Version June 30, 2020 submitted to Electronics

Abstract: Low Density Signature (LDS) is an emerging non-orthogonal multiple access (NOMA) technique that has never been evaluated under a vehicular channel in order to simulate the environment of a V2X communication. Moreover, the LDS structure has been combined with only [Orthogonal Frequency Division Multiplexing \(OFDM\)](#) and [Filter-Bank Multi-Carrier \(FBMC\)](#) waveforms to improve its performances. In this paper, we propose new schemes where the LDS structure is combined with [Universal Filtered Multi-Carrier \(UFMC\)](#) and [Filtered-OFDM](#) waveforms and the [Bit Error Rate \(BER\)](#) is analysed over a frequency selective channel as a reference and over a vehicular channel to analyse the effect of the Doppler shift on the overall performance.

Keywords: V2X, LDS-F-OFDM, LDS-UFMC, EVA channel model

1. Introduction

Vehicular communications have recently caught a lot of attention in the research community thanks to the advantages that can provide the overall vehicular experience. In fact, several technologies have provided the requirements for this type of communication. Connected to the Infrastructure (V2I), to another vehicle (V2V) or to a pedestrian (V2P), the vehicle to everything (V2X), as referred to, is a new solution for road users to enhance safety and improve the traffic efficiency. The [Long Term Evolution \(LTE\)](#) as a widely deployed infrastructure is proposed to be extended in order to support the V2X services, namely the LTE-based V2X [1]. The [3rd Generation Partnership Project \(3GPP\)](#) Release 14 is an evolutionary standard that is dedicated to the LTE-based V2X and published on September 2016 defining two new modes, mode 3 and mode 4 [2][3]. In mode 3, the radio resource is managed by the cellular network consequently vehicles can only communicate under a cellular coverage. Meanwhile in mode 4, the radio resource is managed autonomously by the vehicle itself for the direct V2V communication overcoming the coverage limitation of mode 3. However, LTE-based V2X standard suffers from severe performance degradation in a high density environment - it doesn't allow a high number of users to access to the network. In addition, LTE-based V2X is based on [Single Carrier Frequency Division Multiple Access \(SC-FDMA\)](#) which requires high complexity equalizers. The ITS-G5 is another standard that is introduced by the [European Telecommunications Standards Institute \(ETSI\)](#) and operates in 5 GHz frequency band [4]. The main advantage of ITS-G5 is its low latency, the short transmission delay is due to the fact that data is being transferred directly between neighbors. However, in best case scenarios, ITS-G5 has a short range of 1 km and is extremely sensitive to dense environment which reduces the total throughput and increases the end-to-end latency. Similar to the IEEE 802.11p US standard, both LTE-based V2X and ITS-G5 rely on OFDM on PHY layer, while maintaining the subcarriers orthogonality could be challenging in the vehicular environment leading to a high BER. This is why the 5G cellular network can be a promising technology to support the vehicular communications [5], namely [New Radio-V2X \(NR-V2X\)](#).

35 The 3GPP Release 16 defines the first specifications for NR-V2X sidelink where it supports
36 subcarrier spacings of 15, 30, 60 and 120 kHz. Their associations to [Cyclic Prefix \(CPs\)](#) and frequency
37 ranges are as for NR [Uplink/Downlink \(UL/DL\)](#), but using only the CP-OFDM waveform. The
38 modulation schemes available are [Quadrature Phase Shift Keying \(QPSK\)](#), [Quadrature Amplitude
39 Modulation 16-\(QAM\)](#), 64-QAM, and 256-QAM [6]. Meanwhile, another study has been published for
40 NOMA signature candidates [7] proposing some of the main technologies such as [Interleaver Division
41 Multiple Access \(IDMA\)](#) [8][9][10], [Pattern Division Multiple Access \(PDMA\)](#) [11][12] and [Sparse Code
42 Multiple Access \(SCMA\)](#) [13][14]. However, for V2X communication, no specifications invoke NOMA.

43 As an efficient multiple access technique, we have chosen to modulate LDS and analyse its
44 performances under a vehicular channel for V2X communication. Its sparse structure enables each user
45 to spread its data over a small subset of subcarriers, which means that a single subcarrier will support
46 only a small number of users or symbols, hence reducing the multiuser interference (MUI). Firstly, it is
47 proposed in [15] for a [Code Division Multiple Access \(CDMA\)](#) system and proves that it can afford
48 a high system overload with affordable complexity. To improve its performances, LDS is enhanced
49 by combining it with OFDM [16] to apply the spreading over OFDM subcarriers and evaluate over a
50 frequency selective channel. Furthermore, the LDS has been recently combined with FBMC[17] and a
51 joint sparse graph receiver combining pulse shaping property, NOMA and channel coding is proposed to
52 improve the overall result at the cost of very high complexity. Although LDS-OFDM and [Joint Sparse
53 Graph - Isotropic Orthogonal Transfer Algorithm \(JSG-IOTA\)](#) have shown improved performance
54 evaluation, these schemes have only been analysed over a frequency selective channel. Our objective
55 is to extend the state-of-art work to evaluate the performance of LDS over a high mobility channel
56 to simulate the vehicular environment for V2X applications and combine it with other advanced 5G
57 waveforms, [specifically for an application that requires a high data rate, a medium number of users
58 connected to the network in a certain geographical area and a time of latency smaller than 1 ms](#) [5].

59 Among these promising 5G waveforms, UFMC [18] has drawn attention due to its ability to
60 overcome OFDM shortcomings. By applying properly designed sub-band filtering, UFMC reduces
61 the high out-of-band ([OOB](#)) power emission while retaining the simplicity of the conventional OFDM
62 signal. In fact, one the main advantages of UFMC is its compatibility with the OFDM signals which
63 achieves low system complexity in the NOMA schemes.

64 Filtered-OFDM [19][20] is also one of the proposed advanced waveforms for the future cellular
65 network. Both UFMC and f-OFDM signals use filtering per subband in order to achieve a low OOB,
66 the main difference is the filter length and its flexibility. F-OFDM uses a long filter with different
67 lengths for each subband (Windowed Sinc filter) exceeding the CP while UFMC signals use short
68 fixed length filters for each subband (Chebyshev filter). In this paper, our goal is to propose a
69 scheme that benefits from the waveforms robustness and multicarrier transmission combined with
70 the non-orthogonality of a spreading based NOMA to provide a system with less complexity while
71 keeping the transmission model flexible to any future changes and maintaining a certain compatibility
72 with the current techniques. It is why, we have developed a new LDS-UFMC and LDS-F-OFDM
73 schemes in which the LDS spreading is applied to UFMC and f-OFDM signals. Among the different
74 filters that f-OFDM can offer, we adopt computing the Hann, Hamming and Blackman filters [thanks
75 to the great performance they shown in terms of BER and OOB reduction](#) [21] and also to provide a
76 better comparison. These schemes will be BER analysed for a V2X communication i.e. a high mobility
77 channel. The multiuser detector will be based on [Message Passing Algorithm \(MPA\)](#) [22]. It will be
78 proved that LDS-F-OFDM outperforms the LDS-OFDM and LDS-UFMC by allowing the filter length
79 to exceed the CP length of OFDM and designing the filter appropriately.

80 The remainder of this paper is organized as follow. Section II introduces the system model of
81 LDS-UFMC. Section III is devoted to the LDS-F-OFDM system model. Section IV presents simulation
82 results of LDS-UFMC and LDS-F-OFDM compared to LDS-OFDM in different environments. Finally,
83 section V concludes this work.

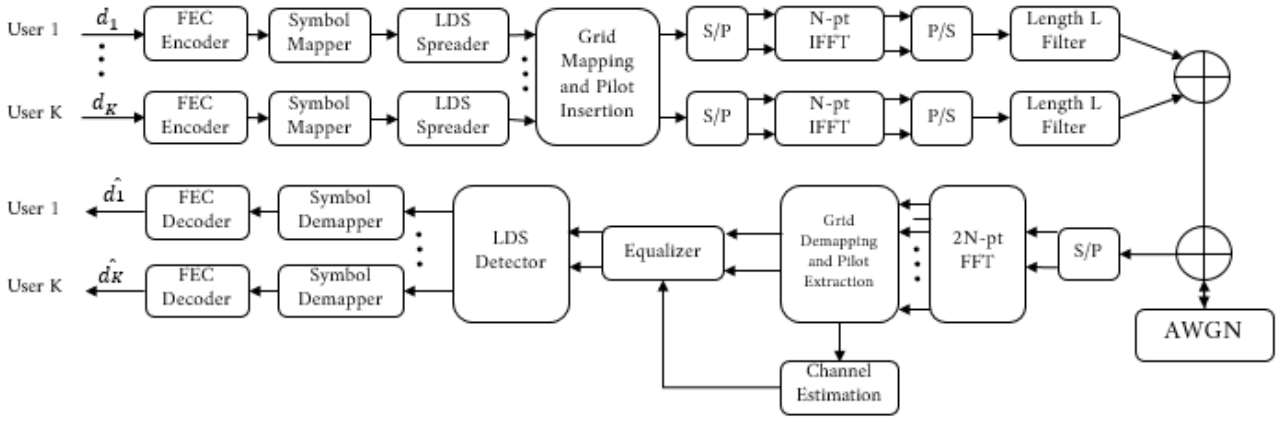

Figure 1. LDS-UFMC block diagram

2. LDS-UFMC system model

In this section, we are going to define the major blocks of an LDS-UFMC system. The LDS-UFMC block diagram is shown in Fig. 1. After coding and modulation, the symbols are multiplied with a Low density spreading sequences then modulated and transmitted simultaneously. Afterwards, spreaded data is shaped into a time-frequency grid. In this configuration, we address the pilots aided channel estimation. For simplicity, we propose to insert the pilots using the Comb Type arrangement. Then, this grid is UFMC modulated using a N-point Inverse Fast Fourier Transform (IFFT) and filtered by a L-length Dolph-Chebyshev filter. At the receiver side, the received signal is UFMC demodulated, then the pilots extraction is performed in order to estimate the channel using the Least Square (LS) method and linear interpolation. The equalizer block uses Zero-Forcing to eliminate the channel effect. The output of the equalizer is passed to the LDS detector where an iterative detection process based on MPA is performed to separate the users' symbols.

2.1. LDS Spreader

Consider an LDS-UFMC system with K users and the users are indexed as follow $k = 1, \dots, K$ and all users are assumed to transmit the same number of data streams M and they are indexed as follow $m = 1, \dots, M$. Assume the number of subcarriers is N , and they are indexed as follow $n = 1, \dots, N$. We define the spreading matrix of the k^{th} user as:

$$\mathbf{S}_k = [s_{k,1}, \dots, s_{k,M}] \in \mathbb{C}^{N \times M} \quad (1)$$

$s_{k,m} = [s_{k,m}^1, \dots, s_{k,m}^N]^T$ is the sparse vector of length N used to spread the m^{th} symbol of the k^{th} user. Thus, the matrix of spreading of all users can be represented as :

$$\mathbf{S} = [\mathbf{S}_1, \dots, \mathbf{S}_K] \in \mathbb{C}^{N \times MK} \quad (2)$$

Thanks to the sparse nature of this matrix, only a small number of users can share the same subcarrier, we define it as d_c the interference degree. Hence, among N subcarriers only d_v will be used to serve one user, d_v is called the effective spreading gain. Unlike the conventional CDMA system, we require $d_v \ll N$ and $d_c \ll K$. Let \mathbf{a}_k be user's k symbols :

$$\mathbf{a}_k = [a_{k,1}, \dots, a_{k,M}]^T \quad (3)$$

After the spreading process, the signal of the k^{th} user $\mathbf{x}_k = [x_k^1, \dots, x_k^N]^T$ is a vector of length N can be written as follow:

$$\mathbf{x}_k = \mathbf{S}_k \cdot \mathbf{a}_k \quad (4)$$

and x_k^n will be the data transmitted over the n^{th} subcarrier by the k^{th} user:

$$x_k^n = \sum_{m=1}^M a_{k,m} s_{k,m}^n \quad (5)$$

Hence, the signal transmitted over the n^{th} subcarrier is given by (6):

$$x^n = \sum_{k \in \xi_n} x_k^n \quad (6)$$

ξ_n is considered as the group of users interfering in the n^{th} subcarrier.

Fig.2 represents the spreading process of the LDS. In this example, we consider that each user transmits one symbol (i.e $M = 1$). The system transmits over 4 subcarriers and serves 8 users which means that the overloading is at 200%. Each subcarrier is allocated to 4 users ($d_c = 4$), and each user spreads its data over 2 subcarriers ($d_v = 2$). The symbols are the variable nodes and the subcarriers are the functions nodes respectively. The edges that connect the nodes define if a symbol will be spreaded over the adjacent subcarrier. For instance the first user is connected to subcarriers 1 and 2, consequently, the first symbol will be spreaded over these adjacent subcarriers only. This representation of spreading process is called the Tanner Graph.

Figure 2. Spreading process of LDS-UFMC system

105

106 2.2. Signal Model

After the LDS spreading, the UFMC modulation is applied to each subcarrier. In fact, UFMC divides the entire bandwidth B of N subcarriers into multiple subbands S_u , each subband consists of Q subcarriers. Hence, the n^{th} subcarrier can now be regarded as the q^{th} subcarrier of the s^{th} subband. After that, the IFFT is performed over the signal of each subband and will be filtered using a L -length prototype filter, usually, the filter is a Dolph-Chebyshev window. The subbands are then superimposed and sent over the channel. The baseband discrete UFMC signal is represented in (7):

$$x_{LDS-UFMC}[n] = \sum_{s=0}^{S_u-1} g_s[n] * x_s[n] \quad (7)$$

$g_s[n]$ defines the filter used in the s^{th} subband :

$$g_s[n] = g[n] e^{j(2\pi n Q/2)/N} e^{j(2\pi n (S_0 + sQ))/N} \quad (8)$$

where S_0 denotes the starting frequency of the lowest subband and $g[n]$ is a well-localized Chebyshev pulse filter of length L . The third term of the equation is the one responsible for frequency shifting to the appropriate subband. $x_s[n]$ is signal transmitted over the s^{th} group of subcarriers. It can be expressed as follow:

$$x_s[n] = \sum_{q=0}^{Q-1} x^{s,q} e^{j(2\pi n q/2)/N} e^{j(2\pi n (S_0 + sQ))/N} \quad (9)$$

hence, $x^{s,q}$ can be nothing but the signal transmitted over the q^{th} subcarrier of the s^{th} subband and just like in (6), it is given by:

$$x^{s,q} = \sum_{k \in \xi_{s,q}} x_k^{s,q} \quad (10)$$

107 where $\xi_{s,q}$ is considered as the group of users interfering in the q^{th} subcarrier of the s^{th} subband.

The received signal is represented as follow:

$$y_{LDS-UFMC}[n] = h[n] * x_{LDS-UFMC}[n] + z[n] \quad (11)$$

where $z[n]$ and $h[n]$ are the additive white gaussian noise with variance σ_z^2 and the channel impulse response respectively. The length of the signal $y_{LDS-UFMC}$ is $N_y = N + L - 1$ due to the convolution with the subband filter, consequently, a 2N-point **Fast Fourier Transform** (FFT) is performed at the UFMC receiver. After the UFMC demodulation process, the input of the LDS Detector corresponding to the n^{th} subcarrier is :

$$Y_n = H_n \sum_{k \in \xi_n} \sum_{m=1}^M a_{k,m} s_{k,m}^n \quad (12)$$

where Y_n and H_n are the 2N-point FFT of the time domain signal respectively. In our system, we have chosen to use the equalizer embedded with the LDS detector for a better performance. **Regarding the LDS decoding, firstly, the LDS turbo receiver uses MPA and Forward Error Correction (FEC) decoder to find the reliability of the symbols. Secondly, the JSG receiver uses pulse shaping, NOMA, and channel coding, however, it is highly complex. For simplicity, we chose to implement the basic LDS detector that uses the Tanner Graph for implementing the MPA receiver in which we consider subcarriers and symbols as function nodes and variable nodes respectively. Adjacent nodes are connected via edges. Based on an extrinsic manner, each node will update its information containing the reliability of the symbol based on the received reliability from other edges and send it back. After an appropriate number of iterations, the reliability which is the log likelihood ratio (LLR) of the symbols will converge and the symbols are transmitted to the FEC decoder. The major goal behind this complex implementation is to find the value of \hat{a} that maximizes the joint a posteriori probability based on the observed signal:**

$$\hat{a} = \arg \max_{a \in \mathbb{X}} p(a|y) \quad (13)$$

where \mathbb{X} is the modulation constellation. **The first LLR update can be written as follow :**

$$\begin{aligned} \ell_{c_n \leftarrow u_k}(a_k) &= \log \frac{P_{\text{ext},n}(a_k = +1)}{P_{\text{ext},n}(a_k = -1)} \\ &= \sum_{m \in \varphi_k \setminus n} \ell_{c_m \rightarrow u_k} \end{aligned}$$

Where u nodes are the variable nodes and c nodes are the function nodes, hence $\ell_{c_n \leftarrow u_k}$ is the message sent from u_k node to the c_n node and $\ell_{c_n \rightarrow u_k}$ message sent from c_n node to the u_k node respectively. It is clear from the above equation that the update of $\ell_{c_n \leftarrow u_k}(a_k)$ is dependent to all nodes besides the node n i.e $m \in \varphi_k \setminus n$, hence, the notation of extrinsic update. Second Update can be calculated as follow:

$$\ell_{c_n \rightarrow u_k}(a_k) = \log \left(\sum_{a_n \in X} P(y_n | a_n) \prod_{l \in \xi_n \setminus k} P_n(a_l) \right)$$

108 **Where φ_k is the group of subcarriers allocated to the k^{th} user and $P(y_n | a_n)$ is the channel observation**
 109 **function at subcarrier y_n . Further explanations are provided in [22].**

Figure 3. LDS-F-OFDM block diagram

110 3. LDS-F-OFDM system model

111 Based on the same LDS spreader used in LDS-UFMC, LDS-F-OFDM applies Filtered-OFDM
 112 waveform on the users' spreaded signals and transmits them over the channel. The LDS based on
 113 f-OFDM block diagram is presented in Fig.3. As depicted, the signal is mapped into a time-frequency
 114 grid and then the pilots are inserted for channel estimation. Afterwards, a N-point IFFT is performed
 115 to transfer the grid from the frequency domain to the time domain, **data is then** serialized and CP is
 116 added to combat **Inter Symbol Interference** (ISI) effect. Like UFMC, the main advantage of f-OFDM
 117 is its compatibility with OFDM, with a difference of passing the signal through a long length filter
 118 before the transmission. Extended over the CP, the filter helps to lower the high OOB radiation while
 119 maintaining the OFDM orthogonality between the subcarriers. Usually, a truncated sinc window is
 120 used as a shaping filter, however in our system we have chosen to implement other types of filters for
 121 a better comparison. For LDS-F-OFDM, we consider all the subcarriers as one subband to lower the
 122 overall complexity. Therefore, our transmitted signal is an OFDM modulated signal passed through an
 123 appropriate shaped filter. Without loss of generality, the signal expression can be written as follow:

$$x_{LDS-F-OFDM}[n] = x_{LDS-OFDM}[n] * f_{TX}[n] \quad (14)$$

where $f_{TX}(n)$ represents the well-designed filter and $x_{LDS-OFDM}[n]$ is the discrete LDS-OFDM signal after the spreading and modulation, it is represented as follow:

$$x_{LDS-OFDM}[n] = \sum_{q=0}^{N-1} x^q e^{j2\pi nq/N} \quad (15)$$

the transmitted signal is given by (16):

$$x_{LDS-F-OFDM}[n] = \sum_{q=0}^{N-1} x^q e^{j2\pi nq/N} * f_{TX}[n] \quad (16)$$

124 3.1. Filter design

The main reason behind the filtering is to eliminate the side lobes for an efficient transmission, it is why filters based on cardinal sin are taken into consideration thanks to their sharp filter response. However, **the filter characteristic** should be truncated due to its infinite impulse response. As a result, we obtain a finite sinc filter and a window pulse $w[n]$ is applied to smooth its transitions. Once the filter is computed, it should be shifted around the central frequency of the subband.

$$p[n] = \text{sinc}\left(\frac{W + 2\delta_W}{N}n\right) \quad (17)$$

$$p_B[n] = \frac{p[n]w[n]}{\sum_n |p[n]w[n]|} \quad (18)$$

$$f_{TX}[n] = p_B[n]e^{\frac{j2\pi n f_c}{N\Delta_f}} \quad (19)$$

125 where W is the number of active subcarriers, δ_W is the tone offset, N is the FFT size, f_c is the frequency
 126 of the centre subcarrier in the baseband and Δ_f is the subcarrier spacing. The window function of the
 127 chosen windows are defined in Table I.

Table 1. Window function of the filters

Window	Window function
Hann	$w[n] = 0.5 \times (1 + \cos(\frac{2\pi n}{L-1}))$
Hamming	$w[n] = \frac{25}{46} + \frac{21}{45} \times \cos(\frac{2\pi n}{L-1})$
Blackman	$w[n] = \frac{7938}{18608} + \frac{9240}{18608} \times \cos(\frac{2\pi n}{L-1}) + \frac{1430}{18608} \times \cos(\frac{4\pi n}{L-1})$

128 At the receiver side, a matching filter $f_{RX}[n]$ to the transmission filter $f_{TX}[n]$ is performed at the
 129 received signal, after that the CP is removed and the signal is transmitted to an OFDM receiver. After
 130 the grid demapping and pilot extraction, channel estimation is performed based on the pilots. The
 131 output data is then considered as the input of LDS detector explained in Section II.

132 4. Performance Evaluation

133 In this section, we propose to compare the performances of the proposed LDS-F-OFDM and
 134 LDS-UFMC schemes with the LDS-OFDM over a vehicular channel with different speed limits and
 135 over a multipath fading channel. The main simulation parameters are used to match the 3GPP Release
 136 16 standard. Based on 3GPP Release 16, we have fixed the total bandwidth to $B = 10MHz$ and a carrier
 137 frequency of $f_c = 5.9GHz$ to match the NR-V2X operating bands in FR1 [23]. Table II summarizes the
 138 simulation parameters.

139 No error correction is employed, so the evaluation is carried out for uncoded bits. The LDS
 140 spreading matrix is generated randomly for all the simulated schemes. However, we do believe
 141 that a well designed matrix with small number of cycle-of-four and a high girth can achieve better
 142 performance.

143 In order to respect the 3GPP recommendations, no overloading scenario is deployed due to the
 144 use of pilots and the waveforms offset. We have overcome this circumstance by respecting the rule
 145 of interfering several users in the same resource and allocating a few subcarriers to the same user i.e.
 146 respecting the LDS structure to justify these new schemes performances. The maximum number of
 147 iterations of the LDS detector is ten.

148 The first channel we have chosen to evaluate the performance of these schemes is the Tapped
 149 Delay Line model, specifically the TDL-A channel. The TDL-A channel model has a Doppler spectrum
 150 which is characterized by a Jake's spectrum shape. The [Power Delay Profile](#) (PDP) of the model is
 151 presented in [24] and the delay spread used to scale the normalized taps delays is $D_s = 93\eta s$. This
 152 delay spread is chosen to correspond to a short delay profile in an Urban Macro environment for a
 153 5.9GHz carrier frequency.

154 Fig.4 depicts the simulation results of LDS-F-OFDM and LDS-UFMC over TDL-A channel. We
 155 first fix the bandwidth at $B = 10MHz$, then we investigate the schemes under two systems, the
 156 first with 1024 subcarriers and $\Delta_f = 15KHz$ subcarrier spacing and the second with 512 subcarriers
 157 and $\Delta_f = 30KHz$. According to the simulation results, the LDS-F-OFDM shows better performance
 158 over both LDS-UFMC and LDS-OFDM. The fact that the f-OFDM subband regroups all the available
 159 subcarriers concentrates the energy in one main lobe [results](#) in less ISI, and thanks to the LDS structure,

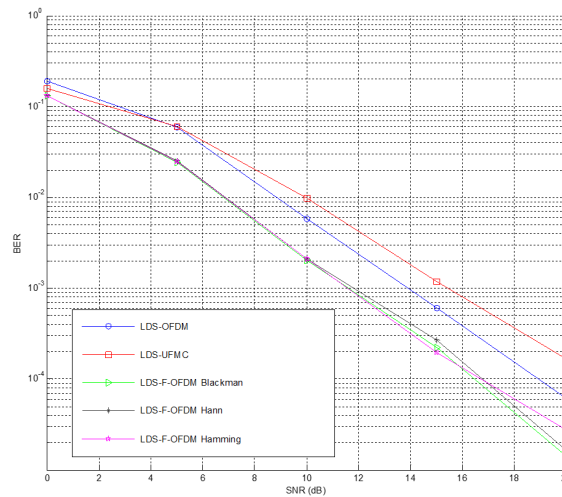

Table 2. Simulation parameters

<i>Parameters</i>	<i>Symbol</i>	<i>Value</i>
Release 16 Parameters		
Bandwidth	B	10 MHz
Carrier frequency	f_c	5.9 GHz
Number of symbols	N_{sym}	14
Subcarriers spacing	Δ_f	15 KHz 30 KHz

Interference Pattern	d_c	3
Number of Users	N_u	468 216
Modulation	-	BPSK

160 the MUI are eliminated, thus, reducing the overall interference. Hence, it is expected that the f-OFDM
 161 with the LDS structure achieve a better BER performance. Meanwhile, LDS-UFMC shows a slight
 162 performance degradation compared to LDS-OFDM. However, UFMC offers lower OOB and the main
 163 advantage of UFMC is the increased spectral efficiency. Consequently, a trade-off must be taken in
 164 consideration depending on the requirements of the application.

165 The second and main channel used to simulate these schemes is the [Extended Vehicular A](#) (EVA)
 166 model channel, its power delay profile is provided in [25]. Similarly to the TDL-A model, the EVA
 167 model is characterized by a Jake's Doppler spectrum and the maximum speed simulated is 300Km/h,
 168 hence the maximum Doppler shift $f_d = 556\text{Hz}$ and specifically modeled to simulate a vehicular
 169 channel.

170 Fig.5 (a) shows the BER performance of the LDS-F-OFDM and LDS-UFMC compared to
 171 LDS-OFDM over an EVA channel with a computed speed of 100Km/h which means that the maximum
 172 Doppler shift is $f_d = 185\text{Hz}$ with a subcarrier spacing of $\Delta_f = 15\text{KHz}$ and an FFT size of 1024, hence
 173 only 468 subcarriers left for data transmissions. For simplicity, we consider 468 users each sending
 174 one BPSK modulated symbol with a power of 1 Watt. In fact, this is the worst loading scenario where
 175 we have the number of users equal to the number of subcarriers allocated to data transmission which

(a) $\Delta_f = 15KHz$ (b) $\Delta_f = 30KHz$ **Figure 4.** Performance of the proposed schemes over an TDL-A Channel

176 means that each user will be able to send only one symbol. It can be noticed that the LDS-F-OFDM
 177 slightly outperforms once more both LDS-OFDM and LDS-UFMC with its all different types of filters
 178 deployed. While Hann, Hamming and Blackman windows achieve almost the same BER performance,
 179 Hann window function is the filter susceptible to give better OOB performance. In terms of spectral
 180 efficiency, LDS-UFMC compared to LDS-F-OFDM and LDS-OFDM comes first due to the removal
 181 of the CP. However, observing the used subcarriers for data transmission due to the use of the pilot
 182 with only 4 subcarrier spacing, we notice the overall degraded spectral efficiency. This is completely
 183 justified by the need of an efficient channel estimation because of the high changing nature of the
 184 channel.

185 The BER performance of the proposed schemes with a computed speed of 100Km/h and a
 186 subcarrier spacing of $\Delta_f = 30KHz$ and 512 subcarriers is presented in Fig.5 (b). It is worth noting that
 187 LDS-F-OFDM shows again better performance at low SNR, while at higher SNR, all the proposed
 188 schemes face slight performance degradation. In fact, while employing higher subcarrier spacing
 189 to combat the Doppler shift, the spectral efficiency is reduced and also the number of subcarriers
 190 allocated to pilots is reduced (156 subcarriers in the first system vs 72 in the second). Consequently,
 191 the channel estimation will not be as efficient as in the first system. Furthermore, in order to investigate
 192 how the LDS-F-OFDM and LDS-UFMC can be affected by the mobility, the schemes are also simulated
 193 over an EVA channel with a speed of 300 Km/h.

(a) $\Delta_f = 15\text{KHz}$ (b) $\Delta_f = 30\text{KHz}$ **Figure 5.** Performance of the proposed schemes over an EVA Channel with speed of 100Km/h

194 Fig.6 (a) and (b) represents the simulation results for $\Delta_f = 15\text{KHz}$ and $\Delta_f = 30\text{KHz}$ respectively.
 195 It can be seen that LDS-F-OFDM shows better performances than LDS-OFDM and LDS-UFMC in
 196 low SNR. Moreover, all the techniques demonstrate huge improvements in the second system with
 197 $\Delta_f = 30\text{KHz}$ subcarrier spacing than the first. Thanks to the large subcarrier spacing, the Doppler
 198 shift does not impact severely the subcarriers orthogonality. In addition, comparing Fig.5 (a) with
 199 Fig.6 (a), all the techniques face severe performance degradation due to the high mobility of the UEs.
 200 Meanwhile, Fig.5 (b) with Fig.6 (b) presents almost the same BER performances thanks to the large
 201 subcarrier spacing.

202 Fig.7. Depicts the comparison of the proposed schemes over the EVA channel with different
 203 speed limits with both systems. We have chosen to evaluate the schemes also over the EVA channel
 204 with a 500Km/h velocity and analyse the degradation of the performance in such an environment.
 205 Obviously, the performance decreases due to the high speed, however as shown in Fig.7(b) i.e. with a
 206 large subcarrier spacing, both LDS-F-OFDM and LDS-UFMC seem to suffers less. Meanwhile with
 207 $\Delta_f = 15\text{KHz}$, all the techniques seem unable to converge at high speed. To improve this, other
 208 receivers can be considered such as the JSG and Expectation Propagation Algorithm EPA receivers.

(a) $\Delta_f = 15\text{KHz}$ (b) $\Delta_f = 30\text{KHz}$ **Figure 6.** Performance of the proposed schemes over an EVA Channel with speed of 300Km/h

209 5. Conclusion

210 In this paper, we have proposed two efficient multiple access techniques namely LDS-F-OFDM
 211 and LDS-UFMC in which the LDS structure is **combined** with the new 5G waveforms. First of all,
 212 we have presented the state-of-art of the previous **work** done on LDS and we have detailed the
 213 transmitters and receivers of these new schemes. Then, we have highlighted our contribution that
 214 consists in evaluating these new schemes over different types of channels, specifically, a vehicular
 215 channel with a high mobility. Simulation results show that LDS-F-OFDM significantly achieves
 216 higher performance improvements compared to LDS-OFDM and LDS-UFMC in all scenarios, while
 217 maintaining an affordable complexity at the transmitter and the receiver side. The improvements are
 218 directly related to the advantages that f-OFDM waveform **offers** by addressing the adequate filter.
 219 In future work, we propose to analyse these schemes with different types of receivers in manner to
 220 reduce the complexity **and** to improve the performances. **Some of the receivers that can be found**
 221 **in the literature are the SIC-MPA** where we combine SIC and MPA to reduce the overall complexity
 222 and the JSG receiver which is a very high complex receiver but provides a lot of improvements to the
 223 system. Furthermore, we consider evaluating theses schemes over different vehicular channels such as

(a) $\Delta_f = 15KHz$ (b) $\Delta_f = 30KHz$ **Figure 7.** Schemes comparison over the EVA channel with different speed limits

224 a confined channel and with different channel specifications considering the other operating band of
 225 FR1 i.e. 25GHz.

 227 validation, R.A., F.E. and N.I.; formal analysis, R.A. and F.E.; investigation, I.K., R.A. and F.E.; resources, R.A.
 228 and F.E.; writing—original draft preparation, I.K.; writing—review and editing, I.K.; supervision, R.A., F.E. and N.I.;
 229 project administration, R.A. and F.E.; funding acquisition, R.A. and F.E. All authors have read and agreed to the
 230 published version of the manuscript.

231 **Acknowledgments:** The present research work has been supported by the European project SECREDAS funded
 232 ECSEL. The preliminary results were partly supported by ELSAT project. ELSAT 2020 project is co-financed by
 233 the European Union with the European Regional Development Fund, the French state and the Hauts de France
 234 Region Council.

235 **Conflicts of Interest:** The authors declare no conflict of interest.

236 Abbreviations

237 The following abbreviations are used in this manuscript:

238

OFDM	Orthogonal Frequency Division Multiplexing
FBMC	Filter-Bank Multi-Carrier
UFMC	Universal Filtered Multi-Carrier
BER	Bit Error Rate
LTE	Long Term Evolution
3GPP	3rd Generation Partnership Project
SC-FDMA	Single Carrier Frequency Division Multiple Access
ETSI	European Telecommunications Standards Institute
NR-V2X	New-Radio V2X
CP	Cyclic Prefix
UL	Uplink
DL	Downlink
QPSK	Quadrature Phase Shift Keying
QAM	Quadrature Amplitude Modulation
239 IDMA	Interleaver Division Multiple Access
PDMA	Pattern Division Multiple Access
SCMA	Sparse Code Multiple Access
CDMA	Code Division Multiple Access
JSG-IOTA	Joint Sparse Graph-Isotropic Orthogonal Transfer Algorithm
MPA	Message Passing Algorithm
FEC	Forward Error Correction
EPA	Expectation Propagation Algorithm
IFFT	Inverse Fast Fourier Transform
LS	Least Square
FFT	Fast Fourier Transform
ISI	Inter Symbol Interference
OOB	Out Of Band
PDP	Power Delay Profile
EVA	Extended Vehicular A
