 $The \ lanthanide \ complexes \ EuL_3, \ GdL_3, \ YbL_3 \ and \ LuL_3 \ of \ the \ N,N'-bis(2-hydroxy-di-3,5-tert-butylphenyl) amine \ were$ prepared. The X-Ray crystal structures of \mathbf{GdL}_3 and \mathbf{LuL}_3 demonstrated a nine-coordinate sphere with three ligand molecules under their anionic diamagnetic form (Cat-N-BQ). The complexes showed three oxidation events (E1/2 ×1 = 0.15-0.16 V, $E_{1/2}^2 = 0.51-55$ V, and $E_{1/2}^3 = 0.75-0.78$ V vs Fc⁺/Fc) via cyclic voltammetry, corresponding to the successive oxidation of the catecholate moeities to iminosemiquinone species. The complexes GdL₃ and YbL₃ were characterized by EPR spectroscopy, allowing for the determination of the zero field splitting (ZFS) parameters in the first case. The monocations $(LnL_3)^*$ and monoanions $(LnL_3)^*$ were electrochemically generated (Ln = Eu, Gd, Yb, Lu), as well as the dications YbL₃²⁺ and $LuL_3^{2^*}$. The spins are anti-ferromagnetically exchange coupled in the diradical species $LuL_3^{2^*}$ (|D| = 260 MHz, E = 0). All the complexes (incl. neutral) possess a strong absorption band in the NIR region (730 - 840 nm, ϵ > 28 mM $^{-1}$ cm $^{-1})$ corresponding to ligand-based transitions

1. Introduction

The coordination chemistry of redox-active ligands currently attracts a considerable interest.¹⁻¹¹ It was boosted by the discovery of metal-radical entities in the active site of several enzymes in the early 90's. $^{12\mathchar`-18}$ A great number of biomimetic radical complexes were described, especially of galactose oxidase, $^{19}\ \mbox{followed}\ \mbox{by}$ impressive catalytic applications, most particularly in organometallic chemistry. $^{\rm I_1}$ $^{\rm 4,\ 20\cdot25}$ Very recently a new approach, which combines redox-active ligands and lanthanide ions has emerged in the literature, with downstream applications in detection and imaging of oxidative stress. $^{26\cdot35}$ Lanthanide complexes have been long developed for medical imaging due to their fascinating optical and magnetic properties. I³⁶ They have been hitherto rarely used as redox probes due to their strong stability in the +III state (except europium). Their association with pro-radical ligands, capable of reversibly shuttling between two oxidation states, was recently proved to confer on them a unique redox character, expending now their potential towards redox probes.³⁷⁻³⁹

We have recently reported a series of lanthanides complexes involving sterically hindered phenolate moieties.3 We

oxidations affording phenoxyl radicals, which manifests in a decrease in lanthanide-centered luminescence. The stability of the phenoxyl radicals was however not sufficient to envisage biological applications in spite of the presence of electron donating tert-butyl and/or methoxy substituents. In addition the phenolate oxidation potentials in these complexes are in general higher than in related d-transition metal complexes due to the tripositive charge of the lanthanides and the ionicity of the coordination bonds. In order to overcome these two limitations we extended our investigations to aminophenol derivatives. This substitution pattern is known to decrease the oxidation potential to such an extent that the ligand usually undergoes air oxidation once deprotonated and engaged in coordination with 1st row metal centers.

demonstrated that the ligand can undergo successive ligand-based

Herein we investigated the coordination chemistry with lanthanide ions of the pincer ligand H₃L, whose redox noninnocence has been established some decades ago (Figure 1) $^{45\text{-}55}$ This ligand architecture has been chosen because it provides a hard

The

 N_2O donor set ideal for lanthanide ions. Furthermore the typical high coordination number of lanthanide ions can be readily assessed by controlling the metal:ligand ratio during the synthesis. 56 Hence, nine-coordinate lanthanide complexes (Ln = Eu, Gd, Yb, Lu) with 1:3 (Ln:L) ratios were isolated. Each ligand adopts the (Cat-N-BQ) oxidation state (Figure 1, Scheme 1). Three oxidation processes are observed, assigned to the successive oxidation of the (Cat-N-BQ) moieties to SQ-N-BQ radicals. The first reduction event leads to a mono radical species comprising the (Cat-N-SQ)²⁻ moiety. All the complexes exhibit strong absorption bands in the NIR region.

Scheme 1. Theoretical oxidation states and charges of the deprotonated pincer ligand L^3 . The t-Bu groups have been omitted for clarity. Cat, catecholate; SQ, iminosemiquinone; BQ, iminobenzoquinone.

2. Results and discussion

2.1 Synthesis

The complexes LnL₃ were synthesised using a directed synthesis with *tert*-butyl catechol, ammonia and the corresponding metal nitrate salt (Eu^{III}, Gd^{III}, Yb^{III}, Lu^{III}) to afford a dark blue solid.⁵⁶ The synthesis of LnL₃ was also carried out by complexation of the lanthanide salt with three molar equivalents of the ligand H₃L,^{45, 46} but templation was faster and resulted in higher yields.

2.2 Structures of the complexes

The four complexes were crystallized by slow evaporation of a dichloromethane solution. Unfortunately only the crystals of GdL₃ and LuL₃ were of an acceptable quality for structure determination by X-Ray diffraction despite many efforts to improve the crystallization conditions. Hence complexes LnL₃ (Ln = Gd, Lu) are found to be isostructural and the absence of any counter-ion in the crystal cell evidences that each ligand coordinates under its closed-shell monoanionic form L (Scheme 1, 2). In other terms, the ligand has been oxidized by air during the synthetic process to finally adopt the iminoquinone-aminophenolate form (Cat-N-BQ)⁻ (L⁻).⁵⁷ These complexes demonstrate each a nine-coordinate lanthanide ion, similarly to the lanthanum, samarium and strontium complexes, which were previously reported.⁵⁸⁻⁶⁰ It was assumed that compounds with (Eu $^{\rm III}$ and Yb $^{\rm III}$) demonstrated the same structure and were analysed accordingly.

(a) (b)

The coordination environment is best described as tricapped

lanthanide ion is coordinated by one nitrogen and two oxygen

atoms of the three ligands L. The Ln-N bond distances ranges

are 2.555-2.578(4) Å (GdL₃) and 2.50-2.52(1) Å (LuL₃). The

slight shortening of the Ln-N bonds with the changing size of

the lanthanides follows the trend of the lanthanide

contraction. It is worth noting that the tert-butyl groups shield

the metal ion and thus preclude further incorporation of a

solvent molecule in the coordination sphere.

trigonal prism (Figure 2, Table S1) in both GdL₃ and LuL₃.

Figure 2. Structure of (a) ${\rm LuL}_3$ (the hydrogen atoms are omitted for clarity) and (b) the coordination polyhedron within ${\rm LuL}_3.$

2.3 Electrochemistry

The complexes LnL_3 were each investigated for their redox activity in CH_2Cl_2 solution using cyclic voltammetry (CV), differential pulse voltammetry (DPV), and rotating disk electrode (RDE) voltammetry.

The CV curve of LuL₃ is shown in Figure 3, while the others are depicted in ESI. The complexes $EuL_3,\ GdL_3,\ YbL_3$ and LuL_3 demonstrated similar oxidation behaviour with three redox processes at $E_{1/2}^{ox1}$ = 0.16 V, $E_{1/2}^{ox2}$ = 0.51-55 V, and $E_{1/2}^{ox3}$ = 0.75-0.78 V vs Fc^+/Fc . The complexes of the smallest lanthanides exhibit the highest oxidation potentials, presumably due to the close proximity between the positively charged metal and the redox-active phenolate moieties. Each of these oxidation events corresponds to a one-electron oxidation, as confirmed by rotating disk electrode. They are assigned to the successive oxidations of the aminophenolate moieties to iminosemiquinone radicals.^{45-49, 51-54} At 298 K the first oxidation process is reversible for all four complexes. attesting that the stability of the monocation is noteworthy. The second oxidation wave is reversible at 298 K for ${\bf YbL_3}$ and LuL₃, but not for EuL₃ and GdL₃. The reversibility is restored upon decreasing the temperature to 233 K for these latter complexes, showing that the nature of the lanthanide significantly affects the stability of the diradical species. Hence the dications ${\rm LnL_3^{2+}}$ of the smaller lanthanides are the most stable ones based on the reversibility of the CV. Finally it must be emphasized that the shifts in potentials observed upon decreasing the temperature do not exceed that predicted by the Nernst law. Hence, ion-pairing effects with perchlorate ions from TBAP electrolyte are negligible in the present series, in contrast with previously found for lanthanide complexes of tripodal tris(salicylidene) ligands.38,3

Figure 3. Cyclic voltammetry curve of a 0.5 mM CH₂Cl₂ solution (containing 0.1 M TBAP as supporting electrolyte) of LuL₃ at a carbon electrode. The potentials are referenced vs. the Fc/Fc redox couple. T = 238 K, scan rate = 0.1 V/sec.

The electrochemical behaviour of the four neutral complexes has been also investigated in reduction. They all display a reversible monoelectronic reduction wave in the range -1.33 to -1.39 V. The similarity in reduction potentials within the series argues for redox processes of identical nature, which is assigned to the reduction of one L⁻ ligand molecule to an iminosemiquinone radical L²⁻ (Figure 2).^{45, 48, 49, 51-53} Additional reduction waves are observed but these are irreversible, indicative of coupled chemical reactions. Due to the irreversibility they have not been further investigated.

Table 1. Electrochemical data of the complexes ^[a]

 $^{[a]}$ In 0.5 mM CH₂Cl₂ solutions containing TBAP as supporting electrolyte. All the potentials values are given in V and referred to the Fc'/Fc redox couple. T = 298 K; scan rate, 0.1 V/scc. Parameters for the ferrocene against the reference used (AgNO₃ 0.01 M): E_{1/2} = 0.185 V (AE = 0.08).

 $^{[b]}$ Irreversible at 298 K. The $E_{1/2}^{\rm ox2}$ and $E_{1/2}^{\rm ox3}$ values are calculated from the DPV curve by adding half of the pulse amplitude to the peak potential.

2.4 Vis-NIR properties of the complexes

The Vis-NIR spectra of the neutral lanthanide complexes LnL₃ are very similar (Figure 4 and ESI) and display a characteristic twin band at 742-757 nm ($\epsilon \sim 38-42$ mM 1 cm 1) and 818-824 nm ($\epsilon \sim 35-40$ mM 1 cm 1), together with a band in the range 442-450 nm ($\epsilon \sim 8.6-9.9$ mM 1 cm 1). These bands are assigned to quinone based transitions on the basis of similarities with the oxidized free (Cat-N-BQ)K ligand 54 and previously reported d- and f-metal complexes of the same ligand. $^{51, 53}$ Their

presence corroborates air oxidation of the *in situ* formed ligand into (Cat-N-BQ)[°] during complexation.

The cations LnL₃⁺, LnL₃²⁺ and anions LnL₃⁻ (Ln = Gd, Eu, Yb, Lu) were generated electrochemically. Upon one-electron oxidation the shape of the NIR feature evolves significantly (black to red line, Figure 4), giving a triple band with maxima at ca. 684-704 nm (ϵ ~ 28-43 mM $^{-1}\,cm^{-1}$), 748-768 nm (ϵ ~ 28-42 mM⁻¹ cm⁻¹) and 818-836 nm (ϵ ~ 29-44 mM⁻¹ cm⁻¹). Sharp bands are additionally detected at 460-466 nm (ϵ ~ 14-20 mM 1 cm $^{-1}$), where the semiquinone transitions are usually found, disclosing oxidation of one (Cat-N-BQ) moieties into radical (SQ-N-BQ). The two-electron oxidation was limited to YbL₃ and LuL₃, e.g. the complexes that show the greatest reversibility of the second redox wave in their CV. For both complexes the current decreases continuously during electrolysis, giving a current lower than 5% of the initial one after theoretical removal of about 1.6 electrons, time at which electrolysis was stopped. By rotating disc electrode (RDE) voltammetry the ratio dication:monocation was confirmed to be 56:44 and 59:41 at the end of electrolysis for YbL_3^{2+} and LuL_3^{2+} , respectively. We tentatively interpret this behaviour by the formation of passivating ion pairs, which prevent full electrolysis. It is further supported by a significant decrease in the intensities of the plateaux of the RDE in the case of YbL₃² The electrolytic solution after electrolysis shows the triple NIR band evidenced in the cations, with a somewhat weaker intensity (Table 2), while a new intense feature is observed at 370 nm (ratio of absorbance at 370 over 680 nm larger than 1). where phenolate/phenoxyl transitions are expected to be found (blue line, Figure 4). This behaviour is consistent with two successive ligand-centered oxidations which afford the bis(SQ-N-BQ) radical species.

Figure 4. UV-Vis-NIR spectra of 0.5 mM CH₂Cl₂ solutions (containing 0.1 M TBAP as supporting electrolyte) of LuL₂, Black line: neutral complex; Red line: cation; Blue line: dication (recalculated spectrum by correcting the experimental spectrum from the contribution of the monocation - 41 % determined by RDE); Green line: monoanion. J = 1.00 mm. 7 = 288 K.

Interestingly the electrochemically generated dications YbL_3^{2+} and LuL_3^{2+} were stable at the hour timescale at 233 K, but decompose rapidly at r.t. (within the minute timescale for

J. Name., 2013, 00, 1-3 | 3

Lul₃²⁺). The decomposition path affords primarily the monocation, which further evolves towards the neutral precursor within one hour range.

Please do not adjust margins

2.6 Magnetic susceptibility

in Figure 5.

The electrochemical reduction of the neutral complexes is accompanied by changes in the intensity of the bands in the 730-850 nm region, as well as the appearance of a NIR shoulder (at 950 nm, green line in Figure 4). These modifications are accompanied by the appearance of a sharp band at 410 nm, which is reminiscent of phenoxyl radical $\ensuremath{\mathsf{species}}\xspace{\ensuremath{\mathsf{.53}}\xspace}$ It is worth noting that similar spectra were obtained for EuL₃ and the other anions. Furthermore a similar spectral evolution was reported for the one-electron reduction of the related bis(aminophenolate)zinc complex. $^{\rm 51}$ This supports a ligand-centered reduction processes for all the complexes. In other terms the europium ion, which is the only one prone to reduction, ⁶² retains its (+III) oxidation state in the anion. Hence the anion forms via reduction of one ligand molecule to ${\rm (Cat-N-SQ)}^{2\text{-}}$ ${\rm (L}^{\bullet2\text{-}})$ (Figure 1). Not surprisingly the one-electron reduced products are sensitive to oxygen. In every case the exposure to air of a CH_2Cl_2 solution of LnL_3 results in the recovery of the spectrum of LnL3.

2.5 Photophysical properties of the complexes

The lanthanide ions Eu^{III} and Yb^{III} are classical visible and NIR emitters, respectively. In our case the emission spectra of EuL_3 and YbL_3 (both at r.t. and 200 K) however do not show any metal-centered luminescence. The strong ligand-centered absorption bands in the Vis and NIR regions likely preclude the population of the excited state of the lanthanide ions. Consequently the luminescence of both the Eu^{III} and Yb^{III} ion is efficiently quenched due to reabsorption. The same behaviour was observed for the corresponding cations and dications.

 $^{[a]}$ In 0.5 mM CH₂Cl₂ solutions containing TBAP as supporting electrolyte (0.1 M). The cations and monocations were electrochemically generated. All the potentials values are given in V and referred to the Fc⁺/Fc redox couple. T = 298 K; scan rate, 0.1 V/sec.

^[b] From spectral deconvolution. For the dication [YbL₃]^{2*} the height of the plateaux of the RDE was significantly lower than for the monocation. This suggests loss of material (possibly by precipitation onto the electrode surface), precluding spectral deconvolution and determination of molar extinction coefficients. ⁹ , Jewy w 100 - 0000 - 000 - 000 - 000 - 000 - 000 - 000 - 000 - 000 - 000 - 000

The temperature dependence of the product of the molar

magnetic susceptibility of the neutral complexes EuL₃, GdL₃

and \textbf{YbL}_{3} is presented in the form of the χT product, as shown

Figure 5: Experimental χ T vs. T plots for EuL₃ (bottom), YbL₃ (middle) and GdL₃ (top) with solid lines for best fit with PHI software (see text).

For EuL₃ the χT is 1.20 emu K mol⁻¹ at 300K then decreases continuously upon cooling to zero at 2 K as is expected for such an Eu³⁺ complex (Figure 5).^{64, 65} This comes from the thermal depopulation of the exited states issued of the splitting of the ⁷F_{0>6} ground term by the spin–orbit coupling.⁶⁶ Accordingly the magnetic susceptibility of EuL₃ is well fitted (Figure 5) with a spin–orbit coupling parameter λ of 237(±1) cm⁻¹ which compares well with others.^{64, 65, 67}

For **YbL**₃ the χ T value is 2.62 emu K mol⁻¹ at 300K then decreases continuously upon cooling to reach 0.64 emu K mol⁻¹ at 2 K (Figure 5). As well for the magnetization, it is continuously increasing with the magnetic field to reach 1.45 μ_{B} at 5T. These values and behavior are in agreement with previous works.^{62, 66, 69} For a better description, the magnetic susceptibility data have been fitted⁶³ (Figure 5) with Crystal Field Parameters B_{2}^{0}, B_{4}^{0} and B_{6}^{0} in Steven's notation for the tricapped trigonal prism of symmetry D_{3h} and anisotropic *g*-factors (g_x, g_y and g_z) as reported in Tables S1 (in ESI). These CF and g-factor parameters give a good simulation of the field dependence of magnetization, especially at low fields (Figure S1).

For **GdL**₃ the χ T value is 8.34 emu K mol⁻¹ at 300K and it is almost constant during cooling down to 20K then decrease slightly to reach 7.38 emu K mol⁻¹ at 2 K. As well for the magnetization, it is continuously increasing with the magnetic field to reach almost saturation (6.69 μ_{B}) at 5T. These behavior are in agreement with one Gd³⁺ (S=7/2, χ T=7.375 emu K mol⁻¹).⁶⁹ and accordingly is well fitted with g-factor=2.04 and an almost non-significant intermolecular antiferromagnetic interaction ZJ=-0.002(±1) cm⁻¹.

2.7 EPR spectrocopy

4 | J. Name., 2012, 00, 1-3

The neutral complexes EuL₃, GdL₃ and YbL₃ contain a paramagnetic lanthanide ion and therefore were subjected to an EPR analysis. Conversely, complex ${\sf LuL}_3$ can be used as a diamagnetic reference whereby only the oxidised compounds (cation and dication) give rise to paramagnetic species.

<u>dγ</u>" dB

Figure 6. Powder EPR spectrum of (a) **GdL**₃ and (b) **YbL**₃. Black lines: Experiming spectra; Red lines: Simulations. The spin Hamiltonian parameters are: (a) 7/2), g = 2, |D| = 3580 MH₂, E = 0; D strain = 300 MHz. (b) $g_{4} = 3.9$, $g_{2} = 2.7$, |D| = 3580 MHz, |T| = 0; D strain = 300 MHz. (b) $g_{4} = 3.9$, $g_{2} = 2.7$, |D| = 3580 MHz, |T| = 10, |D| = 3, 4000 MHz (TV) and $A_{2} = A_{2} = 1200$ MHz (TV) g_{3} strain = Microwave Freq. 9.6416 GHz, power: (a) 0.06 mW; (b) 2 mW. Mod. Freq. KHz Amp. 0.4 mI. 7 = 9.K

The complex EuL_3 proved to be difficult to observe in the temperature range 100-10 K. This result is not unexpected due to the combined effects of the fast relaxation of the lanthanide ion, and its odd multiplicity (S = 3). Conversely, the Gd^{III} ion could be readily detected by EPR (Figure 6a) because the fshell is half-filled (S = 7/2) and hence the total momentum J and the spin momentum S are equal ("S-state" metal ion). Consequently the energy gap between the ground and excited multiplets is large, resulting in a slow relaxation and allowing the observation of spectra even up to room temperature. The powder spectrum of the corresponding GdL₃ species displays at least nine lines in the spectral window 1-660 mT (Figure 6a). The broad distribution of resonances suggests that the zero field splitting (ZFS) is operating and that the ZFS parameter D is larger than the X-Band quantum. The D value in Gd complexes is proved to be very sensitive to the geometry and can span

320 340 360 380 B/mT (b)

over a broad range. $^{70\mathchar`-72}$ Unfortunately, the spectra are often

broad 72 due to a distribution of the ZFS parameters, which

needs to be correctly modelled. The unique resolution of the

Figure 7. Powder EPR spectrum of (a) LuL_{2}^{*} and (b) LuL_{2}^{*} . Black lines: Experimental spectra; Red lines: Simulations. The spin Hamiltonian parameters are: (a) (S = 172, $g_{uo} = 2.000$. (b) (S = 11, $g_{uo} = 1.997$, [D] = 260 MHz, E = 0; D strain = 120 MHz. Microwave Freq. 9.6362 GHz, power: (a) 0.2 mW; (b) 2 mW. Mod. Freq. 100 KHz, 200, 0) (a) 0.3 mT. (b) 0.4 mT. 7 = 7 K.

The Yb^{III} ion within YbL_3 is a system with even multiplicity. The powder spectrum of this complex displays features in the 100-300 mT region, as well as a broader line at higher field (Figure

6b). The low field component is composed of two main lines as well as satellite shoulders of lower intensity. We fitted this spectrum by using the spin Hamiltonian parameters $g_1 = 3.9$, g_2 = 2.7 and g₃ = 1.15 for all the Yb isotopes. In order to account for the outermost lines we considered the ¹⁷¹Yb isotope (I_{Yb} = $\frac{1}{2}$, natural abundance 14 %) with HFC constants $A_{Yb}^{1} = A_{Y}$ 4000 MHz. We estimated the HFC constants with the $^{173}\mathrm{Yb}$ isotope (I_{Yb} = 5/2, natural abundance 16 %) to $A_{Yb}^{-1} = A_{Yb}^{-2} =$ 1200 MHz from the ratio of the gyromagnetic ratio ¹⁷³Yb/¹⁷¹Yb. Having characterized the neutral precursors we next examined the oxidized species. The spectrum of the cation EuL_3^+ consists of an unresolved and intense resonance centered at g = 1.955 (peak-to-peak line width of 9.5 mT). It is the result of a halfinteger spin system that forms upon one-electron oxidation of the neutral EuL₃ and likely arises from the transition within the 1/2 Kramers' doublet. The oxidized species GdL3⁺ is an integer spin system, which proved to be difficult to observe over the investigated temperature range (T = 7-25 K).

For the ytterbium complexes both the monocation and the dication were found to be essentially EPR-silent. While this might be expected for monoradical complexes of ytterbium this is rather surprising for YbL₃²⁺, which is a half-integer spin system. Possible explanations are strong Yb-radical interactions in the diradical system and further line broadening or dimerization equilibria in solution. Due to the lack of specific signature it was not possible to go further in the EPR analysis for this complex.

oxidation process involves two successive one-electron transfers on distinct ligand molecules according to Scheme 2. The |D| value is slightly smaller than those reported for octahedral zinc bis(phenoxyl) radical systems based on Schiff bases (360-540 MHz)⁷³ and gallium bis(iminosemiquinone) complexes (617-672 MHz)⁷⁴. This suggests an increased spatial separation of the radicals in LuL₃²⁺, in agreement with larger coordination bond distances in the lanthanide series, in addition to changes in the orientation of the radical moieties. By using the dot dipole approximation the interspin distance is calculated at ca. 7.5 Å. This value compares with the distances between the centroids of the aromatic rings of distinct ligand molecules (in the 6.5-8.6 Å range depending on the considered aromatic ring). We further investigated the temperature dependence of the triplet signal over the 5-25 K temperature range. The plot of I as a function of 1/T shows a saturation behaviour at ca. 1/T = 0.2, indicative of weak antiferromagnetic interactions between the two ligand-radical spins. The fit of the curve IT as a function of T (Figure 6) gives an exchange coupling constant $J = -3 \pm 1$ cm⁻¹. The J value is smaller than that determined for zinc(II) bis(phenoxyl) radical systems, disclosing weaker magnetic coupling in our tris(ligand) system. Further comparison is difficult since the nature of the exchange depends strongly on the orientation of the radical planes and hence the geometry of the coordination sphere.

Scheme 2. Successive oxidation processes in $\mbox{LuL}_3.$ The t-Bu groups have been omitted for clarity.

The oxidized complex that is the easiest to characterize by EPR spectroscopy is LuL₃⁺. Its spectrum (Figure 7a) is typical of an (S = 1/2) radical system, with a single resonance at g = 2.000 (peakto-peak linewidth of 1.7 mT). The g value is close to that of free electron, as expected for organic radicals, while no HFC could be resolved, presumably as a result of the substantial linewidth. The spectrum of the dication ${\rm LuL_3^{2+}}$ consists of two overlapped signals (Figure 7b). One is similar to LuL3+, suggesting that the monocation is present as contaminant in the solution. By analysis of the intensity we estimate the amount of LuL₃⁺ to 30-40 % with respect to the total expected spin concentration, which is consistent with rotating disc electrode voltammetry. Satellite lines, which correspond to a triplet system, are observed around the band at g = 2.000. This assumption is further confirmed by the presence of a weak half-field "forbidden" ΔM_{S} = 2 transition at 175 mT (insert in Fig. 7b). The triplet resonances are assigned to LuL²⁺. They could be satisfactorily simulated by using the following spin Hamiltonian parameters: g = 1.997, |D| = 260 MHz, E = 0. Both the g value and the ZFS parameter D are consistent with a bis(radical) nature of LuL_3^{2+} . Thus they confirm that the

Figure 8. Solution EPR spectrum of LuL₃ in 0.5 mM CH₂Cl₂ solution containing 0.1 M TBAP. Black line: Experimental spectrum; Red line: Simulation using the spin Hamiltonian parameters (S = 1/2), $B_{\rm eps} = 2.002$, $A_{\rm e} = 16$ MHz, $A_{\rm e} = 6$ MHz. Microwave Freq. 9.4319 GHz, power: 1 mW; Mod. Freq. 100 KHz; Amp. 0.3 mT. 7 = 293 K.

Finally we examined the anionic complexes, which were generated electrochemically in the glove box. All the complexes exhibit a similar resonance at g = 2.00 that is reminiscent of monosemiquinone radical systems.⁷⁵ For the lutetium complex LuL₃, which is the only genuine ($S = \frac{1}{2}$) system of the series, we additionally recorded the spectrum at 293 K. Under isotropic regime the spectrum shows a well-defined four-line pattern. It was simulated by considering the hyperfine interaction with one ¹⁴N nucleus (16 MHz), and two inequivalent ¹H nuclei (14 and 6 MHz), which are assigned to

6 | J. Name., 2012, 00, 1-3

This journal is © The Royal Society of Chemistry 20xx

the nitrogen and the two aromatic hydrogens of the semiquinone, respectively. $^{\rm 51,\,76}$ The fact that there is only one strongly coupled ¹H nucleus indicates that the radical tends to localize on one ring, within a single ligand moiety.

3. Conclusions

In summary we have prepared lanthanide complexes of the N,N'-bis(2-hydroxy-di-3,5-tertredox non-innocent butylphenyl)amine pincer ligand. The metal is ninecoordinated, surrounded by three ligand moieties under their monoanionic (Cat-N-BQ) form. The complexes demonstrate three one-electron oxidations, which are assigned to the successive oxidation of the three ligands, as well as a reduction event that is also assigned to a ligand-centered redox process. The oxidized and reduced products contain semiquinone radical moieties, with distinct Vis-NIR features. The dication LuL_3^{2+} , which was formed with the diamagnetic lutetium ion, allowed for the determination of both the ZFS parameters and the exchange coupling constant J_{τ}

4. Experimental Section

4.1 Materials and methods

All chemicals were of reagent grade and were used without purification. Lanthanide nitrate salts were purchased from Aldrich and titrated for metal content before use, in the presence of EDTA and xylene orange. High resolution mass spectra were recorded on a Waters Xevo G2-S QTof apparatus. The UV/Vis spectra were recorded on a Cary Varian 50 spectrophotometer equipped with a Hellma immersion probe (1.000 cm path length) or a Perkin Elmer Lambda 1050 spectrophotometer. NMR spectra were recorded on a Bruker AM 400 (¹H at 400 MHz) spectrometer. Chemical shifts are quoted relative to tetramethylsilane (TMS). X-band EPR spectra were recorded on a Bruker EMX Plus spectrometer equipped with a Bruker Helium flow cryostat and a dual mode cavity. Cyclic voltammetry curves as well as differential pulse voltammetry curves were recorded using a CHI 620 potentiostat. The measurements were performed in 0.5 mM CH₂Cl₂ solution containing 0.1 M tetra-*n*-butyl ammonium perchlorate (TBAP) as supporting electrolyte. Experiments were performed in a standard three-electrode cell under argon atmosphere (glove box). A glassy carbon disc electrode (3 mm diameter), which was polished with 1 mm diamond paste, was used as the working electrode. The auxiliary electrode is a compartmentalized platinum wire, while an Ag/AgNO₃ 0.01 M electrode was used as reference. The electrolysis was carried out at 233 K on a Biologic SP 300 potentiostat, by using a carbon foam working electrode.

Luminescence spectra of the lanthanide complexes were recorded using a modular Fluorolog FL3-22 spectrometer Horiba-Jobin Yvon-Spex equipped with a double grating excitation monochromator and an iHR320 imaging spectrometer. Hamamatsu R928P and Hamamatsu R5509 photomultipliers were used for visible and NIR measurements,

ARTICLE

respectively. All spectra were corrected for detection and optical spectral response (instrumental functions) of the spectrofluorimeters. Quartz capillaries 4 mm in diameter were used. For the acquisition of the excitation and emission spectra in the NIR, a long pass coloured filter was always used at 870 nm to block the signal of the 2nd harmonics.

The temperature dependence of the magnetic susceptibility was measured in the temperature range 2-350 K in an applied magnetic field of 0.1 T using a SQUID magnetometer from Quantum Design model MPMS-XL. Magnetization versus magnetic field (0-0.5 T) was measured at 2 K. All data were corrected for the contribution of the sample holder and diamagnetism of the samples estimated from Pascal's constants.77 The PHI software was used for the fitting of the experimental magnetic data.63

4.2 Synthesis

Please do not adjust margins

The ligand was synthesised using literature procedures. $^{\rm 45,\ 46}$ The complexes were synthesised via a template synthesis. In a typical experiment a solution of 3,5-di-tert-butylcatechol (0.099 g, 0.44 mmol, 6 eq) in 10 mL of EtOH was added to a solution of Ln(NO₃)₃.xH₂O (0.073 mmol, 1 equiv.) in EtOH (10 mL). Concentrated ammonia (2 ml) was added, forming a deep blue solution. A dark precipitate was formed which was collected by filtration. Each of the complexes was prepared and isolated under crystalline form following the same procedure.
