## Abstract

The presence of nuclear ERBB2 receptor-type tyrosine kinase is one of the causes of the resistance to membrane ERBB2-targeted therapy in breast cancers. It has been previously reported that this nuclear location arises through at least two different mechanisms: proteolytic shedding of the extracellular domain of the full-length receptor and translation of the mRNA encoding *ERBB2* from internal initiation codons. Here, we report a new mechanism and function where a significant portion of nuclear ERBB2 results from the translation of the variant *ERBB2* mRNA under the transcriptional control of a distal promoter which is actively used in breast cancer cells. We show that both membrane ERBB2a and nuclear ERBB2b isoforms are prevalently expressed in breast cancer cell lines and carcinoma samples. The ERBB2b isoform, which is translated from mRNA variant 2, can directly translocate into the nucleus due to the lack of the signal peptide which is required for an intermediate membrane location. siRNA-mediated gene silencing showed that ERBB2b can repress ERBB2a expression, encoded by variant 1, whereas ERBB2a activates ERBB2b. Nuclear ERBB2 binding to its own promoter was revealed by chromatin immunoprecipitation assay. Altogether, our results provide new insights into the origin and function of nuclear ERBB2 where it can participate at the same time in a positive or a negative feedback autoregulatory loop, dependent on which of its promoters this bona fide transcription factor is acting. They also provide a new understanding for the resistance to therapies targeting the membrane-anchored ERBB2 in breast cancer.

Key words: ERBB2, isoform, nuclear translocation, breast cancer, resistance

## 1 INTRODUCTION

The ERBB2/HER2 oncogene encodes a 185 kDa receptor tyrosine kinase (RTK) [Akiyama et al., 1986; Yarden and Sliwkowski, 2001] that belongs to the epithelial growth factor receptor (EGFR) family, including epidermal growth factor receptor (EGFR)/ERBB1 [Ullrich et al., 1984], ERBB3 [Kraus et al., 1989], and ERBB4 [Plowman et al., 1993]. These receptors are composed of an extracellular domain, a transmembrane domain, and an intracellular domain. ERBB2 has no known ligand binding to its extracellular domain [Klapper et al., 1999]; however, it becomes the preferred heterodimeric partner of the other three ERBB members [Graus-Porta et al., 1997]. Ligand binding to these high-affinity complexes stimulates the kinase activity, phosphorylates tyrosine residues and activates diverse downstream signaling cascades, such as mitogen-activated protein kinase (MAPK), signal transducers and activators of transcription (STAT), and the phosphatidylinositol 3-OH kinase (PI3K) pathway [Citri and Yarden, 2006; Egan and Weinberg, 1993].

Amplification and overexpression of the ERBB2/HER2 receptor are observed in ~20% of breast cancers, and in other types of cancer with variable proportions, and are associated with poor prognosis and higher metastatic potential [Hurst, 2001; Kim and Scott, 2017; Vernimmen et al., 2003; Yarden and Sliwkowski, 2001]. Major clinical treatments of ERBB2-positive breast cancers include humanized monoclonal antibodies (trastuzumab and pertuzumab), which bind to the extracellular domain of ERBB2, disrupting the dimerization of the receptor and the downstream signaling [Franklin et al., 2004; Hudis, 2007], and tyrosine kinase inhibitors (TKI, lapatinib and neratinib), which antagonize the kinase activity of the homo- or heterodimerized receptors, inhibiting phosphorylation of their substrates and downstream signaling [Barok et al., 2014; Burris, 2004; Burstein et al., 2010; Diéras et al., 2017; Xia et al., 2005]. These therapies have greatly improved the overall survival of ERBB2-positive breast cancer patients [Slamon et al., 2001]. However, resistances to monoclonal antibody and TKI treatments are observed in the majority of patients [Blackwell et al., 2009; Esteva et al., 2002; Nahta et al., 2006]. Although different mechanisms have been proposed [Esteva et al., 2010; Spector and Blackwell, 2009], the resistance to anti-ERBB2 treatment remains a major clinical issue.

The presence of nuclear forms of RTKs, including the four members of the EGFR family, has been revealed since the last two decades [Carpenter, 2003; Lin et al., 2001; Ni et al., 2001; Offterdinger et al., 2002; Wang et al., 2004] and several mechanisms for the nuclear translocation and the function of those nuclear RTKs have been reported [Giri et al., 2005; Lin et al., 2001; Lo et al., 2006; Ni et al., 2001; Offterdinger et al., 2002; Rio et al., 2000; Wang et al., 2004; Williams et al., 2004]. Interestingly, recent studies shed new light on the role played by the nuclear form of ERBB2 in the resistance to anti-ERBB2 treatments [Cordo Russo et al., 2015, 2019; Li et al., 2011; Schillaci et al., 2012; Venturutti et al., 2016].

The *ERBB2* gene can be transcribed as at least 17 different transcripts generated by alternative

1  
2  
3 splicing and alternative promoter usage [Nezu et al., 1999]. All transcript variants are apparently under  
4 the control of two major promoters separated by 12 Kb (Fig. 1). The proximal promoter controls the  
5 transcription of *ERBB2* transcript variant 1 (NM\_004448) which encodes the canonical form of the  
6 receptor ERBB2a, generally named ERBB2, while the 5'-end distal promoter controls the transcription  
7 of *ERBB2* transcript variant 2 (NM\_001005862.2). *ERBB2* transcript variant 1 is composed of 27 exons.  
8 Its first exon codes for 30 amino acids, where the first 22 amino acids constitute a signal peptide which  
9 is cleaved during the migration of ERBB2 mature form to the cell membrane. *ERBB2* transcript variant  
10 2 is composed of 30 exons where the first 4 exons are non-coding. Consequently, the translation of the  
11 ERBB2b isoform starts at an alternative ATG within its fifth exon which is identical to the second exon  
12 of variant 1 (Fig. 1). Therefore, sequences coding for the signal peptide in ERBB2a exon 1 are missing  
13 in the ERBB2b isoform. Because this signal peptide is cleaved once it transports the protein to the cell  
14 membrane, the sequence difference of mature proteins between ERBB2a and ERBB2b isoforms is only  
15 eight N-terminal amino acids. Beside its canonical location at cell membrane, alternative forms of the  
16 ERBB2/HER2 receptor have been observed into cell nuclei where they can escape current therapeutic  
17 approaches. These nuclear forms have been described as the result of at least two different  
18 mechanisms: proteolytic shedding of the extracellular domain of the full-length receptor and  
19 translation of the mRNA encoding ERBB2 from internal initiation codons [Anido et al., 2006;  
20 Christianson et al., 1998].  
21  
22

23  
24  
25 Here, we report a new mechanism for ERBB2 nuclear expression, where the ERBB2b isoform  
26 can directly translocate into the nucleus without requirement of an intermediate membrane location.  
27 siRNA analyses showed that ERBB2b isoform can repress the ERBB2a isoform, whereas ERBB2a isoform  
28 can activate the ERBB2b isoform. In addition, nuclear ERBB2 binding to its own promoter was revealed  
29 by chromatin immunoprecipitation (ChIP) assay. Altogether, our results provide new insights into the  
30 function of ERBB2 and provide an additional explanation for the resistance to therapies targeting the  
31 membrane-anchored ERBB2 in breast cancer.

## 2 MATERIALS AND METHODS

### 2.1 Cell lines and antibodies

The non-oncogenic human primary mammary epithelium cells HME-1 (Clontech, Mountain View, CA, USA) and the breast cancer cell lines BT474, BT-483, HCC-202, HCC-1806, HCC-1954, HCC-1569, MDA-MB-175, MDA-MB-361, MDA-MB-453, SK-BR-3, UACC-812, ZR-75-30, Br-Ca-Mz-01 (<http://www.atcc.org>) and SUM-185, SUM-190, SUM-206 ([http://www.cancer.med.umich.edu/breast\\_cell/production](http://www.cancer.med.umich.edu/breast_cell/production)) were grown according to the recommendations of the supplier. Twenty-eight breast carcinoma samples were obtained from patients treated at the Institut Paoli-Calmettes (Marseille, France), and corresponded to surgical specimens in case of early-stage disease and/or diagnostic biopsies in case of advanced stage. Their characteristics are summarized in Table 1 and detailed in Table 2. Twenty cases were ERBB2+, whereas 8 were ERBB2-. Each patient gave written informed consent and the study was approved by our institutional review board. The following antibodies were purchased from a commercial source: ERBB2 (Santa Cruz, sc-284), Sp1 (Upstate, 07-645), anti- $\beta$ -tubulin (Abcam, ab11307), IgG Rabbit (ab171870).

### 2.2 ChIP-seq data processing

Reads were aligned to the hg19 genome using bowtie 1.1.1 [Langmead et al., 2009], with the parameters --all --best --strata -v 2 -m 1 -S. Peak detection was performed using MACS 1.4.2 [Zhang et al., 2008] using -g hs --keep-dup=auto -w -S. Annotation of peaks was performed using Homer annotatePeaks (version 4.7.2) [Heinz et al., 2010]. Public BT474 rabbit IgG and RNAPII HCC-1806 data were recovered from the Gene Expression Omnibus (GEO) from accessions GSM1145935 [Heinonen et al., 2015] and GSM3317507 [Perreault et al., 2019], respectively. Intersection of peaks was carried out using bedtools intersect 2.19.0 [Quinlan and Hall, 2010]. Annotation to the closest gene was performed using bedtools closest 2.19.0 using -t first as a parameter. Read depth coverage were normalized to BT474 Pol II ChIP-seq data.

### 2.3 siRNA Assay

Three 25-mer duplex small interfering RNAs (siRNAs) to specifically target either ERBB2a or b mRNA variants were designed and ordered (Select Stealth™ RNAi, Invitrogen, Table 3). A mixed of each three siRNA duplexes (10 nM) and a mixed Stealth™ RNAi Negative Control Duplexes were transiently transfected by Lipofectamine™ RNAiMAX (Invitrogen) for 48 h at 37°C in a CO<sub>2</sub> incubator according to the manufacturer instruction. Gene knockdown was confirmed by quantitative reverse transcription-PCR and immunoblotting.

#### 2.4 ERBB2a- / ERBB2b-GFP construction

The full-length cDNAs of the two isoforms ERBB2a and b were obtained by reverse transcription (Super Script™ First-Strand, Invitrogen) of mRNA extracted from BT474 cells (RNeasy® Micro Kit, Qiagen) and amplified by PCR (Platinum® TaqDNA Polymerase High Fidelity, Invitrogen) using Gateway Specific Primers: ERBB2a-GW-F 5'-AttB2-GGGGACAAGTTTGTACAAAAAAGCAGGCTAGCCGAGTGAGCACCAT-3'; ERBB2b-GW-F 5'-AttB2-GGGGACAAGTTTGTACAAAAAAGCAGGCTTGTGCACCGGCACAGACAT-3'; ERBB2-GW-R 5'-AttB1-GGGGACCACTTTGTACAAGAAAGCTGGGTGACTTGGCCTTCTGGTTCA-3'. They were subsequently cloned into the expression vectors pEGFP, according to the Gateway protocol (Invitrogen).

#### 2.5 Transient transfection

Cells were transfected using FuGENE 6 reagent (Roche Diagnostics).  $3 \times 10^5$  cells were seeded in 6-well plates (Falcon 3046, BD Biosciences, Lincoln Park, NJ) and then transfected the next day using the FuGENE reagent (FuGENE:DNA ratio of 3  $\mu$ l: 2  $\mu$ g) for 48 h in complete medium.

#### 2.6 RNA extraction and Reverse-Transcription PCR

Total RNA was extracted from cells using RNeasy® Micro Kit (QIAGEN) according to the manufacturer's protocol. Total RNA was quantified using a Nanodrop 1000 Spectrophotometer device. RT-PCR was performed using SuperScript™ II Reverse Transcriptase (Invitrogen) and random hexamer primers.

#### 2.7 Subcellular fractionation

The cytosolic, membrane, and nuclear fractions were prepared from fractions 1, 2 and 3 using ProteoExtract® Subcellular Proteome Extraction (Calbiochem, Merck). The fractionation efficiency was assessed by antibodies against Sp1 and  $\beta$ -tubulin.

#### 2.8 Immunofluorescence

Cultured cells were fixed with 4% paraformaldehyde for 20 min, permeabilized with 0.1% Tween-20 for 10 min, and then immunostained with primary antibodies against ERBB2 (1:200 dilution in PBS with 1% BSA) for 1 hr at room temperature. After three washes with PBS, the Alexa 488-conjugated secondary antibody was then applied for 45 min at room temperature. The nucleus was stained with DAPI before mounting. For immunofluorescence microscopy, the images were captured with a Zeiss 510 Meta UV confocal microscope.

#### 2.9 Western blot

1  
2  
3 10<sup>5</sup> cultured cells were lysed in 10 µl of lysis buffer (25 mM Tris pH 7.9, 1% w/v SDS, 1 mM dithiothreitol)  
4 and fractionated on a 7.5% SDS-polyacrylamide gel, electrotransferred to a PVDF membrane. Specific  
5 polypeptides were revealed with the rabbit polyclonal anti-ERBB2 (C18, sc-284), rabbit polyclonal anti-  
6 Sp1 (Upstate, 07-645), and mouse monoclonal anti-β-tubulin (Abcam, ab11307) at a proper dilution in  
7 TBS-Tween containing 5% non-fat milk or BSA according to the recommendations of the supplier, and  
8 then reacted with secondary antibodies at a dilution of 1:10<sup>4</sup> in the same buffer.  
9  
10  
11  
12  
13  
14

## 15 2.10 Chromatin Immunoprecipitation Assay

16 BT474 cells were fixed with 1% formaldehyde for 15 min, and the cross-linking reaction was stopped  
17 by the addition of 125 mM glycine incubating 5 min. Cells were washed and lysed in three Lysis Buffers  
18 containing 1x Complete Protease Inhibitors Cocktail (Roche) respectively. 1% Triton X-100 was added  
19 to the lysate and all lysates were sonicated at 4°C to generate 100-300 base pair chromatin fragments.  
20 Pretreated mixture of 3 µg of antibody (rabbit polyclonal anti-ERBB2, C18 sc-284 or rabbit polyclonal  
21 anti-PolIII, N20 sc-899), and protein G-conjugated magnetic Dynabeads (DynaL Biotech, Invitrogen) was  
22 added to the supernatant and incubated on a rotating wheel at 4°C for overnight. The  
23 immunocomplexes were then washed with RIPA wash buffer (S1) for 6 times and once with TE  
24 containing 50 mM NaCl. The Ab-protein-DNA complexes were eluted twice in 100 µl elution buffer at  
25 65°C for 15 min, briefly vortexed every 2 min. The combined eluates as well as the input sample (1%  
26 of the amount used in the IP procedure) were treated to reverse the crosslink by incubating overnight  
27 at 65°C. After Rnase and proteinase K digestion, the DNA fragments were extracted using phenol-  
28 chloroform and purified using a Qiagen PCR purification kit.

## 40 2.11 Quantitative PCR and normalization

41 DNA was quantified using LC FastStart DNA Master SYBR Green I and read with a Light Cycler® 2  
42 instrument (Roche Diagnostics) according to the manufacturer. For cDNA analysis, threshold cycles (Ct)  
43 were determined for quantification of the input target number. For comparison between different  
44 biological samples, the target gene expression level in each breast cancer cell line and breast carcinoma  
45 sample was normalized using a calibrator RNA sample extracted from the HME-1 cell line. The  
46 normalized gene expression (NGE) of the target gene was expressed as the  $N_{ratio}$ , where each  
47 normalized gene expression gene value was divided by a calibrator normalized gene value (*TBP*):  $N_{target}$   
48 =  $(Ct_{target,HME-1} - Ct_{TBP,HME-1}) - (Ct_{target,sample} - Ct_{TBP,sample})$ . Primers used in this study are listed in Table 4.  
49  
50  
51  
52  
53  
54

55 For RNA interference assay, the relative gene expression (RGE) was calculated as a percentage  
56 of the measured mRNA level in cells transfected with target siRNA compared to cells transfected with  
57 matched control siRNA. Data were normalized against the *TBP* signal and the  $2^{-\Delta\Delta Ct}$  method was used  
58 to calculate the relative expression level of a given gene [Livak and Schmittgen, 2001].  
59  
60

1  
2  
3 For chromatin immunoprecipitation (ChIP) assay, the amount of target and endogenous  
4 reference DNA was determined from a standard curve. The standard curve was constructed with four-  
5 fold serial dilutions of input DNA. The results from specific antibodies were reported to that observed  
6 in the corresponding IgG samples. A region between the *GAPDH* and *CNAP1* genes was used as the  
7 negative control to standardize the results from COX2 and ERBB2 HAS regions (ChIP-It protocol, Active  
8 Motif). Primers used in ChIP assays are: ERBB2 F 5'- TCCTTCGATGTGACTGTCTCC – 3', ERBB2 R 5'-  
9 CTAATGCAGAGGCTGGTGACT – 3'; COX2 F 5'- AACATGGCTTCTAACCCAAAC – 3', COX2 R 5'-  
10 AGGAAGCCTTTCTCCTCTC – 3'; Neg F 5'- ATGGTTGCCACTGGGGATCT -3', Neg R 5'-  
11 TGCCAAAGCCTAGGGGAAGA- 3'.

15  
16  
17  
18  
19

## 20 **2.12 Motif discovery and average profiles**

21 A custom position weight matrix was created for HAS motifs [Wang et al., 2004]. Mapping of motifs to  
22 specific and shared peaks was performed via Homer annotatePeaks using -hist 10 -m <motif> -size  
23 2000 as parameters. Average profiles were computed for each peak population. Motif discovery was  
24 performed using Homer findMotifsGenome using hg19 as a parameter.  
25  
26  
27  
28  
29

## 30 **2.13 Gene Set Enrichment Analyses**

31 Publicly available gene expression data for BT474 and HCC-1806 cells were retrieved from GEO  
32 accessions GSM1230347 and GSM1230072 [Dezső et al., 2014; Milosevic et al., 2013] and were  
33 processed in R using the affy package. Gene Set Enrichment Analyses (GSEAs) were computed using  
34 GSEA 2.2.4 [Subramanian et al., 2005], using the top RNAPII 500 peaks in summit height for BT474 and  
35 HCC-1806 as the genesets, the GENE\_SYMBOL.chip chip platform, gene\_set permutation for p-value  
36 computation, log<sup>2</sup> ratio of classes as the ranking metric, and weighted statistic.  
37

39  
40  
41  
42  
43

## 44 **2.14 Statistical Analysis**

45 Statistical analyses were done using the SPSS 16.0 program for Windows. The Spearman's correlation  
46 coefficient ( $\rho$ ) was used to compare the correlation between two target gene expression levels in  
47 breast cancer cell lines and tumor samples. A p-value < 0.05 was set as the criteria for statistical  
48 significance, while a p-value < 0.01 was considered highly significant. For p-values pertaining to motif  
49 densities, paired, two-tailed student t-tests were performed.

## 3 RESULTS

### 3.1 Both proximal and distal ERBB2 gene promoters are actively used in breast cancer cells

To confirm that both proximal and distal ERBB2 gene promoters are actively used in breast cancer cells, we performed a PolII ChIP-seq assay using BT474 cells and extracted data pertinent to the *ERBB2* gene locus. As shown in Figure 1A, PolII was significantly recruited at both promoters with predominance for the well characterized proximal promoter that controls the expression of the canonical transmembrane form of this RTK. Pol II signal was indeed enriched at both promoters as compared to a publicly available IgG ChIP-Seq control dataset performed in BT474 cells [Heinonen et al., 2015]. The recruitment of PolII at the distal promoter clearly indicates that both promoters might contribute to ERBB2 overexpression in breast cancer cells.

### 3.2 Prevalent presence of ERBB2b isoform in breast cancer

To determine the relative expression of the *ERBB2a* and *ERBB2b* mRNA isoforms in human breast cancer, mRNAs were extracted from 16 breast cancer cell lines and 28 clinical tumour samples (see Table 1 and Table 2). The human normal epithelial breast cell line (HME-1) was used as a reference to measure the relative gene expression (RGE). Quantitative-RT-PCRs using primers specific for either *ERBB2a* or *ERBB2b* isoform showed that both *ERBB2a* and *ERBB2b* isoforms were expressed in 15 breast cancer cell lines and all carcinoma samples (Fig.

2A-B), whereas the *ERBB2b* isoform was not expressed in the HCC-1569 cell line. Importantly, *ERBB2b* expression was highly correlated to that of *ERBB2a* with a Spearman rank correlation coefficient equal to 0.912 and 0.882 for cell lines (without HCC-1569) and carcinoma samples, respectively (Fig. 2C-D). Because the amplification of the chromosome 17q12 region is often observed in various solid tumours [Kao and Pollack, 2006; Maqani et al., 2006], three genes adjacent to the *ERBB2* locus within this chromosome region, *PERLD1* (*PGAP*, NM\_033419.5), *C17orf37* (*MIEN1*, NM\_032339.5), and *GRB7* (NM\_005310.5) were also analysed for their RGEs in this series of breast cancer samples. Highly positive correlations were observed among all five transcripts. The highest correlation was observed around the *ERBB2* locus (Fig. 2E). These results indicated the prevalent presence of *ERBB2b* isoform in breast cancer.

### 3.3 ERBB2b isoform is a nuclear form of ERBB2

To study the protein expression of the two ERBB2 isoforms in different cell compartments, four breast cancer cell lines were selected based on the RGE of the two *ERBB2* isoforms: BT474 and HCC-1954 overexpress both isoforms, whereas HCC-1569 overexpresses only *ERBB2a*, and Br-Ca-Mz-01 weakly expresses *ERBB2b* but not *ERBB2a* (Fig. 2A). Cytosolic, membrane, and nuclear fractions were

1  
2  
3 separated for each of these four cell lines. ERBB2 protein expression was observed mainly in the  
4 membrane fraction, but also in the cytosolic and nuclear fractions in BT474 and HCC-1954 cells, which  
5 is expected for a transmembrane receptor (Fig. 3A). Interestingly, no ERBB2 nuclear expression was  
6 revealed in HCC-1569 cells (Fig. 3A). However, no detectable expression of ERBB2 by Western-blot was  
7 observed for Br-Ca-Mz-01 cell lines probably due to its very weak expression level (Fig. 3A).  
8  
9

10  
11 Immunofluorescence assays were used to precisely determine the expression location of  
12 ERBB2a and ERBB2b in single breast cancer cells. Confocal microscopy analyses revealed that clear  
13 membrane ERBB2 expression was observed in BT474, HCC-1954, and HCC-1569 cells, but not in Br-Ca-  
14 Mz-01 cells, which is in agreement with the lack of *ERBB2a* isoform expression (Fig. 3B). However,  
15 nuclear ERBB2 expression was observed in all the four tested cell lines, including HCC-1569 in which  
16 *ERBB2b* mRNA was not detected by transcription analysis (Fig. 3B). Altogether these results  
17 demonstrated that ERBB2b isoform does not contribute to a detectable membrane expression of  
18 ERBB2.  
19  
20

21  
22 To confirm that ERBB2b is a *bona fide* nuclear form of ERBB2, we constructed two expression  
23 vectors that contain either *ERBB2a* or *ERBB2b* cDNA fused to green fluorescent protein (GFP) using the  
24 Gateway cloning system (Invitrogen Tm). These two vectors were then transiently transfected into  
25 BT474 (high ERBB2 expression) and HCC-1806 (low ERBB2 expression) cell lines. ERBB2-GFP expression  
26 was observed in whole cells (Fig. 3C left panels) with the transfection of *ERBB2a*, whereas ERBB2-GFP  
27 expression was specifically located in cell nucleus upon transfection of the *ERBB2b* isoform (Fig. 3C  
28 right panels). These results clearly demonstrated that *ERBB2* mRNA variant 2 (*ERBB2b*) encodes a *bona*  
29 *fide* nuclear isoform of ERBB2.

### 40 **3.4 ERBB2a isoform upregulates ERBB2b whereas ERBB2b isoform inhibits ERBB2a**

41 To study putative functional relations between ERBB2a and ERBB2b isoforms, RNA interference assays  
42 were carried out in BT474 and HCC-1954 cell lines, in which both isoforms are overexpressed. Three  
43 specific custom Stealth™ siRNAs (Invitrogen) were designed against each isoform and transiently  
44 transfected into two cell lines (Fig. 4A). Control siRNAs were simultaneously transfected into cells and  
45 resulting RGEs were defined as 100%. qRT-PCR showed that ERBB2a siRNAs inhibited 30-40% of  
46 *ERBB2a* isoform expression, and 50-70% of *ERBB2b* isoform expression in both cell lines (Fig. 4B).  
47 However, in marked contrast, ERBB2b siRNAs induced a significant increase of *ERBB2a* expression,  
48 while efficiently inhibited *ERBB2b* expression (Fig. 4B). These results suggested that the ERBB2a  
49 isoform upregulates the expression of the *ERBB2b* isoform, whereas ERBB2b inhibits the expression of  
50 *ERBB2a*.  
51

53  
54  
55  
56  
57

58 Immunofluorescence assay were further carried out in HCC-1954 and Br-Ca-Mz-01 cell lines  
59 treated with siRNAs against either ERBB2a or ERBB2b isoforms. In HCC-1954 cells, the diffusion of  
60

1  
2  
3 ERBB2 protein expression was observed upon transfection of ERBB2a siRNAs: less ERBB2 membrane  
4 protein was observed and nuclear proteins were present (Fig. 4C mid panels). In marked contrast,  
5 ERBB2 protein expression was strongly increased in membranes, and reduced in nuclei when cells were  
6 transfected with ERBB2b siRNAs (Fig. 4C lower panels). In Br-Ca-Mz-01 cells, the already weak  
7 cytoplasmic and nuclear ERBB2 expressions were further reduced by both ERBB2a and ERBB2b siRNAs  
8 (Fig. 4D). However, no convincing ERBB2 membrane accumulation was observed when ERBB2b  
9 expression was inhibited, due to the low expression of ERBB2a (Fig. 4D). These observations, together  
10 with the siRNA assays, strongly suggest a 2-stage feedback interaction between ERBB2a and ERBB2b  
11 where the ERBB2b isoform upregulated by ERBB2a can subsequently downregulates ERBB2a  
12 expression.

### 20 21 22 **3.5 Binding of nuclear ERBB2 to a specific HAS motif of the *ERBB2* gene proximal promoter**

23 Nuclear ERBB2 was reported to bind to the *COX2* gene promoter *via* an HER2/ERBB2-associated  
24 sequence (HAS), a specific AT-rich DNA motif [Wang et al., 2004]. By searching a similar HAS regulatory  
25 element in the vicinity of the *ERBB2* gene promoter, a potential ERBB2-binding sequence was found  
26 500 bps upstream of the transcriptional start site of *ERBB2a* isoform (NM\_004448) (Fig. 5A). Chromatin  
27 immunoprecipitation assays in BT474 cells confirmed the binding of nuclear ERBB2 to the *COX2* gene  
28 promoter *via* HAS (Fig. 5B). Most importantly, our ChIP assay also revealed the binding of nuclear  
29 ERBB2 to *ERBB2* proximal promoter region (Fig. 5B).

34  
35  
36

### 37 38 **3.6 Regulatory regions are enriched in HAS motifs and correlate with increased gene expression in 39 BT474 cells**

40 We next sought to determine whether HAS motifs were enriched in other regulatory regions in BT474  
41 cells. To this end, we used the RNAPII ChIP-seq that we performed above (Fig. 1A) and performed peak  
42 detection. This analysis identified 13,897 peaks, which mostly corresponded to distal regions, with  
43 ~1/5 of peaks annotated to promoter and 5' UTR regions (Fig. 6A). We hypothesized that if ERBB2b  
44 binds to certain regulatory regions in BT474 cells, those regions would not be present in ERBB2b low-  
45 expressing cells. We thus compared our genome-wide mapping of RNAPII with that performed in HCC-  
46 1806 [Perreault et al., 2019], a triple-negative, low- *ERBB2a* and *ERBB2b* expressing breast cancer cell  
47 line (Fig. 2A and Fig. 6B). By mapping HAS motifs to BT474-, HCC-1806- specific and shared peaks, we  
48 observed that BT474-specific peaks were significantly more enriched in HAS motifs than shared or HCC-  
49 1806-specific peaks (Fig. 6C). Further, unsupervised motif discovery revealed a compatible motif  
50 enriched in BT474-specific RNAPII peaks (Fig. 6D), consistent with putative ERBB2b binding in those  
51 regions. We next aimed to determine whether the elements identified via genome-wide mapping of  
52 RNAPII targets corresponded to putative enhancers regions. Importantly, gene set enrichment analysis

(GSEAs) [Subramanian et al., 2005] done using previously published BT474 and HCC-1806 gene expression data [Dezsó et al., 2014; Milosevic et al., 2013] showed positive, significant correlations between RNAPII peaks and gene expression fold change in BT474 as well as in HCC-1806 cells, consistent with a trans-activating roles for those regions (Fig. 6E).

## 4 DISCUSSION

Nuclear translocation of receptor tyrosine kinases (RTKs) has been described for twenty years. Here, we report a new mechanism for a constant and ubiquitous presence of a nuclear form of ERBB2. The ERBB2b isoform, lacking a signal peptide as compared to the canonical ERBB2a isoform (see Fig. 1), most probably cannot be expressed at the cell membrane. This was confirmed by immunofluorescence analyses of Br-Ca-Mz-01 cells, which do not express the ERBB2a isoform (Fig. 3B). Our results also indicate that membrane ERBB2 is mostly if not exclusively expressed by the *ERBB2a* isoform. Importantly, transient transfection of an *ERBB2b* expression vector coupled with a GFP reporter gene clearly demonstrated that ERBB2b is a nuclear form of ERBB2 (Fig. 3C). It was reported that membrane ERBB2 could contribute to the nuclear translocation as a consequence of endocytic internalization [Giri et al., 2005], which could explain the nuclear expression of ERBB2 observed in HCC-1569 cells which express only ERBB2a isoform, but not ERBB2b isoform (Fig. 3B). Nuclear ERBB2 has been reported to regulate target gene expression through binding to HASs or tethered binding to other transcription factors [Béguelin et al., 2010; Diaz Flaqué et al., 2013; Li et al., 2011; Proietti et al., 2009; Venturutti et al., 2016; Wang et al., 2004]. Accordingly, we observed that nuclear ERBB2 binds to a HAS located in the promoter region of the *ERBB2* gene (Fig. 5). However, we could not exclude that nuclear ERBB2 binds to this sequence through tethered binding to other transcription factors, since no DNA-binding domain has been yet identified in the ERBB2 protein.

Transcriptional analyses from both breast cancer cell lines and clinical samples revealed a positive correlation between the expression of *ERBB2a* and *ERBB2b* mRNAs (Fig. 2A-D). Using siRNAs targeting specifically and independently both mRNA species, we have established a functional link between these two isoforms, where ERBB2a could upregulate the ERBB2b, in agreement with the positive correlation observed between these two isoforms (Fig. 4). However, our siRNA assays provided an unexpected result when overexpressed ERBB2b inhibited ERBB2a mRNA expression in breast cancer cell lines. This apparent discrepancy could be explained when considering that the positive correlation between these two isoforms were observed in breast cancer cell lines and carcinomas samples under near physiological condition, whereas siRNA assays knock-out target gene expression and alter its downstream gene expression which subsequently break the physiological balance between these two ERBB2 isoforms. In addition and perhaps more importantly, the well-

1  
2  
3 known amplification of the ERBB2 locus in chromosome region 17q12 in breast cancers may also  
4 contribute to this positive correlation between the two isoforms by overcoming ERBB2b repressive  
5 activity as previously hypothesized for several other transcriptional repressors of the *ERBB2* gene such  
6 as FOXP3, GATA4, MYB, PAX3 [Birnbaum et al., 2009]. Further *in vivo* experiments using transgenic  
7 mouse models in which the expression of either isoform would be knocked-out or knocked-in should  
8 help to further decipher the respective functional role played by each ERBB2 isoform.  
9  
10  
11  
12

13 Nuclear ERBB2 has been reported to be involved in tumour growth and metastasis as well as  
14 resistance to anti-ERBB2 treatment in breast cancers [Béguelin et al., 2010; Cordo Russo et al., 2019;  
15 Diaz Flaqué et al., 2013; Díaz Flaqué et al., 2013; Venturutti et al., 2016; Wang et al., 2004]. C-terminal  
16 fragments of ERBB2 generated by alternative initiation from the internal AUG codon have also been  
17 shown to have tumorigenic property [Anido et al., 2006; Arribas et al., 2011; Vernieri et al., 2019]. In  
18 this study, we provide evidence that nuclear ERBB2, in addition to the two known origins (proteolytic  
19 shedding of the extracellular domain of the full-length receptor, translation of the mRNA encoding  
20 *ERBB2/HER2* from internal initiation codons) also result from the translation of the *ERBB2* mRNA  
21 variant 2 lacking the exons encoding the first 30 amino acids that are present in the ERBB2a full-length  
22 isoform. Our results together with published observations strongly indicate that the ERBB2a and  
23 ERBB2b isoforms may have different functions both in normal and breast cancer cells. Thus, a specific  
24 antibody against the small peptide encoded by amino acids 23-30 of the ERBB2a isoform might help to  
25 further study the role of nuclear ERBB2. With such discriminative tool, the composition of ERBB2  
26 nuclear fraction would be further characterize, and specifically study each ERBB2 isoform both in  
27 normal and breast cancer cells, which could contribute to the screen and identification of new  
28 potential treatments in HER2-positive breast cancer.

40 Receptor-type tyrosine kinases (RTK) are major regulators of cellular processes that are often  
41 mutated resulting in their constitutive activation in human cancers. In contrast to many oncogenic  
42 RTKs oncogenes, some others such as ERBB2 are amplified without mutation or rearrangement. We  
43 have previously hypothesized that ERBB2 gene amplification is used to overcome repression of its  
44 expression by several sequence-specific transcription factors [Birnbaum et al., 2009]. The present  
45 characterization of a new negative feedback autoregulatory loop where ERBB2b can repress ERBB2a  
46 fits with this model, adding one more member in the list of the transcription factors known to repress  
47 *ERBB2* gene expression [Hua et al., 2009].

## Figure legends

**FIGURE 1** ERBB2 gene proximal and distal promoter usage and schematic representation of its two major mRNA isoforms. A, UCSC genome browser screenshot of RNAPII and IgG read depth (2 upper black profiles) at the *ERBB2* gene locus in BT474 cells. Vertical arrows indicate the genomic location of both distal and proximal ERBB2 promoters. Known isoforms are annotated underneath, with mammal conservation at the bottom (blue). B, Domain structure of ERBB2a isoform: signal peptide in grey; transmembrane domain in black which separates the extracellular domain from intracellular domain; tyrosine kinase domain in red. C, Exon map for ERBB2a isoform, the Exon 1 containing sequences coding the signal peptide in red. D, Domain structure of ERBB2b isoform with transmembrane domain in black and tyrosine kinase domain in red. E, Exon map for ERBB2b isoform, the first four non-coding exons in brown.

**FIGURE 2** The expression of *ERBB2a* and *ERBB2b* isoforms are positively correlated in breast cancer. Quantitative-RT-PCR was performed from breast cancer cell lines and tumor samples. Relative gene expressions (RGE) of *ERBB2a* and *ERBB2b* were presented: as  $2^{\Delta\Delta Ct}$  in breast cancer cell lines (A) and carcinomas samples (B); or as  $\Delta\Delta Ct$  in breast cancer cell lines (C) and tumor samples (D). E, The correlation coefficient and significant rate were calculated using  $\Delta\Delta Ct$  of relative gene expressions of three genes co-amplified at the 17q12 locus *PERLD1*, *C17orf37* and *GRB7* in breast cancer carcinomas samples.

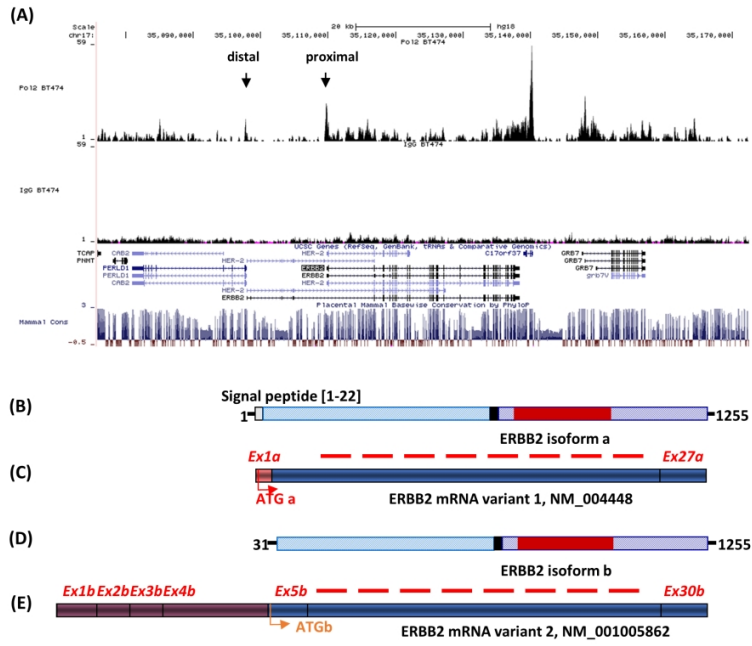

**FIGURE 3** ERBB2b isoform is a nuclear form of ERBB2. A, Subcellular fractionations were performed in BT474, HCC-1954, HCC-1569 and Br-Ca-Mz-01 cell lines to separate cytosolic, membrane and nuclear fraction. Western blot analyses were followed to determine ERBB2 localization in these two cell lines, Sp1 and  $\beta$ -tubulin were chosen as nuclear and cytosolic marker, respectively. B, Immunofluorescence assay coupled with confocal microscopy were carried out with an ERBB2 antibody against its carboxyl terminus. Nuclei were stained with DAPI. C, Expression of pEGFP-ERBB2a or pEGFR-ERBB2b in BT474 and HCC1806 cells. Upper panels: plain fluorescent microscope fields. Lower panels: GFP-positive cell magnification. These representative examples are extracted from 6 to 10 randomly selected confocal microscope fields per conditions.
