ABSTRACT

The large protein (L) of mononegaviruses is a key player of virus infection as its N-terminal region bears the RNA-dependent RNA polymerase activity, which is essential for replication/transcription, and its C-terminus contains a cap assembly line composed of a capping domain, and a methyltransferase domain followed by a C-terminal domain (CTD) of unknown function. For viruses belonging to the *Mononegavirales* order, the capping domain, which harbours a polyribonucleotidyltransferase activity, has been shown to transfer a GTP molecule to the 5' end of nascent viral RNA forming the cap structure. The MTase activity of L protein next sequentially methylates the 2'O and the N7 position of the cap structure. In addition, the MTase of *Sudan ebolavirus* (SUDV) induces also internal adenosine 2'O-methylations, which might prevent viral RNA sensing by innate immunity. In this work, we addressed the regulating role of the CTD of SUDV L protein on the MTase activity. We demonstrated that the CTD, which is enriched in basic amino acids, plays a key role in the RNA recognition. Consequently, we showed that the MTase domain is inactive when expressed in absence of CTD (MTase- Δ CTD) whereas the MTase+CTD is enzymatically active. The role of the CTD in the RNA recognition and in the regulation of the MTase activity was further confirmed by mutagenesis. We demonstrated that single mutations in the CTD domain can uncouple or abolish the different MTase activities. Altogether, our results elucidate the role of the SUDV L protein CTD domain in the RNA capping pathway, which is essential for RNA translation into viral proteins and virus escape from detection by innate immunity.

INTRODUCTION

1 Ebola virus is an emerging virus causing severe epidemics such as the unprecedented devastating
2 outbreak of 2015 in West Africa, which killed more than 11,000 people [1]. Although Ebola faded from
3 public attention, outbreaks continue to occur especially in Democratic Republic of the Congo (DRC)
4 where the current epidemic, which has been declared in August 2018, has already killed more than
5 1,000 citizens [2]. This virus infects human and non-human primates to provoke a massive viremia
6 leading to haemorrhagic fever, which is fatale in most cases. Despite a vaccine is currently in
7 development [3][4] and some therapeutic antibodies have shown antiviral activities [5], we urgently
8 need to develop new therapeutic compounds to treat infected people and contact patients.

9 *Ebolavirus* genus contains five strains: *Zaire ebolavirus* (Ebola virus, EBOV), *Sudan ebolavirus*
10 (Sudan virus, SUDV), *Tai Forest ebolavirus* (Tai Forest virus, TAFV), *Bundibugyo ebolavirus*
11 (Bundibugyo virus, BDBV), and *Reston ebolavirus* (Reston virus, RESTV). These filamentous viruses
12 together with *Marburg marburgvirus* (Marburg virus, MARV), also responsible of acute haemorrhagic
13 fever, and *Lloviu cuevavirus* form the *Filoviridae* family [6]. They are enveloped virus with non-
14 segmented negative strand RNA genome (NNS) belonging to the *Mononegavirales* order. These
15 mononegaviruses, which contain several important human pathogens such as measles, RSV and rabies
16 viruses, display similar genetic organization and share common replication strategies.

17 The genome of filoviruses is about 19 kb long and codes for seven major proteins: the nucleoprotein
18 (NP), viral proteins VP35 and VP40, the glycoprotein (GP), viral proteins VP30 and VP24 and the
19 “large” protein L [7][8]. The viral life cycle is initiated by the interaction of the GP envelope protein
20 with cell surface determinants allowing virus entry into the cell by macropinocytosis. The NP-
21 encapsidated viral genome is next released in the host cell cytoplasm where the virus replication cycle
22 is initiated. The large protein L, associated with NP, VP35 and VP30 first transcribes viral mRNAs by
23 using a discontinuous transcription mechanism that generates seven monocistronic capped and poly-
24 adenylated RNAs [9][10]. The polymerase complex initiates the mRNA synthesis at a conserved gene-
25 start (GS) sequence and transcribes the genes to the gene-stop sequence (GE) [11]. The poly-A tail is
26 then added by a slippage mechanism of the polymerase occurring in a conserved poly(U)₆ tract in the
27 GE sequence [12]. The RNA-dependent RNA polymerase (RdRp) then scans the intergenic sequences
28 and reinitiates the RNA transcription at the next GS sequence. The viral mRNAs of mononegaviruses
29 are co-transcriptionally capped by an unusual sequence of capping reactions. This process was
30 elucidated for vesicular stomatitis virus (VSV) and takes place when the nascent RNA chain has reached
31 31 nucleotides length [13]. The cap synthesis starts with the formation of a covalent adduct between a
32 conserved histidine residue of the polyribonucleotidyltransferase (PRNTase) embedded into the Cap
33 domain and the 5'-phosphate of viral mRNA. In presence of GDP, the PRNTase transfer a GMP moiety
34 to the 5'-diphosphate of the covalently bound RNA, yielding to the formation of the cap structure
35 (GpppN). The 5' cap structure is subsequently methylated at the 2'O position of the first nucleotide
36 (N1) and at the N7 position of the guanosine (^mGpppN_m or cap-1) [14]. This cap-1 structure is
37 undistinguishable from cellular caps and plays a critical role for virus replication as it protects viral

1 mRNAs from cellular 5' exonucleases and it allows the eIF4e-dependent initiation of mRNA
2 translation. Additionally, the cap-2'O methylation is a self-marker that limits the detection of infecting
3 viral RNAs by the innate immunity sensors of the retinoic acid-inducible gene-I (RIG-I) like family.
4 Thus, viruses expressing RNAs lacking cap 2'O methylation (^mGpppN-RNA or cap-0) are early
5 detected by RIG-I receptors in infected cells leading to the secretion type I interferon (INF_{α/β}).
6 Furthermore, INFs stimulate the expression of INF-stimulated genes (ISG) such as INF Induced Protein
7 with Tetratricopeptide Repeats (IFIT) that sequesters miss-capped RNAs (ie: cap-0) leading to
8 restriction of virus propagation (for review see [15]). Capping enzymes such as cap-MTases are thus
9 considered as potent antiviral targets as the inhibition of N7 MTase is supposed to limit RNA translation
10 into viral proteins and 2'O MTase inhibitors should unmask viral RNA to the intracellular self-sensors.

11 The structure of VSV L protein, recently solved by cryo-electromicroscopy (cryo-EM) at 3.8 Å,
12 reveals its organization in 5 main topological domains [16]. The RdRp, that contains three conserved
13 regions (CRI, CRII, and CRIII), is intimately associated with the PRNTase domain (CRIV) forming a
14 “donut-like” structure observed by negative staining [17]. The RdRp is organised as a right-hand
15 “fingers-palm-thumb” structure, typical of polymerases. The Cap domain (PRNTase), which harbours
16 an original fold, projects a loop near the catalytic site of the polymerase. This structural interplay
17 suggests that the PRNTase domain participates to the initiation of polymerisation similarly to
18 polymerases having a priming loop. In addition, the cryo-EM structure corroborates biochemical
19 analysis showing the interplay between RdRp and capping activities [13]. The EM studies shows that
20 the “donuts-like” structure (RdRp and PRNTase domains) is followed by 3 globular structures
21 corresponding to the connector domain (CD), the MTase domain and a small C-terminal domain (CTD),
22 respectively. The CD forms a globular domain, separating the PRNTase domain from the MTase
23 domain, which is composed of a bundle of eight helices. It is likely that the CD domain plays an
24 organizational role as it interacts with the viral P protein. Conversely, the MTase domain contains a K-
25 D-K-E catalytic tetrad, characteristic of 2'O MTases. The VSV cryo-EM structure reveals its
26 organization in a typical Rossmann fold of S-adenosyl methionine (SAM) dependent methyltransferases.
27 The 2.2 Å X-ray structure of human metapneumovirus (hMPV) MTase+CTD domain confirms the
28 methyltransferase fold with a SAM-binding site positioning the released methyl group face to the
29 catalytic tetrad (Paesen et al.). In contrast, the MTase+CTD lacks a canonical cap-binding site like
30 observed in flavivirus MTases [18][19][20]. Thus, it is likely that the RNA substrate accommodates an
31 unusually narrow RNA-binding groove formed by the MTase domain overlaid by the CTD enriched
32 in basic amino acids.

33 The MTase activity of VSV L protein was demonstrated *in vitro* for VSV L protein that sequentially
34 methylates the RNA cap structure at the ribose 2'O and the guanosine N7 positions [21]. The catalytic
35 activity of the MTase domain has been confirmed *in vitro* using MTase+CTD constructs of hMPV and
36 filovirus (SUDV) [22][23]. The MTase+CTD domains of these viruses have also been reported to

1 methylate the 2'O position of the N1 of capped and triphosphate RNAs. The subsequent methylation of
2 the N7 guanosine was evidenced using longer RNA substrates using SUDV MTase+CTD. Besides this,
3 we also demonstrated recently that the SUDV MTase and hMPV MTase (in a lesser extend) harbour a
4 cap-independent methyltransferase activity inducing internal adenosine 2'O methylations. The role of
5 such epitranscriptomic RNA modification is not yet fully understood, but similar internal 2'O
6 methylations observed inside the HIV RNA genome have been shown to protect viral RNAs from
7 detection by the RIG-like receptor Melanoma Differentiation-Associated protein 5 (MDA5) [24].
8 Altogether, these results suggest that the filovirus MTase evolved towards a dual activity with distinct
9 substrate specificities. The cap-N7 MTase activity that promotes viral protein translation, the cap-
10 dependent and independent 2'O MTase activities inducing cap 2'O methylation and internal 2'O
11 methylation limiting the viral RNA sensing by RIG-I and MDA5 respectively [25][26][27][28].

12 In this work, we addressed the functional role of the SUDV CTD domain by comparing the MTase
13 activity of MTase+CTD and MTase-ΔCTD constructs. After expression and purification of various
14 SUDV MTase constructs, we demonstrated the critical role of the CTD domain for RNA substrate
15 recognition and thereby controlling the MTase activity. The importance of CTD basic residues in RNA
16 recognition and MTase activity was confirmed by directed mutagenesis and we identified single
17 mutations uncoupling the different activities carried by SUDV MTase. These results highlight the key
18 regulation role of the CTD domain in the RNA methylation process and raise the possibility to identify
19 compounds inhibiting specifically these viral MTases by targeting the CTD.

20

21 RESULTS

22 *The CTD domain of SUDV L protein is enriched in basic amino acids and stabilizes the MTase*
23 *domain.*

24 The C-terminal part of SUDV L protein contains a conserved MTase domain including the conserved
25 region VI (CRVI) followed by a CTD domain of unknown function (**Fig. 1A**). The MTase harbours a
26 K-D-K-E catalytic tetrad, canonic of 2'O MTases, and a SAM binding GxGxG motif highlighted in the
27 multi-alignment of filovirus C-terminal part of L proteins (**Fig. S1**). The MTase domain (residues 1693
28 to 2036) is followed by the CTD (residues 2037 to 2210), which greatly varies in length within the
29 *Mononegavirales* order (from ~120 residues in *Pneumoviridae* to ~240 residues in *Rhabdoviridae*) (**Fig.**
30 **S2**). Despite this weak conservation, CTDs are enriched in basic residues in most of *Mononegavirales*.
31 Calculated isoelectric points of each CTD vary between 8.33 and 9.94 except for rubelavirus and
32 bornavirus (**Fig. S2**). The alignment of filovirus CTDs also reveals the presence of 3 strictly conserved
33 basic amino acids (arginine and lysine, indicated by *) and 2 other conserved positions with either
34 arginine or lysine residues (indicated by x) (**Fig. S1**). Two conserved aromatic residues (histidine and
35 phenylalanine, indicated by *), which might participate to RNA recruitment by interacting with

1 nucleobases by staking, are also present in the CTD. We also analysed the conservation of residues in
2 the protein alignment of the MTase+CTD domains of *Mononegavirales*. Results are represented onto
3 the hMPV structure (**Fig. 1B&C**). The conservation model indicates that the most conserved residues
4 are localized around the catalytic pocket, the SAM binding site and in a groove enriched in basic amino
5 acids previously proposed to accommodate the RNA substrate [22]. These observations together with
6 the structural analysis of hMPV MTase+CTD showing that MTase domain is overlaid by the CTD to
7 form a narrow RNA binding groove suggest that the CTD plays a key role in RNA recognition.

8 ***The CTD domain L protein is essential for the SUDV MTase activity.***

9 We expressed in bacteria the MTase adjoining the CTD (MTase+CTD) and the SUDV MTase
10 domain (MTase- Δ CTD). Both proteins were purified by affinity chromatography on NTA column
11 combined with exclusion chromatography. The purity of both proteins was assessed by SDS-PAGE
12 analysis upon Coomassie blue staining. **Fig. 2A** shows that MTase+CTD and SUDV MTase- Δ CTD
13 migrate at their expected apparent molecular weight of 58 and 39 kDa, respectively. Their identity was
14 confirmed by MALDI-TOF (not shown). Both proteins were also analysed by thermal shift assay (TSA)
15 in order to assess their folding and compare their stability (**Figure 2B**). The proteins revealed typical
16 denaturation curve of folded proteins with a T_m value of 54.3°C and 46.0°C for the MTase+CTD and
17 the MTase- Δ CTD, respectively. These data suggest that the CTD domain increases the stability of the
18 MTase domain. We next demonstrated the involvement of the CTD in the MTase activity by comparing
19 the enzymatic activity of both proteins on a capped RNA (GpppN-RNA) mimicking the conserved 5'
20 sequence of SUDV 5' transcripts. The 13-nucleotides length-capped RNA substrate was incubated with
21 both enzymes in presence of radiolabeled methyl donor (3H-SAM). The reaction products were filtered
22 through a DEAE membrane, and the radioactivity transferred to the RNA substrate was determined
23 (filter binding assay). **Fig. 2C** shows that the MTase- Δ CTD domain was not active on the short capped-
24 RNA substrate whereas the MTase+CTD domain induced the methylation of the capped-RNA
25 substrate.

26 We also compared RNA binding properties of MTase+CTD and MTase- Δ CTD proteins by
27 fluorescence polarization assay (FP). For this purpose, the capped RNA substrate was labelled at its
28 3'end by ligation of a pCp-Cy5 residue (GpppN-RNA-pCp-Cy5) and was incubated with increasing
29 concentration of MTase+CTD or MTase- Δ CTD. The interaction of RNA with both proteins was next
30 determined by FP measurement. **Fig. 2D** demonstrates that MTase- Δ CTD does not interact with the
31 capped RNA substrate. Conversely, the MTase+CTD induces an increased FP signal confirming its
32 interaction with the synthetic capped RNA substrate with a K_m value of 740 nM. Altogether, these
33 results demonstrated that the CTD domain of SUDV plays a key role in RNA recognition and, in turn,
34 promotes the MTase activity.

35 ***Effect of a single mutation of conserved residues in the SUDV CTD on the MTase activity.***

1 We previously demonstrated that the SUDV MTase+CTD induces 2'O methylation of internal
2 adenosines in addition to N7 and 2'O methylations of the cap [23]. To further characterize the role of
3 the CTD in the RNA recruitment and unravel the involvement of CTD in the regulation of the different
4 MTase activities carried by MTase+CTD, we mutated conserved residues of filoviruses (**Fig.S1**) into
5 alanine. The mutant proteins were expressed in bacteria and purified by affinity chromatography on
6 NTA column. **Figure 3A** shows that the mutated proteins migrate at a molecular weight similar to the
7 WT MTase+CTD. The mutated proteins were also analysed by TSA and show typical denaturation
8 curve of folded proteins (**Fig.S3**) with T_m value ranging from 50.6 °C to 55.6 °C (**Table 1**). **Table 1**
9 indicates that most mutants display T_m values similar to the wild-type MTase+CTD protein. In contrast,
10 we observed that the mutant R2068A has a slightly decreased melting temperature ($\Delta T_m = -3.7^\circ\text{C}$)
11 suggesting that this mutation affects the protein stability. We next tested the effect of mutations in the
12 CTD on the RNA binding properties by FP assay. We performed FP measurements using the GpppG-
13 RNA-Cy5 and mGpppGm-RNA-Cy5 SUDV-RNA (**Table 1** and **Fig. S4**). Mutations K2043A and
14 K2189A lead to an alteration of interactions between the substrate (GpppG-SUDV₁₂) and the protein
15 and a loss of recognition for the product ^mGpppGm-SUDV₁₂ ($K_d > 9\mu\text{M}$). We next tested the effect of
16 mutations on cap-dependent and cap-independent MTase activities using different RNA substrates. By
17 incubating the WT and mutated MTase+CTD proteins with either GpppG_m(A_m)-SUDV₁₂,
18 ^mGpppA(A_m)-SUDV₁₂ or ^mGpppG_m-SUDV₁₂ in presence of radiolabelled methyl donor (3H-SAM), we
19 determined the effect of CTD mutations on cap-N7 MTase, cap-2'O MTase and internal 2'O-A MTase
20 activities, respectively (**Fig. 3B**). We identified three categories of mutations. (i) Mutations leading to
21 the reduction (H2112A and F2113A) or the lost (R2068A, K2118A and K2189A) of all MTase
22 activities. Interestingly, the RNA recognition feature of R2068A, K2118A and K2189A is also strongly
23 impaired and R2068A mutation is also associated to a reduced protein stability compared to the WT
24 ($\Delta T_m - 3.7^\circ\text{C}$). (ii) Mutations decreasing the 2'O MTase activities (cap-2'O MTase and internal 2'O-A
25 MTase), but not the cap-N7 MTase activity (K2043A). This result could be correlated with the alteration
26 of recognition observed in FP, where the interaction with the RNA substrate ^mGpppG_m-SUDV₁₂ is more
27 impaired in comparison to the interaction between mutated protein and substrate GpppG-SUDV₁₂. (iii)
28 Mutation reducing more specifically the internal 2'O-A MTase activity (H2067A) than the cap-MTase
29 activities. Altogether, these results demonstrate that mutations in the SUDV CTD of L protein regulate
30 the RNA recognition and the MTase activities. We highlighted mutations uncoupling cap methylations
31 (cap-2'O MTase and cap-N7 MTase) from internal 2'O-A methylation or N7 methylation from 2'O
32 methylations (cap-2'O MTase and internal 2'O-A MTase) demonstrating that the CTD plays a key role
33 in the fine tuning of the N7 and 2'O MTase activities of the L protein.

34

35 DISCUSSION

1 The mononegavirus L protein plays a key role in replication/transcription and RNA capping. Cryo-
2 EM and biochemical studies have evidenced its organization in 5 main topological domains [16]
3 embedding the RdRp, the PRNTase and the MTase activities. Nevertheless, the role of the Connector
4 Domain (CD) and the CTD, framing the MTase domain, is still elusive. In this work, we focused on the
5 regulation role of the CTD on the SUDV MTase activities.

6 The CTD domain, the less conserved domain of mononegavirus L protein, is enriched in basic amino
7 acid suggesting their involvement in RNA recruitment. This hypothesis is also supported by the X-ray
8 structure of hMPV MTase+CTD showing that the CTD together with the MTase form a kind of
9 conserved RNA binding groove at immediate proximity of the MTase catalytic site (**Fig. 1B & C**). In
10 this work, we experimentally demonstrated that the CTD domain is essential for the RNA recognition
11 as the recognition of capped RNA is strongly impaired in absence of the CTD (**Fig. 2D**). The key role
12 of the CTD in RNA recognition was further confirmed by alanine mutagenesis of the CTD. A single
13 mutation of conserved basic and hydrophobic residues was engineered and different mutated proteins
14 were produced and purified. We next demonstrated by TSA that these mutations barely affect the
15 protein folding and stability (**Table 1**). In addition, all these single mutations decrease the recognition
16 of capped RNAs (**Table 1**), but less than observed with the MTase- Δ CTD protein. Our results indicate
17 that some mutations strongly impair the interaction with ^mGpppG_m-SUDV₁₂, more than with GpppG-
18 SUDV₁₂ (K2043A and K2189A) suggesting that these mutations might regulate in a different way the
19 MTase activity targeting the cap structure or adenosine residues within RNA sequence. Thus, all these
20 results demonstrate the crucial role of CTD conserved residues in MTase substrate recognition. These
21 data agree with the X-ray structure of hMPV and the cryo-EM structure of VSV full length protein
22 indicating that the canonical cap binding domain is virtually absent in these proteins. Conversely, it was
23 suggested that the RNA substrate might accommodate a groove enriched in basic amino acids at the
24 interface between the MTase and the CTD domain.

25 We next evaluated the effect of CTD deletion and single mutations on the MTase activities. The cap-
26 N7 MTase and the cap-2' O MTase activities were followed by incubating the different mutants with
27 specific RNA substrates previously described [23]. In addition, we followed the methylation of
28 adenosines within RNA sequence using a cap-1 RNA substrate (^mGpppG_m-SUDV₁₂). We observed that
29 MTase activities are completely abrogated by the deletion of the CTD that hampers the RNA
30 recognition. In contrast, single mutations in the CTD induce more contrasted effects on the SUDV
31 MTase activities. We identified mutations decreasing or abrogating the overall MTase activities
32 (F2113A, H2112A, R2068A, K2118A and K2189A), as well as one mutation uncoupling the N7 MTase
33 activity from the 2' O MTase activities (K2043A), and one mutation affecting internal methylation
34 rather than cap methylations (H2067A). These results are consistent with the RNA binding assay as
35 mutations decreasing efficiently RNA recognition (MTase- Δ CTD > K2118A > R2068A) also strongly
36 impair MTase activities. Conversely, we identified one mutant (K2189A), which still binds partially to
37 GpppG-SUDV₁₂, but is barely active, suggesting that such mutation affects the RNA position in the

1 catalytic site. Finally, we also observed that mutants keeping partially the capacity to recognize RNA
2 (K2043A, H2112A, F2113A, H2067A) also keep cap-N7 and/or cap-2'O MTase activities.

3 Altogether, these results elucidate one function of the CTD domain of SUDV, which regulates RNA
4 substrate recognition and in turns, participate to the fine-tuning of the MTase activity. Interestingly, we
5 recently demonstrated that the SUDV MTase induces *in vitro* internal adenosine 2'O methylation in
6 addition to the N7 and 2'O methylation of the cap structure [23]. On the other hand, other viruses
7 belonging to the *Mononegavirales* order such as hMPV seem to induce preferentially cap-N7 and cap-
8 2'O methylations beside internal methylation. The different specificities between these enzymes might
9 depend on their capacity to recognize and position the RNA substrate into the MTase catalytic site
10 linked to the CTD recognition properties, which is barely conserved among the mononegavirus families.
11 We do not know yet whether SUDV induces the methylation of adenosines inside its own genomic or
12 messenger RNAs in infected cells. In addition, the role of such methylations in viral RNA sensing,
13 mRNA translation into viral protein, or RNA encapsidation is still elusive. In contrast to other viral
14 systems such as HIV infection, it was recently demonstrated that internal 2'O methylations of RNAs
15 induced by a cellular MTase recruited by the virus during infection (FTSJ3) limits RNA detection by
16 the MDA5 pathway yielding to reduction of interferon secretion [24]. The identification of mutations
17 in the CTD of SUDV uncoupling the different MTase activities of the L protein opens the way to
18 elucidate the function of internal methylations in filovirus infection and would participate to develop
19 new antiviral strategies leading to an activation of the innate immunity system, especially through RIG-
20 I/MDA5 pathway.

14

15

1 **Methods**

2 **Cloning and expression**

3 Codon-optimized CRVI-CTD synthetic gene (Biomers) was designed for expression in c2566
4 pRARE2. N-terminal truncated construct of CRVI-CTD was synthesized by cloning the sequence of
5 interest from full-length CRVI-CTD into a pDEST14 plasmid with Gateway system for expression in
6 c2566 bacteria. After transformation, bacteria were cultured at 30°C until a OD of 0.6, and induced
7 overnight with 500 mM IPTG (Sigma) at 17°C. Finally, cultures were centrifuged at 8,000 xg for 10
8 min at 4°C using a Sorval Lynx 6000 centrifuge (Thermo), and pellets were conserved at -80°C until
9 purification.

10

11 **Purification**

12 Pellets were thawed on ice, and lysed in a 10 times final culture OD volume of optimized lysis buffer
13 (50 mM Tris pH 8, 150 mM NaCl, 5% glycerol, 30 mM imidazole, 1 mM PMSF, 100 µg/mL lysozyme,
14 1 µg/mL DNase, 0.1% Triton X100) supplemented with BugBuster (Merck Millipore) for MTase+CTD.
15 After clarification (18,000 xg, 30 min, 4 °C), the lysate was incubated with CoNTA resin (Thermo; 0.5
16 mL/L culture) for 1 h at 4 °C, with gentle shaking. The beads were transferred to a 25-mL column and
17 washed with 2 x 20 mL of buffer W1 (50 mM Tris pH 8, 1 M NaCl, 5% glycerol, 30 mM imidazole)
18 and 2 x 10 mL of buffer W2 (50 mM Tris pH 8, 150 mM NaCl, 5% glycerol). Protein was eluted in
19 buffer E (50 mM Tris pH 8, 150 mM NaCl, 5% glycerol) supplemented with 150 mM imidazole in the
20 case of MTase-ΔCTD and 1 M arginine for CRVI+CTD. Imidazole was removed by gel filtration using
21 a Superdex S75 16/60 (GE Healthcare) for MTase-ΔCTD. Finally, proteins were concentrated on
22 Amicon Ultra (EMD Millipore), and conserved in 50% glycerol at -20°C.

23

24 **Synthesis of RNA substrates**

25 RNA sequences were chemically synthesized on solid support using an ABI 394
26 oligonucleotides synthesizer. After RNA elongation with 2'-*O*-pivaloyloxymethyl phosphoramidite
27 ribonucleotides,¹⁰⁻¹¹ and 2'-*O*-methyl phosphoramidite ribonucleotides (Chemgenes, USA), the 5'-
28 hydroxyl group was phosphorylated and the resulting *H*-phosphonate derivative¹² was oxidized and
29 activated into a phosphoroimidazolidate derivative to react with guanosine diphosphate (GpppRNA)¹³⁻
30 ¹⁴. After deprotection and release from the solid support, GpppRNAs were purified by IEX-HPLC and
31 validated to be >95 % pure by MALDI-TOF spectrometry. *N*7-methylation of the purified GpppRNA
32 was performed enzymatically using *N*7-hMTase¹³⁻¹⁴.

33

34 **MTase activity assays**

35 To evaluate methyltransferase activities, a radioactive test was set up by mixing 4 µM of protein with
36 1 µM of purified and validated synthetic RNAs (see all RNAs in **Table S1**), 10 µM of SAM and 0.5

1 μM of ^3H -SAM (Perkin Elmer) in an optimized MTase assay buffer (50 mM Tris-HCl variable pH, 10
2 mM arginine). Reactions were stopped by a 10-fold dilution in water after 3 h at 30°C. Samples were
3 transferred to DEAE filtermats (Perkin Elmer) using a Filtermat Harvester (Packard Instruments).
4 Methyl transfer was then evaluated as described before [29]. Briefly, the RNA-retaining mats were
5 washed twice with 10 mM ammonium formate pH 8, twice with water and once with ethanol. They
6 were then soaked with liquid scintillation fluid, allowing the measurement of ^3H -methyl transfer to the
7 RNA substrates using a Wallac MicroBeta TriLux Liquid Scintillation Counter13.

8

9 **Fluorescence polarization (PF)**

10 Using T4 RNA ligase 1 (20 units; New England Biolabs), cyanine 5-cytidine-5-phosphate-3-(6-
11 aminoethyl)phosphate (12.5 μM , Jena Bioscience) was ligated to the 3'ends of the RNA substrates (10
12 μM) in T4 RNA ligase 1 buffer (NEB), 1 mM ATP (16 °C, overnight). Ligase was removed by RNA
13 precipitation in 3 M sodium acetate supplemented with 1 $\mu\text{g}/\mu\text{L}$ of glycogen (Thermo Scientific). The
14 fluorescent RNA was incubated (5 min at room temperature) with increasing concentrations of
15 CRVI+CTD, in 20 mM Tris pH 8 or pH 8,5 150 mM NaCl, 5% glycerol. Fluorescence polarization
16 (FP) measurements were performed in a microplate reader (PHERAstar FS; BMG Labtech) with an
17 optical module equipped with polarizers and using excitation and emission wavelengths of 590 and 675
18 nm, respectively. Dissociation constants (K_d) were determined using Hill slope curve fitting (Prism).

19

20 **Thermal shift assay (TSA)**

21 A mix of 4 μM protein, buffered by resuspension buffer (50 mM Tris pH 8, 150 mM NaCl, 5% glycerol)
22 with 0,02% (v/v) SYPRO Orange dye (Thermo Scientific) was made up to a total volume of 20 μL .
23 Samples were placed in a semi skirted 96 well PCR plate (BioRad), sealed and heated in an Mx3005p
24 qPCR machine (BioRad) from 25 to 95°C at a rate of 1 °C.min⁻¹. Fluorescence changes were monitored
25 with excitation and emission wavelengths at 492 and 610 nm respectively.

Figure 1 – Bioinformatic analysis of the C-terminal domain (MTase+CTD) of mononegavirus L protein based on hMPV structure.

(A) Sequence organization of the mononegavirus L protein revealed six conserved regions (CRI to CRVI, black boxes) that contain motifs responsible for the different activities of the L (motifs mapped with asterisks). The SUDV MTase domain was defined as the fragment encompassing amino acids 1713–2046 using the alignments with the VSV L protein. The SAM-binding site motifs (GxGxG) and the 2'O catalytic tetrad K-D-K-E have also been identified (asterisks). The CTD of SUDV L follows the MTase domain (amino acids 2047–2211). (B) The X-ray structure of hMPV methyltransferase (MTase, orange) and C-terminal (CTD, red) domains at a resolution of 2.2 Å is presented (Paesen *et al.*, 2015). The residues involved in the catalytic tetrad, SAM-binding site and RNA-binding groove are mapped respectively in blue, green and purple. (C) Conservation model of hMPV MTase+CTD domains of mononegavirus L based on proteins alignment presented in Fig. S1. Colors indicate the level of residue conservation (white: not conserved, pink: barely conserved, red: highly conserved).

Figure 2 – Production and purification of SUDV MTase+CTD and MTase-ΔCTD and effect of CTD on MTase activity and RNA binding.

(A) MTase+CTD (58 kDa) and MTase-ΔCTD (39 kDa) of *Sudan ebolavirus* (SUDV), purified by two-steps chromatography, were separated by SDS-PAGE analysis before Coomassie blue staining. (B) Thermostability assay of SUDV MTase+CTD and MTase-ΔCTD constructs (n=1). Melting temperature indexes (T_m) have been calculated following a Boltzmann sigmoidal regression and evaluated at both 54,6°C and 46°C, respectively. Data represent raw data. (C) MTase activity evaluation of *Sudan ebolavirus* (SUDV) MTase-ΔCTD (orange) and MTase+CTD (red) incubated with a 13-mers capped RNA substrate mimicking the capped 5' extremity of viral mRNA (GpppG-SUDV₁₂). MTase activity was determined by filter binding assay (n=6). Data represent mean ± standard deviation. (D) RNA-binding assay by fluorescence polarization of a 13-mers capped SUDV RNA substrate labelled in 3' by pCp-Cy5 on SUDV methyltransferase domain (MTase-ΔCTD, grey) and SUDV MTase associated with the C-terminal domain (MTase+CTD, black) (n=3). A dissociation coefficient (K_d) has been calculated by one site specific binding regression with Hill slope. The MTase+CTD domain affinity for GpppG-SUDV₁₂ is estimated to be $740 \pm 1,1$ nM. Data represent mean ± standard deviation.

Figure 3- Production and purification of mutated MTase+CTD and effect of a single mutation of conserved residues in CTD on MTase activity and RNA binding.

(A) Mtase+CTD and mutated MTase+CTD (58 kDa) of *Sudan ebolavirus* (SUDV), purified by chromatography, were separated by SDS-PAGE analysis before Coomassie blue staining. (B) MTase activity evaluation of *Sudan ebolavirus* (SUDV) wild-type (WT) and mutated SUDV MTase+CTD incubated with either GpppGm(A_m)-SUDV₁₂, ^mGpppA(A_m)-SUDV₁₂ or ^mGpppG_m-SUDV₁₂ in presence of radiolabelled methyl donor (3H-SAM), to get access to cap-N7 MTase, cap-2'O MTase and internal 2'O-A MTase activities, respectively. MTase activity was determined by filter binding assay.

Table 1- Effect of a single mutation of conserved residues in CTD on MTase activity and RNA binding.

Thermostability assay (TSA) of SUDV MTase+CTD and SUDV MTase+CTD mutated proteins. Melting temperature indexes (T_m) have been calculated following a Boltzmann sigmoidal regression. RNA-binding assay by fluorescence polarization of a 13-mers SUDV-specific capped RNA (GpppG-SUDV₁₂ and ^mGpppG_m-SUDV₁₂) labelled at the 3'end by pCp-Cy5 on SUDV MTase+CTD and mutated MTase+CTD proteins. A dissociation coefficient (K_d) has been calculated by one site specific binding regression.

1

Supplementary figure 1 - Alignment of MTase+CTD domain of filovirus L protein

Sequences of filovirus methyltransferase (MTase) and C-terminal (CTD) domains have been identified from L protein sequences picked up on NCBI Protein data bank: EBOV (Zaire ebolavirus, AAG40171.1), SUDV (Sudan ebolavirus, YP_138527.1), TAFV (Tai Forest ebolavirus, ALT19766.1), BDBV (Bundibugyo ebolavirus, AKB09568.1), RESTV (Reston ebolavirus, APA16576.1), MARV (Marburg virus, CAA82542.1), LLOV (Llovio cuavirus, YP_004928143.1) and MENGV (Mengla dianlovirus, AZL87829.1). Alignment has been generated with Seaview, then treated with ESPrpt. Orange and red lines model MTase and CTD domains, respectively. The 2^o MTase-specific catalytic tetrad K-D-K-E (Ferron *et al.*, 2002) and SAM-binding motif GxGxG have been indicated by blue and green respectively. Strictly conserved amino acids are indicated by *, and conserved positions with either arginine or lysine residues are indicated by X.

Supplementary figure 2– Analysis of the residue content of mononegavirus MTase and CTD domains

Based on alignment of different Mononegavirales, residue content of the methyltransferase (MTase) and C-terminal (CTD) domains of mononegavirus L proteins has been analysed. For each virus, MTase, CTD and MTase+CTD total number of residues, number of basic residues and the percentage of basic residues have been determined. Isoelectric points have also been estimated using ProtParam. Differences between MTase and CTD pIs have been calculated and modeled by a blue gauge normalized to the greater difference.

Supplementary figure 3 - Thermal Shift Assay

Thermostability assay of SUDV MTase+CTD and SUDV MTase+CTD mutated proteins. Melting temperature indexes (T_m) have been calculated following a Boltzmann sigmoidal regression.

Supplementary figure 4 - RNA-binding assay by fluorescence polarization of SUDV-specific capped RNA of 13 mers (GpppG-SUDV₁₂ and mGpppG_m-SUDV₁₂) labelled at the 3' end by pCp-Cy5 on SUDV MTase+CTD and mutated MTase+CTD proteins. A dissociation coefficient (K_d) has been calculated by one site specific binding regression.
