincide.

Let \boldsymbol{z} be a maximum for φ_{β} . Then, it is a critical point for φ_{β} . As

$$\nabla \varphi_{\beta}(\boldsymbol{z}) = \beta \nabla \mathcal{P}(\beta \boldsymbol{z}) - \beta \boldsymbol{z}$$

this yields $\boldsymbol{z} = \nabla \mathcal{P}(\beta \boldsymbol{z})$. Using (12) we get

$$\mathcal{H}(\boldsymbol{z}, \overrightarrow{\boldsymbol{\psi}}) = \mathcal{H}(\nabla \mathcal{P}(\beta \boldsymbol{z}), \overrightarrow{\boldsymbol{\psi}}) = \mathcal{P}(\beta \boldsymbol{z}) - \beta \boldsymbol{z} \cdot \nabla \mathcal{P}(\beta \boldsymbol{z}) = \mathcal{P}(\beta \boldsymbol{z}) - \beta \|\boldsymbol{z}\|^2,$$

therefore

$$\mathcal{P}(\beta \boldsymbol{z}) = \mathcal{H}(\boldsymbol{z}, \overrightarrow{\boldsymbol{\psi}}) + \beta \|\boldsymbol{z}\|^2.$$

Using step 1 and this last equality we get

$$\overline{\varphi}_{\beta}(\boldsymbol{z}) \leq \varphi_{\beta}(\boldsymbol{z}) = \mathcal{P}(\beta \boldsymbol{z}) - \frac{\beta}{2} \|\boldsymbol{z}\|^{2} = \mathcal{H}(\boldsymbol{z}, \overrightarrow{\boldsymbol{\psi}}) + \beta \|\boldsymbol{z}\|^{2} - \frac{\beta}{2} \|\boldsymbol{z}\|^{2} = \overline{\varphi}_{\beta}(\boldsymbol{z}),$$

which shows that $\overline{\varphi}_{\beta}(\boldsymbol{z}) = \varphi_{\beta}(\boldsymbol{z}).$

On the other hand for any z',

$$\overline{\varphi}_{\beta}(\boldsymbol{z}') \leq \varphi_{\beta}(\boldsymbol{z}') \leq \varphi_{\beta}(\boldsymbol{z}) = \overline{\varphi}_{\beta}(\boldsymbol{z}),$$

which shows that \boldsymbol{z} is also a maximum for $\overline{\varphi}_{\beta}$.

Conversely, if \boldsymbol{z} is a maximum for $\overline{\varphi}_{\beta}$, let \boldsymbol{z}' be any maximum for φ_{β} . We get

$$\overline{\varphi}_{\beta}(\boldsymbol{z}) \geq \overline{\varphi}_{\beta}(\boldsymbol{z}') = \varphi_{\beta}(\boldsymbol{z}') \geq \varphi_{\beta}(\boldsymbol{z}) \geq \overline{\varphi}_{\beta}(\boldsymbol{z}).$$

This shows that \boldsymbol{z} is also a maximum for φ_{β} , which finishes the proof. Corollary 3.6. Maxima for $\overline{\varphi}_{\beta}$ are reached on $\nabla \mathcal{P}(\mathbb{R}^q)$.

20

Proof. Proposition 3.5 states that maxima for $\overline{\varphi}_{\beta}$ are maxima for φ_{β} . We have seen after Lemma 3.1 that all the maxima for φ_{β} are reached at critical points.

Now,
$$\boldsymbol{t}$$
 is a critical point for $\varphi_{\beta}(\boldsymbol{t}) = -\frac{\beta}{2} \|\boldsymbol{t}\|^2 + \log r_{\beta \boldsymbol{t}} \cdot \vec{\psi}$ means
$$\boldsymbol{t} = \nabla \mathcal{P}(\beta \boldsymbol{t}) \in \nabla \mathcal{P}(\mathbb{R}^q).$$

21

3.2. Measures maximizing quadratic pressure.

3.2.1. Another expression for $\mathcal{P}_2(\beta)$. We remind that the metric entropy $\mu \mapsto \widehat{\mathcal{H}}(\mu)$ is upper semi-continuous (see Remark 2).

Therefore the function

$$F: \mu \mapsto \widehat{\mathcal{H}}(\mu) + \frac{\beta}{2} \left\| \int \overrightarrow{\psi} \, d\mu \right\|^2$$

is upper semicontinuous hence attains it supremum on the compact set $M_{\sigma}(\Omega)$.

$$egin{aligned} \mathcal{P}_2(eta) &= \max_{\mu \in \ M_\sigma(\Omega)} F(\mu) \ &= \max_{oldsymbol{z} \in \mathbb{R}^q} \max\left\{\widehat{\mathcal{H}}(\mu) + rac{eta}{2}||oldsymbol{z}||^2, \ \int ec{oldsymbol{\psi}} \, d\mu = oldsymbol{z}
ight\} \ &= \max_{oldsymbol{z} \in \mathbb{R}^q} \left(\widetilde{\mathcal{H}}(oldsymbol{z}) + rac{eta}{2}\|oldsymbol{z}\|^2
ight) \ &= \max_{oldsymbol{z} \in
abla \mathcal{P}(\mathbb{R}^q)} \overline{arphi}_eta(oldsymbol{z}) \ &= \max_{oldsymbol{z} \in \mathbb{R}^q} arphi_eta(oldsymbol{z}) \ &= \max_{oldsymbol{z} \in \mathbb{R}^q} arphi_eta(oldsymbol{z}) \end{aligned}$$

where the last equality comes from Proposition (3.5) and the fourth equality comes from Corollaries 3.4 and 3.6.

3.2.2. Good DGM maximize quadratic pressure. We note

$$M := \{ \boldsymbol{z} \in \mathbb{R}^q; \overline{\varphi}_{\beta}(\boldsymbol{z}) \text{ is maximal} \}.$$

Let $\boldsymbol{z} \in M$. We saw in the proof of Proposition (3.5) that \boldsymbol{z} is then a critical point for φ_{β} hence $\boldsymbol{z} = \nabla \mathcal{P}(\beta \boldsymbol{z}) = \int \overrightarrow{\boldsymbol{\psi}} d\mu_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}$. From (2) we know that

$$\widehat{\mathcal{H}}(\mu_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}) = \mathcal{P}(\beta \boldsymbol{z}) - \int \beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}} \, d\mu_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}$$

hence from (12) we deduce that $\mathcal{H}(\boldsymbol{z}, \overrightarrow{\boldsymbol{\psi}}) = \widehat{\mathcal{H}}(\mu_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}})$, thus

$$\overline{\varphi}_{\beta}(\boldsymbol{z}) = F(\mu_{\beta \boldsymbol{z}}, \overrightarrow{\boldsymbol{\psi}}).$$

Let μ be any measure, $\boldsymbol{z}' := \int \overrightarrow{\boldsymbol{\psi}} d\mu$. Then

$$F(\mu) = \widehat{\mathcal{H}}(\mu) + \frac{\beta}{2} ||\boldsymbol{z}'||^2 \leq \widetilde{\mathcal{H}}(\boldsymbol{z}') + \frac{\beta}{2} ||\boldsymbol{z}'||^2 = \overline{\varphi}_{\beta}(\boldsymbol{z}') \leq \overline{\varphi}_{\beta}(\boldsymbol{z}).$$

Therefore, $\mu_{\beta z \cdot \overrightarrow{\psi}}$ maximizes F.

3.2.3. Maxima for quadratic pressure are realized only by good DGM. Conversely let μ maximizing the function F. Set $\boldsymbol{z} := \int \vec{\psi} d\mu$. Then \boldsymbol{z} is in M hence satisfies

$$\boldsymbol{z} = \int \overrightarrow{\boldsymbol{\psi}} \, d\mu_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}} = \int \overrightarrow{\boldsymbol{\psi}} \, d\mu,$$

and $\widehat{\mathcal{H}}(\mu) = \widetilde{\mathcal{H}}(\boldsymbol{z})$. Now using (2) we can write

$$\mathcal{P}(\beta \boldsymbol{z}) = \widehat{\mathcal{H}}(\boldsymbol{\mu}_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}) + \beta \boldsymbol{z} \cdot \int \overrightarrow{\boldsymbol{\psi}} \, d\boldsymbol{\mu}_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}} = \widetilde{\mathcal{H}}(\boldsymbol{z}) + \beta \boldsymbol{z} \cdot \boldsymbol{z} = \widehat{\mathcal{H}}(\boldsymbol{\mu}) + \beta \boldsymbol{z} \cdot \int \overrightarrow{\boldsymbol{\psi}} \, d\boldsymbol{\mu},$$

which means that μ is equal to $\mu_{\beta z \cdot \vec{\psi}}$ by uniqueness of the (linear) equilibrium state.

4. Proof of Theorem 3

4.1. A useful computation. Let $f : \Omega \to \mathbb{R}$ be continuous. We want to evaluate the limit of $\int f(\omega)d\mu_{n,\beta}(\omega)$ as $n \to +\infty$. In the first step we do the computation without the normalizing term $Z_{n,\beta}$ and estimate it in the second step. We recall the identity

(17)
$$e^{\|\boldsymbol{\xi}\|^2} = \frac{1}{(2\pi)^{q/2}} \int_{\mathbb{R}^q} \exp\left(-\frac{1}{2}\|\boldsymbol{t}\|^2 + \sqrt{2}\boldsymbol{t}.\boldsymbol{\xi}\right) d\boldsymbol{t}.$$

Then we have

$$\begin{aligned} Z_{n,\beta} \int_{\Omega} f(\omega) d\mu_{n,\beta}(\omega) &= \int_{\Omega} e^{\frac{\beta}{2n} ||S_n(\overrightarrow{\psi})(\omega)||^2} f(\omega) d\mathbb{P}(\omega) \\ &= \frac{1}{(2\pi)^{q/2}} \int_{\Omega} \int_{\mathbb{R}^q} e^{-\frac{1}{2} ||\mathbf{t}||^2} e^{\sqrt{\frac{\beta}{n}} \mathbf{t}.S_n(\overrightarrow{\psi})(\omega)} f(\omega) d\mathbf{t} d\mathbb{P}(\omega) \\ &= \frac{1}{(2\pi)^{q/2}} \int_{\mathbb{R}^q} e^{-\frac{1}{2} ||\mathbf{t}||^2} \int_{\Omega} \int_{\Omega_n(\omega_0)} e^{\sqrt{\frac{\beta}{n}} \mathbf{t}.S_n(\overrightarrow{\psi})(\alpha\omega)} f(\alpha\omega) d\rho^{\otimes n}(\alpha) d\mathbb{P}(\omega) d\mathbf{t} \\ &= \frac{1}{(2\pi)^{q/2}} \int_{\mathbb{R}^q} e^{-\frac{1}{2} ||\mathbf{t}||^2} \int_{\Omega} \mathcal{L}_{N\frac{\beta}{n}}^n \mathbf{t}.\overrightarrow{\psi}}(f)(\omega) d\mathbb{P}(\omega) d\mathbf{t} \\ &= \left(\frac{\beta n}{2\pi}\right)^{q/2} \int_{\mathbb{R}^q} e^{-\frac{n\beta}{2} ||\mathbf{z}||^2} \int_{\Omega} \mathcal{L}_{\beta\mathbf{z}}^n \overrightarrow{\psi}(f)(\omega) d\mathbb{P}(\omega) d\mathbf{z} \end{aligned}$$

where we made the change of variable $\beta \boldsymbol{z} = \sqrt{\frac{\beta}{n}} \boldsymbol{t}$ to get the last equality.

We claim that the part of the integral in z outside the hypercube $[-K, K]^q$ is negligible with respect to the other part. Indeed,

(18)
$$\int_{\mathbb{R}^{q}\setminus[-K,K]^{q}} e^{-\frac{n\beta}{2}\|\boldsymbol{z}\|^{2}} \int_{\Omega} \mathcal{L}_{\boldsymbol{\beta}\boldsymbol{z}\cdot\vec{\boldsymbol{\psi}}}^{n}(f)(\omega) d\mathbb{P}(\omega) d\boldsymbol{z}$$
$$\leq \int_{\mathbb{R}^{q}\setminus[-K,K]^{q}} e^{-\frac{n\beta}{2}\|\boldsymbol{z}\|^{2}} \|\mathcal{L}_{\boldsymbol{\beta}\boldsymbol{z}\cdot\vec{\boldsymbol{\psi}}}^{n}\|_{\infty} \|f\|_{\infty} d\boldsymbol{z},$$

and $\|\mathcal{L}_{\beta z \cdot \overrightarrow{\psi}}^{n}\|_{\infty} \leq e^{n\beta \|z\| \|\overrightarrow{\psi}\|_{\infty}}$, so that

$$e^{-\frac{n\beta}{2}\|\boldsymbol{z}\|^2} \|\mathcal{L}^n_{\beta\boldsymbol{z}\cdot\overrightarrow{\boldsymbol{\psi}}}\|_{\infty} \le e^{n\beta(\|\boldsymbol{z}\|\|\overrightarrow{\boldsymbol{\psi}}\|_{\infty} - \frac{1}{2}\|\boldsymbol{z}\|^2)} \le e^{-n\beta\frac{\|\boldsymbol{z}\|^2}{4}}$$

for $\|\boldsymbol{z}\| > 4 \| \overrightarrow{\boldsymbol{\psi}} \|_{\infty}$, as we noticed in the proof of Lemma (3.1). Now

$$\int_{\mathbb{R}^q \setminus [-K,K]^q} e^{-n\beta \frac{\|\boldsymbol{z}\|^2}{4}} d\boldsymbol{z} \le \sum_{i=1}^q \int_{|z_i| > K} e^{-n\beta \frac{z_i^2}{4}} \prod_{j \neq i} e^{-n\beta \frac{z_j^2}{4}} d\boldsymbol{z}$$
$$= \left(\frac{4\pi}{n\beta}\right)^{\frac{q-1}{2}} \sum_{i=1}^q \int_{|z_i| > K} e^{-n\beta \frac{z_i^2}{4}} dz_i,$$

and

$$\int_{|z_i| > K} e^{-n\beta \frac{z_i^2}{4}} \, dz_i \le \frac{4}{n\beta K} e^{-n\beta \frac{K^2}{4}}.$$

Returning to (18) we get

(19)
$$\int_{\mathbb{R}^q \setminus [-K,K]^q} e^{-\frac{n\beta}{2} \|\boldsymbol{z}\|^2} \int_{\Omega} \mathcal{L}^n_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}(f)(\omega) \, d\mathbb{P}(\omega) \, d\boldsymbol{z} = O\left(\frac{e^{-n\beta \frac{K^2}{4}}}{n^{\frac{q+1}{2}}}\right).$$

if K is greater than $4 \| \vec{\psi} \|_{\infty}$.

Now, we recall that

$$\varphi_{\beta}(\boldsymbol{z}) = -\frac{\beta}{2} \|\boldsymbol{z}\|^2 + \log r_{\beta \boldsymbol{z}. \vec{\psi}}$$

and that if f belongs to $\mathcal{C}^{+1}(\Omega)$ then

$$\mathcal{L}^{n}_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}(f)(\omega) = e^{n \log r_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}} \left[\left(\int_{\Omega} f \, d\nu_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}} \right) G_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}(\omega) + \Psi^{n}_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}(f)(\omega) \right],$$

where the operator norm of $\Psi_{\beta z \cdot \vec{\psi}}$ acting on $\mathcal{C}^{+1}(\Omega)$ is strictly less than one. We write $\Psi_{\beta z \cdot \vec{\psi}} = e^{-\varepsilon(\beta, z)}T(\beta, z)$ where $\varepsilon(\beta, z)$ is the spectral gap of the operator $\mathcal{L}_{\beta z \cdot \vec{\psi}}$

and $||T(\beta, z)||_{L} = 1$. Then

$$(20) \quad \int_{[-K,K]^q} e^{-\frac{n\beta}{2} \|\boldsymbol{z}\|^2} \int_{\Omega} \mathcal{L}^n_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}(f)(\omega) \, d\mathbb{P}(\omega) \, d\boldsymbol{z}$$
$$= \int_{[-K,K]^q} e^{n\varphi_\beta(\boldsymbol{z})} \int_{\Omega} \left[\left(\int_{\Omega} f \, d\nu_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}} \right) G_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}}(\omega) + e^{-n\varepsilon(\beta,\boldsymbol{z})} T^n(\beta,\boldsymbol{z})(f)(\omega) \right] \, d\mathbb{P}(\omega) \, d\boldsymbol{z}$$

The spectral gap $\varepsilon(\beta, \mathbf{z})$ is lower semi-continuous in \mathbf{z} hence it attains its infimum $m(\beta)$ on the compact set $[-K, K]^q$, which is strictly positive. We set

$$\alpha(n, z, f) = \int_{\Omega} e^{-n\varepsilon(\beta, z)} T^n(\beta, z)(f)(\omega) \, d\mathbb{P}(\omega),$$

and notice that for any \boldsymbol{z} in $[-K, K]^q$,

$$|\alpha(n, z, f)| \le e^{-nm(\beta)} ||f||_L.$$

Eventually we get

(21)
$$Z_{n,\beta} \int_{\Omega} f(\omega) \, d\mu_{n,\beta}(\omega) = \left(\frac{\beta n}{2\pi}\right)^{q/2} \int_{[-K,K]^q} e^{n\varphi_{\beta}(\boldsymbol{z})} \left[\left(\int_{\Omega} f \, d\nu_{\beta\boldsymbol{z}}.\overrightarrow{\psi} \right) \left(\int_{\Omega} G_{\beta\boldsymbol{z}}.\overrightarrow{\psi} \, d\mathbb{P} \right) + \alpha(n,\boldsymbol{z},f) \right] \, d\boldsymbol{z} + O\left(\frac{e^{-n\beta\frac{K^2}{4}}}{n^{\frac{q+1}{2}}}\right)$$

The normalization term $Z_{n,\beta}$ is obtained taking $f \equiv 1$. This yields

$$(22) \quad \int_{\Omega} f(\omega) \, d\mu_{n,\beta}(\omega) = \\ \frac{\int_{[-K,K]^q} e^{n\varphi_{\beta}(\boldsymbol{z})} \left[\left(\int_{\Omega} f \, d\nu_{\beta\boldsymbol{z}}.\overrightarrow{\psi} \right) \left(\int_{\Omega} G_{\beta\boldsymbol{z}}.\overrightarrow{\psi} \, d\mathbb{P} \right) + \alpha(n,\boldsymbol{z},f) \right] \, d\boldsymbol{z} + O\left(\frac{e^{-n\beta\frac{K^2}{4}}}{n^{\frac{q+1}{2}}}\right)}{\int_{[-K,K]^q} e^{n\varphi_{\beta}(\boldsymbol{z})} \left[\int_{\Omega} G_{\beta\boldsymbol{z}}.\overrightarrow{\psi} \, d\mathbb{P} + \alpha(n,\boldsymbol{z},\mathfrak{I}) \right] \, d\boldsymbol{z} + O\left(\frac{e^{-n\beta\frac{K^2}{4}}}{n^{\frac{q+1}{2}}}\right)}.$$

where $\alpha(n, \boldsymbol{z}, f)$ and $\alpha(n, \boldsymbol{z}, \boldsymbol{\mathbb{I}})$ converge uniformly to 0 with respect to \boldsymbol{z} when n tends to infinity.

4.2. The case q = 1. In this case the function φ_{β} is analytic hence admits only finitely many maxima, and we can argue as in [14].

4.3. The higher dimensional case. We assume that all the maxima for φ_{β} are non-degenerated.

Lemma 4.1. The function φ_{β} only admits finitely many maxima.

Proof. The proof is done by contradiction. Let us consider a sequence (\boldsymbol{z}_n) of maxima for φ_{β} . We have seen that all the maxima are critical points and are in some compact set $[-K, K]^q$ (see Lemma 3.1 and discussion after).

Therefore, we may consider some accumulation point z for the z_n 's. For simplicity we set $z = \lim_{n \to +\infty} z_n$ and we assume that $z_n \neq z_{n+1}$ holds for every n. Note that by continuity, z is also a critical point for φ_β and φ_β is maximal at z

We remind that φ_{β} is \mathcal{C}^{∞} . If we consider the restriction φ_{β_n} of φ_{β} to each segment $[z_n, z_{n+1}]$, then φ_{β_n} is \mathcal{C}^{∞} and $\varphi_{\beta'_n}(\boldsymbol{z}_n) = \varphi_{\beta'_n}(\boldsymbol{z}_{n+1}) = 0$. Hence, Rolle's theorem shows that there exists $\boldsymbol{z}'_n \in [\boldsymbol{z}_n, \boldsymbol{z}_{n+1}]$ such that

(23)
$$\varphi_{\beta_n''}(\boldsymbol{z}_n') = 0.$$

Set $\vec{u}_n := \boldsymbol{z}_n - \boldsymbol{z}_{n+1}$ and consider any accumulation point \vec{u} for $\frac{\boldsymbol{z}_n - \boldsymbol{z}_{n+1}}{||\boldsymbol{z}_n - \boldsymbol{z}_{n+1}||}$. Equality (23) can be rewritten under the form

$$d^2\varphi_\beta(\boldsymbol{z}_n')(\vec{u}_n,\vec{u}_n)=0,$$

which yields as $n \to +\infty d^2 \varphi_\beta(\boldsymbol{z})(\boldsymbol{u}, \boldsymbol{u}) = 0$. This means that \boldsymbol{z} is a degenerated maximal point for φ_β , which is in contradiction with our assumption.

Let z_1, \dots, z_k be the points where φ_β attains its maximum. We recall that the Laplace method (see [18, Ch.IX Th.3]) states

$$\int_{0} e^{n\varphi_{\beta}(\boldsymbol{z})} g(\boldsymbol{z}) \, d\boldsymbol{z} \sim_{n \to \infty} \frac{(2\pi)^{q/2} g(\boldsymbol{z}_{1}) e^{n\varphi_{\beta}(\boldsymbol{z}_{1})}}{n^{q/2} \sqrt{|\det d^{2}\varphi_{\beta}(\boldsymbol{z}_{1})|}}.$$

provided that φ_{β} admits no other critical point than \boldsymbol{z}_1 in an open set O of \mathbb{R}^q , that $g(\boldsymbol{z}_1) \neq 0$ and that the Hessian matrix $d^2 \varphi_{\beta}(\boldsymbol{z}_1)$ is negative definite (which holds by our assumption).

Remark 5. We emphasize the assumption $g(\boldsymbol{z}_1) \neq 0$.

We choose K such that $\varphi_{\beta}(\boldsymbol{z}_1) + \beta \frac{K^2}{4} > 0$, and letting $n \to +\infty$ in (22), we get that for every f in $\mathcal{C}^{+1}(\Omega)$,

$$\lim_{n \to +\infty} \int_{\Omega} f(\omega) \, d\mu_{n,\beta}(\omega) = \frac{\sum_{j=1}^{k} \frac{\int G_{\beta \boldsymbol{z}_{j} \cdot \overrightarrow{\psi}} \, d\mathbb{P}}{\sqrt{\det d^{2} \varphi_{\beta}(\boldsymbol{z}_{j})}} \int f \, d\nu_{\beta \boldsymbol{z}_{j} \cdot \overrightarrow{\psi}}}{\sum_{j=1}^{k} \frac{\int G_{\beta \boldsymbol{z}_{j} \cdot \overrightarrow{\psi}} \, d\mathbb{P}}{\sqrt{\det d^{2} \varphi_{\beta}(\boldsymbol{z}_{j})}}},$$

which finishes the proof of Theorem 3.

5. Application to the mean-field XY model

5.1. The cosine potential. The mean-field XY model is a system of n globally coupled planar spins (or alternatively of n globally interacting particles constrained on a ring), with Hamiltonian

$$H_n = -\frac{1}{2n} \sum_{i,j=1}^n \cos(p_i - p_j),$$

where $p_i \in [0, \pi[$. We can interpret it as a generalized Curie-Weiss-Potts model by setting $E = \mathbb{T} = \{z \in \mathbb{R}^2, \|z\| = 1\}, \Omega = \mathbb{T}^{\mathbb{N}}$, and $\overrightarrow{\psi}(\omega) = \omega_0$. Indeed every ω_k in the word $\omega = \omega_0 \omega_1 \cdots$ of Ω is uniquely expressed as $\omega_k = (\cos \theta_k, \sin \theta_k)$ with θ_k in $[-\pi, \pi[$, and then

$$\|S_n(\overrightarrow{\psi})(\omega)\|^2 = \|\sum_{k=0}^{n-1} \omega_k\|^2 = \sum_{i,j=0}^{n-1} \langle \omega_i, \omega_j \rangle = \sum_{i,j=0}^{n-1} \cos(\omega_i - \omega_j).$$

We endow \mathbb{T} with the usual distance on \mathbb{R}^2 , and the Haar measure ρ given by

$$\int_{\mathbb{T}} h(z) \,\rho(dz) = \int_{-\pi}^{\pi} h(\vec{u}_{\theta}) \,\frac{d\theta}{2\pi}, \text{ where } \vec{u}_{\theta} = (\cos\theta, \sin\theta).$$

As $\overrightarrow{\psi}$ only depends on the first coordinate, we see that for any t in \mathbb{R}^2 and any f in $\mathcal{C}^0(\Omega)$,

$$\mathcal{L}_{t \cdot \overrightarrow{\psi}}(f)(\omega) = \int_{-\pi}^{\pi} e^{t \cdot \overrightarrow{u}_{\theta}} f(\overrightarrow{u}_{\theta}\omega) \frac{d\theta}{2\pi},$$

so that the spectral radius of $\mathcal{L}_{\beta t \cdot \overline{y}}$ is

$$r_{\beta t \cdot \vec{\psi}} = \lambda_{\beta t \cdot \vec{\psi}} = \int_{-\pi}^{\pi} e^{\beta t \cdot \vec{u}_{\theta}} \frac{d\theta}{2\pi},$$

with eigenfunction $G_{\beta t \cdot \vec{\psi}} = \mathbb{I}$, and $\nu_{\beta t \cdot \vec{\psi}} = \mu_{\beta t \cdot \vec{\psi}}$. We notice that $r_0 = 1$. If $t \neq 0$, we denote by |t| its euclidean norm and by θ_t the unique element of $[-\pi, \pi[$ such that $t = |t| \vec{u}_{\theta_t}$. Then

$$r_{\beta t \cdot \vec{\psi}} = \int_{-\pi}^{\pi} e^{\beta |t| \cos(\theta_t - \theta)} \frac{d\theta}{2\pi}$$
$$= \int_{\theta_t - \pi}^{\theta_t + \pi} e^{\beta |t| \cos y} \frac{dy}{2\pi}$$
$$= \int_{-\pi}^{\pi} e^{\beta |t| \cos y} \frac{dy}{2\pi}$$

because the integral does not depend on the interval of length 2π where we compute it. Eventually we have

(24)
$$r_{\beta t \cdot \vec{\psi}} = \int_0^\pi e^{\beta |t| \cos y} \frac{dy}{\pi} = I_0(\beta |t|),$$

where I_0 is the modified Bessel function of order zero, and we get

$$\varphi_{\beta}(\boldsymbol{t}) = -\frac{\beta}{2} |\boldsymbol{t}|^2 + \log r_{\beta \boldsymbol{t} \cdot \vec{\boldsymbol{\psi}}} = -\frac{\beta}{2} |\boldsymbol{t}|^2 + \log I_0(\beta |\boldsymbol{t}|).$$

This shows that $\varphi_{\beta}(t)$ is constant on all the circles centered in 0.

Remark 6. Unless φ_{β} is maximal only at 0, which does not hold for every β as we will see below, we have here an example where all the maxima of the auxiliary function are degenerated.

We set

$$\phi_{\beta}(x) := -\frac{\beta}{2}x^2 + \log I_0(\beta x) \text{ for } x \ge 0.$$

The equality (22) becomes

(25)
$$\int_{\Omega} f(\omega) d\mu_{n,\beta}(\omega) = \frac{\int_{B(0,K)} e^{n\varphi_{\beta}(\boldsymbol{z})} \left[\int_{\Omega} f d\mu_{\beta\boldsymbol{z}} \cdot \vec{\psi} + \alpha(n, \boldsymbol{z}, f) \right] d\boldsymbol{z} + O\left(\frac{e^{-n\beta\frac{K^{2}}{4}}}{n^{\frac{3}{2}}}\right)}{\int_{B(0,K)} e^{n\varphi_{\beta}(\boldsymbol{z})} d\boldsymbol{z} + O\left(\frac{e^{-n\beta\frac{K^{2}}{4}}}{n^{\frac{3}{2}}}\right)}.$$

where we replaced for commodity the square $[-K, K]^2$ by the disk B(0, K). We are thus led to study the asymptotic behaviour of the integral

$$I(n,f) = \int_{B(0,K)} e^{n\varphi_{\beta}(\boldsymbol{z})} \left[\int_{\Omega} f \, d\mu_{\beta \boldsymbol{z} \cdot \overrightarrow{\boldsymbol{\psi}}} \right] \, d\boldsymbol{z}.$$

In polar coordinates we write $\boldsymbol{z} = r \vec{u}_{\theta}$ and we get

$$I(n,f) = \int_0^K \int_{-\pi}^{\pi} e^{n\phi_{\beta}(r)} \left[\int_{\Omega} f \, d\mu_{\beta r \vec{u}_{\theta}} \overrightarrow{\psi} \right] r \, dr \, d\theta.$$

For $x \in \mathbb{R}_+$, we denote by η_x the mean value of DGM's defined by

$$\int_{\Omega} h \, d\eta_x = \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[\int_{\Omega} h \, d\mu_{x\vec{u}_\theta} \cdot \vec{\psi} \right] \, d\theta$$

for any bounded measurable h, so that

$$I(n,f) = 2\pi \int_0^K e^{n\phi_\beta(r)} \left(\int_\Omega f \, d\eta_{\beta r} \right) r \, dr,$$

which is then a one dimensional Laplace integral. We study the maximum of the function ϕ_{β} on \mathbb{R}_+ . First we notice that $0 \leq I_0(\beta x) \leq \beta x$ and $I_0(0) = 1$, hence

$$\phi_{\beta}(x) \leq \beta x(1-\frac{x}{2}) \text{ and } \phi_{\beta}(0) = 0,$$

from which we deduce that $\max_{\mathbb{R}_+} \phi_{\beta} = \max_{[0,2[} \phi_{\beta}$. Next we look for the critical points of ϕ_{β} on [0,2[. We compute the first and second derivatives

(26)
$$\phi_{\beta}'(x) = \beta \left[\left(\frac{I_0'}{I_0} \right) (\beta x) - x \right] = \beta \left[\frac{\int_0^{\pi} e^{\beta x \cos \theta} \cos \theta \, d\theta}{\int_0^{\pi} e^{\beta x \cos \theta} \, d\theta} - x \right].$$

(27)
$$\phi_{\beta}''(x) = \beta \left[\beta \left(\frac{I_0'' I_0 - I_0'^2}{I_0^2} \right) (\beta x) - 1 \right]$$
$$= \beta \left[\frac{\int_0^{\pi} e^{\beta x \cos \theta} \cos^2 \theta \, d\theta}{\int_0^{\pi} e^{\beta x \cos \theta} \, d\theta} - \left(\frac{\int_0^{\pi} e^{\beta x \cos \theta} \cos \theta \, d\theta}{\int_0^{\pi} e^{\beta x \cos \theta} \, d\theta} \right)^2 - 1 \right].$$

We notice that $\phi'_{\beta}(x) \leq \beta(1-x)$, from which we deduce that $\max_{\mathbb{R}_+} \phi_{\beta} = \max_{[0,1]} \phi_{\beta}$. As $I'_0(0) = 0$ we know that $\phi'_{\beta}(0) = 0$. We compute

$$\phi_{\beta}''(0) = \beta \left[\beta I_0''(0) - 1\right] = \beta \left[\frac{\beta}{\pi} \int_0^{\pi} \cos^2 \theta \, d\theta - 1\right] = \beta \left[\frac{\beta}{2} - 1\right].$$

We shall thus consider three cases: $\beta > 2$, $\beta = 2$, and $\beta < 2$. First we take a closer look at the critical points of ϕ_{β} . We recall that the Bessel function I_0 satisfies the differential equation (we refer for instance to [2] for information about Bessel functions)

(28)
$$I_0''(x) + \frac{1}{x}I_0'(x) - I_0(x) = 0$$

so that

$$\left(\frac{I_0''}{I_0}\right)(\beta x) = 1 - \frac{1}{\beta x} \left(\frac{I_0'}{I_0}\right)(\beta x).$$

Replacing in (27) we get that for every x,

(29)
$$\phi_{\beta}''(x) = \beta^2 \left[\left(\frac{I_0''}{I_0} \right) (\beta x) - \left(\frac{I_0'}{I_0} \right)^2 (\beta x) - \frac{1}{\beta} \right]$$
$$= -\beta^2 \left[\left(\frac{I_0'}{I_0} \right)^2 (\beta x) + \frac{1}{\beta x} \left(\frac{I_0'}{I_0} \right) (\beta x) - 1 + \frac{1}{\beta} \right].$$

Now from (26) we know that r is a critical point of ϕ_{β} if and only if

$$\left(\frac{I_0'}{I_0}\right)(\beta r) = r$$

If r is such a point then replacing in (29) we get

(30)
$$\phi_{\beta}''(r) = -\beta^2 \left[r^2 + \frac{2}{\beta} - 1 \right].$$

Case $\beta > 2$: In this case $\phi''_{\beta}(0) > 0$ hence 0 is not a maximum point. We claim that ϕ has a unique maximum and that it belongs to $\sqrt{\frac{\beta-2}{\beta}}, 1$].

We denote by $r_1 < \cdots < r_m$ the *m* points of]0,1] where ϕ_β attains its maximum *M* on \mathbb{R}_+ . Then every r_k satisfies $\phi'_\beta(r_k) = 0$ and $\phi''_\beta(r_k) \leq 0$. Remember that every critical point *r* satisfies (30) which we rewrite

(31)
$$\phi_{\beta}''(r) = \beta^2 \left[\frac{\beta - 2}{\beta} - r^2 \right] = \beta^2 \left(\sqrt{\frac{\beta - 2}{\beta}} - r \right) \left(\sqrt{\frac{\beta - 2}{\beta}} + r \right).$$

As $\phi_{\beta}''(r_k) \leq 0$ we deduce that $r_1 \geq \sqrt{\frac{\beta-2}{\beta}}$. We observe that any critical point r strictly bigger than r_1 satisfies $\phi_{\beta}''(r) < 0$, which means r is a local maximum for ϕ_{β} . Now, if $m \geq 2$ then between r_1 and r_2 there must be a local minimum which is also a critical point. This yields a contradiction. Therefore, m = 1 and r_1 is the unique critical point for ϕ .

Let us show that $r_1 > \sqrt{\frac{\beta-2}{\beta}}$. Indeed if $r_1 = \sqrt{\frac{\beta-2}{\beta}}$ then $\phi'_{\beta}(r_1) = \phi''_{\beta}(r_1) = 0$. From (26) we know that

$$\forall x, \left(\frac{I_0'}{I_0}\right)(\beta x) = x + \frac{\phi_{\beta}'(x)}{\beta}.$$

Replacing in (29) we get that

(32)
$$\forall x, \phi_{\beta}''(x) = -\phi_{\beta}'^{2}(x) - \left(2\beta x + \frac{1}{x}\right)\phi_{\beta}'(x) - \beta^{2}x^{2} + \beta^{2} - 2\beta$$

which is a differential equation satisfied by ϕ_{β} . When we derive this equality we get that

(33)
$$\forall x, \phi_{\beta}''(x) = -2\phi_{\beta}'(x)\phi_{\beta}''(x) - \left(2\beta - \frac{1}{x^2}\right)\phi_{\beta}'(x) - \left(2\beta x + \frac{1}{x}\right)\phi_{\beta}''(x) - 2\beta^2 x.$$

We deduce that $\phi_{\beta}''(r_1) = -2\beta^2 r_1$ is strictly negative, therefore r_1 can not be a maximum, which yields a contradiction. Hence $r_1 > \sqrt{\frac{\beta-2}{\beta}}$ holds and this finishes to prove the claim.

Now we are ready to conclude the case $\beta > 2$. We apply the Laplace method to the integral I(n, f) and we find that

$$I(n,f) \sim 2\pi \frac{\sqrt{2\pi} e^{n\phi_{\beta}(r)} r\left(\int_{\Omega} f \, d\eta_{\beta r}\right)}{n^{1/2} \sqrt{|\phi_{\beta}''(r)|}},$$

hence

$$\int_{\Omega} f(\omega) \, d\mu_{n,\beta}(\omega) \sim \frac{I(n,f)}{I(n,\mathbb{I})} \sim \int_{\Omega} f \, d\eta_{\beta r}.$$

Case $\beta < 2$: In this case $\phi'_{\beta}(0) = 0$ and $\phi''_{\beta}(0) < 0$ hence 0 is a local maximum of ϕ_{β} . The equation (30) tells us that every critical point r satisfies

$$\phi_{\beta}^{\prime\prime}(r) = -\beta^2 \left[r^2 + \frac{2-\beta}{\beta} \right],$$

which is strictly negative, therefore every critical point is a local maximum. The same argument than above shows that ϕ_{β} attains its maximum at 0 and only at 0.

As the maximum is reached at 0, we cannot directly apply Laplace method as it is emphasized in Remark 5. We then use the following lemma. It is a special version of Laplace method and can be found in [7].

Lemma 5.1. Let α and γ be two positive real numbers. Then, for any sequence (b_n) such that $nb_n^{\alpha} \to +\infty$

$$\int_{0}^{b_{n}} x^{\gamma} e^{-nx^{\alpha}} dx \sim_{n \to +\infty} \frac{1}{\alpha n^{\frac{\gamma+1}{\alpha}}} \Gamma\left(\frac{\gamma+1}{\alpha}\right)$$

Proof. Just set $u = nx^{\alpha}$.

We apply Lemma (5.1) for $\int_{0}^{b_{n}} e^{n\phi_{\beta}(r)} \left(\int_{\Omega} f \, d\eta_{\beta r} \right) r \, dr$, with $b_{n} = 1/\sqrt[4]{n}$. Because $b_{n} \to 0$, we can get $\phi_{\beta}(r) = -\phi_{\beta}''(0)r^{2} + O(r^{3})$ on $[0, b_{n}]$. Note that for $r \in [0, b_{n}]$, by continuity for the eigen-measures $\nu_{\beta t} \overrightarrow{\psi}$ for operators $\mathcal{L}_{t} \overrightarrow{\psi}$ we also have.

$$r \int f \, d\eta_{\beta r} \sim_{n \to +\infty} r \int f \, d\eta_0$$

A computation shows that $\int_{b_n}^{b} e^{n\phi_{\beta}(r)} \left(\int_{\Omega} f \, d\eta_{\beta r} \right) r \, dr$, is of order less than $e^{-nb_n^2/2}$ if b is chosen small but positive such that $\phi_{\beta}(r) \leq -\phi_{\beta}''(0)\frac{r^2}{2}$ on [0, b]. Then, $nb_n^2 \to +\infty$ yields that this quantity is exponentially small (in n). Because 0 is the unique maximum for ϕ_{β} , $\int_{b_n}^{b} e^{n\phi_{\beta}(r)} \left(\int_{\Omega} f \, d\eta_{\beta r} \right) r \, dr$, is of order less than $e^{-n\varepsilon(b)}$ with $\varepsilon(b) > 0$.

Hence we get

$$I(n,f) \sim 2\pi \frac{\int_{\Omega} f \, d\eta_0}{n |\phi_{\beta}''(0)|} \Gamma(1) = 2\pi \frac{\int_{\Omega} f \, d\mu_0}{n |\phi_{\beta}''(0)|}$$

hence

$$\int_{\Omega} f(\omega) \, d\mu_{n,\beta}(\omega) \sim \frac{I(n,f)}{I(n,\mathbb{I})} \sim \int_{\Omega} f \, d\mu_0$$

Case $\beta = 2$: In this case $\phi'_{\beta}(0) = \phi''_{\beta}(0) = 0$ and every critical point $r \neq 0$ is a local maximum since it satisfies

$$\phi_{\beta}''(r) = -\beta^2 r^2,$$

L.	_	

which is strictly negative. We deduce, as above, that there exists only one maximum, which may be 0 or not. If it is 0, then we conclude as before but we have to pick an higher order for the derivative (and use Lemma 5.1 with $\alpha \ge 4$). If it is not 0, then we conclude the computation as above.

We conclude that for every $\beta > 0$, the sequence of measures $(\mu_{n,\beta})_{n \in \mathbb{N}}$ weakly converges to $\eta_{\beta r}$ where r is the unique point at which ϕ_{β} reaches its maximum on \mathbb{R}^+ .
