ABSTRACT

We report mid-infrared supercontinuum generation in a silicon germanium-on-silicon waveguide. We show that, by adding a chalcogenide cladding, it is possible to trim *a posteriori* the waveguide's dispersion profile which, in turn, governs the properties of the generated supercontinuum. In particular, we experimentally show that a shift from anomalous to normal dispersion takes place when a $1.26\,\mu m$ thick cladding layer of $Ge_{11.5}As_{24}Se_{64.5}$ is added. Finally, we show that the group velocity dispersion of the waveguide can be precisely controlled by changing the thickness of the cladding layer.

Keywords: Supercontinuum generation; nonlinear optics; integrated optics; mid-infrared; dispersion trimming

1. INTRODUCTION

On-chip mid-infrared (mid-IR, between 3 µm and 20 µm) supercontinuum (SC) generation is a technological challenge that is promising to have a strong impact in many different fields such as bio imaging, environmental sensors and security [1-5]. The prediction of great nonlinear properties, wide transparency window from 3 to 15 µm and CMOS compatibility of germanium have attracted a growing interest toward germanium-based platforms [6,7]. An octave spanning supercontinuum generation up to 8.5 µm has been already demonstrated by our group in a SiGe on Si waveguide [8-10]. The bandwidth and the coherence properties of the generated SC are mainly determined by the waveguide's dispersion profile. In general, the dispersive properties are set at the design stage and cannot be adjusted once the device has been fabricated. However, fabrication inaccuracies, surface roughness, surface contamination and the presence of defects may lead to a deviation from the targeted dispersion profile. Therefore, post-process mechanisms to post-trim the waveguide dispersion depending on the actual structure produced by fabrication are of great interest. Here we demonstrate mid-IR supercontinuum generation in a SiGe and in a hybrid chalcogenide/SiGe waveguide with shifted dispersion. We show that it is possible to fine tune the dispersion profile *a posteriori* by changing the chalcogenide cladding thickness, introducing a simple post-processing tool to control the supercontinuum dynamics and its properties.

2. SUPERCONTINUUM GENERATION AND DISPERSION TRIMMING

A 7 cm long $3.75 \times 2.7 \,\mu\text{m}^2$ cross-section $Si_{0.6}Ge_{0.4}/Si$ waveguide was coated with a $1.26 \,\mu\text{m}$ thick layer of chalcogenide $Ge_{11.5}As_{24}Se_{64.5}$. Numerical simulations show that the group velocity dispersion shifts from anomalous (air clad, fig. 1(a)) to normal (chalcogenide clad, fig. 1(b)) when the coating layer is added. The waveguide, operating in TE single mode, was pumped before and after the deposition of the chalcogenide layer with ~200 fs pulses at 4 μ m (air clad) and 4.15 μ m (chalcogenide clad) delivered from a MIROPA-fs optical parametric amplifier with 63 MHz repetition rate. Fig. 1(c) and 1(d) show the experimental (and theoretical) SC generated out of the air clad and chalcogenide clad waveguide respectively. In the former case the resulting SC, spanning from 2.63 up to 6.18 μ m, shows asymmetric profile and uneven amplitude across the spectrum, both typical of SC generation in the anomalous dispersion regime. In the latter

case a narrower and smoother spectrum (with a -30 dB bandwidth extending from 3.1 to 5.5 μ m), typical of SC generation in normal dispersion regime, was obtained. The SC generation process was simulated by numerically solving the nonlinear Schrödinger equation, obtaining a good agreement with experiments. Finally, a numerical analysis of the impact of the chalcogenide thickness on the dispersion was performed, showing that the dispersion properties can be finely tuned with a reasonable chalcogenide thickness resolution of ≈ 100 nm. These results introduce the deposition of a chalcogenide cladding layer as a simple post-processing tool to trim the waveguide's group velocity dispersion depending on the actual structure produced by fabrication.

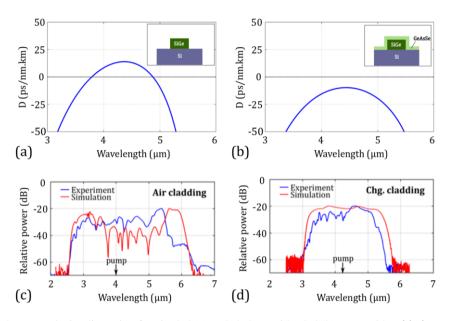

Figure 1. Calculated group velocity dispersion for air clad (a) and chalcogenide clad (b) waveguide with the same $3.75 \times 2.7 \ \mu m^2$ core cross-section. Experimental (blue) and simulated (red) spectra out of the air cladded (c) and chalcogenide cladded (d) waveguide. The waveguides were pumped by 200 fs pulses at 4 and $4.15 \ \mu m$ respectively with $2.35 \ kW$ coupled peak power.
