Abstract

We present a manuscript of Paul Lorenzen that provides a proof of consistency for elementary number theory as an application of the construction of the free countably complete pseudocomplemented semilattice over a preordered set. This manuscript rests in the Oskar-Becker-Nachlass at the Philosophisches Archiv of Universität Konstanz, file OB 5-3b-5. It has probably been written between March and May 1944. We also compare this proof to Gentzen's and Novikov's, and provide a translation of the manuscript.

Keywords: Paul Lorenzen, consistency of elementary number theory, free countably complete pseudocomplemented semilattice, inductive definition, ω -rule.

We present a manuscript of Paul Lorenzen that arguably dates back to 1944 and provide an edition and a translation, with the kind permission of Lorenzen's daughter, Jutta Reinhardt.

It provides a constructive proof of consistency for elementary number theory by showing that it is a part of a trivially consistent cut-free calculus. The proof resorts only to the inductive definition of formulas and theorems.

More precisely, Lorenzen proves the admissibility of cut by double induction, on the complexity of the cut formula and of the derivations, without using any ordinal assignment, contrary to the presentation of cut elimination in most standard texts on proof theory.

Prior to that, he proposes to define a countably complete pseudocomplemented semilattice as a deductive calculus, and shows how to present it for

constructing the free countably complete pseudocomplemented semilattice over a given preordered set.

He arrives at the understanding that the existence of this free kind of lattice captures the formal content of the consistency of elementary number theory, the more so as he has come to understand that the existence of another free kind of lattice captures the formal content of ideal theory. In this way, lattice theory provides a bridge between algebra and logic: by the concept of preorder, the divisibility of elements in a ring becomes commensurate with the material implication of numerical propositions; the lattice operations give rise to the ideal elements in algebra and to the compound propositions in logic.

The manuscript has remained unpublished, being superseded by Lorenzen's 'Algebraische und logistische Untersuchungen über freie Verbände' that appeared in 1951 in *The Journal of Symbolic Logic*. These 'Algebraic and logistic investigations on free lattices' have immediately been recognised as a landmark in the history of infinitary proof theory, but their approach and method of proof have not been incorporated into the corpus of proof theory.

1 The beginnings

In 1938, Paul Lorenzen defends his Ph.D. thesis under the supervision of Helmut Hasse at Göttingen, an 'Abstract foundation of the multiplicative ideal theory', i.e. a foundation of divisibility theory upon the theory of cancellative monoids. He is in a process of becoming more and more aware that lattice theory is the right framework for his research. Lorenzen (1939a, footnote on p. 536) thinks of understanding a system of ideals as a lattice, with a reference to Köthe 1937; in the definition of a semilattice-ordered monoid on p. 544, he credits Dedekind's two seminal articles of 1897 and 1900 for developing the concept of lattice. On 6 July 1938 he reports to Hasse: 'Momentarily, I am at making a lattice-theoretic excerpt for Köthe'.¹ He also reviews several articles on this subject for the *Zentralblatt*, e.g. Klein 1939 and George 1939 which both introduce semilattices, Whitman 1941 which studies free lattices. He also knows about the representation theorem for boolean algebras in Stone 1936 and he discusses the axioms for the arithmetic of real numbers in Tarski 1937 with Heinrich Scholz.²

¹ Helmut-Hasse-Nachlass, Niedersächsische Staats- und Universitätsbibliothek Göttingen, Cod. Ms. H. Hasse 1:1022, edited in Neuwirth 2019, § 4.

² See the collection of documents grouped together by Scholz under the title 'Paul Lorenzen: Gruppentheoretische Charakterisierung der reellen Zahlen [Group theoretic characterisation of the real numbers]' and deposited at the Bibliothek des Fachbereichs Mathematik und Informatik of the Westfälische Wilhelms-Universität Münster, as well as several letters filed

In 1939, he becomes assistant to Wolfgang Krull at Bonn. During World War II, he serves first as a soldier and then, from 1942 on, as a teacher at the naval college Wesermünde. He devotes his ‘off-duty evenings all alone on [his] own’³ to mathematics with the goal of habilitating. On 25 April 1944, he writes to his advisor that ‘[...] it became clear to me—about 4 years ago—that a system of ideals is nothing but a semilattice’.⁴

He will later recall a talk by Gerhard Gentzen on the consistency of elementary number theory in 1937 or 1938 as a trigger for his discovery that the reformulation of ideal theory in lattice-theoretic terms reveals that his ‘algebraic works [...] were concerned with a problem that had *formally* the same structure as the problem of freedom from contradiction of the classical calculus of logic’;⁵ compare also his letter to Eckart Menzler-Trott (see *Menzler-Trott 2001*, p. 260).

In his letter dated 13 March 1944, he announces: ‘Subsequently to an algebraic investigation of orthocomplemented semilattices, I am now trying to get out the connection of these questions with the freedom from contradiction of classical logic. [...] actually I am much more interested into the algebraic side of proof theory than into the purely logical’.⁶ The concept of ‘orthocomplementation’⁷ (see p. 19 for its definition) must have been motivated by logical negation from the beginning. On the one hand, such lattices correspond to the calculus of sequents considered by Gentzen (1936, section IV), who shows that a given derivation can be transformed into a derivation ‘in which the connectives \vee , \exists and \supset no longer occur’ and provides a proof of consistency for this calculus (see section 3 below). On the other hand, note that Lorenzen reviews *Ogasawara 1939* for the *Zentralblatt*.

2 The 1944 manuscript

The result of this investigation can be found in the manuscript ‘Ein halbordnungstheoretischer Widerspruchsfreisheitsbeweis’.⁸

in the Heinrich-Scholz-Archiv at Universitäts- und Landesbibliothek Münster, the earliest dated 7 April 1944.

³Carbon copy of a letter to Krull, 13 March 1944, Paul-Lorenzen-Nachlass, Philosophisches Archiv, Universität Konstanz, PL 1-1-131, edited in *Neuwirth 2019*, § 6.

⁴Carbon copy of a letter to Krull, PL 1-1-132, edited in *Neuwirth 2019*, § 6.

⁵Letter to Carl Friedrich Gethmann, see *Gethmann 1991*, p. 76.

⁶PL 1-1-131, edited in *Neuwirth 2019*, § 6.

⁷The terminology might be adapted from *Stone 1936*, where it has a Hilbert space background; today one says ‘pseudocomplementation’.

⁸‘A proof of freedom from contradiction within the theory of partial order’, Oskar-Becker-Nachlass, Philosophisches Archiv, Universität Konstanz, OB 5-3b-5, <https://archive.org/>

We believe that it is the one that he assertedly sends to Wilhelm Ackermann, Gentzen, Hans Hermes and Heinrich Scholz between March and May 1944, and for which he gets a dissuasive answer from Gentzen, dated 12 September 1944: ‘I have looked through your attempt at a consistency proof, not in detail, for which I lack the time. However I say this much: the consistency of number theory cannot be proven so simply’.⁹

Our identification of the manuscript is made on the basis of the following dating: Lorenzen mentions such a manuscript and its recipients in his letters to Scholz dated 13 May 1944 and 2 June 1944,¹⁰ and in a postcard to Hasse dated 25 July 1945;¹¹ a letter by Ackermann dated 11 November 1946 states that he lost a manuscript by Lorenzen ‘at the partial destruction of his flat by bombs’.¹² Our identification is also consistent with the content of Lorenzen’s letter to Menzler-Trott mentioned above. On the other hand, we have not found any hint at another manuscript by Lorenzen for which it could have been mistaken.¹³ The generalisation of his proof of consistency to ramified type theory is first mentioned in a letter from Scholz to Bernays dated 11 December 1945:¹⁴ it corresponds to the manuscript ‘Die Widerspruchsfreiheit der klassischen Logik mit verzweigter Typentheorie’ and is the future part II of his 1951 article.

This manuscript renews the relationship between logic and lattice theory: whereas boolean algebras were originally conceived for modeling the classical calculus of propositions, and Heyting algebras for modeling the intuitionistic one, here logic comes at the rescue of lattice theory for studying countably complete pseudocomplemented semilattices.

We have found only three contemporaneous occurrences of the notion of countably complete lattice other than σ -fields of subsets of a given set used in measure theory: Birkhoff (1938, p. 795; article reviewed by Lorenzen for the

[details/lorenzen-ein_halbordnungstheoretischer_widerspruchsfreisbeweis](#). The file OB 5-3b consists of documents related to Lorenzen, the oldest being the 1944 manuscript and the youngest a letter from 1951. Lorenzen and Becker are both at Bonn from 1945 to 1956 and have been in close contact since at least 1947: see Lorenzen’s letter to Gethmann (in *Gethmann 1991*, p. 77).

⁹The letter is reproduced in Menzler-Trott 2001, p. 372, and translated in Menzler-Trott 2007.

¹⁰Heinrich-Scholz-Archiv and PL 1-1-138.

¹²‘So ist auch ein Manuscript, das Sie mir seiner Zeit zuschickten, bei der teilweisen Zerstörung meiner Wohnung durch Bomben verschwunden’ (PL 1-1-125).

¹³The ‘unpublished’ manuscript ‘Ein finiter Logikkalkül’ mentioned by Lorenzen (1948, p. 20) may be dated to 1947 even if we have not spotted a copy of it: the review given there shows that it corresponds to a thread of research described in a letter to Bernays dated 21 February 1947 (ETH-Bibliothek, Hochschularchiv, Hs 975:2950).

¹⁴Hs 975:4111.

Zentralblatt) speaks of ‘ σ -lattice, by analogy with the usual notions of σ -rings and σ -fields of sets’; in the appendix *The somen as elements of partially ordered sets* of the posthumously published book *Carathéodory 1956*; the ‘ \aleph_1 -lattice’ in *von Neumann 1937*.

Lorenzen describes a countably complete pseudocomplemented semilattice as a deductive calculus on its own, without any reference to a larger formal framework:¹⁵ this conception dates back to the ‘system of sentences’ of Hertz (1922, 1923). The rules of the calculus construct the free countably complete pseudocomplemented semilattice over a given preordered set by taking as axioms the inequalities in the set, by defining inductively formal meets and formal negations, and by introducing inequalities between the formal elements. The introduction rule for formal countable meets, stating that

$$\text{if } c \leqslant a_1, c \leqslant a_2, \dots, \text{ then } c \leqslant \bigwedge M, \text{ where } M = (a_1, a_2, \dots)$$

(rule c on p. 21), stands out: it has an infinity of premisses, so that it is an ‘ ω -rule’ in today’s terminology. Lorenzen’s boldness is most probably due to his training in algebra, where such a rule is very natural, so that when he arrives at a clear constructive understanding of ideal theory, he has also got a clear constructive understanding of the ω -rule.

In ideal theory, Lorenzen (1950, § 4) defines a system of ideals for a preordered set as the free semilattice generated by it: it consists in the formal meets $a_1 \wedge \dots \wedge a_m$ of finitely many elements a_1, \dots, a_m ; this formal element is introduced with the following rules: if $c \leqslant a_1, \dots, c \leqslant a_m$, then $c \leqslant a_1 \wedge \dots \wedge a_m$; $a_1 \wedge \dots \wedge a_m \leqslant a_1, \dots, a_1 \wedge \dots \wedge a_m \leqslant a_m$. The ω -rule is the infinitary counterpart of the first rule, and the infinitary counterpart of the second rule is the admissible rule ε on p. 23.

Lorenzen’s presentation of elementary number theory can be compared to that of Gödel 1933 as follows.

- Lorenzen starts with ‘prime formulas’, i.e. the numerical propositions as e.g. $1 = 1''$ or $1 + 1 = 1'$. These are preordered by material implication and may be combined into compound formulas. Lorenzen works in a constructive metatheory, in which infinitely many propositions may be supervised if given by a construction, e.g. the propositions $\mathfrak{C} \rightarrow \mathfrak{A}(1)$, $\mathfrak{C} \rightarrow \mathfrak{A}(2)$, …, and rule c on p. 31 is the rule of introduction of the universal quantifier that one may infer from these $\mathfrak{C} \rightarrow (\mathfrak{x})\mathfrak{A}(\mathfrak{x})$.
- Gödel starts with ‘elementary formulas’, which may also contain variables. He works in a finitary metatheory in which only finitely many propositions

¹⁵In contradistinction to the ‘consequence relation’ of Tarski 1930 which presupposes set theory.

may be supervised, and formalises elementary number theory with the universal quantifier handled in a way that is equivalent to its usual introduction and elimination rules. Here one may construct as in Gödel 1931 a predicate $\mathfrak{A}(x)$ such that each of the propositions $\mathfrak{C} \rightarrow \mathfrak{A}(1), \mathfrak{C} \rightarrow \mathfrak{A}(2), \dots$ holds, but $\mathfrak{C} \rightarrow (\exists x) \mathfrak{A}(x)$ does not.

In elementary number theory, the rule of complete induction plays a central rôle. The statement of this rule is complex from a logical point of view because of the presence of a free variable, of a universal quantifier, or of an implication. The ω -rule appears as an analysis of this complexity: the rule of complete induction is the derivation of $\mathfrak{A}(1) \rightarrow (\exists x) \mathfrak{A}(x)$ from $\mathfrak{A}(a) \rightarrow \mathfrak{A}(a + 1)$ with a free variable a ; in the latter, replacement of a by $1, 2, \dots$ and the cut rule yield $\mathfrak{A}(1) \rightarrow \mathfrak{A}(2), \mathfrak{A}(1) \rightarrow \mathfrak{A}(3), \dots$; therefore this rule is a combination of the admissible cut rule k on p. 31 with the ω -rule that derives $\mathfrak{A}(1) \rightarrow (\exists x) \mathfrak{A}(x)$ from $\mathfrak{A}(1) \rightarrow \mathfrak{A}(1), \mathfrak{A}(1) \rightarrow \mathfrak{A}(2), \mathfrak{A}(1) \rightarrow \mathfrak{A}(3), \dots$. Conversely, the only expected uses of the ω -rule correspond to the rule of complete induction and to the rule of introduction of the universal quantifier. The ω -rule has a very simple structure: its premisses are stated without further need of free variables and quantifiers; however, there are infinitely many. Its main feature is that it allows for derivations without detour.

Sundholm (1983) and Feferman (1986) provide a historical account of such rules. Hilbert (1931a, b) states an ω -rule with the motivation of, respectively, proving the completeness of arithmetic and the law of excluded middle.¹⁶ He declares that it is a ‘finitary deduction rule’, that it has a ‘rigorously finitary character’. Lorenzen makes no reference to these articles, but, in the 1945 manuscript ‘Die Widerspruchsfreiheit der klassischen Logik mit verzweigter Typentheorie’, he expands on the finitary character of its usage: ‘One has to persuade oneself at each appearance of this rule that its application occurs to the effect of a “finitary deduction”, because the proof of freedom from contradiction would otherwise become meaningless’.¹⁷ E.g. in the derivation of the rule of complete induction on p. 33, the infinitely many premisses $\mathfrak{A}(1) \rightarrow \mathfrak{A}(1), \mathfrak{A}(1) \rightarrow \mathfrak{A}(2), \dots$

¹⁶Hilbert (1931a) states a restricted ω -rule, in the sense that its premisses must be decidable (i.e. numerical); he states the axiom of complete induction separately. This is noted in the letter that Bernays addresses to Gödel on 18 January 1931 (Feferman, Dawson, Goldfarb, Parsons et al. 2003, pp. 80–91), where he formulates its unrestricted counterpart. See also Gödel’s answer dated 2 April 1931. The ω -rule in Hilbert 1931b is not restricted. Compare Ewald, Sieg, Hallett, Majer, and Schlimm 2013, pp. 788–805, 967–973, 983–984.

¹⁷‘Man hat sich bei jedem Vorkommen dieser Regeln zu überzeugen, daß ihre Anwendung im Sinne des “finiten Schließens” geschieht, weil sonst der Wf-Beweis sinnlos würde’ (‘The freedom from contradiction of classical logic with ramified type theory’; a version of this manuscript can be found in Niedersächsische Staats- und Universitätsbibliothek Göttingen, Cod. Ms. G. Köthe M 10).

must result from a construction whose explanation is finitary, but whose realisation is endless: ‘For every number m follows therefrom at once $\mathfrak{A}(1) \rightarrow \mathfrak{A}(m)$ by m -fold application of the rule of inference k ’. Lorenzen shares this intuitionistic framework with Gentzen (1936, p. 526): ‘After all, we need not associate the idea of a closed infinite number of individual propositions with this $[(\mathfrak{x})\mathfrak{A}(\mathfrak{x})]$, where \mathfrak{A} shall not yet contain an universal or existential quantifier], but can, rather, interpret its sense “finitistically” as follows: “If, starting with 1, we substitute for \mathfrak{x} successive natural numbers then, however far we may progress in the formation of numbers, a true proposition results in each case”’.

In his letter to Bernays dated 2 April 1931, Gödel points out that such a rule presupposes a framework in which this infinity of premisses may be asserted: ‘the very complicated and problematical concept “finitary proof” is assumed [...] without having been made mathematically precise’ (see Feferman, Dawson, Goldfarb, Parsons et al. 2003, p. 97). This framework is thus an informal one; and, as the proof of consistency rests on its reliability, this framework is to be the intuitionistic one, as Herbrand (1931, ‘groupe D’, p. 5) and Novikoff (1943, p. 231) state, i.e. the constructive one (Lorenzen 1951, p. 82). In this sense, a calculus including the ω -rule is of a different nature than a mechanical calculus, where we can check by a finitary process the correctness of a given derivation. In fact, neither the Hilbert program nor Lorenzen’s proof of consistency take place in a mechanical formal system, i.e. in a system whose objects are finitary and whose derivations are finitary and decidable.

The proof that the calculus thus defined is a countably complete pseudocomplemented semilattice illustrates, as Lorenzen realises a posteriori,¹⁸ that the strategy of Gentzen’s dissertation (1934, IV, § 3) for proving the consistency of elementary number theory without complete induction may be maintained for proving the consistency of all of elementary number theory: the introduction rules (rules a to f on p. 21) introduce inequalities for formal elements of increasing complexity, i.e. no inequality can result from a detour; then the corresponding elimination rules (rules γ to ε on p. 23) are shown to hold by an induction on the complexity of the introduced inequality (in Lorenzen’s later terminology, one would say that these rules are shown to be ‘admissible’ and can be considered as resulting from an ‘inversion principle’); at last transitivity of the preorder, i.e. the cut rule (rule β on p. 23: if $a \leq b$ and $b \leq c$, then $a \leq c$), is established by proving a stronger rule through an induction on the complexity of the cut element b nested with inductions on the complexity of the derivation of the rule’s premisses.

The inductions used here are the ones accurately described by Jacques

¹⁸This is how we interpret the beginning of the second paragraph on p. 17: ‘Without knowledge of [...]’.

Herbrand (1930, pp. 4–5) after having been emphasised by David Hilbert (1928, p. 76): the first proceeds along the construction of formulas starting from prime formulas through rules, and has no special name (it will be called ‘formula induction’ in Lorenzen 1951); the second proceeds along the construction of theorems starting from prime theorems through deduction rules, and is called ‘premiss induction’.¹⁹

In other words, Lorenzen starts with a preordered set P , constructs the free countably complete pseudocomplemented semilattice K over P and emphasises conservativity, i.e. that no more inequalities come to hold among elements of P viewed as a subset of K than the ones that have been holding before:²⁰ one says that P is embedded into K and that the preorder of P is embedded into the countably complete preorder of K .

Then the consistency of elementary number theory with complete induction is established in § 3 by constructing the free countably complete pseudocomplemented semilattice over its ‘prime formulas’, i.e. the numerical formulas, viewed as a set preordered by material implication.

Note the presence of rule g on pp. 21 and 31, a contraction rule. This should be put in relation

- with the rôle of contraction, especially for steps 13.5 1–13.5 3, in Gentzen’s proofs of consistency (1936, 1974);
- with the calculus of P. S. Novikoff (1943, lemma 6), in which contraction may be proved.

3 Comparison with Gentzen’s proof of consistency

There are similarities and differences with respect to the strategy developed by Gentzen for proving the consistency of elementary number theory with complete induction. In his first proof, submitted in August 1935, withdrawn and finally published posthumously by Bernays in 1974 (after its translation by Szabo 1969), Gentzen defines a concept of reduction procedure for a sequent and shows that such a procedure may be specified for every derivable sequent but not for the contradictory sequent $\rightarrow 1 = 2$. Let us emphasise two aspects of this concept.

¹⁹See Lorenzen 1939b for his interest in the foundation of inductive definitions.

²⁰This is exactly the approach of Skolem (1921, § 2) for constructing the free lattice over a preordered set, in the course of studying the decision problem for lattices.

- If the succedent of the sequent has the form $\forall x F(x)$, the following step of the reduction procedure consists in replacing it by $F(n)$, where n is a number to be chosen freely.
- A reduction procedure is defined as the specification of a sequence of steps for all possible free choices, with the requirement that the reduction terminates for every such choice.

In his letter to Bernays dated 4 November 1935,²¹ Gentzen visualises a reduction procedure as a tree whose every branch terminates.

The proof that a reduction procedure may be specified for every derivable sequent is by theorem induction. For this, a lemma is needed, claiming that if reduction procedures are known for two sequents $\Gamma \rightarrow D$ and $D, \Delta \rightarrow C$, then a reduction procedure may be specified for their cut sequent $\Gamma, \Delta \rightarrow C$. The proof goes by induction on the construction of the cut formula D and traces the claim back to the same claim with the same cut formula, but with the sequent $D, \Delta \rightarrow C$ replaced by a sequent $D, \Delta^* \rightarrow C^*$ resulting from it after one or more reduction steps and the cut sequent replaced by $\Gamma, \Delta^* \rightarrow C^*$. By definition of the reduction procedure, this tracing back must terminate eventually.

This last kind of argument may be considered as an infinite descent in the reduction procedure. In his letter to Bernays, Gentzen seems to indicate that this infinite descent justifies an induction on the reduction procedure; as analysed by William W. Tait (2015), this would be an instance of the Bar theorem. But in his following letter, dated 11 December 1935,²² he writes that ‘[his] proof is not satisfactory’ and announces another proof, to be submitted in February 1936: in it, he defines the concept of reduction procedure for a derivation (and not for a sequent), associates inductively an ordinal to every derivation, and shows that a reduction procedure may be specified for every derivation by an induction on the ordinal.

Let us compare this strategy with Lorenzen’s.

- The free choice is subsumed in a deduction rule, an ω -rule as described above (rules c and j on p. 31).²³
- Elementary number theory is constructed as the cut-free derivations starting from the numerical formulas, so that it is trivially consistent, and the cut rule (rule k on p. 31) is shown to be admissible: if derivations are known for two sequents $\mathfrak{A} \rightarrow \mathfrak{B}$ and $\mathfrak{B} \rightarrow \mathfrak{C}$, then a derivation may be

²¹Hs 975:1652, translated by von Plato (2017, pp. 241–244).

²²Hs 975:1653, translated by von Plato (2017, p. 244).

²³Compare Bernays’ suggestion in his letter to Gentzen dated 9 May 1938, Hs 975:1661, translated by von Plato (2017, pp. 254–255).

specified for their cut sequent $\mathfrak{A} \rightarrow \mathfrak{C}$ by a formula induction on the cut formula \mathfrak{B} nested with several instances of a theorem induction.

In this way, Lorenzen's strategy may be used to realise the endeavour expressed by Tait (2015): 'the gap in Gentzen's argument is filled, not by the Bar Theorem, but by taking as the basic notion that of a [cut-free] deduction tree in the first place rather than that of a reduction tree'. His 1944 proof can thus be seen as a formal improvement on Gentzen's 1935 argument, which is all the more remarkable given Gentzen's reaction to Lorenzen's proof.

4 Comparison with Novikov's proof of consistency

Novikoff (1943) introduces an intuitionistic calculus that contains an ω -rule (rule 6 on p. 233). He defines in § 4 the concept of 'regular formula' that expresses that the formula has a cut-free proof, and shows in § 8 that it is an explanation of classical truth. In fact, he proves essentially that cut ('the rule of inference') is admissible. This proof does not use any induction on the cut formula, contrary to Gentzen's and Lorenzen's proofs (see Mints 1991 and Tupailo 1992). In his introduction, Novikov writes: 'As a basis, the consistency of which is assumed, the intuitionistic mathematics is taken. From such a point of view it appears to be possible to prove the consistency of [elementary number theory]'.

5 Mathematical comments

On p. 23, the premiss induction that establishes rule γ is given the form of a reductio ad absurdum, but the reasoning may easily be unraveled into a direct form.

The calculus N presented on p. 31 is in fact common to intuitionistic and classical arithmetic: recall that 'the connectives \vee , \exists and \supset no longer occur'. It may be criticised for its sloppy way of treating variables.

Furthermore, the introduction of free variables seems dispensable in the presence of an ω -rule. Rule j and the corresponding elimination rule p may be omitted from the calculus at the affordable price of giving complete induction the less elegant form $\mathfrak{A}(1) \& (\mathfrak{x}) \mathfrak{A}(\mathfrak{x}) \& \overline{\mathfrak{A}(\mathfrak{x}')} \rightarrow (\mathfrak{x}) \mathfrak{A}(\mathfrak{x})$ as in Lorenzen 1962.

6 Conclusion

Proof theory continues to focus on measures of complexity by ordinal numbers. The fact that Lorenzen does not resort to ordinals in his proof of consistency should be considered as a feature of his approach.

Lorenzen's article is remarkable for its metamathematical standpoint. A mathematical object is presented as a construction described by rules. A claim on the object is established by an induction that expresses the very meaning of the construction.

The relations between these objects, of the form of an inequality or of an implication, also admit such a presentation: it has the feature that the construction of a relation proceeds as accumulatively ('without detour', i.e. cut) as the construction of the formulas appearing in the relation. It is only in a second place that the corresponding elimination rules and the cut rule are shown to be admissible.

In elementary number theory and for the free countably complete pseudocomplemented semilattice, the construction of a relation uses an ω -rule that is stronger than the rule of complete induction but requires infinitely many premisses, so that a relation corresponds to a well-founded tree.

Lorenzen's standpoint holds equally well for a logical calculus and for a lattice: 'logical calculuses²⁴ are semilattices or lattices' (*Lorenzen 1951*, p. 89). The consistency of the logical calculus of elementary number theory is recognised as a consequence of the following fact: a preordered set embeds into the free countably complete pseudocomplemented semilattice generated by it in a conservative way.

Other reflections on the philosophical significance of Lorenzen's approach to logic are addressed by Matthias Wille (2013, 2016).

Acknowledgments

We thank Brigitte Parakenings for having provided ideal working conditions and her expertise at Philosophisches Archiv of Universität Konstanz, and Henri Lombardi and Jan von Plato for helpful discussions. This research has been supported through the program 'Research in pairs' of Mathematisches Forschungsinstitut Oberwolfach in 2016 and through the hospitality of the university of Gothenburg.

Ein halbordnungstheoretischer Widerspruchsfreiheitsbeweis.

Die Dissertation von G. Gentzen enthält einen Wf-beweis der reinen Zahlentheorie ohne vollständige Induktion, der auf dem folgenden Grundgedanken beruht: jede herleitbare Sequenz muß sich auch ohne Umwege herleiten lassen, sodaß während der Herleitung nur die Verknüpfungen eingeführt werden, die unbedingt notwendig sind, nämlich diejenigen, die in der Sequenz selbst enthalten sind. In dem Wf-beweis der Zahlentheorie mit vollständiger Induktion tritt dieser Grundgedanke gegenüber anderen zurück. Ich möchte jedoch im folgenden zeigen, daß er allein genügt, auch diese Wf. zu erhalten.

Ohne Kenntnis der Dissertation von Gentzen bin ich auf diese Möglichkeit auf Grund einer halbordnungstheoretischen Frage gekommen. Diese lautete: wie läßt sich eine halbgeordnete Menge in einen orthokomplementären vollständigen Halbverband einbetten? Im allgemeinen sind mehrere solche Einbettungen möglich – unter den möglichen Einbettungen ist aber eine ausgezeichnet, nämlich die, welche sich in jede andere homomorph abbilden läßt. Die Existenz dieser ausgezeichneten Einbettung wird in § 2 bewiesen.

Um hieraus in § 3 den gesuchten Wf-beweis zu erhalten, ist nur noch eine Übersetzung des halbordnungstheoretischen Beweises in die logistische Sprache notwendig. Denn der Kalkül, den wir betrachten und auf den sich die üblichen Kalküle zurückführen lassen, ist in der ausgezeichneten Einbettung der halbgeordneten Menge der zahlentheoretischen Primformeln enthalten.^{1/2}

§ 1. Eine Menge M heißt halbgeordnet, wenn in M eine zweistellige Relation \leqslant definiert ist, sodaß für die Elemente a, b, \dots von M gilt:

$$\begin{aligned} a &\leqslant a \\ a \leqslant b, b \leqslant c &\Rightarrow a \leqslant c. \end{aligned}$$

Gilt $a \leqslant b$ und $b \leqslant a$, so schreiben wir $a \equiv b$.

Gilt $a \leqslant x$ für jedes $x \in M$, so schreiben wir $a \leqslant .$ Ebenso schreiben wir $\leqslant a$, wenn $x \leqslant a$ für jedes x gilt. (\leqslant bedeutet also, daß $x \leqslant y$ für jedes $x, y \in M$ gilt.)

Eine halbgeordnete Menge M heißt Halbverband, wenn es zu jedem $a, b \in M$ ein $c \in M$ gibt, sodaß für jedes $x \in M$ gilt

$$x \leqslant a, x \leqslant b \iff x \leqslant c.$$

c heißt die *Konjunktion* von a und b : $c \equiv a \wedge b$.

A proof of freedom from contradiction within the theory of partial order.

The dissertation of G. Gentzen contains a proof of freedom from contradiction of elementary number theory without complete induction that relies on the following basic thought: every derivable sequent must also be derivable without detour, so that during the derivation only those connectives are being introduced that are absolutely necessary, i.e. those that are contained in the sequent itself. In the proof of freedom from contradiction of number theory with complete induction, this basic thought steps back with regard to others. I wish however to show in the following that it alone suffices to obtain also this freedom from contradiction.

Without knowledge of the dissertation of Gentzen, I have arrived at this possibility on the basis of a semilattice-theoretic question. This question is: how may a partially ordered set be embedded into an orthocomplemented complete semilattice? In general, several such embeddings are possible – but among the possible embeddings one is distinguished, i.e. the one which may be mapped homomorphically into every other. The existence of this distinguished embedding will be proved in § 2.

In order to obtain from this in § 3 the sought-after proof of freedom from contradiction, now just a translation of the semilattice-theoretic proof into the logistic language is necessary. For the calculus that we consider, and to which the usual calculuses may be reduced, is contained in the distinguished embedding of the partially ordered set of the number-theoretic prime formulas.^[2]

§ 1. A set M is called **partially ordered** if a binary relation \leqslant is defined in M so that for the elements a, b, \dots of M holds:

$$\begin{aligned} a &\leqslant a \\ a \leqslant b, b \leqslant c &\Rightarrow a \leqslant c. \end{aligned}$$

If $a \leqslant b$ and $b \leqslant a$ holds, then we write $a \equiv b$.

If $a \leqslant x$ holds for every $x \in M$, then we write $a \leqslant \cdot$. We write as well $\leqslant a$ if $x \leqslant a$ holds for every x . (\leqslant means thus that $x \leqslant y$ holds for every $x, y \in M$.)

A partially ordered set M is called **semilattice** if to every $a, b \in M$ there is a $c \in M$ so that for every $x \in M$ holds

$$x \leqslant a, x \leqslant b \iff x \leqslant c.$$

Ein Halbverband M heißt **orthokomplementär**, wenn es zu jedem $a \in M$ ein $b \in M$ gibt, so daß für jedes $x \in M$ gilt

$$a \wedge x \leqslant \iff x \leqslant b.$$

b heißt das *Orthokomplement* von a : $b \equiv \bar{a}$.

Ein Halbverband M heißt ω -vollständig, wenn es zu jeder abzählbaren Folge $M = a_1, a_2, \dots$ in M ein $c \in M$ gibt, so daß für jedes $x \in M$ gilt:

$$(\text{für jedes } n: x \leqslant a_n) \iff x \leqslant c.$$

c heißt die *Konjunktion der Elemente von M* : $c \equiv \bigwedge_n a_n \equiv \bigwedge_M$.

Sind M und M' halbgeordnete Mengen, so heißt M ein Teil von M' , wenn M Untermenge von M' ist und für jedes $a, b \in M$ genau dann $a \leqslant b$ in M' gilt, wenn $a \leqslant b$ in M gilt.

Sind M und M' halbgeordnete Mengen, so verstehen wir unter einer Abbildung von M in M' eine Zuordnung, die jedem $a \in M$ ein $a' \in M'$ zuordnet, so daß gilt

$$a \equiv b \Rightarrow a' \equiv b'. |^3$$

Sind M und M' orthokomplementäre ω -vollständige Halbverbände, so verstehen wir unter einem Homomorphismus von M in M' eine Abbildung \rightarrow von M in M' , so daß für jedes $a, b \in M$ und $a', b' \in M'$ mit $a \rightarrow a'$ und $b \rightarrow b'$ gilt:

$$\begin{aligned} a \wedge b &\rightarrow a' \wedge b' \\ \bar{a} &\rightarrow \overline{a'}. \end{aligned}$$

Ferner soll für jede Folge $M = a_1, a_2, \dots$ in M und $M' = a'_1, a'_2, \dots$ in M' mit $a_n \rightarrow a'_n$ gelten:

$$\bigwedge_M \rightarrow \bigwedge_{M'}.$$

Wir wollen jetzt beweisen, daß es zu jeder halbgeordneten Menge P einen orthokomplementären ω -vollständigen Halbverband K gibt, so daß

- 1) P ein Teil von K ist,
- 2) K in jeden orthokomplementären ω -vollständigen Halbverband, der P als Teil enthält, homomorph abbildbar ist.

Wäre K' ein weiterer orthokomplementärer ω -vollständiger Halbverband, der die Bedingungen 1) und 2) erfüllt, so gäbe es eine Zuordnung, durch die K in K' und K' in K homomorph abgebildet würde, d. h. K und K' wären isomorph.

c is called the *conjunction* of a and b : $c \equiv a \wedge b$.

A semilattice M is called **orthocomplemented** if to every $a \in M$ there is a $b \in M$ so that for every $x \in M$ holds

$$a \wedge x \leqslant \iff x \leqslant b.$$

b is called the *orthocomplement* of a : $b \equiv \bar{a}$.

A semilattice M is called **ω -complete** if to every countable sequence $M = a_1, a_2, \dots$ in M there is a $c \in M$ so that for every $x \in M$ holds:

$$(\text{for every } n: x \leqslant a_n) \iff x \leqslant c.$$

If M and M' are partially ordered sets, then M is called a **part** of M' if M is a subset of M' and for every $a, b \in M$ $a \leqslant b$ holds in M' exactly if $a \leqslant b$ holds in M .

If M and M' are partially ordered sets, we understand by a **mapping** of M into M' an assignment that to every $a \in M$ assigns an $a' \in M'$ so that

$$a \equiv b \Rightarrow a' \equiv b'. |^3$$

If M and M' are orthocomplemented ω -complete semilattices, we understand by a **homomorphism** of M into M' a mapping \rightarrow of M into M' , so that for every $a, b \in M$ and $a', b' \in M'$ with $a \rightarrow a'$ and $b \rightarrow b'$ holds:

$$\begin{aligned} a \wedge b &\rightarrow a' \wedge b' \\ \bar{a} &\rightarrow \bar{a}'. \end{aligned}$$

Moreover, for every sequence $M = a_1, a_2, \dots$ in M and $M' = a'_1, a'_2, \dots$ in M' with $a_n \rightarrow a'_n$ is to hold:

$$\bigwedge_M \rightarrow \bigwedge_{M'}.$$

We want to prove now that to every partially ordered set P there is an orthocomplemented ω -complete semilattice K so that

- 1) P is a part of K ,
- 2) K may be mapped homomorphically into every orthocomplemented ω -complete semilattice that contains P as part.

If K' were a further orthocomplemented ω -complete semilattice that fulfils conditions 1) and 2), then there would be an assignment by which K would be mapped homomorphically into K' and K' into K , i.e. K and K' would be **isomorphic**. K is thus determined uniquely up to isomorphism by conditions

K ist also durch die Bedingungen 1) und 2) bis auf Isomorphie eindeutig bestimmt. Wir nennen K den ausgezeichneten orthokomplementären ω -vollständigen Halbverband über P .

§ 2. Satz: Über jeder halbgeordneten Menge gibt es den ausgezeichneten orthokomplementären ω -vollständigen Halbverband.

Wir konstruieren zu der halbgeordneten Menge P eine Menge K auf folgende Weise:

- 1) K enthalte die Elemente von P . (Diese nennen wir die Primelemente von K).⁴
- 2) K enthalte mit endlich vielen Elementen a_1, a_2, \dots, a_n auch die hieraus gebildete Kombination als Element. (Diese bezeichnen wir durch $a_1 \wedge a_2 \wedge \dots \wedge a_n$.)
- 3) K enthalte mit jedem Element a auch ein Element \bar{a} .
- 4) K enthalte mit jeder abzählbaren Folge M auch ein Element \bigwedge_M .

Jedes Element von K lässt sich also eindeutig als Kombination $a_1 \wedge a_2 \wedge \dots \wedge a_n$ von Primelementen und Elementen der Form \bar{a} oder \bigwedge_M schreiben.

Wir definieren eine Relation \leqslant in K auf folgende Weise:

- 1) Für Primelemente p, q gelte $p \leqslant q$ in K , wenn $p \leqslant q$ in P gilt. (Diese Relationen nennen wir die Grundrelationen.)
- 2) Es soll jede Relation \leqslant in K gelten, die sich aus den Grundrelationen mit Hilfe der folgenden Regeln herleiten lässt:

$$\begin{array}{ll}
 a) \frac{c \leqslant a \quad c \leqslant b}{c \leqslant a \wedge b} & d) \frac{a \leqslant c}{a \wedge b \leqslant c} \\
 b) \frac{a \wedge c \leqslant}{c \leqslant \bar{a}} & e) \frac{a \leqslant b}{a \wedge \bar{b} \leqslant c} \\
 c) \frac{c \leqslant a_1, \dots, c \leqslant a_n, \dots}{c \leqslant \bigwedge_M} & f) \frac{a_n \wedge b \leqslant c}{\bigwedge_M \wedge b \leqslant c} \\
 & (M = a_1, a_2, \dots) \\
 g) \frac{a \wedge a \wedge b \leqslant c}{a \wedge b \leqslant c} & |^5
 \end{array}$$

1) and 2). We call K the **distinguished orthocomplemented ω -complete semi-lattice over P**.

§ 2. Theorem: *There is over every partially ordered set the distinguished orthocomplemented ω -complete semilattice.*

We construct for the partially ordered set P a set K in the following way:

- 1) Let K contain the elements of P. (These we call the **prime elements** of K.)⁴
- 2) Let K contain with finitely many elements a_1, a_2, \dots, a_n also the **combination** formed out of these as element. (These we designate by $a_1 \wedge a_2 \wedge \dots \wedge a_n$.)
- 3) Let K contain with every element a also an element \bar{a} .
- 4) Let K contain with every countable sequence M also an element \bigwedge_M .

Every element of K may thus be written uniquely as combination $a_1 \wedge a_2 \wedge \dots \wedge a_n$ of prime elements and elements of the form \bar{a} or \bigwedge_M .

We define a relation \leqslant in K in the following way:

- 1) For prime elements p, q let $p \leqslant q$ hold in K if $p \leqslant q$ holds in P. (These relations we call the basic relations.)
- 2) Every relation \leqslant that may be derived from the basic relations by the aid of the following rules is to hold in K:

$$a) \frac{c \leqslant a \quad c \leqslant b}{c \leqslant a \wedge b} \quad d) \frac{a \leqslant c}{a \wedge b \leqslant c}$$

$$b) \frac{a \wedge c \leqslant}{c \leqslant \bar{a}} \quad e) \frac{a \leqslant b}{a \wedge \bar{b} \leqslant c}$$

$$c) \frac{c \leqslant a_1 \quad \dots \quad c \leqslant a_n \quad \dots}{c \leqslant \bigwedge_M} \quad f) \frac{a_n \wedge b \leqslant c}{\bigwedge_M \wedge b \leqslant c}$$

$$(M = a_1, a_2, \dots)$$

$$g) \frac{a \wedge a \wedge b \leqslant c}{a \wedge b \leqslant c}$$

We call the relations above the line the **premisses** of the relation below the line.

Wir nennen die Relationen über dem Strich die Prämisse der Relation unter dem Strich.

Wir haben jetzt zunächst zu zeigen, daß K ein orthokomplementärer ω -vollständiger Halbverband bezügl. der Relation \leqslant ist. Dazu müssen wir beweisen

- $\alpha)$ $a \leqslant a$
- $\beta)$ $a \leqslant b, b \leqslant c \Rightarrow a \leqslant c$
- $\gamma)$ $c \leqslant a \wedge b \Rightarrow c \leqslant a$
- $\delta)$ $c \leqslant \bar{a} \Rightarrow a \wedge c \leqslant$
- $\varepsilon)$ $c \leqslant \bigwedge_M \Rightarrow c \leqslant a_n \quad (M = a_1, a_2, \dots)$

Diese Eigenschaften zusammen mit a), b) und c) drücken nämlich aus, daß K ein orthokomplementärer ω -vollständiger Halbverband ist.

a) gilt für Primelemente. Gilt $\alpha)$ für a und b , so auch für $a \wedge b$ wegen

$$\frac{\begin{array}{c} a \leqslant a \\ a \wedge b \leqslant a \end{array}}{a \wedge b \leqslant a} \quad \frac{\begin{array}{c} b \leqslant b \\ a \wedge b \leqslant b \end{array}}{a \wedge b \leqslant b}$$

Gilt $\alpha)$ für jedes $a_n \in M$, so auch für \bigwedge_M wegen

$$\frac{\begin{array}{cccc} a_1 \leqslant a_1 & \dots & a_n \leqslant a_n & \dots \\ \bigwedge_M \leqslant a_1 & & \bigwedge_M \leqslant a_n & \\ \hline \end{array}}{\bigwedge_M \leqslant \bigwedge_M}$$

Gilt $\alpha)$ für a , so auch für \bar{a} , wegen

$$\frac{\begin{array}{c} a \leqslant a \\ a \wedge \bar{a} \leqslant \end{array}}{\bar{a} \leqslant \bar{a}}$$

Dadurch ist $\alpha)$ allgemein bewiesen.^[6]

Da $\beta)$ am schwierigsten zu beweisen ist, nehmen wir zunächst $\gamma)$.

Um $\gamma)$ zu beweisen, haben wir zu zeigen, daß, wenn $c \leqslant a \wedge b$ herleitbar ist, dann auch stets $c \leqslant a$ herleitbar sein muß.

Wir führen den Beweis indirekt durch eine *transfinite Induktion*. Es sei $c \leqslant a \wedge b$ herleitbar, aber nicht $c \leqslant a$. Der letzte Schritt der Herleitung von $c \leqslant a \wedge b$

We have now to show first that K is an orthocomplemented ω -complete semilattice w.r.t. the relation \leqslant . For this we must prove

$$\begin{array}{ll} \alpha) & a \leqslant a \\ \beta) & a \leqslant b, b \leqslant c \Rightarrow a \leqslant c \\ \gamma) & c \leqslant a \wedge b \Rightarrow c \leqslant a \\ \delta) & c \leqslant \bar{a} \Rightarrow a \wedge c \leqslant \\ \varepsilon) & c \leqslant \bigwedge_M \Rightarrow c \leqslant a_n \quad (M = a_1, a_2, \dots) \end{array}$$

These properties together with a), b), and c) express in fact that K is an orthocomplemented ω -complete semilattice.

a) holds for prime elements. If $\alpha)$ holds for a and b , then also for $a \wedge b$ because of

$$\frac{\begin{array}{c} a \leqslant a \\ b \leqslant b \end{array}}{\begin{array}{c} a \wedge b \leqslant a \\ a \wedge b \leqslant b \end{array}} \frac{}{a \wedge b \leqslant a \wedge b}$$

If $\alpha)$ holds for every $a_n \in M$, then also for \bigwedge_M because of

$$\frac{\begin{array}{ccccc} a_1 \leqslant a_1 & \dots & a_n \leqslant a_n & \dots \\ \bigwedge_M \leqslant a_1 & & \bigwedge_M \leqslant a_n & \end{array}}{\bigwedge_M \leqslant \bigwedge_M}$$

If $\alpha)$ holds for a , then also for \bar{a} , because of

$$\frac{a \leqslant a}{\begin{array}{c} a \wedge \bar{a} \leqslant \\ \bar{a} \leqslant \bar{a} \end{array}}$$

Hereby $\alpha)$ is proved in general.^[6]

As $\beta)$ is the most difficult to prove, we take first $\gamma)$.

In order to prove $\gamma)$, we have to show that if $c \leqslant a \wedge b$ is derivable, then also $c \leqslant a$ must always be derivable.

We lead the proof indirectly by a *transfinite induction*. Let $c \leqslant a \wedge b$ be derivable, but not $c \leqslant a$. Then the last step of the derivation of $c \leqslant a \wedge b$ cannot be $\frac{c \leqslant a \quad c \leqslant b}{c \leqslant a \wedge b}$, likewise not $\frac{c_1 \leqslant c_2}{c_1 \wedge \bar{c}_2 \leqslant a \wedge b}$ ($c = c_1 \wedge \bar{c}_2$), as then $\frac{c_1 \leqslant c_2}{c_1 \wedge \bar{c}_2 \leqslant a}$ would be derivable at once.

kann dann nicht sein $\frac{c \leq a \quad c \leq b}{c \leq a \wedge b}$ ebenfalls nicht $\frac{c_1 \leq c_2}{c_1 \wedge \overline{c_2} \leq a \wedge b} \quad (c = c_1 \wedge \overline{c_2})$ da dann sofort $\frac{c_1 \leq c_2}{c_1 \wedge \overline{c_2} \leq a}$ herleitbar wäre.

Für den letzten Schritt bleiben nur die Möglichkeiten

$$\frac{\begin{array}{c} c_1 \leq a \wedge b \\ c_1 \wedge c_2 \leq a \wedge b \end{array}}{c_1 \wedge c' \leq a \wedge b \quad \dots \quad c_n \wedge c' \leq a \wedge b} \quad \frac{\begin{array}{c} c_1 \wedge c_1 \wedge c_2 \leq a \wedge b \\ c_1 \wedge c_2 \leq a \wedge b \end{array}}{\bigwedge_M c' \leq a \wedge b} \quad \left(\begin{array}{l} M = a_1, a_2, \dots \\ c = \bigwedge_M c' \end{array} \right)$$

Hier muß jetzt $c_1 \leq a$ bzw. $c_1 \wedge c_1 \wedge c_2 \leq a$ bzw. für mindestens ein n $c_n \wedge c' \leq a$ nicht herleitbar sein, da sonst sofort $c \leq a$ herleitbar wäre. In der Herleitung von $c \leq a \wedge b$ wäre also schon für eine Prämisse die Behauptung γ) falsch. Gehe ich in der Herleitung von einer Relation zu einer Prämisse über, von dieser wieder zu einer Prämisse usw., so bin ich nach endlich vielen Schritten bei einer Grundrelation. Wir erhielten also eine Grundrelation, für die die Behauptung γ) falsch wäre. Da dieses aber unmöglich ist, ist damit γ) bewiesen.

Wir nennen die Induktion, die wir hier durchgeführt haben, eine Prämisseninduktion.

Mit Hilfe von Prämisseninduktionen verläuft der Beweis für δ) und ε) ebenso einfach wie für γ), so daß ich hierauf nicht weiter eingehen.¹⁷

Es bleibt nur noch β) zu zeigen. Statt dessen beweisen wir die stärkere Behauptung

$$\zeta) \quad a \leq b, b \wedge b \wedge \dots \wedge b \wedge c \leq d \Rightarrow a \wedge c \leq d$$

um hierauf Prämisseninduktionen anwenden zu können.

Es seien zunächst b , c und d Primelemente. Dann gilt $\zeta)$ für jede Grundrelation $a \leq b$. Wir nehmen als *Induktionsvoraussetzung* an, daß $\zeta)$ für jede Prämisse von $a \leq b$ gelte.

Da b ein Primelement ist, kann der letzte Schritt der Herleitung von $a \leq b$ nur sein:

$$\frac{\begin{array}{c} a_1 \leq b \\ a_1 \wedge a_2 \leq b \end{array}}{a_1 \leq a_2 \quad (a = a_1 \wedge \overline{a_2})} \quad \frac{\begin{array}{c} a_1 \wedge a_1 \wedge a_2 \leq b \\ a_1 \wedge a_2 \leq b \end{array}}{\bigwedge_M a' \leq b \quad \left(\begin{array}{l} M = a_1, a_2, \dots \\ a = \bigwedge_M a' \end{array} \right)}$$

Nach der Induktionsvoraussetzung ist dann $a_1 \wedge c \leq d$ bzw. $a_1 \wedge a_1 \wedge a_2 \wedge c \leq$

For the last step remain only the possibilities

$$\frac{\begin{array}{c} c_1 \leqslant a \wedge b \\ c_1 \wedge c_2 \leqslant a \wedge b \end{array}}{c_1 \wedge c' \leqslant a \wedge b \quad \dots \quad c_n \wedge c' \leqslant a \wedge b \quad \dots} \quad \frac{\begin{array}{c} c_1 \wedge c_1 \wedge c_2 \leqslant a \wedge b \\ c_1 \wedge c_2 \leqslant a \wedge b \end{array}}{\bigwedge_M c' \leqslant a \wedge b} \quad \left(\begin{array}{l} M = a_1, a_2, \dots \\ c = \bigwedge_M c' \end{array} \right)$$

Here must now $c_1 \leqslant a$ resp. $c_1 \wedge c_1 \wedge c_2 \leqslant a$ resp. for at least one n $c_n \wedge c' \leqslant a$ not be derivable, as otherwise at once $c \leqslant a$ would be derivable. In the derivation of $c \leqslant a \wedge b$ the claim γ) would thus already be false for a premiss. If in the derivation of a relation I go over to a premiss, of this again to a premiss, etc., then I am after finitely many steps at a basic relation. We would thus obtain a basic relation for which the claim γ) would be false. But as this is impossible, γ) is thereby proved.

We call the induction that we have undertaken here a **premiss induction**.

By the aid of premiss inductions, the proof for δ) and ε) proceeds just as simply as for γ), so that I am not going into this any further.⁷

It remains only to show in addition β). Instead of this we prove the stronger claim

$$\zeta) \quad a \leqslant b, b \wedge b \wedge \dots \wedge b \wedge c \leqslant d \Rightarrow a \wedge c \leqslant d$$

in order to be able to apply premiss inductions hereupon.

Let first b , c and d be prime elements. Then $\zeta)$ holds for every basic relation $a \leqslant b$. We assume as *induction hypothesis* that $\zeta)$ holds for every premiss of $a \leqslant b$.

As b is a prime element, the last step of the derivation of $a \leqslant b$ can only be:

$$\frac{\begin{array}{c} a_1 \leqslant b \\ a_1 \wedge a_2 \leqslant b \end{array}}{a_1 \leqslant a_2 \quad (a = a_1 \wedge \overline{a_2})} \quad \frac{\begin{array}{c} a_1 \wedge a_1 \wedge a_2 \leqslant b \\ a_1 \wedge a_2 \leqslant b \end{array}}{\bigwedge_M a' \leqslant b \quad \left(\begin{array}{l} M = a_1, a_2, \dots \\ a = \bigwedge_M a' \end{array} \right)}$$

According to the induction hypothesis, then $a_1 \wedge c \leqslant d$ resp. $a_1 \wedge a_1 \wedge a_2 \wedge c \leqslant d$ resp. $a_n \wedge a' \wedge c \leqslant d$ is derivable. In every case $a \wedge c \leqslant d$ is at once derivable, as well from $a_1 \leqslant a_2$ because of

$$\frac{\begin{array}{c} a_1 \leqslant a_2 \\ a_1 \wedge \overline{a_2} \leqslant d \end{array}}{a \wedge c \leqslant d}$$

d bzw. $a_n \wedge a' \wedge c \leq d$ herleitbar. In jedem Falle ist sofort $a \wedge c \leq d$ herleitbar, ebenso aus $a_1 \leq a_2$ wegen

$$\frac{\frac{a_1 \leq a_2}{a_1 \wedge \overline{a_2} \leq d}}{a \wedge c \leq d}$$

Damit ist $\zeta)$ bewiesen für Primelemente b, c und d .

Jetzt sei nur noch b ein Primelement. Dann gilt also $\zeta)$ für beliebiges a und Primelemente c, d . Eine *Prämisseninduktion* ergibt jetzt, daß $\zeta)$ für jede Relation $b \wedge b \wedge \dots \wedge b \wedge c \leq d$ gilt. Jede Prämissen von $b \wedge b \wedge \dots \wedge b \wedge c \leq d$ hat nämlich wieder die Form $b \wedge \dots \wedge b \wedge c \leq d$. Damit ist $\zeta)$ allgemein für *Primelemente* b bewiesen.

Gilt $\zeta)$ für Elemente b_1 und b_2 , so auch ersichtlich für $b_1 \wedge b_2$. Gilt $\zeta)$ für jedes $b_n \in M$, so auch für $b = \bigwedge_M$. (Beweis durch Prämisseninduktion:
 $\bigwedge_M \wedge \bigwedge_M \wedge \dots \wedge \bigwedge_M \wedge c \leq d$ kann folgende Prämissen haben: $b_n \wedge \bigwedge_M \wedge \dots \wedge \bigwedge_M \wedge c \leq d$. Nach Induktionsvoraussetzung gilt dann $a \leq \bigwedge_M, b_n \wedge \bigwedge_M \wedge \dots \wedge \bigwedge_M \wedge c \leq d \Rightarrow b_n \wedge a \wedge c \leq d$. Da $\zeta)$ aber auch für $b = b_n$ vorausgesetzt ist, und wegen

$$a \leq \bigwedge_M \Rightarrow a \leq b_n$$

gilt auch $a \leq \bigwedge_M, b_n \wedge a \wedge c \leq d \Rightarrow a \wedge a \wedge c \leq d$. Aus $a \wedge a \wedge c \leq d$ ist aber $a \wedge c \leq d$ herleitbar. Jede andere Prämissen von $\bigwedge_M \wedge \bigwedge_M \wedge \dots \wedge \bigwedge_M \wedge c \leq d$ ist trivial.)

Gilt $\zeta)$ für b , so auch für \bar{b} . (Beweis durch Prämisseninduktion: $\bar{b} \wedge \bar{b} \wedge \dots \wedge \bar{b} \wedge c \leq d$ kann die folgende Prämissen haben: $\bar{b} \wedge \dots \wedge \bar{b} \wedge c \leq b$. Dann gilt nach Induktionsvoraussetzung

$$a \leq \bar{b}, \bar{b} \wedge \dots \wedge \bar{b} \wedge c \leq b \Rightarrow a \wedge c \leq b.$$

Da $\zeta)$ auch für b vorausgesetzt ist, gilt auch

$$a \wedge c \leq b, a \wedge b \leq d \Rightarrow a \wedge a \wedge c \leq d.$$

Also gilt auch $a \leq \bar{b}, \bar{b} \wedge \dots \wedge \bar{b} \wedge c \leq b \Rightarrow a \wedge c \leq d$ wegen $a \leq \bar{b} \Rightarrow a \wedge b \leq d$. Jede andere Prämissen ist wieder trivial.)

Also ist $\zeta)$ allgemein gültig. Damit ist bewiesen, daß K ein orthokomplementärer ω -vollständiger Halbverband ist.

Thereby ζ) is proved for prime elements b, c and d .

Now let only b still be a prime element. Then $\zeta)$ holds thus for arbitrary a and prime elements c, d . A *premiss induction* results now in $\zeta)$ holding for every relation $b \wedge b \wedge \dots \wedge b \wedge c \leq d$. Every premiss of $b \wedge b \wedge \dots \wedge b \wedge c \leq d$ has in fact again the form $b \wedge \dots \wedge b \wedge c \leq d$. Thereby $\zeta)$ is proved in general for *prime elements* b .

If $\zeta)$ holds for elements b_1 and b_2 , then obviously also for $b_1 \wedge b_2$. If $\zeta)$ holds for every $b_n \in M$, then also for $b = \bigwedge_M$. (Proof by premiss induction: $\bigwedge_M \wedge \bigwedge_M \wedge \dots \wedge \bigwedge_M \wedge c \leq d$ can have the following premiss: $b_n \wedge \bigwedge_M \wedge \dots \wedge \bigwedge_M \wedge c \leq d$. According to induction hypothesis holds then $a \leq \bigwedge_M$, $b_n \wedge \bigwedge_M \wedge \dots \wedge \bigwedge_M \wedge c \leq d \Rightarrow b_n \wedge a \wedge c \leq d$. But as $\zeta)$ is also assumed for $b = b_n$, and because of

$$a \leq \bigwedge_M \Rightarrow a \leq b_n,$$

also $a \leq \bigwedge_M$, $b_n \wedge a \wedge c \leq d \Rightarrow a \wedge a \wedge c \leq d$ holds. But from $a \wedge a \wedge c \leq d$ may be derived $a \wedge c \leq d$. Every other premiss of $\bigwedge_M \wedge \bigwedge_M \wedge \dots \wedge \bigwedge_M \wedge c \leq d$ is trivial.)

If $\zeta)$ holds for b , then also for \bar{b} . (Proof by premiss induction: $\bar{b} \wedge \bar{b} \wedge \dots \wedge \bar{b} \wedge c \leq d$ can have the following premiss: $\bar{b} \wedge \dots \wedge \bar{b} \wedge c \leq b$. Then holds according to induction hypothesis

$$a \leq \bar{b}, \bar{b} \wedge \dots \wedge \bar{b} \wedge c \leq b \Rightarrow a \wedge c \leq b.$$

As $\zeta)$ is also assumed for b , also holds

$$a \wedge c \leq b, a \wedge b \leq d \Rightarrow a \wedge a \wedge c \leq d.$$

Thus holds also $a \leq \bar{b}$, $\bar{b} \wedge \dots \wedge \bar{b} \wedge c \leq b \Rightarrow a \wedge c \leq d$ because of $a \leq \bar{b} \Rightarrow a \wedge b \leq d$. Every other premiss is again trivial.)

Thus $\zeta)$ is valid in general. This proves that K is an orthocomplemented ω -complete semilattice.

P is a part of K , as

$$p \leq q \text{ in } P \iff p \leq q \text{ in } K$$

holds. We have for this to convince ourselves that no relation $p \leq q$ is derivable in K that is not already holding in P . But this goes without saying, as none of the rules except $g)$ actually yields relations $p \leq q$ below the line. A derivation

P ist ein Teil von K, da

$$p \leq q \text{ in } P \iff p \leq q \text{ in } K$$

gilt. Wir haben uns dazu zu überzeugen, daß keine Relation $p \leq q$ in K herleitbar ist, die nicht schon in P gilt. Das ist aber selbstverständlich, da keine der Regeln außer g) überhaupt Relationen $p \leq q$ unter dem Strich liefert. Eine Herleitung einer Relation $p \leq q$ kann also nur die Regeln d) und g) benutzen. Mit diesen sind aber nur die Grundrelationen herleitbar.

Zum Beweis unseres Satzes bleibt jetzt noch zu zeigen, daß sich K in jeden anderen orthokomplementären ω -vollständigen Halbverband K', der P als Teil enthält, homomorph abbilden⁹ läßt. Diese Abbildung definieren wir durch

- 1) für Primelemente p gilt $p \rightarrow p$,
- 2) ferner soll gelten

$$\begin{aligned} a \rightarrow a', b \rightarrow b' &\Rightarrow a \wedge b \rightarrow a' \wedge b' \\ a \rightarrow a' &\Rightarrow \bar{a} \rightarrow \overline{a'} \\ a_n \rightarrow a'_n &\Rightarrow \bigwedge_M \rightarrow \bigwedge_{M'} \quad \begin{cases} M = a_1, a_2, \dots \\ M' = a'_1, a'_2, \dots \end{cases} \end{aligned}$$

Dadurch wird ersichtlich ein Homomorphismus definiert, denn es gilt für $a \rightarrow a'$ und $b \rightarrow b'$ stets $a \leq b \Rightarrow a' \leq b'$.

Jede Herleitung von $a \leq b$ beweist nämlich sofort auch $a' \leq b'$, da die Herleitungsschritte a) - g) in jedem orthokomplementären ω -vollständigen Halbverband stets richtig sind.

§ 3. Um aus dem im § 2 bewiesenen Satz die Widerspruchsfreiheit der reinen Zahlentheorie mit vollständiger Induktion beweisen zu können, benutzen wir die folgende Formalisierung. Als Primformeln nehmen wir die Zeichen für zahlentheoretische Prädikate A(...), B(...), ... mit den Zahlen 1, 1', 1'', ... als Argumenten, z. B. $1 = 1''$, $1 + 1 = 1'$.

Diese Primformeln $\mathfrak{P}, \mathfrak{Q}, \dots$ bilden eine halbgeordnete Menge, wenn wir $\mathfrak{P} \rightarrow \mathfrak{Q}$ setzen, falls das Prädikat \mathfrak{P} das Prädikat \mathfrak{Q} impliziert. Zu den Grundrelationen $\mathfrak{P} \rightarrow \mathfrak{Q}$ nehmen wir auch noch die Relationen der Form $\rightarrow \mathfrak{P}$, $\mathfrak{P} \rightarrow , \rightarrow$ hinzu, soweit sie inhaltlich richtig sind.

Über dieser halbgeordneten Menge P der Primformeln konstruieren wir jetzt wie in § 2 den ausgezeichneten orthokomplementären ω -vollständigen Halbverband. Wir benutzen dazu die logistischen Zeichen, also \rightarrow statt \leq , $\&$ statt \wedge .

of a relation $p \leq q$ can thus use only the rules d) and g). But with these only the basic relations are derivable.

For the proof of our theorem, it remains now in addition to show that K may be mapped homomorphically into every other orthocomplemented ω -complete semilattice K' that contains P as part⁹. This mapping we define by

1) for prime elements p holds $p \rightarrow p$,

2) moreover is to hold

$$\begin{aligned} a \rightarrow a', b \rightarrow b' &\Rightarrow a \wedge b \rightarrow a' \wedge b' \\ a \rightarrow a' &\Rightarrow \bar{a} \rightarrow \bar{a}' \\ a_n \rightarrow a'_n &\Rightarrow \bigwedge_M \rightarrow \bigwedge_{M'} \quad \begin{cases} M = a_1, a_2, \dots \\ M' = a'_1, a'_2, \dots \end{cases} \end{aligned}$$

Hereby obviously a homomorphism is being defined, for with $a \rightarrow a'$ and $b \rightarrow b'$ always holds $a \leq b \Rightarrow a' \leq b'$.

Every derivation of $a \leq b$ proves in fact at once also $a' \leq b'$, as the derivation steps $a)-g)$ are always correct in every orthocomplemented ω -complete semilattice.

§ 3. In order to be able to prove the freedom from contradiction of elementary number theory with complete induction from the theorem proved in § 2, we use the following formalisation. We take as prime formulas the signs for number-theoretic predicates $A(\dots)$, $B(\dots)$, ... with the numbers $1, 1', 1'', \dots$ as arguments, e.g. $1 = 1''$, $1 + 1 = 1'$.

These prime formulas $\mathfrak{P}, \mathfrak{Q}, \dots$ form a partially ordered set if we set $\mathfrak{P} \rightarrow \mathfrak{Q}$ in case the predicate \mathfrak{P} implies the predicate \mathfrak{Q} . To the basic relations $\mathfrak{P} \rightarrow \mathfrak{Q}$ we are also adding the relations of the form $\rightarrow \mathfrak{P}$, $\mathfrak{P} \rightarrow , \rightarrow ,$ as far as they are correct in terms of content.

Over this partially ordered set P of the prime formulas, we construct now as in § 2 the distinguished orthocomplemented ω -complete semilattice. We use for this the logistic signs, thus \rightarrow instead of \leq , $\&$ instead of \wedge .

To the formulas belong thus the prime formulas, with \mathfrak{A} and \mathfrak{B} also $\mathfrak{A} \& \mathfrak{B}$, with \mathfrak{A} also $\bar{\mathfrak{A}}$. We restrict the conjunction of countable¹⁰ sequences to the sequences of the form $\mathfrak{A}(1), \mathfrak{A}(1'), \dots$. We designate this conjunction by $(\mathfrak{x}) \mathfrak{A}(\mathfrak{x})$.

Zu den Formeln gehören also die Primformeln, mit \mathfrak{A} und \mathfrak{B} auch $\mathfrak{A} \& \mathfrak{B}$, mit \mathfrak{A} auch $\overline{\mathfrak{A}}$. Die Konjunktion abzählbarer¹⁰ Folgen beschränken wir auf die Folgen der Form $\mathfrak{A}(1), \mathfrak{A}(1'), \dots$ Diese Konjunktion bezeichnen wir durch $(\mathfrak{x})\mathfrak{A}(\mathfrak{x})$.

Ferner führen wir noch freie Variable $\mathfrak{a} = a, b, \dots$ ein durch folgende Schlußregel:

sind $A(1), A(1'), \dots$ herleitbare Relationen, so soll auch $A(\mathfrak{a})$ herleitbar sein.

Hierdurch werden die Beweise von § 2 nur unwesentlich modifiziert. Wir erhalten insgesamt einen Kalkül N mit den folgenden Schlußregeln

$$\begin{array}{ll}
 a) \frac{\mathfrak{C} \rightarrow \mathfrak{A} \quad \mathfrak{C} \rightarrow \mathfrak{B}}{\mathfrak{C} \rightarrow \mathfrak{A} \& \mathfrak{B}} & d) \frac{\mathfrak{A} \rightarrow \mathfrak{C}}{\mathfrak{A} \& \mathfrak{B} \rightarrow \mathfrak{C}} \\
 b) \frac{\mathfrak{A} \& \mathfrak{C} \rightarrow}{\mathfrak{C} \rightarrow \overline{\mathfrak{A}}} & e) \frac{\mathfrak{A} \rightarrow \mathfrak{B}}{\mathfrak{A} \& \overline{\mathfrak{B}} \rightarrow \mathfrak{C}} \\
 c) \frac{\mathfrak{C} \rightarrow \mathfrak{A}(1) \quad \dots \quad \mathfrak{C} \rightarrow \mathfrak{A}(n) \quad \dots}{\mathfrak{C} \rightarrow (\mathfrak{x})\mathfrak{A}(\mathfrak{x})} & f) \frac{\mathfrak{A}(n) \& \mathfrak{B} \rightarrow \mathfrak{C}}{(\mathfrak{x})\mathfrak{A}(\mathfrak{x}) \& \mathfrak{B} \rightarrow \mathfrak{C}} \\
 g) \frac{\mathfrak{A} \& \mathfrak{A} \& \mathfrak{B} \rightarrow \mathfrak{C}}{\mathfrak{A} \& \mathfrak{B} \rightarrow \mathfrak{C}} & \\
 h) \frac{\mathfrak{A} \& \mathfrak{B} \rightarrow \mathfrak{C}}{\mathfrak{B} \& \mathfrak{A} \rightarrow \mathfrak{C}} & i) \frac{\mathfrak{A} \& (\mathfrak{B} \& \mathfrak{C}) \rightarrow \mathfrak{D}}{(\mathfrak{A} \& \mathfrak{B}) \& \mathfrak{C} \rightarrow \mathfrak{D}} \\
 j) \frac{\mathfrak{A}(1) \quad \dots \quad \mathfrak{A}(n) \quad \dots}{A(\mathfrak{a})} & |^{11}
 \end{array}$$

Die Schlußregeln *h)* und *i)* waren in § 2 überflüssig, da wir dort $a \wedge b \wedge c \dots$ sofort als Zeichen für die Kombination von a, b, c, \dots eingeführt haben.

Der Beweis in § 2 liefert jetzt das folgende Ergebnis: Der Kalkül N ist widerspruchsfrei, z. B. ist die leere Relation \rightarrow nicht herleitbar, da nur die inhaltlich richtigen Relationen in P gelten und P ein Teil von N ist. Zu dem Kalkül N können die folgenden Schlußregeln hinzugenommen werden, ohne daß die Menge der herleitbaren Relationen vergrößert wird:

$$\begin{array}{ll}
 k) \frac{\mathfrak{A} \rightarrow \mathfrak{B} \quad \mathfrak{B} \rightarrow \mathfrak{C}}{\mathfrak{A} \rightarrow \mathfrak{C}} & \\
 l) \frac{\mathfrak{C} \rightarrow \mathfrak{A} \& \mathfrak{B}}{\mathfrak{C} \rightarrow \mathfrak{A}} & m) \frac{\mathfrak{C} \rightarrow \mathfrak{A} \& \mathfrak{B}}{\mathfrak{C} \rightarrow \mathfrak{B}} \\
 n) \frac{\mathfrak{C} \rightarrow \overline{\mathfrak{A}}}{\mathfrak{A} \& \mathfrak{C} \rightarrow} & o) \frac{\mathfrak{C} \rightarrow (\mathfrak{x})\mathfrak{A}(\mathfrak{x})}{\mathfrak{C} \rightarrow \mathfrak{A}(n)}
 \end{array}$$

Moreover, we introduce in addition free variables $\mathfrak{a} = a, b, \dots$ by the following rule of inference:

if $A(1), A(1'), \dots$ are derivable relations, then
 $A(\mathfrak{a})$ is also to be derivable.

By this the proofs of § 2 are only modified unessentially. We obtain overall a calculus N with the following rules of inference

$$\begin{array}{ll}
a) \frac{\mathfrak{C} \rightarrow \mathfrak{A} \quad \mathfrak{C} \rightarrow \mathfrak{B}}{\mathfrak{C} \rightarrow \mathfrak{A} \& \mathfrak{B}} & d) \frac{\mathfrak{A} \rightarrow \mathfrak{C}}{\mathfrak{A} \& \mathfrak{B} \rightarrow \mathfrak{C}} \\
b) \frac{\mathfrak{A} \& \mathfrak{C} \rightarrow}{\mathfrak{C} \rightarrow \overline{\mathfrak{A}}} & e) \frac{\mathfrak{A} \rightarrow \mathfrak{B}}{\mathfrak{A} \& \overline{\mathfrak{B}} \rightarrow \mathfrak{C}} \\
c) \frac{\mathfrak{C} \rightarrow \mathfrak{A}(1) \quad \dots \quad \mathfrak{C} \rightarrow \mathfrak{A}(n) \quad \dots}{\mathfrak{C} \rightarrow (\mathfrak{x}) \mathfrak{A}(\mathfrak{x})} & f) \frac{\mathfrak{A}(n) \& \mathfrak{B} \rightarrow \mathfrak{C}}{(\mathfrak{x}) \mathfrak{A}(\mathfrak{x}) \& \mathfrak{B} \rightarrow \mathfrak{C}} \\
g) \frac{\mathfrak{A} \& \mathfrak{A} \& \mathfrak{B} \rightarrow \mathfrak{C}}{\mathfrak{A} \& \mathfrak{B} \rightarrow \mathfrak{C}} & \\
h) \frac{\mathfrak{A} \& \mathfrak{B} \rightarrow \mathfrak{C}}{\mathfrak{B} \& \mathfrak{A} \rightarrow \mathfrak{C}} & i) \frac{\mathfrak{A} \& (\mathfrak{B} \& \mathfrak{C}) \rightarrow \mathfrak{D}}{(\mathfrak{A} \& \mathfrak{B}) \& \mathfrak{C} \rightarrow \mathfrak{D}} \\
j) \frac{A(1) \quad \dots \quad A(n) \quad \dots}{A(\mathfrak{a})} & |^{11}
\end{array}$$

The rules of inference *h*) and *i*) were dispensable in § 2, as we have introduced there $a \wedge b \wedge c \dots$ at once as sign for the combination of a, b, c, \dots

The proof in § 2 yields now the following result: the calculus N is consistent, e.g. the empty relation \rightarrow is not derivable, as only the relations correct in terms of content hold in P and P is a part of N. To the calculus N the following rules of inference can be added without increasing the set the derivable relations:

$$\begin{array}{ll}
k) \frac{\mathfrak{A} \rightarrow \mathfrak{B} \quad \mathfrak{B} \rightarrow \mathfrak{C}}{\mathfrak{A} \rightarrow \mathfrak{C}} & \\
l) \frac{\mathfrak{C} \rightarrow \mathfrak{A} \& \mathfrak{B}}{\mathfrak{C} \rightarrow \mathfrak{A}} & m) \frac{\mathfrak{C} \rightarrow \mathfrak{A} \& \mathfrak{B}}{\mathfrak{C} \rightarrow \mathfrak{B}} \\
n) \frac{\mathfrak{C} \rightarrow \overline{\mathfrak{A}}}{\mathfrak{A} \& \mathfrak{C} \rightarrow} & o) \frac{\mathfrak{C} \rightarrow (\mathfrak{x}) \mathfrak{A}(\mathfrak{x})}{\mathfrak{C} \rightarrow \mathfrak{A}(n)}
\end{array}$$

To the basic relations can be added $\mathfrak{A} \rightarrow \mathfrak{A}$.

This result from § 2 we can now complete:

Zu den Grundrelationen kann $\mathfrak{A} \rightarrow \mathfrak{A}$ hinzugenommen werden.

Dieses Ergebnis aus § 2 können wir jetzt ergänzen:

- 1) es kann auch die Schlußregel $p) \frac{A(\mathfrak{a})}{A(n)}$ hinzugenommen werden.

Der Beweis wird wieder durch eine *transfinite Prämisseinduktion* geführt.
Ist $A(\mathfrak{a})$ herleitbar in N und ist die letzte Schlußregel dieser Herleitung nicht

$$\frac{A(1) \quad \dots \quad A(n) \quad \dots}{A(\mathfrak{a})}$$

so hat die Prämisse die Form $A'(\mathfrak{a})$. Nehmen wir als Induktionsvoraussetzung an, daß für jede Prämisse $A'(\mathfrak{a})$ auch $A'(n)$ herleitbar ist, so folgt sofort $A(n)$.¹²

- 2) Zu den Grundrelationen darf $\overline{\mathfrak{A}} \rightarrow \mathfrak{A}$ hinzugenommen werden.

Für jede Primformel \mathfrak{P} gilt nämlich stets $\rightarrow \mathfrak{P}$ oder $\mathfrak{P} \rightarrow$. Wegen $\frac{\mathfrak{P} \rightarrow}{\overline{\mathfrak{P}} \rightarrow \mathfrak{P}}$ ist also für jede Primformel stets $\overline{\overline{\mathfrak{P}}} \rightarrow \mathfrak{P}$ herleitbar. Hieraus folgt $\overline{\overline{\mathfrak{P}}} \rightarrow \mathfrak{P}$

allgemein die Herleitbarkeit von $\overline{\overline{\mathfrak{A}}} \rightarrow \mathfrak{A}$ (vergl. etwa Hilbert-Bernays, *Grundlagen der Mathematik II*).

- 3) Es kann auch die *vollständige Induktion*

$$q) \frac{\mathfrak{A}(\mathfrak{a}) \rightarrow \mathfrak{A}(\mathfrak{a}')}{\mathfrak{A}(1) \rightarrow \mathfrak{A}(\mathfrak{b})}$$

zu den Schlußregeln hinzugenommen werden ohne die Menge der herleitbaren Relationen zu vergrößern.

Ist nämlich $\mathfrak{A}(\mathfrak{a}) \rightarrow \mathfrak{A}(\mathfrak{a}')$ herleitbar, so auch die Relation $\mathfrak{A}(n) \rightarrow \mathfrak{A}(n')$ für jede Zahl n .

Für jede Zahl m folgt daraus durch m -malige Anwendung der Schlußregel $k)$ sofort $\mathfrak{A}(1) \rightarrow \mathfrak{A}(m)$.

Wegen $\frac{\mathfrak{A}(1) \rightarrow \mathfrak{A}(1) \quad \dots \quad \mathfrak{A}(1) \rightarrow \mathfrak{A}(m) \quad \dots}{\mathfrak{A}(1) \rightarrow \mathfrak{A}(\mathfrak{b})}$ ist also auch $\mathfrak{A}(1) \rightarrow \mathfrak{A}(\mathfrak{b})$ herleitbar.

Damit ist die Wf. der reinen Zahlentheorie bewiesen, da die insgesamt zulässigen Schlußregeln einen Kalkül definieren, der den klassischen Prädikatenkalkül ersichtlich enthält.

- 1) The rule of inference $p) \frac{A(a)}{A(n)}$ can also be added.

The proof is again being led by a *transfinite premiss induction*. If $A(a)$ is derivable in N and if the last rule of inference of this derivation is not

$$\frac{A(1) \quad \dots \quad A(n) \quad \dots}{A(a)}$$

then the premiss has the form $A'(a)$. If we assume as induction hypothesis that for every premiss $A'(a)$ also $A'(n)$ is derivable, then $A(n)$ follows at once.^[12]

- 2) To the basic relations may be added $\overline{\overline{\mathfrak{A}}} \rightarrow \mathfrak{A}$.

For every prime formula \mathfrak{P} holds in fact always $\rightarrow \mathfrak{P}$ or $\mathfrak{P} \rightarrow$. Because of

$$\frac{\rightarrow \mathfrak{P}}{\overline{\overline{\mathfrak{P}}} \rightarrow \mathfrak{P}} \quad \frac{\mathfrak{P} \rightarrow}{\overline{\overline{\mathfrak{P}}} \rightarrow \mathfrak{P}}, \quad \overline{\overline{\mathfrak{P}}} \rightarrow \mathfrak{P} \text{ is thus always derivable for every prime formula.}$$

From this follows in general the derivability of $\overline{\overline{\mathfrak{A}}} \rightarrow \mathfrak{A}$ (cf. e.g. Hilbert-Bernays, *Grundlagen der Mathematik II*).

- 3) The *complete induction*

$$q) \frac{\mathfrak{A}(a) \rightarrow \mathfrak{A}(a')}{\mathfrak{A}(1) \rightarrow \mathfrak{A}(b)}$$

can also be added to the rules of inference without increasing the set the derivable relations.

In fact, if $\mathfrak{A}(a) \rightarrow \mathfrak{A}(a')$ is derivable, then also the relation $\mathfrak{A}(n) \rightarrow \mathfrak{A}(n')$ for every number n .

For every number m follows therefrom at once $\mathfrak{A}(1) \rightarrow \mathfrak{A}(m)$ by m -fold application of the rule of inference k).

Because of $\frac{\mathfrak{A}(1) \rightarrow \mathfrak{A}(1) \quad \dots \quad \mathfrak{A}(1) \rightarrow \mathfrak{A}(m) \quad \dots}{\mathfrak{A}(1) \rightarrow \mathfrak{A}(b)}$ also $\mathfrak{A}(1) \rightarrow \mathfrak{A}(b)$ is thus derivable.

Thereby the freedom from contradiction of the elementary number theory is proved, as the overall admissible rules of inference define a calculus that obviously contains the classical calculus of predicates.
