Version June 23, 2020 submitted to Symmetry

**Abstract:** In this work we investigate the properties of elastic waves propagating in gyroid lattices. First, we rigorously characterize the lattice from the point of view of crystallography. Second, we use Bloch-Floquet analysis to compute the dispersion relations for elastic waves. The results for very long wavelengths are then compared to those given by classic elasticity for a cubic material. A discrepancy is found in terms of the polarization of waves and it is related to the noncentrosymmetry of the gyroid. The gyroid lattice results to be acoustically active, meaning that transverse waves exhibit a circular polarization when they propagate along an axis of rotational symmetry. This phenomenon is present even for very long wavelengths and it is not captured by classic elasticity.

**Keywords:** elastic waves, noncentrosymmetry, gyroid, crystallography, chirality

## 1. Introduction

Architected materials are those that possess an inner geometry [1]. This multi-scale spatial arrangement of the constitutive materials allows for achieving mechanical properties that are not present in the bulk material itself [2]. Although this appears to be an engineering-based approach to materials design, it should be noted that this strategy is, in fact, central in nature where biomaterials must perform many functions from a small and limited set of elementary chemical elements [3,4]. Therefore, to enhance some target properties, regular patterns often emerge. The best-known example is the honeycomb, where bees need to maximise the volume of the cells while minimizing the quantity of matter (wax) used [5]. Another example is the iridescent color of the wings of some butterflies. This phenomenon is due to the non-centrosymmetric mesostructure of the material constituting the wings which acts a photonic crystal [6,7].

The study of elastic waves propagating in architected materials is of particular interest since unconventional effects due to the local organisation of the matter can emerge at the macroscale. In order to study these phenomena adequately, two points of view can be adopted. Either to describe all the details of the architecture, or to consider an effective continuum as replacement. The first option is very general since no particular modeling assumptions are involved. However, since the inner geometry of the material has to be explicitly described and meshed, the numerical cost is often prohibitive for actual applications. Moreover, the computed solution often contains many unnecessary details for practical use. The second option, which is based on elastodynamic homogenization [8–10] amounts to substitute the initial heterogeneous material by an equivalent homogeneous continuum. This equivalence is only valid under specific assumptions on the range of variation of some intrinsic parameters, and hence more restrictive than the first approach. However, within the validity domain of

32 the method, the physics, up to a certain order<sup>1</sup>, is correctly described. This results in a fairly important  
33 reduction in the computational cost, which is very interesting for optimizing an architected material,  
34 since in that case the numerical model has to be computed many times along the process.

35 For infinite Periodic Architected Materials (PAM), which are the subject of this paper, the  
36 condition under which the complete wave problem can be substituted by an effective one relies on the  
37 ratio ( $\eta$ ) between the size of the periodic unit cell ( $L$ ) and the wavelength ( $\lambda$ ) of the mechanical field.  
38 When this ratio approaches zero the classical Long-Wavelength (LW) approximation is obtained and,  
39 provided that the frequency  $\omega$  is also low (Low-Frequency (LF) approximation), the heterogeneous  
40 material can be replaced by a classical effective continuum. This situation, which has been well  
41 investigated, is completely contained in what is called LF-LW elastodynamics homogenization [8–10].  
42 When the equivalent medium is a classical continuum (Cauchy continuum), the effective behavior  
43 is non-sensitive to certain features of the inner geometry such as noncentrosymmetry, chirality or  
44  $n > 4$ -fold axis of rotational anisotropy [11–13].

45 Now, when the scale separation ratio  $\eta$  is small, but not vanishingly small, elastic waves  
46 propagating through the matter interact with the inner architecture. In this situation, several  
47 propagation quantities, such as the phase and group velocities, become frequency dependent and the  
48 wave propagation is *dispersive* [14]. Non standard dependencies on the architecture, that were left over  
49 in LF-LW approximation, may thus appear. These situations, which are outside the frame of standard  
50 elastodynamic homogenization, can nevertheless be modeled if the Cauchy equivalent continuum is  
51 replaced by a generalized continuum [15–17]. In this work we focus on bulk propagation, however it  
52 is important to notice that effects near boundaries, such as surface waves [18,19], are also of particular  
53 interest.

54 Wave propagation in non-centrosymmetric or chiral materials, the two concepts being distinct<sup>2</sup>,  
55 has been a subject of interest among physicists for centuries, mainly in the field of optics and  
56 electromagnetism. The first experiments showing the interaction of light with chiral molecules  
57 like sugar goes back to the beginning of the 19th century [20]. The effect which is associated to  
58 electromagnetic waves propagating in non-centrosymmetric crystals is the rotation of the plane of  
59 polarization when the wave propagates along an optical axis, i.e. an axis of rotational symmetry. The  
60 rotation is due to the decomposition of the linearly polarised transverse wave into two circularly  
61 polarised waves with opposite handedness and different phase velocities [21]. This phenomenon is  
62 known under the name of "optical activity". The analogue of this effect can be observed for elastic  
63 waves, and it is known as "acoustical activity" [21]. It is interesting to remark that optically active  
64 crystals are also found to be acoustically active and that, as it will be shown in this paper, this effect  
65 can occur also in the LF-LW regime.

66 Recently, the interest in investigating the properties of materials based on chiral and  
67 non-centrosymmetric architectures has grown. To this end it is important to point out that chirality  
68 and noncentrosymmetry are not equivalent, and that their impact on the physics of the problem can be  
69 different.

70 The set of transformations that let the unit cell of an architected material invariant constitutes  
71 its symmetry group. The material is said *chiral* if its symmetry group contains only rotations, and it is  
72 said to be centrosymmetric when it contains the inversion [22]. It is important to observe that in a 2D  
73 space the inversion is a rotation (preserving the material orientation) while, in 3D, it is a transformation  
74 reversing the material orientation. Since the nature of the inversion depends on the dimension of the  
75 space, the implication between chirality and centrosymmetry are not the same in 2D and 3D. In 2D,

---

<sup>1</sup> An effective theory is a reduced model obtained by filtering the actual physics so as to retain, in the continuum formulation, only the most prominent effects. Depending on the targeted applications, the effective model can be of different degrees of richness.

<sup>2</sup> see Appendix A for a dictionary of point groups and their associated properties

76 the chirality and centrosymmetry are independent [15], while in 3D chiral materials are necessarily  
77 non-centrosymmetric [23].

78 Several works can be found in the literature that investigate 2D chiral elasticity, and focus on their  
79 unusual mechanical properties such as negative Poisson ratio [24,25]. Concerning wave propagation,  
80 these architectures have been extensively studied [26–28] and the need for a generalized continuum  
81 theory in order to capture the onset of dispersion and anisotropy at higher frequencies has been  
82 pointed out [15,16]. In all these cases, the unit cells under investigation are chiral and centrosymmetric.  
83 It is worth noting that such a combination is possible uniquely in 2D. When moving to 3D, the picture  
84 becomes more complex, and due to habits coming from the 2D situation, an ambiguity between the two  
85 definitions can be usually found in the literature. For instance, the well-known and studied in-plane  
86 hexachiral and tetrachiral patterns [29,30], are no more chiral once extruded in 3D.

87 Concerning wave propagation in non-centrosymmetric materials, if the phenomenon can be  
88 studied in 2D [15], the effects become even more interesting in 3D as polarization of waves are then  
89 richer. As a consequence, interest in 3D non-centrosymmetric metamaterials have recently emerged for  
90 their stretch-twist coupling [31] or their acoustical activity [32]. The effects related to size dependent  
91 properties and characteristic lengths are also exploited and investigated in [33] and a micropolar  
92 generalized model is used to investigate acoustical activity in [34].

93 In the present work, the features of elastic wave propagation in non-centrosymmetric architected  
94 materials are investigated. Among them, gyroid materials are probably the most commonly used.  
95 In electromagnetics they are widely studied as metamaterials [6], in acoustics as phononic crystals  
96 [35], and in biomechanics as bone substitutes [36,37]. In this paper, we will highlight a particular  
97 situation for which the solution predicted by classic continuum mechanics is wrong even for very  
98 long wavelengths. It is important to note that the sensitivity of the mechanical behavior to the lack of  
99 centrosymmetry can also manifest in statics [38–40].

100 The paper is organized as follows: in section 2 the gyroid lattice is described. In section 3 the  
101 Bloch-Floquet analysis is introduced along with some necessary definitions for polarization studies.  
102 Dispersion analysis is performed and discussed in section 4. Section 5 compares the results from  
103 section 4 to those obtained in the LW-LF approximation. Finally, some conclusions are drawn in  
104 section 6.

## 105 *Notations*

Throughout this paper, the Euclidean space  $\mathcal{E}^3$  is equipped with a rectangular Cartesian coordinate system with origin  $O$  and an orthonormal basis  $\mathcal{B} = \{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$ . Upon the choice of a reference point  $O$  in  $\mathcal{E}^3$ , the Euclidean space and its underlying vector space  $E^3$  can be considered as coincident. As a consequence, points will be designated by their vector positions with respect to  $O$ . For the sake of simplicity,  $E^3$  will, from now on, simply be denoted  $E$ . In the following,  $\mathbf{r}$  will designate the position vector of a point  $P$ , and, with respect to  $\mathcal{B}$ ,

$$\mathbf{r} = x\mathbf{e}_1 + y\mathbf{e}_2 + z\mathbf{e}_3.$$

106 When needed, Einstein summation convention is used, i.e., when an index appears twice in an  
107 expression, it implies summation of that term over all the values of the index. The dot operator  $(\cdot)$   
108 stands for the scalar product, the  $\wedge$  for the cross product and  $\delta_{ij}$  is the Kronecker delta.  
109 Moreover, the following convention is retained:

- 110 • Blackboard fonts will denote tensor spaces:  $\mathbb{T}$ ;
- 111 • Tensors of order  $> 1$  will be denoted using uppercase Roman Bold fonts:  $\mathbf{T}$ ;
- 112 • Vectors will be denoted by lowercase Roman Bold fonts:  $\mathbf{t}$ .

113 The orthogonal group in  $\mathbb{R}^3$  is defined as  $O(3) = \{\mathbf{Q} \in GL(3) | \mathbf{Q}^T = \mathbf{Q}^{-1}\}$ , in which  $GL(3)$  denotes  
114 the set of invertible transformations acting on  $\mathbb{R}^3$ .

## 115 2. The gyroid lattice

116 The gyroid is a triply periodic minimal surface introduced for the first time in [41,42]. Since it is a  
 117 minimal surface, it has a zero mean curvature, meaning that every point on the surface is a saddle  
 118 point with equal and opposite principal curvatures [43]. It is periodic with respect to three orthogonal  
 119 space vectors and is chiral, meaning that the surface only possesses rotation symmetry elements or,  
 120 equivalently, that it does not possess any symmetry plane nor symmetry center [44].

### 121 2.1. Parametrization of the gyroid lattice

The gyroid's morphology is usually described using a level surface given by the following equation:

$$\phi(x, y, z; a, b) = 0 \quad (1)$$

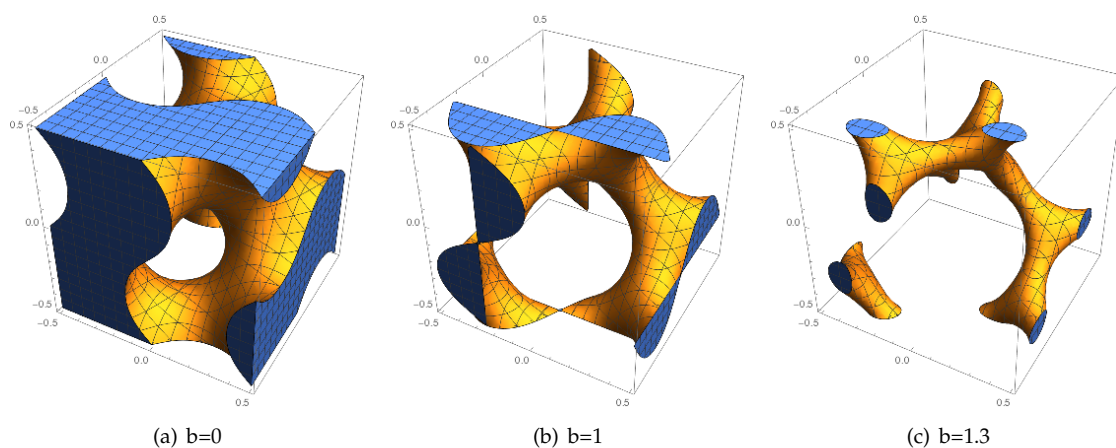

with  $a$  and  $b$  real parameters and  $x, y, z$  coordinates of the position vector  $\mathbf{r}$ .  
 In this paper, we will focus on a particular gyroid defined by :

$$\phi(x, y, z; a, b) := \sin 2\pi ax \cos 2\pi ay + \sin 2\pi ay \cos 2\pi az + \sin 2\pi az \cos 2\pi ax - b, \quad (2)$$

that exists only in the range  $|b| < \sqrt{2}$  [44]. Indeed, beyond this peculiar value of  $b$ , it is possible to show that the surface described by  $\phi$  presents discontinuities located at the borders of the fundamental (or asymmetrical) unit cell. A proof of this geometric constraint is provided in Appendix C. Due to its chiral nature, the gyroid surface exists in two enantiomorphic forms : dextrogyre and levogyre. The surface described by the implicit equation Equation 1 will be, arbitrarily, chosen to be the dextrogyre form. The levogyre form of the implicit equation is easily obtained by applying, for instance, the transformation  $x \rightarrow -x$  in the Equation 1 . From the definition of the surface, one can then obtain a volume by defining the presence of matter for points satisfying the following inequality:

$$\phi(x, y, z; a, b) > 0. \quad (3)$$

122 The parameter  $a$  controls the spatial period while the parameter  $b$  controls the porosity  $p$ , defined as  
 123 the ratio between the volume of the gyroid lattice and that of the unit cell. Examples of unit cells of  
 124 such solids obtained with different values of  $b$  are plotted in Figure 1.

**Figure 1.** The unit cells of gyroid lattices obtained for different values of the parameter  $b$  and  $a=1$  mm. Despite what the angle of view may suggest, all these structures are simply connected.

The relationship between the porosity  $p$  and the parameter  $b$  is not analytical but can be estimated numerically. As can be observed in Figure 2 this relationship is almost linear and for porosities between 0.2 and 0.8, the following linearized formula can be used to estimate the porosity:

$$p = -0.325b + 0.5.$$

**Figure 2.** The relationship between the parameter  $b$  and the porosity, dashed line represents a linear approximation of real porosity plotted in plain line. The evaluation of the porosity is obtained numerically.

125

## 126 2.2. Symmetry properties

127 Thanks to its triply periodic nature, the gyroid structure can be considered as a crystal [35] with  
 128 Body Centred Cubic (BCC) Bravais lattice and point group  $\mathcal{O}$ , using group theoretic notation [45], or  
 129 432 using Hermann-Mauguin notation. It should be noted that this cubic group only contains rotations<sup>3</sup>,  
 130 the geometry of the gyroid is hence chiral. The symmetry of the spatial structure is described by  
 131 the space group, which details how transformations from the Bravais lattice and the point group are  
 132 combined in the actual crystal. The space group ( $\mathcal{SG}$ ) of the gyroid crystal is, using Hermann-Mauguin  
 133 notation,  $I4_132$  (space group #214 in the International Tables of Crystallography [46]), where the  $I$   
 134 stands for body-centered (BC), meaning that the conventional unit cell defined in crystallography is  
 135 not primitive, but body-centered (more details provided in subsection 2.3). This space group contains  
 136 screw axes and, as such, is not symmorphic<sup>4</sup>.

If  $\mathcal{C}$  stands for the "crystal" structure, and  $\star$  for the group action as defined in Appendix section B

$$\forall \mathbf{r} \in \mathcal{C}, \forall g \in \mathcal{SG}, \quad \mathbf{r}' = g \star \mathbf{r} \in \mathcal{C}.$$

From the generating transformations defined in Appendix B and using the equation of the gyroid surface (c.f. Equation 1) it is straightforward to verify that

$$\forall g \in \mathcal{SG}, \quad \phi(g \star \mathbf{r}) = \phi(\mathbf{r}).$$

<sup>3</sup> To be more specific there are 3 different cubic point groups:  $\mathcal{O}$ ,  $\mathcal{O}^-$  and  $\mathcal{O} \oplus \mathbb{Z}_2^c$ . The first one just contains rotations, the group is hence chiral and non-centrosymmetric. The second,  $\mathcal{O}^-$ , possesses symmetry planes but not the inversion, the group is achiral and non-centrosymmetric. The last group  $\mathcal{O} \oplus \mathbb{Z}_2^c$  is centrosymmetric hence achiral. Some details are provided in the Appendix A, and more information can be found in [23].

<sup>4</sup> A space group is called symmorphic if, apart from the lattice translations, all generating symmetry operations leave one common point fixed. Permitted as generators are thus only the point-group operations: rotations, reflections, inversions and rotoinversions. The symmorphic space groups may be easily identified because their Hermann-Mauguin symbol does not indicate a glide or screw operation.

**Figure 3.** The conventional unit cell. The lattice vectors are indicated in blue.

### 137 2.3. Unit cell

Due to the periodicity of the geometry, the study of the gyroid structure can be restricted to a *unit cell*

$$\forall \mathbf{r} \in E, \exists (\mathbf{r}_0, \mathbf{t}) \in (\mathcal{T}, \mathcal{R}), \quad \mathbf{r} = \mathbf{r}_0 + \mathbf{t} \quad (4)$$

where  $\mathcal{T}$  designates a unit cell and  $\mathcal{R}$  a periodicity lattice. Note that for a given lattice  $\mathcal{R}$ , the choice of  $\mathcal{T}$  is not unique. It can be convenient to chose a reference unit cell from which other unit cells will be defined using lattice vectors  $\mathbf{a}_i$  and a triplet  $(n^1, n^2, n^3)$  combined as follow:  $\mathbf{t} = n^1 \mathbf{a}_1 + n^2 \mathbf{a}_2 + n^3 \mathbf{a}_3$ ,  $n_i \in \mathbb{Z}$ . The triplet  $(0, 0, 0)$  is then associated to the reference unit cell. Once a lattice basis chosen, the considered unit cell is defined as follows,

$$\mathcal{T}_C = \{\mathbf{r}_0 \in E | \mathbf{r}_0 = r\mathbf{a}_1 + s\mathbf{a}_2 + t\mathbf{a}_3, (r, s, t) \in [0, 1]^3\}$$

and the associated periodicity lattice is given by:

$$\mathcal{R}_C = \{\mathbf{t} \in E | \mathbf{t} = n^1 \mathbf{a}_1 + n^2 \mathbf{a}_2 + n^3 \mathbf{a}_3, n_i \in \mathbb{Z}\}$$

138 These geometrical sets can have been described using lattice vectors  $\mathbf{a}_i$ , gathered into a basis as  
 139  $\mathcal{B}' = \{\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3\}$ . Note that they can as well be described with respect to the basis  $\mathcal{B} = \{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$  of  $E$ .  
 140

141 Among all the possible unit cells, some are special and have been given a standard name in the  
 142 crystallography community: the *conventional unit cell* (CUC) and *primitive unit cell* (PUC).  
 143 The *conventional unit cell* (CUC) of the a BCC lattice is depicted in Figure 3. It is defined as the  
 144 smallest cell having its edges along the symmetry directions of the Bravais lattice. Notice that, for  
 145 body centered (BC) lattice, this unit cell is not minimal and a so-called *primitive unit cell* (PUC) can be  
 146 considered instead. For a continuous structure tiling of the space, the primitive unit cell is defined as  
 147 the smallest tile that generates the whole tiling using only translations. As such the primitive unit cell  
 148 is a *fundamental domain* with respect to translational symmetries only.

#### 149 2.3.1. BCC Conventional Unit Cell

150 For a BCC lattice, the conventional unit cell is defined as depicted in Figure 3. As its faces are  
 151 perpendicular to Bravais lattice directions, despite its non minimality, this unit cell is easy to use  
 152 for numerical computations. In this case, the conventional lattice vectors  $\mathbf{a}_i$ , are chosen such that  
 153  $\mathbf{a}_i \wedge \mathbf{e}_i = \mathbf{0}$ .

#### 154 2.3.2. BCC Primitive Unit Cell

For a BCC lattice, two possible primitive unit cells (PUC) are represented in Figure 4. The primitive  
 lattice vectors  $\mathbf{a}_i$  are not unique and the ones for the PUC depicted in Figure 4a) are defined as:

$$\mathbf{b}_1 = \frac{a}{2}(\mathbf{e}_1 + \mathbf{e}_2 - \mathbf{e}_3), \quad \mathbf{b}_2 = \frac{a}{2}(-\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3), \quad \mathbf{b}_3 = \frac{a}{2}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3),$$

**Figure 4.** Two examples of primitive unit cells. The lattice vectors are indicated in red

while the ones presented in Figure 4b) are defined as:

$$\mathbf{b}'_1 = a\mathbf{e}_1, \quad \mathbf{b}'_2 = a\mathbf{e}_2, \quad \mathbf{b}'_3 = \frac{a}{2}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3).$$

They form  $\mathcal{P} = \{\mathbf{b}_i\}_{1 \leq i \leq 3}$  and  $\mathcal{P}' = \{\mathbf{b}'_i\}_{1 \leq i \leq 3}$  two other bases of  $\mathcal{E}^3$ , which metric tensors are given by:

$$g(\mathcal{P}) = (\mathbf{b}_i \cdot \mathbf{b}_j) = \frac{a^2}{4} \begin{pmatrix} 3 & -1 & -1 \\ -1 & 3 & -1 \\ -1 & -1 & 3 \end{pmatrix}, \quad g(\mathcal{P}') = (\mathbf{b}'_i \cdot \mathbf{b}'_j) = \frac{a^2}{4} \begin{pmatrix} 4 & 0 & 2 \\ 0 & 4 & 2 \\ 2 & 2 & 3 \end{pmatrix}.$$

155 Being defined by a more symmetrical set of vectors  $\mathcal{P}$ , only the first primitive unit cell will be  
156 considered here after.

#### 157 2.4. Reciprocal basis and Brillouin Zone

The vector space dual to  $E$  is symbolized by  $E^*$ , and is formally defined as the space of linear forms on  $E$ ,

$$\forall l \in E^*, \forall \mathbf{u} \in E, l(\mathbf{u}) = \alpha \in \mathbb{R}.$$

Upon the choice of a scalar product the two spaces can be identified

$$(\forall l \in E^*, \exists \mathbf{v} \in E), \forall \mathbf{u} \in E, l(\mathbf{u}) = \mathbf{v} \cdot \mathbf{u} = \alpha \in \mathbb{R}$$

and from a basis of  $E$  a basis of  $E^*$  can be constructed. In the field of physics,  $E^*$  corresponds to the space of wavevectors, and a generic element of  $E^*$  is denoted by  $\mathbf{k}$ . For our applications, it is fundamental to introduce the reciprocal lattice  $\mathcal{R}^*$  of  $\mathcal{R}$ :

$$\mathcal{R}^* = \{\boldsymbol{\zeta} \in E^* | \boldsymbol{\zeta} = \zeta_1 \mathbf{a}^{*1} + \zeta_2 \mathbf{a}^{*2} + \zeta_3 \mathbf{a}^{*3}, \zeta_i \in \mathbb{Z}\}.$$

The vectors  $(\mathbf{a}^{*1}, \mathbf{a}^{*2}, \mathbf{a}^{*3})$  constitute the lattice basis  $\mathcal{B}^*$  of  $\mathcal{R}^*$  and verify

$$\mathbf{a}^{*i} \cdot \mathbf{a}_j = \delta_{ij}, \quad \text{where} \quad \delta_{ij} = \begin{cases} 1 & \text{if } i = j, \\ 0 & \text{if } i \neq j. \end{cases} \quad (5)$$

$\mathcal{B}^*$  can be computed from any lattice basis  $(\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3)$  of  $\mathcal{R}$  according to

$$\mathbf{a}^{*1} = \frac{\mathbf{a}_2 \wedge \mathbf{a}_3}{\mathbf{a}_1 \cdot (\mathbf{a}_2 \wedge \mathbf{a}_3)}, \quad \mathbf{a}^{*2} = \frac{\mathbf{a}_3 \wedge \mathbf{a}_1}{\mathbf{a}_2 \cdot (\mathbf{a}_3 \wedge \mathbf{a}_1)}, \quad \mathbf{a}^{*3} = \frac{\mathbf{a}_1 \wedge \mathbf{a}_2}{\mathbf{a}_3 \cdot (\mathbf{a}_1 \wedge \mathbf{a}_2)}. \quad (6)$$

Due to the following property,

$$\forall (\mathbf{t}, \boldsymbol{\zeta}) \in \mathcal{R} \times \mathcal{R}^*, \quad e^{2\pi i \boldsymbol{\zeta} \cdot \mathbf{t}} = 1 \quad (7)$$

vectors of the reciprocal lattice are the supports of  $\mathcal{R}$ -periodic functions on  $E$  since,

$$\forall(\mathbf{r}_0, \mathbf{t}) \in \mathcal{T} \times \mathcal{R}, \quad f(\mathbf{r}_0 + \mathbf{t}) = \sum_{\xi \in \mathcal{R}^*} \lambda_{\xi} e^{2\pi i \xi \cdot (\mathbf{r}_0 + \mathbf{t})} = \sum_{\xi \in \mathcal{R}^*} \lambda_{\xi} e^{2\pi i \xi \cdot \mathbf{r}_0} e^{2\pi i \xi \cdot \mathbf{t}} = f(\mathbf{r}_0).$$

In addition, use will be made of the *First Brillouin Zone* (FBZ)  $\mathcal{T}^*$  of the reciprocal lattice  $\mathcal{R}^*$  defined as:

$$\mathcal{T}^* := \{\mathbf{k} \in E^* \mid \forall \xi \in \mathcal{R}^* - 0, \|\mathbf{k}\| < \|\mathbf{k} - \xi\|\} \quad (8)$$

Using the reciprocal lattice  $\mathcal{R}^*$  and the FBZ  $\mathcal{T}^*$ , any wavevector  $\mathbf{k}$  can be expressed as

$$\forall \mathbf{k} \in E^*, \exists (\mathbf{k}_0, \xi) \in (\mathcal{T}^*, \mathcal{R}^*), \quad \mathbf{k} = \mathbf{k}_0 + \xi.$$

158 We can geometrically interpret  $\mathcal{T}^*$  as the set of wavevectors  $\mathbf{k}$  which are closer to the null  
 159 wavevector than to any other wavevector  $\xi$  of the reciprocal lattice  $\mathcal{R}^*$ . It is the *Wigner-Seitz* cell of the  
 160 reciprocal lattice, this cell is uniquely defined and independent of the choice of  $\mathcal{T}$ . Similarly to the  
 161 primitive unit cell in the direct space, the FBZ is a fundamental domain with respect to translations.  
 162 Physically, the wavelength  $\lambda$  is defined as the inverse of the wavenumber, which is the norm of the  
 163 wavevector :  $\lambda = 1/\|\mathbf{k}\|$ . Then, wavevectors belonging to  $\mathcal{T}^*$  have wavelengths that are greater  
 164 than the wavelength of the periodicity lattice. When  $\|\mathbf{k}\| \rightarrow 0$  the wavelength becomes infinite,  
 165 sollicitations varying with almost null wavenumber are said to be *scale separated* with respect to the  
 166 periodicity lattice. This is usually the regime in which the LW approximation of elastodynamics  
 167 homogenization holds.

168 The FBZ can be further reduced if we consider also the symmetry operations of the point group. The  
 169 result is an *Irreducible Brillouin Zone* (IBZ), that is delimited by points of high symmetry, summarized  
 170 for the considered gyroid lattice in [Table 1](#). In this table, the high symmetry points are given in  
 171 the non-orthogonal reciprocal lattice basis  $\mathcal{P}^*$ , dual to the primitive lattice basis  $\mathcal{P}$  as well as in the  
 172 orthonormal lattice basis  $\mathcal{B}$  which coincides with its dual in the reciprocal space. The path obtained  
 173 connecting these high symmetry points along the edges of the IBZ is often used to characterize the  
 174 photonic and phononic properties of the lattice [6,26]. However, it has been pointed out that this  
 175 choice is not always reliable as some relevant information, e.g. about band gaps, could be missing [47].  
 176

In this paper we consider the basis  $\mathcal{P}$ , that corresponds to the one depicted in [Figure 4a](#)). The reciprocal lattice is itself a Bravais lattice, and in the case of BCC lattice, it is a Face Centered Cubic (FCC) lattice. Using [Equation 6](#), the reciprocal basis  $\mathcal{P}^*$  is equal to

$$\mathbf{a}^{*1} = \frac{1}{a}(\mathbf{e}_1 + \mathbf{e}_2), \quad \mathbf{a}^{*2} = \frac{1}{a}(\mathbf{e}_2 + \mathbf{e}_3), \quad \mathbf{a}^{*3} = \frac{1}{a}(\mathbf{e}_1 + \mathbf{e}_3).$$

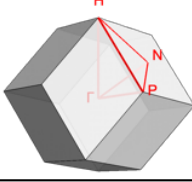

The metric tensor of  $\mathcal{P}^*$  is the inverse of the one of  $\mathcal{P}$

$$g(\mathcal{P}^*) = g(\mathcal{P})^{-1} = \frac{1}{a^2} \begin{pmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 1 & 1 & 2 \end{pmatrix}$$

### 177 3. Analysis tools

178 In the previous section we characterized the lattice from the point of view of crystallography. In  
 179 this next section we will use these results to compute the elastodynamic response of the lattice. The  
 180 objective of the present section is to provide the analysis tools to be used to perform the computation  
 181 and to interpret the results.

**Table 1.** The high symmetry points of the gyroid lattice. The group notations are detailed in Appendix section A.

Symmetry point	Coordinates w.r.t. $\mathcal{P}^*$ ( $k_1, k_2, k_3$ )	Coordinates w.r.t. $\mathcal{B}$ ( $x_1, x_2, x_3$ )	Point Group (Math.)	Point Group (H-M)	Illustration of the first Brillouin zone
$\Gamma$	(0, 0, 0)	(0, 0, 0)	$\mathcal{O}$	432	
H	$(-\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$	$(0, 0, \frac{1}{a})$	$\mathcal{O}$	432	
P	$(\frac{1}{4}, \frac{1}{4}, \frac{1}{4})$	$(\frac{1}{2a}, \frac{1}{2a}, \frac{1}{2a})$	$D_3$	32	
N	$(0, \frac{1}{2}, 0)$	$(0, \frac{1}{2a}, \frac{1}{2a})$	$D_2$	222	

### 182 3.1. Bloch-Floquet analysis

Since the material is periodic, the dispersion diagram will be computed using Bloch-Floquet analysis [48]. The elastodynamics equation for the periodic continuum reads

$$\text{div} [\mathbb{C}(\mathbf{r}) : (\mathbf{u}(\mathbf{r}) \otimes \nabla)] = \rho(\mathbf{r})\ddot{\mathbf{u}}(\mathbf{r}) \quad (9)$$

where  $\rho(\mathbf{r})$  is the  $\mathcal{R}$ -periodic mass density and  $\mathbb{C}(\mathbf{r})$  is the  $\mathcal{R}$ -periodic fourth-order elasticity tensor. As we saw in subsection 2.3, each cell of the assembly can be identified by the triplet  $(n^1, n^2, n^3)$ , where the triplet  $(0, 0, 0)$  is conventionally assigned to the reference unit cell. The position of a point  $\mathbf{r}$  of the  $(n^1, n^2, n^3)$ -cell is obtained from the position of a point in the reference unit cell  $\mathbf{r}_0$  by Equation 4 where  $\mathbf{t} = n^p \mathbf{a}_p$ . Being  $\mathcal{R}$ -periodic,  $\rho(\mathbf{r})$  and  $\mathbb{C}(\mathbf{r})$  verify:

$$\forall (\mathbf{r}_0, \mathbf{t}) \in \mathcal{T} \times \mathcal{R}, \rho(\mathbf{r}_0 + \mathbf{t}) = \rho(\mathbf{r}_0), \mathbb{C}(\mathbf{r}_0 + \mathbf{t}) = \mathbb{C}(\mathbf{r}_0)$$

Thanks to the Floquet-Bloch theorem [48], elementary solutions to the Equation 9 over  $\mathcal{C}$  can be searched for in the form of Bloch-waves :

$$\mathbf{u}_{\mathbf{k}}(\mathbf{r}_0) = \mathbf{U}_{\mathbf{k}}(\mathbf{r}_0) e^{2\pi i(f t - \mathbf{k} \cdot \mathbf{r}_0)}, \quad \mathbf{U}_{\mathbf{k}} \in \mathbb{C}^3, \quad (10)$$

183 where  $\mathbf{U}_{\mathbf{k}}$  is the complex polarisation vector which is  $\mathcal{R}$ -periodic in space and constant in time,  $f$  is  
 184 the frequency of the Bloch-wave and  $\mathbf{k}$  its wavevector<sup>5</sup>.  $\mathbf{U}_{\mathbf{k}}$  describes the movement of matter as the  
 185 wave propagates. In the case of an homogeneous material the polarization vector becomes constant in  
 186 space and the classical plane wave solution is retrieved. Since the displacement field in Equation 10 is  
 187 complex valued, its real part should be computed in order to retrieve the physical solution.

From its definition as a Bloch-wave, the displacement at a point  $\mathbf{r}$  image of the  $\mathbf{r}_0 \in \mathcal{T}$  by a translation  $\mathbf{t} \in \mathcal{R}$  has the following expression

$$\mathbf{u}_{\mathbf{k}}(\mathbf{r}) = \mathbf{u}_{\mathbf{k}}(\mathbf{r}_0 + \mathbf{t}) = \mathbf{U}_{\mathbf{k}}(\mathbf{r}_0 + \mathbf{t}) e^{2\pi i(f t - \mathbf{k} \cdot (\mathbf{r}_0 + \mathbf{t}))} = \mathbf{u}_{\mathbf{k}}(\mathbf{r}_0) e^{-2\pi i \mathbf{k} \cdot \mathbf{t}} \quad (11)$$

188 The physical meaning is that the displacement vector at two homologous points<sup>6</sup> only differs by a  
 189 phase factor.

<sup>5</sup> It is important to remark that wavevectors  $\mathbf{k}$  follow the so-called "crystallographer's definition" which consists in dropping the often seen  $2\pi$  coefficient. This implies, for instance, that the norm  $\|\mathbf{k}\|$ , i.e. the wavenumber, is directly the inverse of the wavelength  $\lambda$ , which is more convenient for physical interpretation of results.

<sup>6</sup> Two points  $\mathbf{r}_1, \mathbf{r}_2$  and are said homologous if  $\mathbf{r}_1 - \mathbf{r}_2 \in \mathcal{R}$ .

Additionally, the Bloch-wave expression in Equation 10 has the interesting property to be also  $\mathcal{R}^*$ -periodic. Indeed, due to its  $\mathcal{R}$ -periodicity,  $\mathbf{U}_{\mathbf{k}}(\mathbf{r}_0)$  can be decomposed as a Fourier series, leading to the equivalent expression for  $\mathbf{u}_{\mathbf{k}}(\mathbf{r}_0)$  :

$$\mathbf{u}_{\mathbf{k}}(\mathbf{r}_0) = \sum_{\xi \in \mathcal{R}^*} \tilde{\mathbf{U}}_{\mathbf{k}+\xi} e^{2\pi i(ft - (\mathbf{k}+\xi) \cdot \mathbf{r}_0)}$$

190 where  $\tilde{\mathbf{U}}_{\mathbf{k}+\xi}$  stands for the Fourier coefficients of the series expansion. Using this particular form, the  
191  $\mathcal{R}^*$ -periodicity of the Bloch-waves is easily proven using the change of variable  $\tilde{\xi} = \xi + \zeta^*$  :

$$\mathbf{u}_{\mathbf{k}+\zeta^*}(\mathbf{r}_0) = \sum_{\xi \in \mathcal{R}^*} \tilde{\mathbf{U}}_{\mathbf{k}+\zeta^*+\xi} e^{2\pi i(ft - (\mathbf{k}+\zeta^*+\xi) \cdot \mathbf{r}_0)} = \sum_{\tilde{\xi} \in \mathcal{R}^*} \tilde{\mathbf{U}}_{\mathbf{k}+\tilde{\xi}} e^{2\pi i(ft - (\mathbf{k}+\tilde{\xi}) \cdot \mathbf{r}_0)} = \mathbf{u}_{\mathbf{k}}(\mathbf{r}_0)$$

192 The main consequence of this property is that the characterization of the elastodynamics behavior of a  
193 periodic material does not require to investigate the mechanical response to all the  $\mathbf{k} \in E^*$  but can be  
194 restricted to the study of  $\mathbf{k} \in \mathcal{T}^*$  via  $\mathcal{R}^*$ -periodicity of the wavevector, where  $\mathcal{T}^*$  corresponds to the  
195 First Brillouin Zone (FBZ), as introduced in 2.3.

### 196 3.2. Polarization of waves in homogeneous materials

Before presenting the results, it is useful to recall some definitions concerning the polarization of elastic waves in homogeneous materials. Let's take us back to the Bloch-wave ansatz introduced in Equation 10, since the material is now considered homogeneous, the polarization vector  $\mathbf{U}_{\mathbf{k}}$  is constant both in space and time. In the most general case, the complex polarization vector  $\mathbf{U}_{\mathbf{k}}$ , that will be denoted  $\mathbf{U}$  from now on for the sake of simplicity, can be decomposed in its real and imaginary parts as follows:

$$\mathbf{U} = \mathbf{U}^{\mathbb{R}} + i\mathbf{U}^{\mathbb{C}}.$$

An interpretation of this decomposition, and of its consequences on wave propagation, can be obtained by considering the real part of Equation 10 :

$$\hat{\mathbf{u}} = \text{Re}(\mathbf{u}) = \mathbf{U}^{\mathbb{R}} \cos(2\pi(ft - \mathbf{k} \cdot \mathbf{r})) - \mathbf{U}^{\mathbb{C}} \sin(2\pi(ft - \mathbf{k} \cdot \mathbf{r})).$$

197 Since the vectors  $\mathbf{U}^{\mathbb{R}}$  and  $\mathbf{U}^{\mathbb{C}}$  are independent, the polarization of the displacement can be very  
198 rich. Its precise nature is directly related to conditions on  $\mathbf{U}^{\mathbb{R}}$  and  $\mathbf{U}^{\mathbb{C}}$ , as summarized in Table 2.  
199 It is important to remark that different conventions are used to define the handedness of circularly  
200 polarized waves. In this paper, we will consider that a wave is right handed if it follows the curl of the  
201 fingers of a right hand whose thumb is directed towards the wave propagation, away from the source.  
202 In the table, the unit normal vector defining the direction of propagation is defined by  $\mathbf{n} = \frac{\mathbf{k}}{\|\mathbf{k}\|}$ .

**Table 2.** The polarizations of plane waves and conditions on the complex amplitude.

Polarization	Condition
Longitudinal polarization	$\mathbf{U} \cdot \mathbf{n} = \alpha$ , with $\alpha \in \mathbb{C}$
Transverse polarization	$\mathbf{U}^{\mathbb{R}}$ and $\mathbf{U}^{\mathbb{C}}$ belong to the plane orthogonal to $\mathbf{n}$
Linear polarization	$\mathbf{U} \wedge \mathbf{U}^* = \mathbf{0}$ , with $\mathbf{U}^*$ complex conjugate of $\mathbf{U}$
Circular polarization	$\mathbf{U} \cdot \mathbf{U} = 0$
↳ Right handedness	$\mathbf{n} \cdot (\mathbf{U}^{\mathbb{R}} \wedge \mathbf{U}^{\mathbb{C}}) < 0$
↳ Left handedness	$\mathbf{n} \cdot (\mathbf{U}^{\mathbb{R}} \wedge \mathbf{U}^{\mathbb{C}}) > 0$
Elliptic polarization	$\mathbf{U} \wedge \mathbf{U}^* \neq \mathbf{0}$ and $\mathbf{U} \cdot \mathbf{U} \neq 0$

**Figure 5.** Some examples of polarizations: a) linear, b) Circular right handed, c) Circular left handed.

203 Thus, a complex polarization vector can lead to a phase shift between the components of the  
 204 displacement vector  $\hat{u}$ , and thus to a polarization that is other than linear, see [Figure 5](#) for illustration  
 205 of a linear and two circular polarizations with opposite handedness.

#### 206 4. Dispersion analysis using Finite Elements Analysis (FEA)

207 In order to investigate the ultrasonic properties of the gyroid lattice, and given the periodicity of  
 208 the architecture as described in the previous sections, an approach based on Bloch-Floquet analysis  
 209 will be followed. For the sake of simplicity, the conventional unit cell depicted in [Figure 6](#) is used  
 210 to define the numerical model. For the investigation of the elastodynamic properties of the gyroid  
 211 crystal, the wavevector will be restricted to the boundaries of the Irreducible Brillouin Zone (IBZ),  
 212 as depicted in red in [Figure 7a](#). The high symmetry points of this IBZ are defined in [Table 1](#). The  
 213 model has been implemented using the commercial software Comsol Multiphysics and considering  
 214 titanium as constitutive material, the parameters of which are displayed in [Table 3](#). The mesh of the  
 215 unit cell is presented in [Figure 6](#), and it consists of 66,232 tetrahedral elements. Lagrange quadratic  
 216 elements are used, for a total of 329,277 degrees of freedom. Periodic Bloch-Floquet conditions are  
 217 implemented by imposing them as displacement conditions at the boundaries, following [Equation 11](#).  
 218 Then, the wavenumber in  $\mathbf{k}$  is imposed and the corresponding frequencies are retrieved by solving the  
 219 corresponding eigenvalue problem. The computation of each wavenumber took an average of 109  
 220 seconds on a workstation equipped with an Intel(R) Xeon(R) CPU E5-1650 v2 at 3.50 GHz using six  
 221 cores.

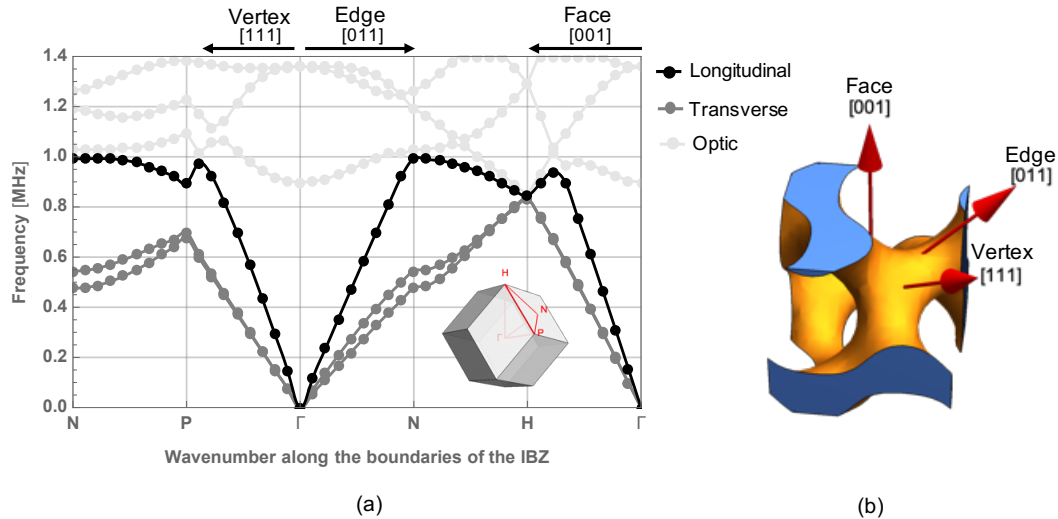

**Figure 6.** The meshed unit cell used in simulations

**Table 3.** The parameters used in the numerical simulations, corresponding to bulk titanium.

Mass Density [kg/m <sup>2</sup> ]	Young Modulus [GPa]	Poisson Ratio [1]	Porosity [1]	Unit cell size [mm]
$\rho_b$	$E_b$	$\nu_b$	$p$	$a$
4506	115.7	0.321	0.7	1

222 The results of the dispersion analysis are depicted in Figure 7(a). It can be observed, qualitatively,  
 223 that these results are similar to those obtained for electromagnetic waves in [6] (see Figure 8). In  
 224 particular, the behavior of the acoustic branches, i.e. those branches starting from the origin  $\Gamma$ ,  
 225 corresponding to transverse waves (gray lines in Figure 7(a)) is remarkably similar.

**Figure 7.** The dispersion diagram of the Gyroid lattice computed along the boundaries of the Irreducible Brillouin Zone (IBZ) and directions of propagation with respect to the unit cell. (a) The dispersion relation of the Gyroid lattice computed along the boundaries of the Irreducible Brillouin Zone (IBZ). (b) The direction of propagation with respect to the unit cell.”

**Figure 8.** The photonic band diagram of a single gyroid photonic crystal. Reproduced with permission from [6].

226 Since the objective of the paper is to investigate the behavior of the lattice within the LW-LF  
 227 approximation given by classic continuum mechanics, the phase velocities and polarization of waves  
 228 have been computed for large but finite values of the wavelength with respect to the size of the unit  
 229 cell – in this case  $\|\mathbf{k}\| = 16.7 \text{ m}^{-1}$ , that corresponds to a wavelength close to 60 times the size of the  
 230 unit cell. For each mode, the polarization vector has been estimated by computing the average of the  
 231 complex displacement of the eigen-mode over the unit cell, and the results are listed in Table 4. We  
 232 will now analyze the results along the following directions of propagation, also depicted in Figure 7(b):

- 233 • [001] : this direction is going from the center of the fundamental cell to the middle of a face. It  
 234 corresponds to an axis of rotation of order 4 (rotations of  $\pi/2$  rad);

**Figure 9.** The phase velocity of the circularly polarized waves in function of the wavenumber or of the ratio between the wavelength  $\lambda$  and the size of the unit cell  $a$  for propagation direction a) [001] and b) [111]. Right handed waves are in black, left handed waves are in gray. The dashed horizontal lines correspond to the phase velocity to which they converge to for infinite wavelength.

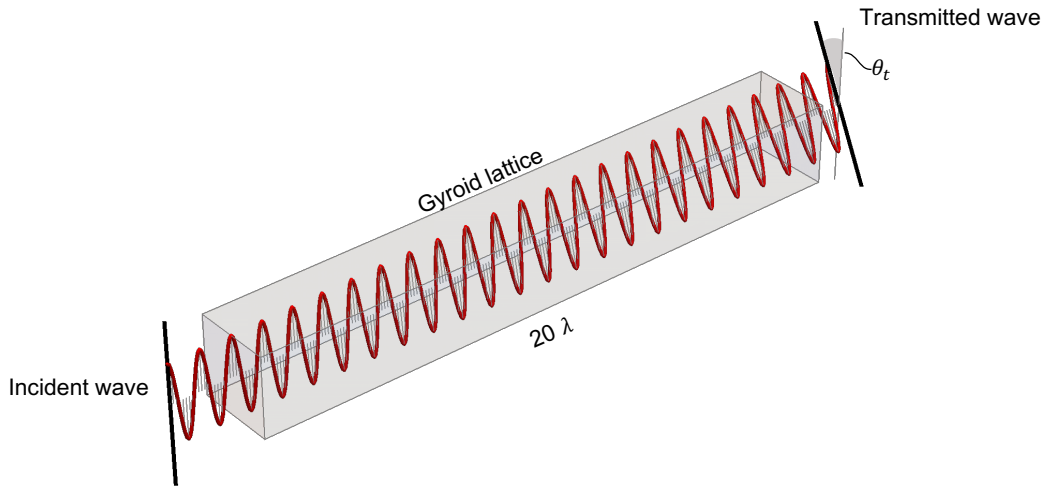

- 235 • [011] : this direction is going from the center of the fundamental cell to the middle of an edge. It  
 236 corresponds to an axis of rotation of order 2 (rotations of  $\pi$  rad);  
 237 • [111] : this direction is going from the center of the fundamental cell to a vertex. It corresponds  
 238 to an axis of rotation of order 3 (rotations of  $2\pi/3$  rad).

239 Using the conditions listed in Table 2, we have characterized the polarization for each of the above  
 240 propagation directions. The results are summarized in Table 4.

241 Along the direction [001] a longitudinal wave propagating at 3018.5 m/s can be observed. The two  
 242 transverse waves have eigenmodes with complex amplitude and propagate with close phase velocity  
 243 that tends to a common value of of 1932.1 m/s for infinite wavelengths, as it can be also observed in  
 244 Figure 9. These complex amplitudes correspond to two circularly polarized transverse waves, with  
 245 opposite handedness. In the direction [011], a longitudinal wave propagating at 3249.8 m/s can be  
 246 observed. One transverse wave is linearly polarized in direction [100], and propagates with a phase  
 247 velocity of 1931.7 m/s. The last solution corresponds again to a transverse wave, linearly polarized  
 248 along  $(0, 1, -1)$ , with velocity 1510.9 m/s. Finally, direction [111] has a linearly polarized longitudinal  
 249 wave at 3322.8 m/s, and two circularly polarized waves with opposite handedness and propagating  
 250 with close velocity, converging to 1663.1 m/s.

251 In summary, circularly polarized waves exist only if the direction of propagation is along a  
 252 rotation axis of symmetry of order greater than 2. Moreover, as can be seen in Figure 9, for both [001]  
 253 and [111] directions, the circularly polarized waves with opposite handedness propagate with the same  
 254 phase velocity only in the infinite wavelength limit, and they start to diverge as wavenumber increase.  
 255 In particular, for direction [001] the left handed wave becomes slower than the right handed one, while  
 256 the opposite phenomenon can be observed for direction [111]. This is due to the chirality of the unit  
 257 cell. As one can notice, phase velocities are different even for very large wavelength compared to the  
 258 size of the unit cell, *i.e.*  $\lambda/a \sim 10$ . Since only the phase velocity is affected, and not the amplitude, this  
 259 effect can be interpreted as the elastic equivalent of *circular birefringence* in optics. This means that if a  
 260 linearly polarized wave passes through a gyroid lattice, the polarization plane of the incident wave  
 261 will be rotated. This is due to the phase difference (retardance) between the two circular components,  
 262 which produces a rotation of the polarization plane. The concept is illustrated in Figure 10. Moreover,  
 263 since phase velocity is involved in reflection of waves at boundaries *via* the Snell-Descartes law, and in  
 264 particular in the definition of the Brewster angle of total reflection, gyroid lattices show the potential  
 265 for being used as elastic circular polarizing filters.

266 Furthermore, the overall dispersion is *normal* for direction [001], *i.e.* phase velocity decreases  
 267 when increasing the frequency, and *anomalous* for direction [001] (see [49] for the definition). The  
 268 anisotropy of the material and the dispersive properties could also have consequences on surface and  
 269 guided waves propagating in presence of boundaries [50,51], as well as in reflection/transmission  
 270 problems [52]. These effects will be investigated in further works.

**Figure 10.** An illustration of circular birefringence observed along direction [100] at  $f_c = 200$  kHz, corresponding to a wavelength around 10 times the size of the unit cell. A linearly polarized wave entering the material is subjected to a rotation of 1.3 degrees/wavelength, then after 20 wavelengths the rotation is  $\theta_t = 26.0$  deg. This illustration does not account for the changes in amplitude due to the reflections at boundaries.

**Table 4.** The phase velocity and polarization in the very long wavelength approximation.

Direction	Phase velocity [m/s]	Polarization ( $x_1, x_2, x_3$ )	Type of wave
[001]	3018.5	(0, 0, 1)	Longitudinal
	1933.4	( $i, 1, 0$ )	Circular R $\odot$
	1931.0	( $1, -i, 0$ )	Circular L $\odot$
[011]	3249.8	(0, 1, 1)	Longitudinal
	1931.7	(1, 0, 0)	Transverse
	1510.9	(0, 1, -1)	Transverse
[111]	3322.8	(1, 1, 1)	Longitudinal
	1662.3	( $-1 + i0.58, 1 + i0.55, -i1.13$ )	Circular R $\odot$
	1664.6	( $-1 - i1.68, -1 + i1.72, 2 - i0.03$ )	Circular L $\odot$

## 271 5. Long-Wavelength and Low-Frequency approximation and classic elasticity

In this last section we will introduce and identify the equivalent homogenized model in the framework of classic linear elasticity. This equivalent homogenized model is characterized by a couple of effective tensors  $\rho^H$  and  $C^H$  in such a way that the displacement field  $\mathbf{v}$  is solution of the following problem:

$$\operatorname{div} \left[ C^H : (\mathbf{v}(\mathbf{r}) \otimes \nabla) \right] = \rho^H \ddot{\mathbf{v}}(\mathbf{r}) \quad (12)$$

272 where  $\mathbf{v}$  verifies  $\langle \mathbf{u} \rangle = \mathbf{v}$ ,  $\langle \cdot \rangle$  denotes the spatial average operator over  $\mathcal{T}$  and  $\mathbf{u}$  is the displacement  
273 field solution to the heterogeneous problem Equation 9, as done for instance in [10].

Since the effective continuum is homogeneous, we consider a plane wave solution with  $\mathbf{k} = f/c \mathbf{n}$  where  $c$  is the phase velocity of the wave and  $\mathbf{n}$  a unitary vector. The substitution of this wave solution and of a linear elastic constitutive law into Equation 12 leads to following equation

$$\Gamma \cdot \mathbf{U} = \rho c^2 \mathbf{U} \quad (13)$$

274 where  $\Gamma = \mathbf{n} \cdot \mathbb{C}^H \cdot \mathbf{n}$  is the Christoffel, or acoustic, tensor. The solution of the eigenvalue problem  
 275 stated in Equation 13 for a given direction  $\mathbf{n}$  gives the phase velocities and polarizations of waves in  
 276 the effective continuum.

In classical elasticity, a material with cubic symmetry is defined by three independent material constants. Using Mandel notation [53], the corresponding elastic tensor for a material having its symmetry axis parallel to is  $\mathcal{B}$  reads:

$$[\tilde{\mathbb{C}}^H] = \begin{bmatrix} c_{11} & c_{12} & c_{12} & 0 & 0 & 0 \\ c_{12} & c_{11} & c_{12} & 0 & 0 & 0 \\ c_{12} & c_{12} & c_{11} & 0 & 0 & 0 \\ 0 & 0 & 0 & c_{44} & 0 & 0 \\ 0 & 0 & 0 & 0 & c_{44} & 0 \\ 0 & 0 & 0 & 0 & 0 & c_{44} \end{bmatrix}_{\mathcal{B}}.$$

277 It is worth noting that classical elasticity is insensitive to the lack of centrosymmetry [54]. The symmetry  
 278 class of the elasticity tensor in the cubic system is  $\mathcal{O} \oplus \mathbb{Z}_2^c$  meaning that even if the material symmetry  
 279 group of the unit cell does not contain the inversion, the symmetry group of elasticity tensor will  
 280 inherit it.

281 In the case of cubic materials, the solutions of Equation 13 listed in Table 5 are directly obtained. Using the phase velocities computed from the Floquet-Bloch analysis, parameters  $c_{11}$ ,  $c_{12}$ ,  $c_{44}$  and  $\rho_s$

**Table 5.** The phase velocity and polarization in classic elasticity.

Direction	Phase velocities [m/s]	Polarization	Type of wave
[001]	$\sqrt{\frac{c_{11}}{\rho}} \approx 3019$	(0, 0, 1)	Longitudinal
	$\sqrt{\frac{c_{44}}{2\rho}} \approx 1932$	(0, 1, 0)	Transverse
	$\sqrt{\frac{c_{44}}{2\rho}} \approx 1932$	(1, 0, 0)	Transverse
[011]	$\sqrt{\frac{c_{11}+c_{12}+2c_{44}}{2\rho}} \approx 3250$	(0, 1, 1)	Longitudinal
	$\sqrt{\frac{c_{44}}{2\rho}} \approx 1932$	(1, 0, 0)	Transverse
	$\sqrt{\frac{c_{11}-c_{12}}{2\rho}} \approx 1511$	(0, -1, 1)	Transverse
[111]	$\sqrt{\frac{c_{11}+2c_{12}+2c_{44}}{3\rho}} \approx 3323$	(1, 1, 1)	Longitudinal
	$\sqrt{\frac{2c_{11}-2c_{12}+c_{44}}{6\rho}} \approx 1663$	(-1, 1, 0)	Transverse
	$\sqrt{\frac{2c_{11}-2c_{12}+c_{44}}{6\rho}} \approx 1663$	(-1, -1, 2)	Transverse

282 can be identified and the homogeneous equivalent properties listed in Table 6 are then deduced. It  
 283 can be noticed that, as presented in Table 5, since we considered the propagation along the rotational  
 284 axes of symmetry, for each direction we observe a purely longitudinal wave and two purely transverse  
 285 waves.  
 286

287 We now move on to comparing phase velocities and polarizations obtained from the Floquet-Bloch  
 288 analysis with the ones forecast by the Long-Wavelength and Low-Frequency approximation using  
 289 classical elasticity. We start with direction [001]. As already mentioned, this direction corresponds  
 290 to a rotational axis of symmetry of order 4. In this case, as the elasticity tensor is non sensitive to  
 291 chirality, the symmetry group of the physical phenomenon<sup>7</sup> is conjugate to  $D_4 \oplus \mathbb{Z}_2^c$ . Indeed, as the  
 292 acoustic tensor defined in Equation 13 is a second-order tensor, the Hermann theorem of Crystal

<sup>7</sup> The symmetry group of the physical phenomenon is the intersection of the symmetry group of the constitutive equations and the symmetry group of the mechanical sollicitation.

**Table 6.** The material properties in the very long wavelength approximation.

Elastic coefficients			Mass density
$c_{11}$ [GPa]	$c_{12}$ [GPa]	$c_{44} = 2c_{1212}$ [GPa]	$\rho$ [kg/m <sup>3</sup> ]
12.32	6.145	10.092	1351.8

physics [11] predicts its behavior as transversely isotropic, i.e.  $O(2) \oplus Z_2^c$ . As a consequence  $\Gamma$  must have an eigenspace of dimension 2. All the directions of wave propagation for which this is verified are called *acoustic axis* of the material. Moving to the results presented in Table 5, we can see that the classic theory indeed predicts one faster longitudinal wave and two slower transverse waves propagating with the same phase velocity.

In the previous section we saw that Bloch-Floquet analysis identifies these waves as circularly polarized with opposite handedness, which is of course equivalent. Indeed, even for very large wavelengths, the numeric evaluation of the polarization provided by Table 4 corresponds to the eigensystem (eigenvalues plus eigenvectors) of a Hermitian acoustic tensor. In such case, the space corresponding to the double eigenvalue (which is real due to Hermitian nature of the matrix) is two dimensional over the complex field  $\mathbb{C}$ . However, in the case of a classic Cauchy continuum the acoustic tensor is symmetric real, and the eigen-space corresponding to the double eigenvalue is two dimensional over the real field  $\mathbb{R}$ . Since the 2D vector space over  $\mathbb{C}$  can be considered as a four dimensional vector space over  $\mathbb{R}$  the span is not equivalent. Moreover, as presented in section 4, when the ratio between the wavelength and the size of the unit cell becomes finite, this 2D eigenspace splits into two 1D eigenspaces with different phase velocities. It is important to notice again that this effect occurs in the LF-LW regime, where the classical elastodynamic homogenization is supposed to hold, or give at least approximated results while preserving the physics of the problem. Similar results are obtained for propagation along [111], which corresponds to rotational axis of symmetry of order 3. In this case the symmetry group of the physical phenomenon is conjugate to  $D_3 \oplus Z_2^c$ , and thus again transverse isotropy is imposed to the acoustic tensor. Finally, the direction of propagation [011] is along to a rotation axis of symmetry of order 2, the physical point group is thus conjugate to  $D_2 \oplus Z_2^c$ . Here, the symmetry class of the acoustic tensor is  $D_2 \oplus Z_2^c$ , and all the eigenspaces are unidimensional. In this last case, as this kind of symmetry can be seen by second order tensors, the results from FEA on the heterogeneous material and classic elasticity are in agreement in the LF-LW regime. In this section we have shown that some discrepancies can be observed when using an overall homogeneous continuum of Cauchy type. Classical elasticity (as opposed to generalized elasticity) is not rich enough to capture certain specific physical phenomena related to the symmetries of the material. In particular, if phase velocities are correctly estimated the polarizations are incorrectly predicted. Moreover, as it is well known, the onset of dispersion when frequency or wavenumber increase cannot be described in the classic Cauchy model.

## 6. Conclusions

In this work we have shown that a classical continuum model cannot capture the correct behavior of elastic waves propagating in gyroid lattices. This is due to the fact that the classic continuum mechanics is insensitive to the lack of centrosymmetry of the architected material. However, it is a well established belief that the effects of noncentrosymmetry are only related to waves having a wavelength which compares to the size of the microstructure. Here we demonstrate that the solution given by the classical theory fails to predict the correct response, even in the Long Wavelength - Low Frequency domain.

In order to capture the onset of this unconventional behavior, called acoustical activity, the elastic continuum model needs to be enriched. Different strategies of enrichment are possible. In particular, the use of strain-gradient elasticity will be investigate in a forthcoming study.

335 The main practical consequence of the results presented in this work is in the evidence that  
 336 circularly polarized waves can be observed in gyroid lattices, and that classic models fail to describe  
 337 such effect. This could have a practical interest, since devices based on manipulation of circular  
 338 polarization are frequently used in optics and electromagnetism. However, if one wants to exploit the  
 339 same effects in mechanics, it appears important not to rely on classical theories of elasticity. Finally,  
 340 it should be noted that, in this work, we address bulk wave propagation in an infinite medium. The  
 341 interaction of these waves with boundaries, in the case of reflection/transmission problems or in the  
 342 case of guided propagation also deserves to be investigated.

#### 352 Appendix A Dictionary

353 To obtain the normal forms for the different classes the generators provided in the following table  
 354 have been used :

Group	Generators
$Z_2^-$	$\mathbf{P}_{\mathbf{e}_3}$
$Z_n$	$\mathbf{R}\left(\mathbf{e}_3; \frac{2\pi}{n}\right)$
$D_n$	$\mathbf{R}\left(\mathbf{e}_3; \frac{2\pi}{n}\right), \mathbf{R}(\mathbf{e}_1; \pi)$
$Z_{2n}^-, n \geq 2$	$-\mathbf{R}\left(\mathbf{e}_3; \frac{\pi}{n}\right)$
$D_{2n}^h, n \geq 2$	$-\mathbf{R}\left(\mathbf{e}_3; \frac{\pi}{n}\right), \mathbf{R}(\mathbf{e}_1, \pi)$
$D_n^v$	$\mathbf{R}\left(\mathbf{e}_3; \frac{2\pi}{n}\right), \mathbf{P}_{\mathbf{e}_1}$
$\mathcal{T}$	$\mathbf{R}(\mathbf{e}_3; \pi), \mathbf{R}(\mathbf{e}_1; \pi), \mathbf{R}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3; \frac{2\pi}{3})$
$\mathcal{O}$	$\mathbf{R}(\mathbf{e}_3; \frac{\pi}{2}), \mathbf{R}(\mathbf{e}_1; \pi), \mathbf{R}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3; \frac{2\pi}{3})$
$\mathcal{O}^-$	$-\mathbf{R}(\mathbf{e}_3; \frac{\pi}{2}), \mathbf{P}_{\mathbf{e}_2 - \mathbf{e}_3}$

**Table A1.** The set of group generators used to construct matrix representation for each symmetry class.

355 Where the following elements of  $O(3)$  will be used in this study:

- 356 •  $\mathbf{R}(\mathbf{v}; \theta) \in SO(3)$  the rotation about  $\mathbf{v} \in \mathbb{R}^3$  through an angle  $\theta \in [0; 2\pi[$ ;
- 357 •  $\mathbf{P}_{\mathbf{n}} \in O(3) \setminus SO(3)$  the reflection through the plane normal to  $\mathbf{n}$  ( $\mathbf{P}_{\mathbf{n}} = \mathbf{1} - 2\mathbf{n} \otimes \mathbf{n}$ ).

361 **Appendix B Generators of space group #214**

Consider the affine space  $\mathcal{E}^3$ , the vector space  $\mathbb{R}^3$  acts on  $\mathcal{E}^3$  by translations. The affine group  $\text{Aff}(\mathcal{E}^3)$  of  $\mathcal{E}^3$ , which is the set of all affine invertible transformations is constructed as the semidirect product of  $\mathbb{R}^3$  by  $GL(3)$ , the general linear group of  $\mathbb{R}^3$

$$\text{Aff}(\mathcal{E}^3) = GL(\mathbb{R}^3) \rtimes \mathbb{R}^3$$

as such, an affine transformation is given by a pair  $(\mathbf{Q}, \mathbf{v}) \in GL(\mathbb{R}^3) \times \mathbb{R}^3$ . Composition of transformations follows from the construction of  $\text{Aff}(\mathcal{E}^3)$  as a semi-direct product, to be explicit:

$$(\mathbf{Q}_2, \mathbf{v}_2) \odot (\mathbf{Q}_1, \mathbf{v}_1) = (\mathbf{Q}_2 \mathbf{Q}_1, \mathbf{Q}_2 \mathbf{v}_1 + \mathbf{v}_2)$$

Elements of  $\text{Aff}(\mathcal{E}^3)$  can be nicely represented by (4x4) block matrices:

$$\left( \begin{array}{c|c} \mathbf{Q} & \mathbf{v} \\ \hline 0 & 1 \end{array} \right)$$

362 the internal law in  $\text{Aff}(\mathcal{E}^3)$  following the matrix product in  $M_{4,4}$ .

For our needs, we are interested not in the full affine group but in the group of isometries of  $\mathcal{E}^3$ , this group  $\text{Euc}(\mathcal{E}^3)$  is a subgroup of  $\text{Aff}(\mathcal{E}^3)$  and defined as the semi direct product of the orthogonal group and the spatial translation of  $\mathbb{R}^3$

$$\text{Euc}(\mathcal{E}^3) = O(\mathbb{R}^3) \rtimes \mathbb{R}^3$$

363 Space groups can be considered as discrete subgroups of  $\text{Euc}(\mathcal{E}^3)$ .

364 The generators of the space group  $I4_132$  (No. 214) are given in the following table in various  
365 notations [55]:

Seitz	Math	Matrices in conventional basis $\mathcal{B}$
$\{2_{001} 1/2\ 0\ 1/2\}$	$(\mathbf{R}(\pi, \mathbf{e}_3); \frac{1}{2}(\mathbf{e}_1 + \mathbf{e}_3))$	$\begin{bmatrix} -1 & 0 & 0 & 1/2 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 1/2 \\ 0 & 0 & 0 & 1 \end{bmatrix}_{\mathcal{B}}$
$\{2_{010} 0\ 1/2\ 1/2\}$	$(\mathbf{R}(\pi, \mathbf{e}_2); \frac{1}{2}(\mathbf{e}_2 + \mathbf{e}_3))$	$\begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1/2 \\ 0 & 0 & -1 & 1/2 \\ 0 & 0 & 0 & 1 \end{bmatrix}_{\mathcal{B}}$
$\{3_{111}^+ 0\}$	$(\mathbf{R}(\frac{2\pi}{3}; \mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3), \underline{0})$	$\begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}_{\mathcal{B}}$
$\{2_{110} 3/4\ 1/4\ 1/4\}$	$(\mathbf{R}(\pi, \mathbf{e}_1 + \mathbf{e}_2); \frac{1}{4}(3\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3))$	$\begin{bmatrix} 0 & 1 & 0 & 3/4 \\ 1 & 0 & 0 & 1/4 \\ 0 & 0 & -1 & 1/4 \\ 0 & 0 & 0 & 1 \end{bmatrix}_{\mathcal{B}}$
$\{1 1/2\ 1/2\ 1/2\}$	$(\text{Id}; \frac{1}{2}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3))$	$\begin{bmatrix} 1 & 0 & 0 & 1/2 \\ 0 & 1 & 0 & 1/2 \\ 0 & 0 & 1 & 1/2 \\ 0 & 0 & 0 & 1 \end{bmatrix}_{\mathcal{B}}$

Table A5. Generators of the Group  $I4_132$  (No. 214)366 **Appendix C Proof**

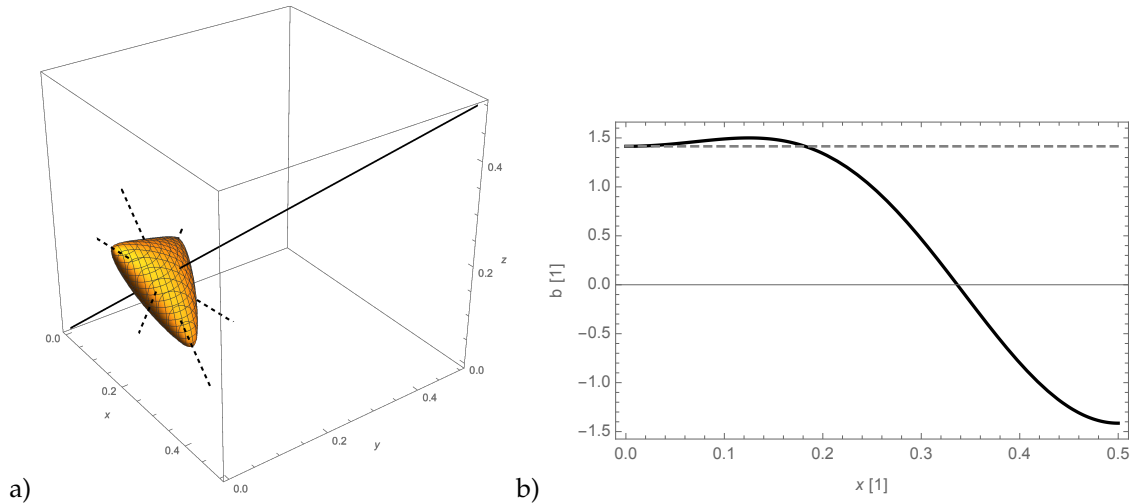

367 The gyroid lattice is defined from an implicit equation (Equation 1) that creates a periodic surface.  
 368 For a given value of parameter  $b (= \sqrt{2})$ , this surface is found to become singular, thus creating an  
 369 unrealistic discontinuous solid. This section presents an explanation for the admissible variation range  
 370 of gyroid parameter:  $|b| < \sqrt{2}$ .

371  
 372 Let us first restrict the variation range of variables  $x, y, z$  in Equation 2 to  $[0, 1/2]$  in order to work  
 373 in the fundamental domain of function  $\phi$ . The gyroid lattice restricted to this domain is presented in  
 374 Figure A1 a).

375 The fundamental domain of the gyroid is invariant with respect to the following symmetry operations:

376 - Rotation of angle  $2\pi/3$  along the axis defined by equations  $y = z = x$ , plotted in plain line in  
 377 Figure A1 and corresponding to the transformation  $(x, y, z) \rightarrow (y, z, x)$ . The directing vector of  
 378 this axis is  $(1, 1, 1)$  in orthonormal basis  $\mathcal{B}$  and it passes through point  $(0, 0, 0)$ .

379 - Three rotations of angle  $\pi$  about the three axes defined by equations  $\{y = 1/4 - x, z = 1/8\}$ ,  
 380  $\{z = 1/4 - x, y = 1/8\}$  and  $\{z = 1/4 - y, x = 1/8\}$  and plotted in dashed lines in  
 381 Figure A1. These axes correspond to transformations  $(x, y, z) \rightarrow (1/4 - y, 1/4 - x, 1/4 - z)$ ,  
 382  $(x, y, z) \rightarrow (1/4 - z, 1/4 - y, 1/4 - x)$ ,  $(x, y, z) \rightarrow (1/4 - x, 1/4 - z, 1/4 - y)$ , respectively. The

**Figure A1.** (a) The gyroid restricted to its fundamental domain along with symmetry axes  $C_3$  (plain) and  $C_2$  (dashed) ; (b) Evolution of parameter  $b$  as a function of  $x$  position along  $\mathbf{e}_1$  axis, dashed line corresponds to  $b = \sqrt{2}$

383 directing vector of these axes are, in orthonormal basis  $\mathcal{B}$ ,  $(1, -1, 0)$ ,  $(1, 0, -1)$  and  $(0, 1, -1)$  and  
 384 they pass through points  $(0, 1/4, 1/8)$ ,  $(0, 1/8, 1/4)$  and  $(1/8, 0, 1/4)$ , respectively.

385 It is trivial to see that these transformations leave Equation 2 unchanged thus defining symmetry  
 386 operations. As a consequence, the point symmetry group of the fundamental domain of the gyroid  
 387 is conjugated to  $D_3$ . For the sake of simplicity, we will only consider generating operations of  $2\pi/3$   
 388 rotation about  $(x, x, x)$  axis and  $\pi$  rotation about  $(x, 1/4 - x, 1/8)$  axis, denoted  $C_3$  and  $C_2$  in the  
 389 following, respectively ; the two other  $\pi$  rotations being generated by combination of these two  
 390 generators.

391  
 392 If the gyroid surface intersects one of the rotation axes non-orthogonally, then the surface  
 393 automatically becomes degenerate. The expression of the normal director to the gyroid surface  
 394 at its intersection point with generating symmetry axes and the equation defining this intersection  
 395 point are summarized in the following Table A6:

Sym. axis & directing vector	normal to the gyroid surface	intersection point
$C_3 (1, 1, 1)_{\mathcal{B}}$	$(\cos^2 2\pi x - \sin^2 2\pi x) (1, 1, 1)_{\mathcal{B}}$	$(x, x, x)$ with $3 \cos 2\pi x \sin 2\pi x = b$
$C_2 (1, -1, 0)_{\mathcal{B}}$	$\sin 2\pi x (\sqrt{2}/2 - \cos 2\pi x) (1, -1, 0)_{\mathcal{B}}$	$(x, -x, 0)$ with $\sqrt{2} \cos 2\pi x + \sin^2 2\pi x = b$

**Table A6.** The expression of the normal director to the gyroid surface at the intersection point with its symmetry axes and expression of this intersection point.

396  
 397 Note that the normal director to the gyroid surface depends on variable  $x$  which, itself, is  
 398 determined by parameter  $b$  through the non-linear equation defining the intersection point at which  
 399 the normal director is computed.

400 One can easily check that the normal directors are generically colinear with directing vectors of  $C_3$  and  
 401  $C_2$  operations. However, for given values of variable  $x$  (or equivalently of parameter  $b$ ), the normal to  
 402 the gyroid surface is null, thus leading to singularity of the gyroid surface. These values are  $x = 0 -$   
 403 and thus  $b = \sqrt{2}$  – leading to singularity of the gyroid surface at its intersection with axis  $C_2$  and  
 404  $x = 1/8 -$  and thus  $b = 3/2$  – leading to singularity of the gyroid surface at its intersection with both axes.

405

406 Finally, the equation defining the intersection point between the gyroid surface and the  $C_2$  axis  
407 (see [Figure A1 b](#)) depends on  $x$  and parameter  $b$ :  $\sqrt{2} \cos x + \sin x^2 - b = 0$ . By plotting this equation  
408 considering  $b$  as a function of  $x$ , we can see that there are two intersection points between the gyroid  
409 surface and the  $C_2$  axis for values of  $b$  over  $\sqrt{2}$  thus showing that the gyroid surface forms a closed  
410 domain in these directions leading to an unrealistic discontinuous solid.
