Abstract. Nowadays, the usefulness of a formal language for ensuring the consistency of requirements is well established. The work presented here is part of the definition of a formally-grounded, model-based requirements engineering method for critical and complex systems. Requirements are captured through the *SysML/KAOS* method and the targeted formal specification is written using the *Event-B* method. Firstly, an *Event-B* skeleton is produced from the goal hierarchy provided by the *SysML/KAOS* goal model. This skeleton is then completed in a second step by the Event-B specification obtained from system application domain properties that gives rise to the system structure. Considering that the domain is represented using ontologies through the *SysML/KAOS Domain Model* method, is it possible to automatically produce the structural part of system Event-B models ? This paper proposes a set of generic rules that translate *SysML/KAOS* domain ontologies into an Event-B specification. They are illustrated through a case study dealing with a landing gear system. Our proposition makes it possible to automatically obtain, from a representation of the system application domain in the form of ontologies, the structural part of the Event-B specification which will be used to formally validate the consistency of system requirements.

Keywords: *Event-B*, Domain Modeling, Ontologies, Requirements Engineering, *SysML/KAOS*, Formal Validation

1 Introduction

This article focuses on the development of systems in critical areas such as railway or aeronautics. The implementation of such systems, in view of their complexity, requires several validation steps, more or less formal⁴, with regard to the current regulations. Our work is part of the *FORMOSE* project [4] which integrates industrial partners involved in the implementation of critical systems for which the regulation imposes formal validations. The contribution presented in this paper represents a straight continuation of our research work on the formal specification of systems whose requirements are captured with *SysML/KAOS* goal models. The *Event-B* method [1] has been chosen for the formal validation steps because it involves simple mathematical concepts and has a powerful refinement logic facilitating the separation of concerns. Furthermore, it is supported by many industrial tools. In [15], we have defined translation rules to produce an Event-B specification from *SysML/KAOS* goal models. Nevertheless, the generated Event-B specification does not contain the system state. This is why in [14], we have presented the use of ontologies and *UML* class and object diagrams for domain properties representation and have also introduced a first attempt to complete the Event-B model with specifications obtained from the translation of these domain representations. Unfortunately, the proposed approach raised several concerns such as the use of several modeling formalisms for the representation of domain knowledge or the disregard of variable entities. In addition, the proposed translation rules did not take into account several elements of the domain model such as data sets or predicates. We have therefore proposed in [20] a formalism for domain knowledge representation through ontologies. This paper is specifically concerned with establishing correspondence links between this new formalism called *SysML/KAOS Domain Modeling* and *Event-B*. The proposed approach allows a high-level modeling of domain properties

⁴ through formal methods

by encapsulating the difficulties inherent in the manipulation of formal specifications. This facilitates system constraining and enables the expression of more precise and complete properties. The approach also allows further reuse and separation of concerns.

The remainder of this paper is structured as follows: Section 2 briefly describes our abstraction of the *Event-B* specification language, the SysML/KAOS requirements engineering method, the formalization in Event-B of SysML/KAOS goal models and the SysML/KAOS domain modeling formalism. Follows a presentation, in Section 3, of the relevant state of the art on the formalization of domain knowledge representations. In Section 4, we describe and illustrate our matching rules between domain models and Event-B specifications. Finally, Section 5 reports our conclusions and discusses our future work.

2 Formalism Overviews

2.1 Event-B

Event-B is an industrial-strength formal method defined by *J. R. Abrial* in 2010 for *system modeling* [1]. It is used to prove the preservation of safety invariants about a system. *Event-B* is mostly used for the modeling of closed systems: the modeling of the system is accompanied by that of its environment and of all interactions likely to occur between them.

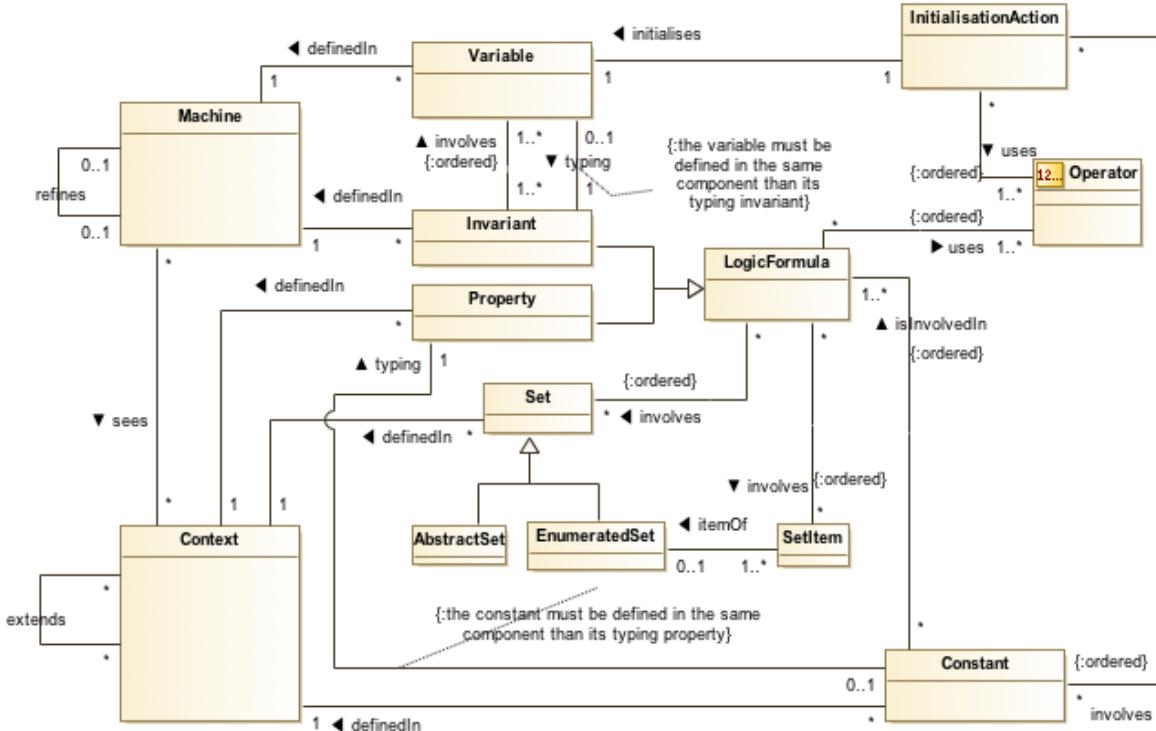

Fig. 1. Our abstraction of the Event-B specification language

Figure 1 is an excerpt from our abstraction of the *Event-B* specification language restricted and adjusted to fulfill the expression of our formalization rules. We have represented in orange some categories that do not appear explicitly in *Event-B* specifications, but which will be useful to better describe our formalization rules. An *Event-B* model includes a static part called ***Context*** and a dynamic part called ***Machine***. The ***context*** contains the definitions of abstract and enumerated sets, constants and properties. An enumerated set is constructed by specifying its items which are instances of **SetItem**. The system state is represented

in the **machine** using variables constrained through invariants and initialised through initialisation actions. Moreover, a machine can see contexts. Properties and invariants can be categorised as instances of **LogicFormula**. An instance of **LogicFormula** consists of a certain number of operators applied, according to their order of appearance, on the operands that may be variables, constants, sets or set items, following their associated order of appearance. An instance of **InitialisationAction** references the operator and the operands of the assignment. We describe here some operators and their actions :

- **Inclusion_OP** is used to assert that the first operand is a subset of the second operand :
 $(Inclusion_OP, [op_1, op_2]) \Leftrightarrow op_1 \subset op_2.$
- **Belonging_OP** is used to assert that the first operand is an element of the second operand :
 $(Belonging_OP, [op_1, op_2]) \Leftrightarrow op_1 \in op_2.$
- **RelationSet_OP** is used to construct the set of relations between two operands :
 $(RelationSet_OP, [op_1, op_2, op_3]) \Leftrightarrow op_1 = op_2 \leftrightarrow op_3.$
- **FunctionSet_OP** is used to construct the set of functional relations between two operands :
 $(FunctionSet_OP, [op_1, op_2, op_3]) \Leftrightarrow op_1 = op_2 \rightarrow op_3.$
- **Maplet_OP** is used to construct a maplet having the operands as antecedent and image :
 $(Maplet_OP, [op_1, op_2, op_3]) \Leftrightarrow op_1 = op_2 \mapsto op_3.$
- **RelationComposition_OP** is used to assert that the first operand is the result of the composition of the second operand by the third operand :
 $(RelationComposition_OP, [op_1, op_2, op_3]) \Leftrightarrow op_1 = op_2 \circ op_3.$
- **Equal2SetOf_OP** is used to define the elements constituting a set :
 $(Equal2SetOf_OP, [op_1, op_2, \dots, op_n]) \Leftrightarrow op_1 = \{op_2, \dots, op_n\}.$
- **Inversion_OP** is used to assert that the first operand is the inverse of the second operand :
 $(Inversion_OP, [op_1, op_2]) \Leftrightarrow op_1 = op_2^{-1}.$
- **Equality_OP** is used to assert that the first operand is equal to the second operand :
 $(Equality_OP, [op_1, op_2]) \Leftrightarrow op_1 = op_2.$
- **BecomeEqual2SetOf_OP** is used to initialize a variable as a set of elements :
 $(BecomeEqual2SetOf_OP, [va, op_2, \dots, op_n]) \Leftrightarrow va := \{op_2, \dots, op_n\}.$
- **BecomeEqual2EmptySet_OP** is used to initialize a variable as an empty set :
 $(BecomeEqual2EmptySet_OP, [va]) \Leftrightarrow va := \emptyset.$

The system specification can be constructed using stepwise refinement. A machine can refine another one, adding new events, reducing nondeterminacy of existing events, introducing new state variables, or replacing abstract variables by more concrete variables. Furthermore, a context can extend another one in order to access the elements defined in it and to reuse them for new constructions.

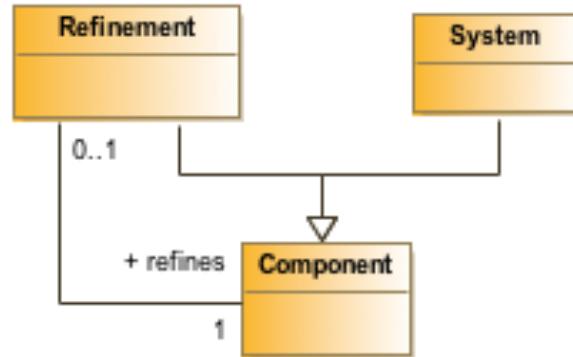

Fig. 2. B System Components

In the rest of this paper, we will illustrate our formal models using **B System**, an *Event-B* variant proposed by *ClearSy*, an industrial partner in the *FORMOSE* project, in its integrated development environment *Atelier B* [7]. A **B System** specification considers the notion of **Component** to specify machines and contexts, knowing

that a component can be a system or a refinement (figure 2). Although it is advisable to always isolate the static and dynamic parts of the *B System* formal model, it is possible to define the two parts within the same component, for simplification purposes. In the following sections, our *B System* models will be presented using this facility.

2.2 SysML/KAOS Requirements Engineering Method

Requirements engineering focuses on defining and handling requirements. These and all related activities, in order to be carried out, require the choice of an adequate means for requirements representation. The *KAOS* method [13,14], proposes to represent the requirements in the form of goals, which can be *functional* or *non-functional*, through five sub-models of which the two main ones are : **the object model** which uses the *UML* class diagram for the representation of domain vocabulary and **the goal model** for the determination of requirements to be satisfied by the system and of expectations with regard to the environment through a goals hierarchy. *KAOS* proposes a structured approach to obtaining the requirements based on expectations formulated by stakeholders. Unfortunately, it offers no mechanism to maintain a strong traceability between those requirements and deliverables associated with system design and implementation, making it difficult to validate them against the needs formulated.

The *SysML UML profile* has been specially designed by the Object Management Group (OMG) for the analysis and specification of complex systems and allows for the capturing of requirements and the maintaining of traceability links between those requirements and design diagrams resulting from the system design phase. Unfortunately, OMG has not defined a formal semantics and an unambiguous syntax for requirements specification. *SysML/KAOS* [10] therefore proposes to extend the *SysML* metamodel with a set of concepts allowing to represent requirements in *SysML* models as *KAOS* goals.

Figure 3 is an excerpt from the landing gear system [6] goal diagram focused on the purpose of landing gear expansion. We assume that each aircraft has one landing gear system which is equipped with three landing sets which can be each extended or retracted. We also assume that in the initial state, there is one landing gear named *LG1* which is extended and is associated to one handle named *HD1* which is down and to landing sets *LS1*, *LS2* and *LS3* which are all extended.

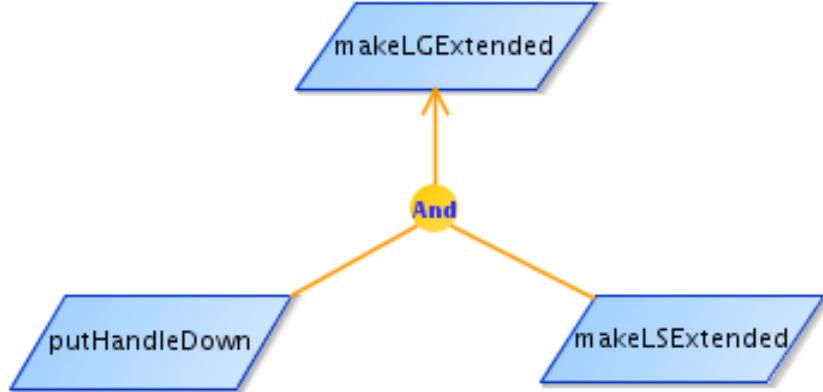

Fig. 3. Excerpt from the landing gear system goal diagram

To achieve the root goal, which is the extension of the landing gear (**makeLGExtended**), the handle must be put down (**putHandleDown**) and landing gear sets must be extended (**makeLSExtended**).

2.3 From SysML/KAOS Goal Model to Event-B

The matching between *SysML/KAOS* modeling and *Event-B* specifications is the focus of the work done by [15]. Each layer of abstraction of the goal diagram gives rise to an *Event-B* machine, each goal of the layer

giving rise to an event. The refinement links are materialized within the *Event-B* specification through a set of proof obligations and refinement links between machines and between events. Figure 4 represents the *B System* specifications associated with the most abstract layer of the *SysML/KAOS* goal diagram of the Landing Gear System illustrated through Figure 3.

```

INVARIANT
INITIALISATION
EVENTS
  makeLGExtended=
    BEGIN /* extension of the landing gear */
    END
END

```

Fig. 4. Formalization of the root level of the Landing Gear System goal model

As we can see, the state of the system and the body of events must be manually completed. The state of a system is composed of variables, constrained by an invariant, and constants, constrained by properties. The objective of our study is to automatically derive this state in the *Event-B* model starting from *SysML/KAOS* domain models.

2.4 SysML/KAOS Domain Modeling

We present, through Figures 5 and 6 the metamodel associated with the *SysML/KAOS* domain modeling approach [20] which is an ontology modeling formalism for the modeling of domain knowledge in the framework of the *SysML/KAOS* requirements engineering method.

Figure 7 represents the *SysML/KAOS* domain model associated to the root level of the landing gear system goal model of Figure 3, and Figure 8 represents the first refinement level. They are illustrated using the syntax proposed by *OWLGred* [22] and, for readability purposes, we have decided to remove optional characteristics representation. It should be noted that the *individualOf* association is illustrated by *OWLGred* within the figures as a stereotyped link with the tag «*instanceOf*». The domain model associated to the goal diagram root level is named *lg_system_ref_0* and the one associated to the first refinement level is named *lg_system_ref_1*.

Each domain model is associated with a level of refinement of the *SysML/KAOS* goal diagram and is likely to have as its parent, through the *parent* association, another domain model. This allows the child domain model to access and extend some elements defined in the parent domain model. For example, in *lg_system_ref_1* (Fig. 8), elements defined in *lg_system_ref_0* (Fig. 7) are imported and reused.

A *concept* (instance of metaclass *Concept* of Figure 5) represents a group of individuals sharing common characteristics. It can be declared *variable* (*isVariable=true*) when the set of its individuals is likely to be updated through addition or deletion of individuals. Otherwise, it is considered to be *constant* (*isVariable=false*). A concept may be associated with another, known as its parent concept, through the *parentConcept* association, from which it inherits properties. For example, in *lg_system_ref_0* (Fig. 7), a *landing gear* is modeled as an instance of Concept named "*LandingGear*". Since it is impossible to dynamically add or remove a landing gear, the attribute *isVariable* of *LandingGear* is set to *false*. *LG1* is modeled as an instance of *Individual* (Fig. 5) named "*LG1*" individual of *LandingGear*.

Instances of *Relation* are used to capture links between concepts, and instances of *Attribute* capture links between concepts and data sets, knowing that data sets (instances of *DataSet*) are used to group data values (instances of *DataValue*) having the same type. The most basic way to build an instance of *DataSet* is by listing its elements. This can be done through the *DataSet* specialization called *EnumeratedDataSet*. A relation or an attribute can be declared *variable* if the list of maplets related to it is likely to change over time. Otherwise,

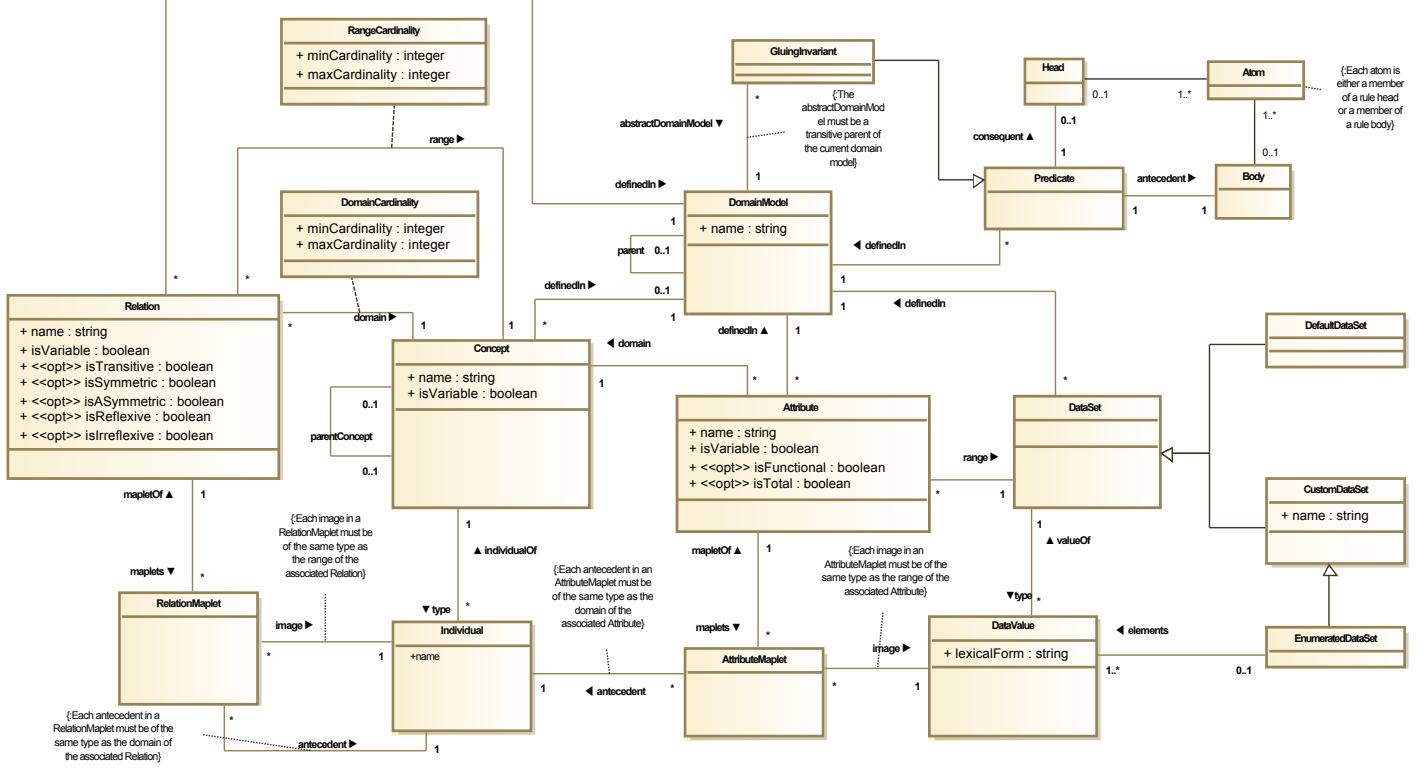

Fig. 5. Metamodel associated with SysML/KAOS domain modeling

it is considered to be *constant*. Each instance of *DomainCardinality* (respectively *RangeCardinality*) makes it possible to define, for an instance of *Relation re*, the minimum and maximum limits of the number of instances of *Individual*, having the domain (respectively range) of *re* as *type*, that can be put in relation with one instance of *Individual*, having the range (respectively domain) of *re* as *type*. The following constraint is associated with these limits : $(minCardinality \geq 0) \wedge (maxCardinality = * \vee maxCardinality \geq minCardinality)$, knowing that if $maxCardinality = *$, then the maximum limit is *infinity*. Instances of *RelationMaplet* are used to define associations between instances of *Individual* through instances of *Relation*. In an identical manner, instances of *AttributeMaplet* are used to define associations between instances of *Individual* and instances of *DataValue* through instances of *Attribute*. Optional characteristics can be specified for a relation : *transitive* (*isTransitive*, default *false*), *symmetrical* (*isSymmetric*, default *false*), *asymmetrical* (*isASymmetric*, default *false*), *reflexive* (*isReflexive*, default *false*) or *irreflexive* (*isIrreflexive*, default *false*). Moreover, an attribute can be *functional* (*isFunctional*, default *true*). For example, in *lg_system_ref_0* (Fig. 7), the possible states of a landing gear is modeled as an instance of *Attribute* named "*landingGearState*", having *LandingGear* as domain and as range an instance of *EnumeratedDataSet* containing two instances of *DataValue* of type *STRING*: "*lg_extended*" for the extended state and "*lg_retracted*" for the retracted state. Since it is possible to dynamically change a landing gear state, its *isVariable* attribute is set to *true*.

The notion of *Predicate* is used to represent constraints between different elements of the domain model in the form of *Horn clauses*: each predicate has a body which represents its *antecedent* and a head which represents its *consequent*, body and head designating conjunctions of atoms (Fig. 6). A *typing atom* is used to define the type of a term : *ConceptAtom* for individuals and *DataSetAtom* for data values. An *association atom* is used to define associations between terms : *RelationshipAtom* for the connection of two terms through a *relation*, *AttributeAtom* for the connection of two terms through an *attribute* and *DataFunctionAtom* for the connection of terms through a *data function*. A *comparison atom* is used to define comparison relationships between terms : *EqualityAtom* for equality and *InequalityAtom* for difference. Built in atoms are some specialized atoms, characterized by identifiers captured through the *AtomType* enumeration, and used for the

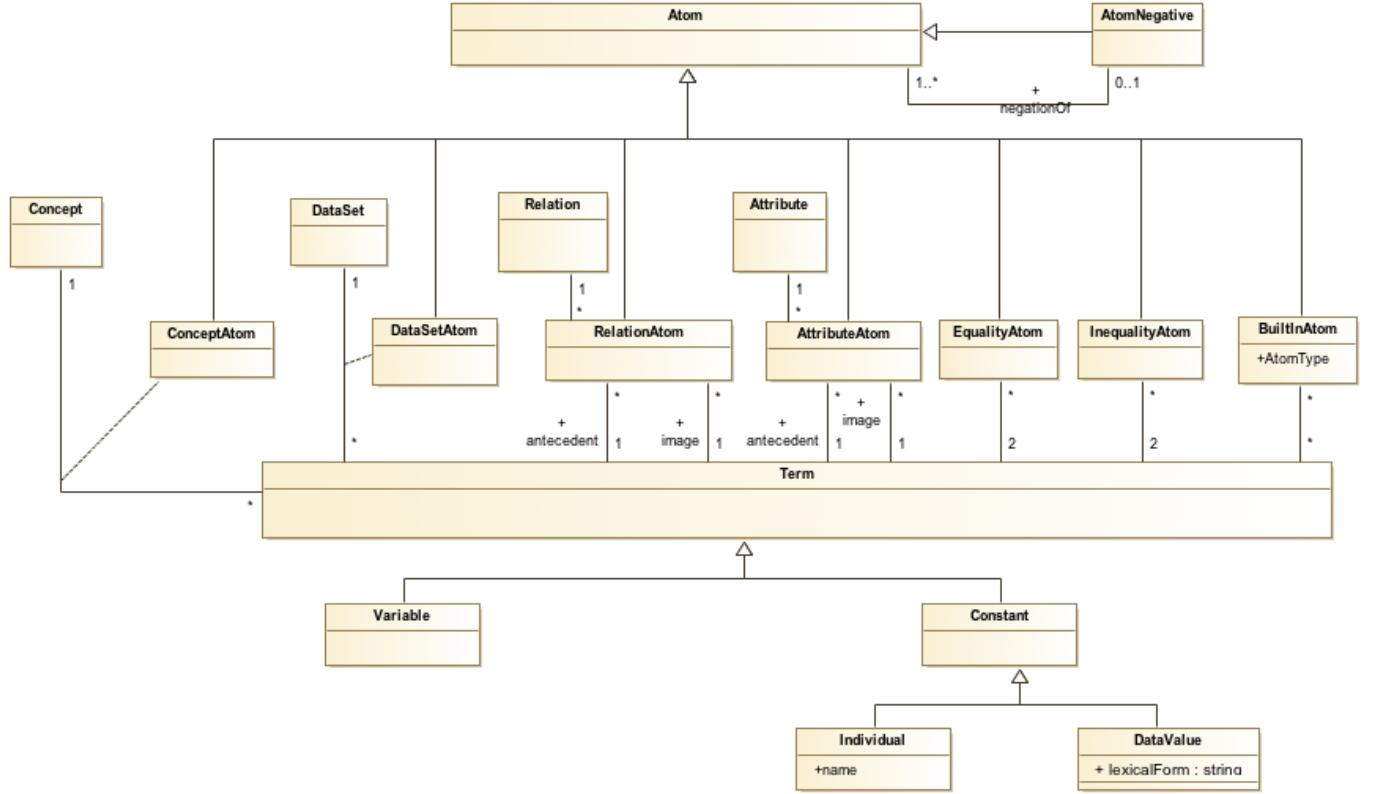

Fig. 6. Extension of the metamodel associated with SysML/KAOS domain modeling for atom specification

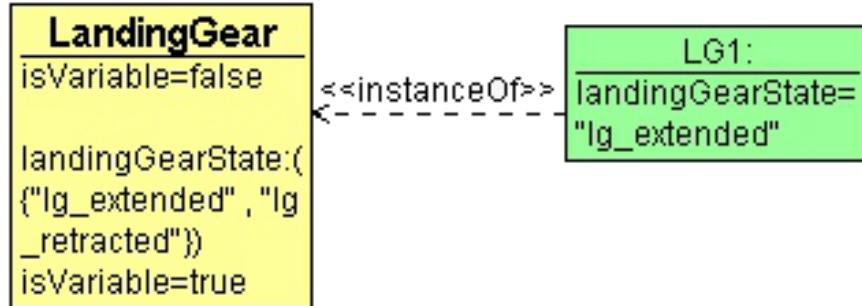

Fig. 7. *lg_system_ref_0*: ontology associated to the root level of the landing gear goal model

representation of particular constraints between several terms. For example, an arithmetic constraint between several integer data values.

GluingInvariant, specialization of Predicate, is used to represent links between variables and constants defined within a domain model and those appearing in more abstract domain models, transitively linked to it through the *parent* association. Gluing invariants are extremely important because they capture relationships between abstract and concrete data during refinement which are used to discharge proof obligations. The following gluing invariant is associated with our case study: if there is at least one landing set having the retracted state, then the state of LG1 is retracted

landingGearState(LG1, "lg_retracted") ← LandingSet(?ls) ∧ landingSetState(?ls, "ls_retracted") (inv1)

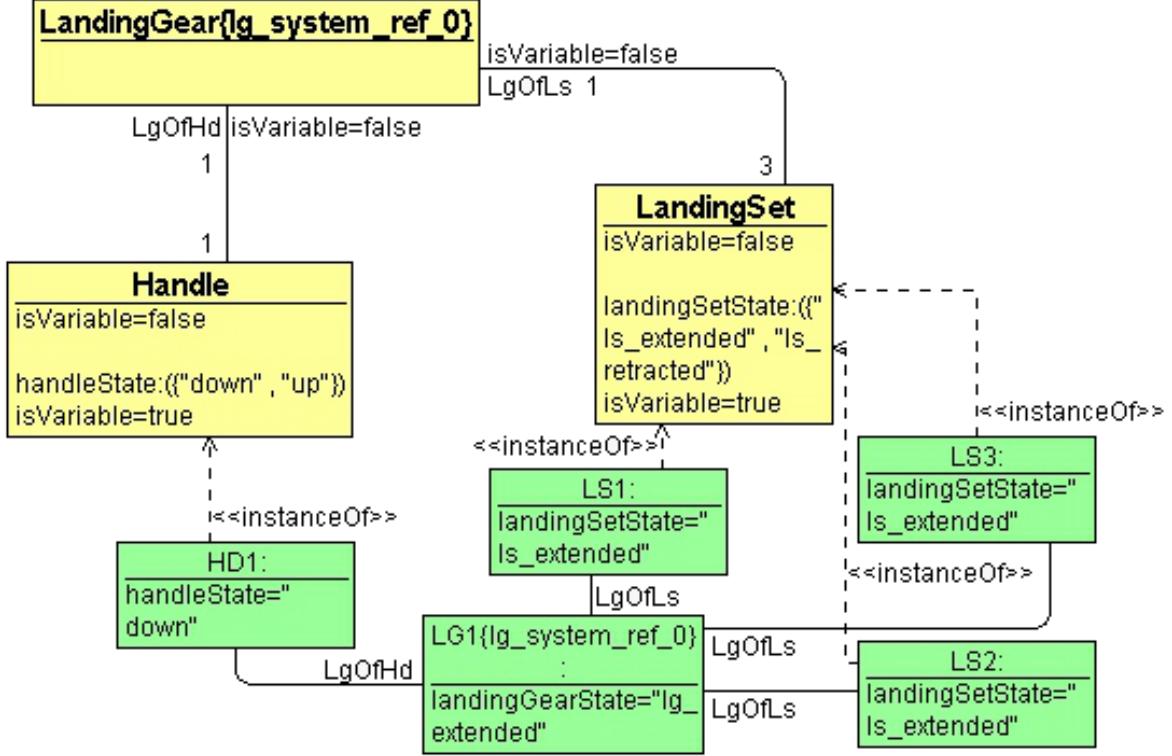

Fig. 8. *lg_system_ref_1*: ontology associated to the first level of refinement of the landing gear goal model

3 Existing Approaches for the Formalization of Domain Models

In [5], domain models consist of entities and operations which can be atomic or composite. Atomic entities correspond to states of the formal model. Composite entities correspond to sets, groups, lists or associations of entities. Furthermore, operations are translated into state-changing actions, composite operations corresponding to composition of actions. In [23], an approach is proposed for the automatic extraction of domain knowledge, as *OWL* ontologies, from *Z/Object-Z (OZ)* models [8] : OZ types and classes are transformed into *OWL* classes. Relations and functions are transformed into *OWL* properties, with the *cardinality* restricted to 1 for total functions and the *maxCardinality* restricted to 1 for partial functions. OZ constants are translated into *OWL* individuals. Rules are also proposed for subsets and state schemas. Unfortunately, the approach is only interested in static domain knowledge and it does not propose any rule regarding predicates. Furthermore, refinement links between models are not handled. A similar approach is proposed in [9], for the extraction of *DAML* ontologies [11] from *Z* models.

An approach for generating an *Event-B* specification from an *OWL* ontology [18] is provided in [3]. The proposed mapping requires the generation of an *ACE (Attempto Controlled English)* version of the *OWL* ontology which serves as the basis for the development of the *Event-B* specification. This is done through a step called *OWL verbalization*. The verbalization method, proposed by [3], transforms *OWL* instances into capitalized proper names, classes into common names, and properties into active and passive verbs. Once the verbalization process has been completed, [3] proposes a set of rules for obtaining the *Event-B* specification: classes are translated as *Event-B* sets, properties are translated as relations, etc. In addition, [3] proposes rules for the *Event-B* representation of property characteristics and associations between classes or properties. Unfortunately, the proposal makes no distinction between constant and variable : It does not specify when it is necessary to use constants or variables, when it is necessary to express an ontology rule as an invariant or as an axiom. Moreover, the proposal imposes a two-step sequence for the transition from an *OWL* ontology to an *Event-B* model, the first step requiring the ontology to be constructed in English. Finally, the approach does not propose anything regarding the referencing from an ontology into another one.

In [17], domain is modeled by defining agents, business entities and relations between them. The paper proposes rules for mapping domain models so designed in *Event-B* specifications : agents are transformed into machines, business entities are transformed into sets, and relations are transformed into *Event-B* variable relations. These rules are certainly sufficient for domain models of interest for [17], but they are very far from covering the extent of *SysML/KAOS* domain modeling formalism.

In [2], domain properties are described through data-oriented requirements for concepts, attributes and associations and through constraint-oriented requirements for axioms. Possible states of a *variable* element are represented using UML state machines. Concepts, attributes and associations arising from data-oriented requirements are modeled as UML class diagrams and translated to *Event-B* using *UML-B* [19] : nouns and attributes are represented as UML classes and relationships between nouns are represented as UML associations. *UML-B* is also used for the translation of state machines to *Event-B* variables, invariants and events. Unfortunately, constraints arising from constraint-oriented requirements are modeled using a semi-formal language called *Structured English*, following a method similar to the *Verbalization* approach described in [3] and manually translated to *Event-B*. Moreover, it is impossible to rely solely on the representation of an element of the class diagram to know if its state is likely to change dynamically. The consequence being that in an *Event-B* model, the same element can appear as a set, a constant or a variable and its properties are likely to appear both in the *PROPERTIES* and in the *INVARIANT* clauses.

Some rules for passing from an *OWL* ontology representing a domain model to *Event-B* specifications are proposed through a case study in [14]. This case study reveals that each ontology class, having no instance, is modeled as an *Event-B* abstract set. The others are modeled as an enumerated set. Finally, each object property between two classes is modeled as a constant defines as a relation. These rules allow the generation of a first version of an *Event-B* specification from a domain model ontology. Unfortunately, the case study does not address several concerns. For example, object properties are always modeled as constants, despite the fact that they may be variable. Moreover, the case study does not provide any rule for some domain model elements such as datasets or predicates. In the remainder of this paper, we propose to enrich this proposal for a complete mapping of *SysML/KAOS* domain models with *Event-B* specifications.

4 SysML/KAOS Domain Model Formalization

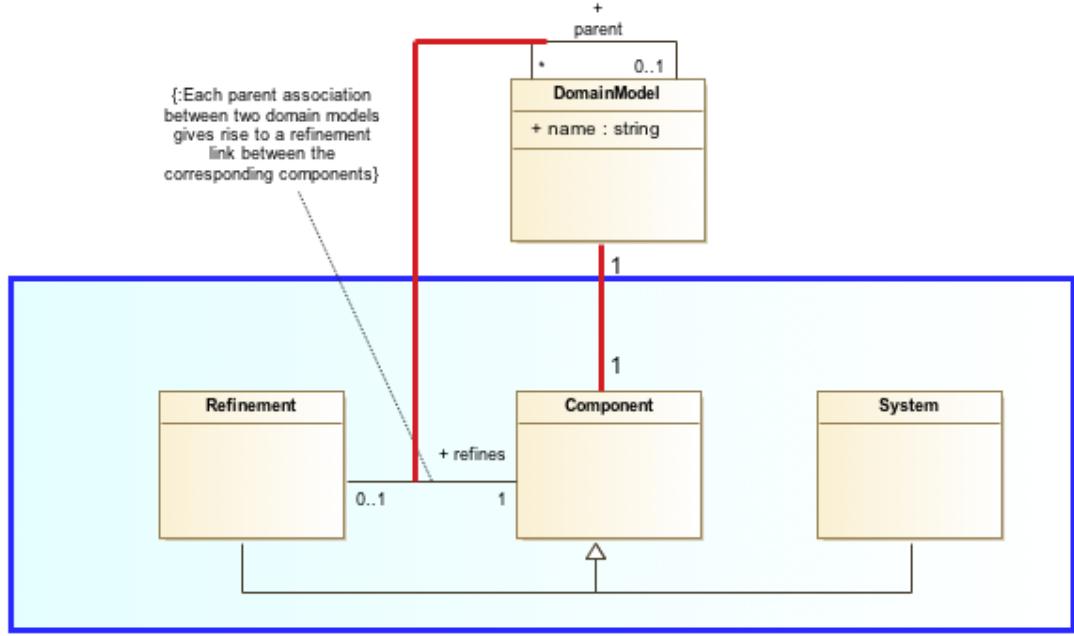

Fig. 9. Correspondence to B System Components

Figures 9, 10 , 11 and 12 are schematizations of correspondence links between domain models and Event-B formal models. Red links represent correspondence links, the part inside the blue rectangle representing the portion of the Event-B metamodel under consideration.

In the following, we describe a set of rules that allow to obtain an *Event-B* specification from domain models associated with refinement levels of a *SysML/KAOS* goal model. They are illustrated using the **B syntax** :

- Regarding the representation of metamodels, we have followed the rules proposed by [19] for the translation of *UML* class diagrams to *B* specifications: for example, classes which are not subclasses give rise to abstract sets, each class gives rise to a variable typed as a subset and containing its instances and each association or property gives rise to a variable typed as a relation. For example, *DomainModel*, *Concept*, *Relation*, *Attribute* and *DataSet* of the *SysML/KAOS* domain metamodel (*Domain_Metamodel_Context*) and *Component*, *Set*, *LogicFormula* and *Variable* of the *Event-B* metamodel (*Event_B_Metamodel_Context*) give rise to abstract sets representing all their possible instances. Variables appear to capture, for each class, all the currently defined instances. Variables are also used to represent attributes and associations such as *ParentConcept*, *Relation_isVariable*, *Attribute_isFunctional* of the *SysML/KAOS* domain metamodel and *Refines* of the *Event-B* metamodel (*event_b_specs_from_ontologies* and *event_b_specs_from_ontologies_ref_1*). In case of ambiguity as to the nomenclature of an element, its name is prefixed and suffixed by that of the class to which it is attached.
- Correspondence links between classes are represented through variables typed as partial injections having the **B** representation of the first class as domain and the **B** representation of the second class as range. For example, correspondence links between instances of *Concept* and instances of *AbstractSet* illustrated through figure 10, are captured through a variable typed as a partial injective function between *Concept* and *AbstractSet* : *Concept_corresp_AbstractSet* \in *Concept* \leftrightarrow *AbstractSet* (*event_b_specs_from_ontologies_ref_1*).
- Each rule is represented as an event by following the correspondence links.

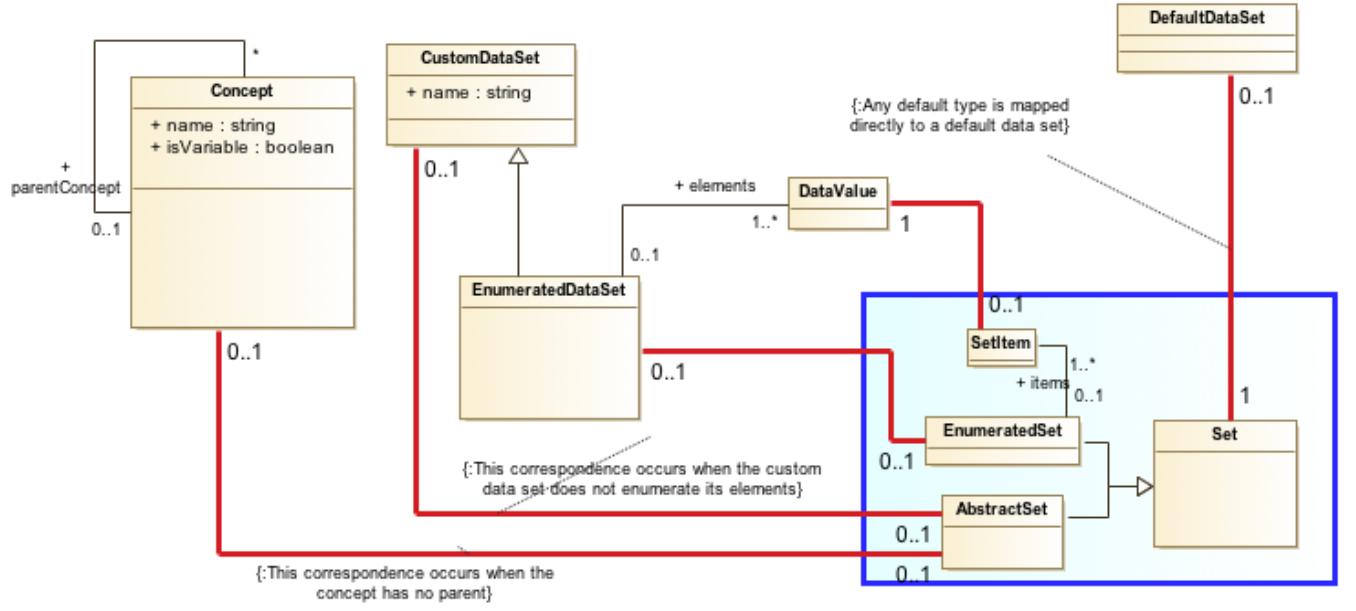

Fig. 10. Correspondence to Sets

- Whereas no additional precision is given, we consider that all *Event-B* content associated with a refinement level is defined within a single component (SYSTEM/REFINEMENT) : it is always possible to separate it into two parts: the context for the static part (SETS, CONSTANTS and PROPERTIES) and the machine for the dynamic part (VARIABLES, INVARIANT, INITIALIZATION and EVENTS).

Figures 13 and 14 represents respectively the *B System* specifications associated with the root level of the landing gear system domain model illustrated through Figure 7 and that associated with the first refinement level domain model illustrated through Figure 8.

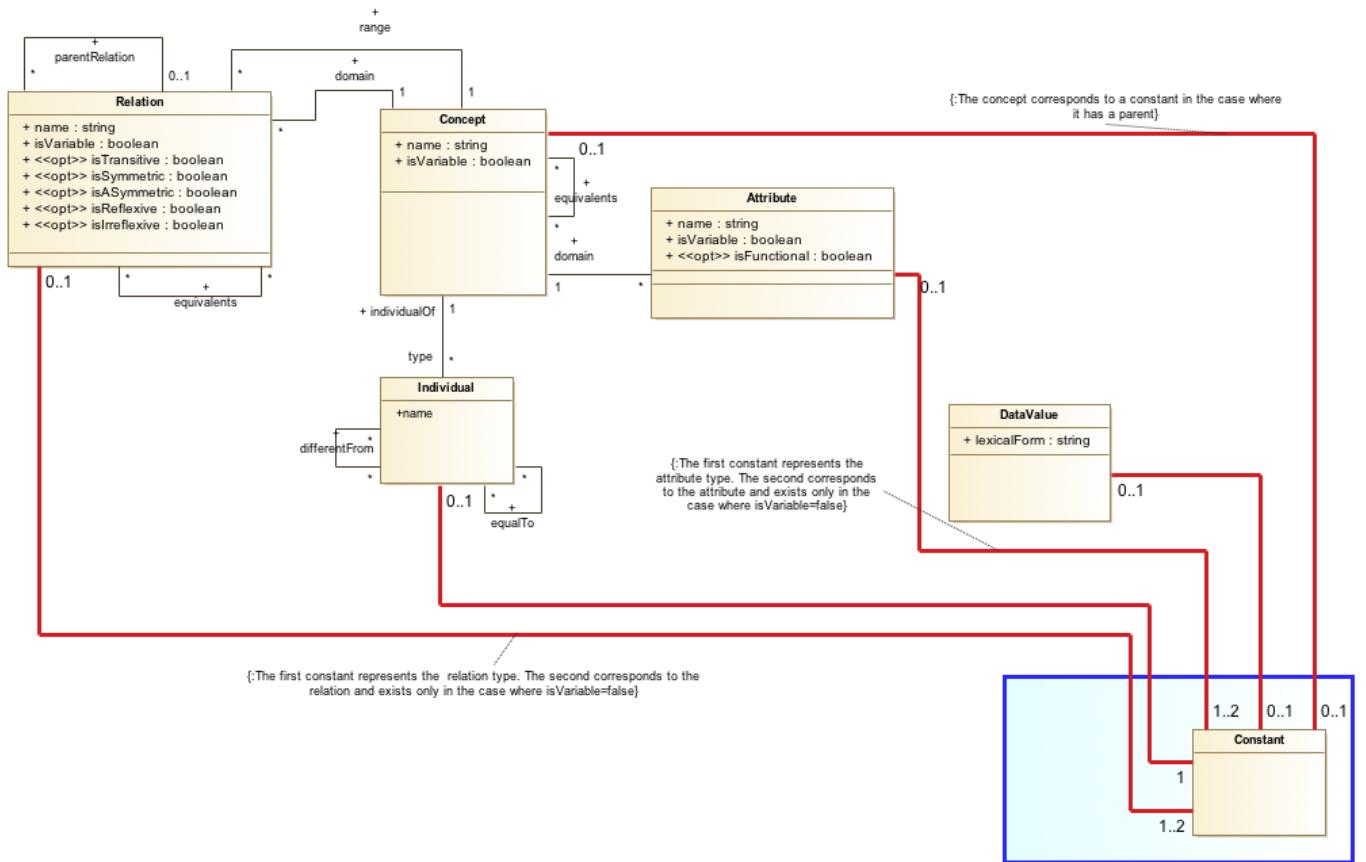

Fig. 11. Correspondence to Constants

4.1 Formalization of SysML/KAOS Domain Modeling and Event-B Formalisms

Event_B_Metamodel_Context and *Domain_Metamodel_Context* represent respectively the context associated to our abstraction of the *Event-B* specification language and that associated to the SysML/KAOS Domain Metamodel. *event_b_specs_from_ontologies* and *event_b_specs_from_ontologies_ref_1* represent the corresponding variables and the associated invariants.

SetItem_Set
LogicFormula_Set

the subset of logical formulas that can directly be expressed within the specification,
without the need for an explicit constructor, will not be contained in this set.
This is for example the case of equality between elements.

4.2 From Domain Models to Event-B Specifications

Event-B Machines and Contexts

Rule 1: Domain model without parent

MACHINE event_b_specs_from_ontologies
SEES EventB_Metamodel_Context,Domain_Metamodel_Context
Event rule_1 *(ordinary)* $\hat{=}$ correspondence of a domain model not associated to a parent domain model

any
 DM
 o_DM

where

grd0: $DomainModel \setminus (dom(DomainModel_corresp_Component) \cup dom(DomainModel_parent_DomainModel)) \neq \emptyset$

grd1: $DM \in DomainModel$
 grd2: $DM \notin dom(DomainModel_corresp_Component)$
 grd3: $DM \notin dom(DomainModel_parent_DomainModel)$
 grd4: $Component_Set \setminus Component \neq \emptyset$
 grd5: $o_DM \in Component_Set \setminus Component$

then

act1: System := System $\cup \{o_DM\}$
 act2: Component := Component $\cup \{o_DM\}$
 act3: DomainModel_corresp_Component(DM) := o_DM

end
END

Any domain model that is not associated with another domain model (Fig. 9), through the *parent* association, gives rise to a system component. **Example :** in Figure 13, the root level domain model is translated into a system component named *lg_system_ref_0*.

Rule 2: Domain model with parent

MACHINE event_b_specs_from_ontologies
SEES EventB_Metamodel_Context,Domain_Metamodel_Context
Event rule_2 *(ordinary)* $\hat{=}$ correspondence of a domain model associated to a parent domain model

any
 DM
 PDM
 o_DM

```

where
  grd0:  $\text{dom}(\text{DomainModel\_parent\_DomainModel}) \setminus \text{dom}(\text{DomainModel\_corresp\_Component}) \neq \emptyset$ 
  grd1:  $DM \in \text{dom}(\text{DomainModel\_parent\_DomainModel})$ 
  grd2:  $DM \notin \text{dom}(\text{DomainModel\_corresp\_Component})$ 
  grd3:  $\text{dom}(\text{DomainModel\_corresp\_Component}) \neq \emptyset$ 
  grd4:  $PDM \in \text{dom}(\text{DomainModel\_corresp\_Component})$ 
  grd5:  $\text{DomainModel\_parent\_DomainModel}(DM) = PDM$ 
  grd6:  $\text{Component\_Set} \setminus \text{Component} \neq \emptyset$ 
  grd7:  $o\_DM \in \text{Component\_Set} \setminus \text{Component}$ 
then
  act1:  $\text{Refinement} := \text{Refinement} \cup \{o\_DM\}$ 
  act2:  $\text{Component} := \text{Component} \cup \{o\_DM\}$ 
  act3:  $\text{Refinement\_refines\_Component}(o\_DM) := \text{DomainModel\_corresp\_Component}(PDM)$ 
  act4:  $\text{DomainModel\_corresp\_Component}(DM) := o\_DM$ 
end
END

```

A domain model associated with another one representing its parent (Fig. 9) gives rise to a refinement component. The refinement component must refine the component corresponding to the parent domain model.

Example : in Figure 14, the first refinement level domain model is translated into a refinement component named *lg_system_ref_1* refining *lg_system_ref_0*.

Event-B Sets

Rule 3: Concept without parent

```

MACHINE event_b_specs_from_ontologies_ref_1
REFINES event_b_specs_from_ontologies
SEES EventB_Metamodel_Context,Domain_Metamodel_Context
Event rule_3 (ordinary)  $\hat{=}$ 

    correspondence of a concept not associated to a parent concept
    any
        CO
        o_CO
    where
        grd0:  $Concept \setminus (dom(Concept\_parentConcept\_Concept) \cup dom(Concept\_corresp\_AbstractSet)) \neq \emptyset$ 
        grd1:  $CO \in Concept$ 
        grd2:  $CO \notin dom(Concept\_parentConcept\_Concept)$ 
        grd3:  $CO \notin dom(Concept\_corresp\_AbstractSet)$ 
        grd4:  $Concept\_definedIn\_DomainModel(CO) \in dom(DomainModel\_corresp\_Component)$ 
        grd5:  $Set\_Set \setminus Set \neq \emptyset$ 
        grd6:  $o\_CO \in Set\_Set \setminus Set$ 
    then
        act1:  $AbstractSet := AbstractSet \cup \{o\_CO\}$ 
        act2:  $Set := Set \cup \{o\_CO\}$ 
        act3:  $Concept\_corresp\_AbstractSet(CO) := o\_CO$ 
        act4:  $Set\_definedIn\_Component(o\_CO) := DomainModel\_corresp\_Component($ 
             $Concept\_definedIn\_DomainModel(CO))$ 
    end
END

```

Any concept that is not associated with another one known as its parent concept (Fig. 10), through the `parentConcept` association, gives rise to an *Event-B* abstract set. **Example :** in Figure 13, the abstract set `LandingGear` appears because of Concept instance **LandingGear**.

Rule 4: Enumerated data set

```

MACHINE event_b_specs_from_ontologies_ref_1
REFINES event_b_specs_from_ontologies
SEES EventB_Metamodel_Context,Domain_Metamodel_Context
Event rule_4 (ordinary)  $\hat{=}$

  act8: DataSet_corresp_Set := DataSet_corresp_Set  $\leftarrow$  {EDS  $\mapsto$  o_EDS}
end
END

```

Rule 5 : Custom data set not defined through an enumeration

```

MACHINE event_b_specs_from_ontologies_ref_1
REFINES event_b_specs_from_ontologies
SEES EventB_Metamodel_Context,Domain_Metamodel_Context
Event rule_5 <ordinary>  $\hat{=}$ 
  correspondence of an instance of CustomDataSet which is not an instance of EnumeratedDataSet
  any
    CS
    o_CS
  where
    grd0: CustomDataSet \ (EnumeratedDataSet  $\cup$  dom(DataSet_corresp_Set))  $\neq$   $\emptyset$ 
    grd1: CS  $\in$  CustomDataSet
    grd2: CS  $\notin$  EnumeratedDataSet
    grd3: CS  $\notin$  dom(DataSet_corresp_Set)
    grd4: DataSet_definedIn_DomainModel(CS)  $\in$  dom(DomainModel_corresp_Component)
    grd5: Set_Set \ Set  $\neq$   $\emptyset$ 
    grd6: o_CS  $\in$  Set_Set \ Set
  then
    act1: AbstractSet := AbstractSet  $\cup$  {o_CS}
    act2: Set := Set  $\cup$  {o_CS}
    act3: CustomDataSet_corresp_AbstractSet(CS) := o_CS
    act4: Set_definedIn_Component(o_CS) := DomainModel_corresp_Component(DataSet_definedIn_DomainModel(CS))
    act5: DataSet_corresp_Set := DataSet_corresp_Set  $\leftarrow$  {CS  $\mapsto$  o_CS}
  end
END

```

Any instance of *CustomDataSet*, defined through an enumeration, gives rise to an *Event-B* enumerated set. **Example :** in Figure 13, the data set {"lg_extended", "lg_retracted"}, defined in domain model represented in Figure (Fig. 7), gives rise to the enumerated set *DataSet_1* = {lg_extended, lg_retracted}.

Any instance of *DefaultDataSet* is mapped directly to an *Event-B* default data set (NATURAL, INTEGER, FLOAT, STRING or BOOL) following the *initialize_default_datasets* event.

Event-B Constants

Rule 6 : Concept with parent

```

MACHINE event_b_specs_from_ontologies_ref_1
REFINES event_b_specs_from_ontologies
SEES EventB_Metamodel_Context,Domain_Metamodel_Context

```

Any concept associated with another one known as its parent concept (Fig. 9), through the `parentConcept` association, gives rise to a constant typed as a subset of the *Event-B* element corresponding to the parent concept.

Each individual (or data value) gives rise to a constant having its name (or with his *lexicalForm* typed as value) and each instance of `CustomDataSet`, not defined through an enumeration of its elements, unlike **DataSet_1** of Figure 13, gives rise to a constant having its name. **Example :** in Figure 14, the constant named **HD1** is the correspondent of the individual **HD1**.

Each relation gives rise to a constant representing the type of its associated *Event-B* element and defined as the set of relations between the *Event-B* element corresponding to the relation domain and the one corresponding to the relation range. Moreover, if the relation has its *isVariable* attribute set to *false*, it is translated through a second constant. **Example :** in Figure 14, **LgOfHd**, for which *isVariable* is set to *false*, is translated into a constant named *LgOfHd* and having as type **T_LgOfHd** defined as the set of relations between **Handle** and **LandingGear** (assertions 1.7 and 1.8).

Similarly to relations, each attribute gives rise to a constant representing the type of its associated *Event-B* element and, in the case when `isVariable` is set to *false*, to another constant having its name. However, when the `isFunctional` attribute is set to *true*, the constant representing the type is defined as the set of functions between the *Event-B* element corresponding to the attribute domain and the one corresponding to the attribute range. The *Event-B* element corresponding to the attribute is then typed as a function.
Example : in Figure 13, `landingGearState` is typed as a function (assertions 0.3 and 0.4) since its type is the set of functions between `LandingGear` and `DataSet_1` ($\text{DataSet_1} = \{\text{lg_extended}, \text{lg_retracted}\}$).

An instance of Relation, of Concept or of Attribute, having its `isVariable` property set to *true* gives rise to a variable (Fig. 12). For a concept, the variable represents the set of *Event-B* elements having this concept as type. For a relation or an attribute, it represents the set of links between individuals (in case of relation) or between individuals and data values (in case of attribute) defined through it. **Example :** in Figure 14, variables named `landingSetState` and `handleState` appear because of Attribute instances `landingSetState` and `handleState` for which the `isVariable` property is set to *true* (Fig. 8).

Invariants and Properties In this section, we are interested in the correspondences between the domain model and the *Event-B* model that are likely to give rise to *invariants*, *properties* or *initialization* clauses.

4.3 Handling Updates on Event-B Specifications within SysML/KAOS Domain Models

Here, we are interested in handling modifications on Event-B specifications within *SysML/KAOS* domain models. We choose to support only the most repetitive operations that can be performed within the formal specification, the domain model remaining the one to be updated in case of any major changes. Currently supported operations include : addition of sets and of items in existing sets, addition of subsets of existing sets, addition of individuals and of data values, addition of relations and of attributes and finally addition of relation and of attribute maplets.

Addition of Non-Existing Sets

Rules 101-102 : addition of a new abstract set

4.4 The SysML/KAOS Domain Model Parser Tool

The correspondence rules outlined here have been implemented within an open source tool called *SysML/KAOS Domain Model Parser* [21]. It allows the construction of domain models (*Fig. 15*) and generates the corresponding *Event-B* specifications (*Fig. 16*). It is build through *Jetbrains Meta Programming System* [12], a tool to design domain specific languages using language-oriented programming.

5 Conclusion and Future Works

This paper was focused on a presentation of mapping rules between SysML/KAOS domain models and Event-B specifications illustrated through a case study dealing with a landing gear system. The specifications thus obtained can also be seen as a formal semantics for SysML/KAOS domain models. They complement the formalization of the SysML/KAOS goal model by providing a description of the state of the system.

Work in progress is aimed at integrating our approach, implemented through the *SysML/KAOS Domain Model Parser* tool, within the open-source platform *Openflexo* [16].

Acknowledgment

This work is carried out within the framework of the *FORMOSE* project [4] funded by the French National Research Agency (ANR).
