57  
58  
59 A novel UV-Vis photodetector consisting of an octahedral molybdenum cluster-  
60

1  
2  
3  
4  
5  
6 functionalized  $Zn_2Al$  layered double hydroxide (LDH) has been successfully synthesized  
7  
8  
9 by co-precipitation and delamination methods under ambient conditions. The  
10  
11  
12 electrophoretic deposition process has been used as a low cost, fast, and effective method  
13  
14  
15 to fabricate thin and transparent nanocomposite films containing a dense and regular  
16  
17  
18 layered structure. The study provided evidence that the presence of the  $Mo_6$  cluster units  
19  
20  
21 between the LDH does not affect the ionic conduction mechanism of the LDH, which  
22  
23  
24 linearly depends on the relative humidity and temperature. Moreover, the photocurrent  
25  
26  
27 response is remarkably extended to the visible domain. The reproducibility and  
28  
29  
30 stabilization of the photocurrent response caused by the  $Mo_6$  cluster-functionalized LDH  
31  
32  
33 have been verified upon light excitation at 540 nm. Additionally, it was demonstrated that  
34  
35  
36 the films show advantageously strong adherence properties for application requirements.

## 42 1. INTRODUCTION

43  
44  
45 Energy converters based on nanoarchitecture-cluster functionalized materials with  
46  
47  
48 stabilization of the physicochemical properties have been developed for materializing a  
49  
50  
51 sustainable society. Particularly, the efficiency and applicability of the light energy  
52  
53  
54 converters or photodetectors essentially depend on their light sensitivity performance, fast  
55  
56  
57 photocurrent response speed, and a linear dependence of the optical and current values in  
58  
59  
60

1  
2  
3  
4  
5  
6 the industry. During the last few decades, the use of various wide band-gap  
7  
8  
9 semiconducting inorganic materials, such as ZnO, MoS<sub>2</sub>, ZnS, SiC for the light energy  
10  
11  
12 converters, has been mainly reported due to their simple structure and high  
13  
14  
15 photoconductive gain.<sup>1-4</sup> The visible (Vis) sensing photodetector using solar light energy  
16  
17  
18 became an interesting study for sustainable energy development goals.<sup>5, 6</sup> However, the  
19  
20  
21 development of broadband photodetectors, having an efficient photoactivity in the UV-  
22  
23  
24 Vis light range, low cost, and environmentally friendly material and process, is facing  
25  
26  
27 many challenges for researchers. The layered double hydroxide (LDH), one of the  
28  
29  
30 promising inorganic matrices for the nanocomposite, was expressed by the formulation  
31  
32  
33 of  $[M^{2+}_{1-x}M^{3+}_x(OH)_2]^{x+} (A^{n-})_{x/n} \cdot mH_2O$  ( $M^{II} = Zn, Ni, Co, Mn, \text{ etc.}; M^{III} = Al, Fe, \text{ etc.}; A$   
34  
35  
36  $= NO_3^-, CO_3^{2-}, SO_4^{2-}, PO_4^{3-}, \text{ etc.}$ ) with  $x$  as the molar ratio  $M^{2+}/(M^{2+} + M^{3+})$  in the range  
37  
38  
39 of 0.2–0.33 and  $A^{n-}$  as an  $n$ -valent anion. LDH is well known as a multifunctional material  
40  
41  
42 with easily scalable fabrication and flexible application for a catalyst,<sup>7</sup> water treatment,<sup>8</sup>  
43  
44  
45 and drug support.<sup>9</sup> The tunability of the trivalent atom metal in an edge-sharing  $M(OH)_6$   
46  
47  
48 octahedral network and internal anion exchangeability increase the chance to fabricate a  
49  
50  
51 wide variety of different LDH-based materials in a large amount. This is mostly due to  
52  
53  
54 the distinction of tunable host layers and functional interlayer guest molecules.<sup>10</sup>  
55  
56  
57 Currently, several studies been comprehensively focused on adsorbability improvement,<sup>11,</sup>

<sup>12</sup> or hydroxyl anionic conductivity<sup>13-16</sup> of the LDH, following the modification of the elemental compositions and charge densities of the host layers. As a result, the LDH-based applications have focused on the device's performances as humidity sensors,<sup>17</sup> gas sensors,<sup>18,19</sup> optical pH sensors,<sup>20</sup> and super-capacitor.<sup>21-23</sup> Particularly, the LDH or photo-functional LDH-based materials have shown promising features for applications in optical devices. For example, G. Prestopino et al. reported the switchable photoluminescent properties of dehydrated Zn/Al-LDH nano-platelets through a dehydration–hydration process.<sup>24</sup> The luminescent organic molecule or quantum dot modified LDH has also been remarkably studied for use in photochemical cells.<sup>25-27</sup>

Recent studies have highlighted the LDH-based materials as potential candidates for photodetector applications due to their photocurrent response under UV-Vis light. For instance, the ZnAl LDH nanosheet scrolls present a photoresponse in the UV spectral range below 420 nm, indicating a visible-blind spectral response.<sup>28</sup> Extending the photocurrent response in the visible range was performed by adding the TiO<sub>2</sub> component to the ZnFeAl-layered double hydroxides, involving a better photocathodic protection performance for 304SS stainless steel due to the unique structure and efficient visible-light response property.<sup>29</sup> In addition, the photo-induced charge combination in the ultrathin-layered double hydroxide nanosheets under light illumination could accelerate

1  
2  
3  
4  
5  
6 the oxygen evolution reaction.<sup>30</sup> Finally, the studies of the photodetector made from the  
7  
8  
9 LDH-based materials have motivated researchers to optimize their stable photochemical  
10  
11  
12 properties for industrial applications.  
13  
14  
15  
16  
17

18 In this study, a new potential photodetector material exhibiting a UV–Vis  
19  
20 photoconductivity response was fabricated from Zn<sub>2</sub>Al LDH intercalated glycine  
21  
22 (abbreviated as ZAG) functionalized by octahedral iodide-bridged molybdenum clusters  
23  
24 (abbreviated as Mo<sub>6</sub>). This octahedral metal cluster (MC) is illustrated by an organic-  
25  
26 inorganic building unit with a 1.2-nm size and belongs to the family composed of the  
27  
28 {M<sub>6</sub>L<sup>i</sup><sub>8</sub>}<sup>4+</sup> (M = Mo, W, Re; L<sup>i</sup> = inner halide ligand) metallic cores bonded with 6 apical  
29  
30 ligands (L<sup>a</sup> = Cl, Br, I or OCOC<sub>n</sub>F<sub>2n+1</sub>...).<sup>31,32</sup> The Mo<sub>6</sub> MCs have been known for several  
31  
32 decades for their luminescence<sup>33-36</sup> and redox properties.<sup>37,38</sup> The photochemical and  
33  
34 electrochemical properties of the MC come from the metal-metal and metal-ligand  
35  
36 bonding, resulting in a strong absorption in both the UV-Vis lights and a prominent  
37  
38 luminescent emission within the deep red/near-infrared (NIR) regions. The remarkable  
39  
40 optical properties of the Mo<sub>6</sub> MC are their i) high quantum yield, ii) large Stoke shift that  
41  
42 avoids re-absorption losses, iii) strong luminescence, iv) phosphorescence in the infrared  
43  
44 range, and v) UV-Vis absorption combined with an excellent photostability due to its  
45  
46  
47  
48  
49  
50  
51  
52  
53

57  
58  
59  
60

1  
2  
3  
4  
5  
6 unique complex structure. The applicable potentials of these MCs have been proved  
7  
8  
9 through the recent developments of the optical-related inorganic devices, such as  
10  
11  
12 photocatalytic water purification,<sup>39</sup> nanoparticles for bioimaging,<sup>40</sup> photoelectrodes for  
13  
14 solar cells<sup>41</sup> and photonic crystals.<sup>34</sup> The flexible interactions between the metal cluster  
15  
16 core, apical ligand, and counter ion in the nanocomposite have become a challenge to  
17  
18 figure out the right explanation for the optical property modification. However, it also  
19  
20 provides a new approach to develop a new molybdenum cluster-based device with a  
21  
22 controlled optical property based on the modification of the elemental compositions and  
23  
24 their physicochemical interactions.  
25

37  
38

39 The electrophoretic deposition (EPD) process, a thin film coating technique which is able  
40  
41 to easily control the homogeneity, thickness, compatibility, and maximum loading ability  
42  
43 of the main functional compositions, possibly allows the applicability of the cluster bulk  
44  
45 materials. Considering the advantages of the EPD process, it will be a smart technique to  
46  
47 fabricate thin films on the devices, particularly, for the devices based on the MCs. Very  
48  
49 recently, this method was successfully used to fabricate thin and transparent pure clusters  
50  
51  
52 or hybrid nanocomposite films with very interesting properties for energy-saving  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 applications.<sup>42</sup>  
7  
8  
9

10  
11  
12 A Mo<sub>6</sub> cluster compound, namely Cs<sub>2</sub>[Mo<sub>6</sub>I<sub>8</sub>I<sup>a</sup><sub>6</sub>] (abbreviated as CMI), with strong  
13 absorption in the visible light up to 600 nm has been selected for its photoresponse under  
14 broad visible light. Meanwhile, Zn-Al LDH (ZA) gives a photoresponse when excited by  
15 ultraviolet (UV) light. A thin and transparent Mo<sub>6</sub>-functionalized LDH film (~ 3μm) was  
16 successfully prepared by the EPD process, exhibiting a dense lamellar structure. The Mo<sub>6</sub>-  
17 functionalized LDH film exhibited several interesting complementary properties, i.e., i)  
18 a red emission centered at the wavelength of 690 nm by UV-Vis light irradiation, ii) an  
19 anionic conductivity of about 10<sup>-6</sup> S.cm<sup>-1</sup> with an activation energy (E<sup>a</sup>) of about 1.08 eV,  
20 iii) a proper photocurrent response under UV-Vis light excitation ranging from 320 to 540  
21 nm, and iv) a photocurrent response depending on the film thickness, temperature, and  
22 humidity. The remarkable point in this study is the determining of the relation between  
23 the photoresponse and the temperature or the humidity level which has not been figured  
24 out, to the best of our knowledge, in previous reports about LDH-based materials.<sup>28-30</sup>  
25  
26 Even if a further understanding of this phenomenon should be investigated in the future,  
27 we have demonstrated that EPD is an excellent process to easily prepare a Mo<sub>6</sub>-  
28 functionalized LDH film exhibiting good mechanical properties.

## 2. EXPERIMENTAL SECTION

### 2.1 Chemicals

Zn(NO<sub>3</sub>)<sub>2</sub> • 6H<sub>2</sub>O (99%) and Al(NO<sub>3</sub>)<sub>3</sub> • 9H<sub>2</sub>O (98%, pH= 2~4) were purchased from Chameleon reagent. Glycine (99%) was purchased from the Fujifilm Wako Pure Chemical Collaboration. The sodium hydroxide (NaOH, 5 mol/L), acetone (99.5%) and formamide (98.5%), and methyl ethyl ketone (MEK, 99%) were supplied from Nacalai Tesque. All chemicals were used without purification. The deionized water was obtained from Water Purifiers WG710 equipment with the conductance of 0.5×10<sup>-4</sup> S/m at 25°C.

### 2.2 Synthesis of CMI, LDH-Zn<sub>2</sub>Al (ZA) and glycine-modified LDH-Zn<sub>2</sub>Al (ZAG)

The CMI cluster powder was synthesized following the procedure reported in a previous publication,<sup>43</sup> i.e., by the reaction of CsI (Alfa Aesar 99.9 %) and MoI<sub>2</sub> at the temperature of 700°C. The Zn<sub>2</sub>Al LDH powder, abbreviated ZA, was synthesized by the co-precipitation method in air with the ratio between the Zn and Al atoms (Zn/Al = 2) referenced from the report of Ahmed et al.<sup>44</sup> In greater detail, a transparent mixed solution of Zn(NO<sub>3</sub>)<sub>2</sub> • 6H<sub>2</sub>O (0.02 mol) and Al(NO<sub>3</sub>)<sub>3</sub> • 9H<sub>2</sub>O (0.01 mol) was prepared in 50 mL of deionized water using a magnetic stirrer for 1 h. The solution was then titrated by NaOH (5 M) at the pH value of 10 to obtain a cloudy suspension, then agitated at room

1  
2  
3  
4  
5  
6 temperature for 24 h to increase the crystallinity of the LDH. This powder was washed  
7  
8  
9 and dried at 80°C for more than 24 h and used as the reference material.  
10

11  
12  
13  
14  
15 A glycine-modified Zn<sub>2</sub>Al LDH, abbreviated ZAG, was similarly synthesized following  
16  
17  
18 the ZA-synthesized steps with the simultaneous dissolution of the glycine (0.01 mol) in  
19  
20  
21 an aqueous salt solution. ZAG was purified by washing in deionized water until the pH  
22  
23  
24 was between 7 and 8, then dried at 60°C for 24 h. The ZAG nanosheets were then obtained  
25  
26  
27 by a delamination process in formamide for subsequently functionalizing the CMI cluster.  
28  
29  
30 Glycine and formamide were chosen as the amino acid anion intercalant and polar solvent  
31  
32  
33 systems, respectively, for the exfoliation process as first described by Hibino and Jones.<sup>45</sup>  
34  
35

## 36 2.2 Synthesis of the CMI Cluster@ZAG Powders and Films

37

38  
39 The CMI powder was first dissolved in formamide at the concentration of 0.4 g/L using  
40  
41  
42 an ultrasonic water bath for 1 h to obtain a red homogeneous solution. The glycine was  
43  
44  
45 added to this red CMI solution, then agitated by a magnetic stirrer for 2 days. Table S1  
46  
47  
48 displays the compositions and ratios between the glycine and the Mo<sub>6</sub> cluster abbreviated  
49  
50  
51 CG<sub>x</sub> with x=1, 2, 3, 4 as an abbreviated representation of the real weight. Secondly, the  
52  
53  
54 as-synthesized ZAG powder with 10 times the weight of the CMI cluster was added to  
55  
56  
57 the CG<sub>x</sub> suspensions, then continually agitated for 3 days. The washing procedure of the  
58  
59  
60

1  
2  
3  
4  
5  
6 CGx@ZAG wet powders in formamide was repeated three times to eliminate the residual  
7  
8  
9 cluster and glycine and stored at room temperature for the film fabrications. Only the  
10  
11  
12 CG1@ZAG wet powder was completely dried at 80°C for X-ray diffraction (XRD), high-  
13  
14  
15 resolution transmission electron microscopy (HR-TEM), and optical characterizations for  
16  
17  
18 reference. In parallel, the ZAG powder was also dissolved in formamide at the  
19  
20  
21 concentration of 4 g/ L for 3 days without the CG mixture for preparing the delaminated  
22  
23  
24 wet ZAG powder.  
25

26  
27 The EPD system was built by two indium tin oxide-coated glass (ITO glass) slides with  
28  
29  
30 a surface area of 1.0×2.5 cm<sup>2</sup>, acting as the anodic or cathodic electrodes (Geomatec Co.,  
31  
32  
33 Ltd., Tokyo, Japan; 6.15-7.27 Ohm/sq), and was connected to a Source Meter (Keithley  
34  
35  
36 Model 2400, Ohio, USA) as an electric field generator. The schematic illustration of the  
37  
38  
39 nanocomposite film preparation by EPD is illustrated in Figure S1. The EPD suspensions  
40  
41  
42 were composed of the ZAG or CGx@ZAG wet powder dissolved in MEK (~ 2.5 g/L)  
43  
44  
45 using an ultrasonication treatment for 30 minutes. A small amount of formamide (~ 1 ml)  
46  
47  
48 was added to the suspension to increase the solubility of the CGx@ZAG in MEK and the  
49  
50  
51 stabilization of the suspension during the EPD process. With a positive zeta potential  
52  
53  
54 value as noted in Table S2, the cathodic EPD process was applied for the ZAG or  
55  
56  
57 CGx@ZAG film fabrication. During the EPD process, the applied voltage controls the  
58  
59  
60

1  
2  
3  
4  
5  
6 migrating speed of the charged particles to the electrodes as well as the homogeneity of  
7  
8  
9 the deposited particle size inside the film. Meanwhile, the deposition time directly  
10  
11  
12 impacts the formation of an insulator film that limits the force of the electric field on the  
13  
14  
15 ionic movement in the slurry. The film fabrication was operated at 15 V for 2 minutes or  
16  
17  
18 25 V for 3 minutes to obtain the best properties.  
19  
20

### 21 2.3 Measurement of the Impedance and Current of the Films under Illumination, 22 23 24 Temperature and Humidity Conditions 25

26  
27 A schematic diagram of the impedance measuring system is illustrated in Figure S2. The  
28  
29  
30 ZAG or CGx@ZAG films deposited on the ITO-coated glass were contacted with a blank  
31  
32  
33 ITO-coated glass as the counter electrode with the measured area of 1 cm<sup>2</sup>. The two  
34  
35  
36 electrodes were connected by a micrometer. The film thickness was estimated to be 3 to  
37  
38  
39 4 μm by measurement using a 3D color microscope. The experimental conditions were  
40  
41  
42 controlled by a bench-top type temperature and humidity chamber (SH-222, Espec Corp.).  
43  
44  
45 The different UV-Vis light illuminations were generated by a 300 W compact Xenon light  
46  
47  
48 source (MAX-303, Asahi Spectra Co., Ltd.). A monochromator combined with an optical  
49  
50  
51 filter (Transmittance ~ 80 %) was used to generate monochromatic light with peaks  
52  
53  
54 centered at 320, 350, 370, 410, 440, 540, and 580 nm followed by the bandwidth of the  
55  
56  
57 light of about 10 nm. The electrical impedance of the films was measured by a 1260A  
58  
59  
60

1  
2  
3  
4  
5  
6 impedance analyzer (Solartron analytical, AMETEK Scientific Instruments) at the  
7  
8  
9 applied voltage of 500 mV in the frequency range between  $10^1$  Hz and  $10^7$  Hz. A source  
10  
11  
12 meter (Keithley Model 2400, Ohio, USA) was used to measure the photocurrent response  
13  
14  
15 of the films at a bias of 1 V in the controlled environmental conditions. The ZAG and  
16  
17  
18 CGx@ZAG films were prepared at 25 V as an upper limit of the applied voltage in order  
19  
20  
21 to obtain the optimal thickness with a relative dense and transparency for 2 minutes. The  
22  
23  
24 thickness is directly proportional to the amount of the adsorbed water as an important  
25  
26  
27 carrier whereas the high condense layered structure distributes to the moving pathway of  
28  
29  
30 the ions inside the material. The electrical conductivity was expressed by the following  
31  
32  
33 equation:

$$\sigma = l / (R \cdot A) \quad (1)$$

34  
35  
36 where  $\sigma$  is the electrical conductivity,  $l$  is the thickness of the film,  $A$  is the area of the  
37  
38  
39 sample ( $1 \times 1 \text{ cm}^2$ ), and  $R$  is the total resistance measured by Electrochemical Impedance  
40  
41  
42 Spectroscopy (EIS).  
43  
44  
45  
46  
47

#### 48 2.4 Characterization

49  
50  
51 The zeta potentials of the suspensions were determined by a zeta-potential analyzer  
52  
53  
54 (Zetasizer Nano Z, Malvern Instrument, Ltd., UK). The average hydrodynamic diameters  
55  
56  
57 and distribution of the LDH nanosheets in a MEK/ formamide medium were measured  
58  
59  
60

1  
2  
3  
4  
5  
6 by an ultrafine particle analyzer (Nanotrac NPA151 - Nanotrac ULTRA, Microtrac, Inc.,  
7  
8  
9 USA) incorporated with the controlled reference method (CRM) in a dynamic light  
10  
11 scattering (DLS) instrument. The crystalline layered structure of the powders and films  
12  
13 were determined by XRD (SmartLab, RIGAKU, 40 kV and 30 mA) in the  $2\theta$  angle range  
14  
15 from  $1^\circ$  to  $50^\circ$  at the scan speed of  $1^\circ/\text{min}$  with Cu  $K\alpha$  radiation ( $\lambda = 1.54 \text{ \AA}$ ). The surface  
16  
17 morphology and elemental composition were analyzed by field emission scanning  
18  
19 electron microscopy (FE-SEM, S4800, Hitachi High-Technologies Corp.) at 5 kV  
20  
21 coupled with an energy-dispersive X-ray (EDX) analysis device. High-resolution  
22  
23 observations of the powder and films were performed by HR-TEM (JEOL JEM 2100F)  
24  
25 equipped with an EDX analysis device. The typical chemical vibration of the powder and  
26  
27 film samples was verified by Fourier transform infrared spectroscopy (FTIR) (Thermo  
28  
29 scientific Nicolet 4700) in the wavenumber range from  $4000$  to  $400 \text{ cm}^{-1}$  using a KBr  
30  
31 pellet. The reflectance of the powders and transmittance of the films were measured by  
32  
33 UV-Vis-NIR spectroscopy (V570, Jasco Corp.) in the wavelength range of  $220$  to  $2000$   
34  
35 nm at the scan rate of  $400 \text{ nm}/\text{min}$ . The luminescent emitting spectra of the films and  
36  
37 powders were measured by high-performance fluorescence spectroscopy (JASCO  
38  
39 FP8500) connected to a Xenon lamp at the scan rate of  $500 \text{ nm}/\text{min}$ . The adhesion tests  
40

### 11 12 13 14 15 3. RESULTS AND DISCUSSION

#### 16 17 18 3.1 Characterizations of the CMI, ZA, ZAG and CGx@ZAG Nanocomposites 19 20 21 (Solutions and Powders)

22  
23  
24 The objective of this study was to obtain the LDH nanosheets treated in formamide for  
25  
26 anchoring the Mo<sub>6</sub> cluster. The simple synthesizing process of ZA and ZAG was  
27  
28 performed in air that leads to the formation of several kinds of LDH phases provided in  
29  
30 Figure 1a. The major structure of the CO<sub>3</sub> type LDH phase (black circles) existing in ZA  
31  
32 was confirmed by the XRD pattern which shows a series of peaks located at the 2θ-angles  
33  
34 of 11.4, 23.4, 31.6, and 34.6° assigned to the (003), (006), (009), and (012) reflections,  
35  
36 respectively.<sup>46</sup> The second series of peaks with a weak intensity assigned to the NO<sub>3</sub> type  
37  
38 LDH phase locates at the 2θ-angle of 10, 20, and 30° for the (003), (006) and (009)  
39  
40 reflections (green squares).<sup>44</sup> Besides, the remarkable patterns of the ZnO phase (pink  
41  
42 lozenge) formed on the brucite-like sheets were also verified with the peaks at the 2θ-  
43  
44 angles of 32°, 34°, and 36° in this study.<sup>44, 46</sup> The XRD pattern of ZA was used as a  
45  
46 reference to provide evidence for identifying the ZAG structure from a similar synthesis  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 condition. It is reasonable to realize that the glycine-intercalated LDH (ZAG) results in a  
7  
8  
9 mixture of three crystalline structures. A minority phase of the NO<sub>3</sub> type LDH shows 2θ-  
10  
11  
12 angle peaks located with a slight shift to 9.7°, 19.1° and 28.6° in comparison to that of  
13  
14  
15 the ZA pattern. Similarly, the second pattern assigned to the CO<sub>3</sub> typed LDH phase is  
16  
17  
18 shown with a significantly reduced intensity. Lastly, a new series characterized by the  
19  
20  
21 (003), (006), and (009) strong reflections corresponding to the 2θ angles of 7.2°, 13.9°,  
22  
23  
24 and 20.9° and d<sub>003</sub> basal spacing value of about 1.22 nm is considered for the glycine type  
25  
26  
27 LDH (blue triangle). The FT-IR spectra shown in Figure S3 also provide evidence of the  
28  
29  
30 vibrational band assigned to the NO<sub>3</sub> and CO<sub>3</sub> groups in the ZA and ZAG powders that  
31  
32  
33 agree with the realized phase in the XRD results. Glycine is a good candidate to  
34  
35  
36 intercalate between LDH and limit the appearance of the CO<sub>3</sub> type LDH which is strongly  
37  
38  
39 generated in ZA. The pattern of the glycine-intercalated LDH (ZAG) obtained in this  
40  
41  
42 study agrees with the studies of the Zn-Al-Gly LDH material reported by Hibino.<sup>46</sup> Li and  
43  
44  
45 coworkers also claimed a similar pattern of the LDH intercalated glyphosate, which is  
46  
47  
48 almost the same size as glycine, simulating the horizontal or vertical geometries of the  
49  
50  
51 glycine molecules on the host layer.<sup>47</sup> The d<sub>003</sub> value of about 1.22 nm means the total  
52  
53  
54 distance involving the 0.48 nm-sized metal host layer and 0.74 nm-sized interlayer space  
55  
56  
57 which adopts exchanged anions, adsorbed water, and vertical glycine monolayer or  
58  
59  
60

1  
2  
3  
4  
5  
6 bilayer. The glycine is reasonably anchored on the surface of the host layer by the  
7  
8  
9 hydrogen bonding with the hydroxyl group. In the case of the CG1@ZAG powder, the  
10  
11  
12 XRD pattern does not display the full series of crystalline peaks. As a result, the loading  
13  
14  
15 of the glycine/Mo<sub>6</sub> cluster mixture leads to destroying the big crystal of the ZAG as well  
16  
17  
18 as the nanosheets that have been formed from very efficient delamination. Moreover, as  
19  
20  
21 expected, the characteristic pattern of the CMI cluster compound completely disappears  
22  
23  
24 in the CG1@ZAG powder.  
25

26  
27 These results are supported by the HR-TEM images. Indeed, the CG1@ZAG powder only  
28  
29  
30 shows the crystalline part of LDH without the signal of the CMI cluster crystals (Fig. 1b).  
31  
32  
33 Even if it was not possible to observe single metal atoms dispersed in the LDH, the  
34  
35  
36 STEM-EDX mapping confirms the existence of Mo and I atoms assigned to the Mo<sub>6</sub>  
37  
38  
39 cluster (with a weak signal of the Cs<sup>+</sup> cations) and, additionally, N atoms assigned for  
40  
41  
42 glycine. The Cs<sup>+</sup> cations are mainly removed during the synthesis by the washing and  
43  
44  
45 centrifuge processes. Indeed, in the dispersing medium, the CMI cluster compound is  
46  
47  
48 mainly dissociated to form Cs<sup>+</sup> cations and [Mo<sub>6</sub>I<sub>8</sub>I<sub>6</sub>]<sup>2-</sup> anions as depicted in Figure 1b  
49  
50  
51 which could explain the disappearance of the Cs<sup>+</sup> ion. Nevertheless, in solution, the I  
52  
53  
54 apical ligands could be quickly exchanged by a simple hydrolysis process to give new  
55  
56  
57 clusters with the theoretical formula [Mo<sub>6</sub>I<sub>8</sub>I<sub>6-x-y</sub>(OH)<sub>x</sub>(H<sub>2</sub>O)<sub>y</sub>]<sup>y-2</sup> (x + y ≤ 6), for instance,  
58  
59  
60

1  
2  
3  
4  
5  
6 the neutral compound  $[\text{Mo}_6\text{I}_8(\text{OH})^a_4(\text{H}_2\text{O})^a_2] n\text{H}_2\text{O}$  ( $n = 2, 12, 14$ ) ( $x = 4$  and  $y = 2$ )  
7  
8  
9 revealed in the previous study.<sup>48</sup> More generally, the studies of the chlorine or bromine  
10  
11  
12  $\text{Mo}_6$  cluster compounds showed similar results.<sup>49, 50</sup> It is well known that the luminescent  
13  
14  
15 characteristic of the  $\text{Mo}_6$  cluster compounds significantly depends on the nature of the  
16  
17  
18 ligand and counter cation or the different excitation-light sources.<sup>51</sup> This is particularly  
19  
20  
21 true for iodine-based compounds. Indeed, the CMI cluster compound shows a strong  
22  
23  
24 absorption below the 600-nm wavelength (Fig. 1c) and has no photoluminescent property  
25  
26  
27 (Fig. 1d) as already clarified,<sup>51</sup> whereas the  $\text{Cs}_2\text{Mo}_6\text{I}_8\text{X}^a_6$  cluster family compounds with  
28  
29  
30  $\text{X}^a = \text{CF}_3\text{COO}, \text{C}_2\text{F}_5\text{COO}, \text{C}_3\text{F}_7\text{COO}$  show the highest emission intensity.<sup>34, 37, 52</sup>

10  
11  
12  
13 To understand the optical properties of the CG<sub>x</sub>@ZAG nanocomposites, the influence of  
14 the glycine on the [Mo<sub>6</sub>I<sub>8</sub>I<sup>a</sup><sub>6</sub>]<sup>-2</sup> cluster units dispersed in formamide was initially  
15 investigated. In a previous study, it was already demonstrated that the octahedral cluster  
16 complexes can be coordinated by the carboxylic acid groups of the glycine molecules.<sup>53</sup>  
17  
18 For instance, the single crystals of the octahedral hexa-zirconium complexes coordinated  
19 with 4 anionic and 4 neutral glycines in aqueous solution have been growing by Pan et  
20 al., with the formula [Zr<sub>6</sub>(OH)<sub>8</sub>(H<sub>2</sub>O)<sub>8</sub>(HGly)<sub>4</sub>(Gly)<sub>4</sub>](SO<sub>4</sub><sup>2-</sup>)<sub>6</sub>·14H<sub>2</sub>O.<sup>54</sup> To the best of  
21 our knowledge, there is no study reporting the interaction between the iodide hexa-  
22 molybdenum cluster compound and glycine but the results, presented below, suggest that  
23 they do exist. Unfortunately, a single crystal was not obtained, so we worked on solutions  
24 and powders. Indeed, the variation in the zeta potential and photoluminescence in solution  
25 were studied.

49 Table 1 shows the zeta potential parameters of different compounds and nanocomposites  
50 in formamide. The average zeta potential values are the result of three measurements at  
51 room temperature. The extremely negative value of the CG<sub>0</sub> solution indicates that the  
52 formula of the cluster units in solution could be [Mo<sub>6</sub>I<sub>8</sub>I<sup>a</sup><sub>6-x</sub>(OH)<sup>a</sup><sub>x</sub>]<sup>-2</sup> (x = 0 to 6 and y =  
53  
54  
55

2  
3  
4  
5  
6 0) or  $[\text{Mo}_6\text{I}_8\text{I}^a_{6-x-y}(\text{OH})^a_x(\text{H}_2\text{O})^a_y]^{-1}$  ( $x = 0$  to  $5$  and  $y = 1$ ), regarding the possible exchange  
7  
8 of I apical ligands by  $\text{H}_2\text{O}$  or OH groups. They are present as impurities in the formamide  
9  
10 solution. The negative zeta potential of the cluster in formamide is reduced with the  
11  
12 addition of glycine that could indicate an interaction between the  $\text{Mo}_6$  clusters and glycine.  
13  
14  
15 Generally, glycine simultaneously exists as a neutral  $\text{HOOC-CH}_2\text{-NH}_2$  molecule and  
16  
17 charged ( $^-\text{OOC-CH}_2\text{-NH}_3^+$ ;  $^-\text{OOC-CH}_2\text{-NH}_2$ ;  $\text{HOOC-CH}_2\text{-NH}_3^+$ ) molecules depending  
18  
19 on the dispersing medium and pH.<sup>55</sup> Based on the decrease in the negative zeta potential  
20  
21 caused by the addition of the glycine, it is assumed that the positively charged glycine  
22  
23 molecule possibly neutralizes the negatively charged surface of the iodide  $\text{Mo}_6$  cluster  
24  
25 unit through the ionic and/or covalent interactions as mentioned by Pan et al.<sup>54</sup> Additional  
26  
27 studies to understand the structure of this new cluster are now in progress.

28  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39 Regarding the CGx@ZAG nanocomposite suspension, the negatively charged cluster unit  
40  
41 could be completely neutralized by the positive charge density on the LDH surface. On  
42  
43 the other hand, the I apical ligands were exchanged by water molecules adsorbed in the  
44  
45 interspace of LDH to form the neutral  $[\text{Mo}_6\text{I}_8\text{I}^a_{6-x}(\text{OH})^a_x(\text{H}_2\text{O})^a_2]$  ( $x = 0$  to  $4$ ) unit. As a  
46  
47 result, the positive charges existing on the metal hydroxide surface determine the zeta  
48  
49 potential of the CGx@ZAG suspension. This value gradually reduces with the increase  
50  
51 in glycine concentration. In this study, the co-precipitated ZAG product shows a pH value  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 higher than 7 in formamide or MEK with the positive zeta potential values as seen in  
7  
8  
9 Table S2. The average zeta potential of the  $\text{NO}_3^-$  containing LDH is highly positive at a  
10  
11  
12 pH higher than 7 in an aqueous solution, also claimed by Kim et al.<sup>56</sup> In order to  
13  
14 understand the existing state and interaction of the glycine and LDH, the FT-IR spectra  
15  
16 were obtained for glycine, CMI, ZA, ZAG, and CG2@ZAG powders as illustrated in  
17  
18  
19 Figure S3. In the powder state, pure glycine almost shows strong absorption peaks at 1133,  
20  
21  
22 1494, 1666  $\text{cm}^{-1}$ , and a broad wavenumber range from 3200 to 2600  $\text{cm}^{-1}$  assigned to the  
23  
24  
25  $\text{NH}_3^+$  group which specializes for the characteristic functional groups of the charged  $^-$   
26  
27  
28  $\text{OOC-CH}_2\text{-NH}_3^+$  or  $\text{HOOC-CH}_2\text{-NH}_3^+$  species.<sup>57</sup> However, these typical characteristic  
29  
30  
31 peaks of the  $\text{NH}_3$  group completely disappear after glycine is combined with LDH in the  
32  
33  
34 ZAG phase that is agreeable with a previous study.<sup>58</sup> In parallel, proof for the existence  
35  
36  
37 of the  $\text{HOOC-CH}_2\text{-NH}_2$  neutral molecules in ZAG is recognized by the stretching mode  
38  
39  
40 vibration assigned to the  $\text{C=O}$  group at 1760  $\text{cm}^{-1}$  indicating the acid group that suggests  
41  
42  
43 an aggregated glycine phase separation. In the base medium containing LDH, glycine  
44  
45  
46 preferentially exists in the states of  $^- \text{OOC-CH}_2\text{-NH}_2$  and  $\text{HOOC-CH}_2\text{-NH}_2$ . In the FT-IR  
47  
48  
49 spectrum of CG2@ZAG, besides the N-H bending mode vibration is assigned at 1625  
50  
51  
52  $\text{cm}^{-1}$ , the spectrum also shows a new signal at 1653  $\text{cm}^{-1}$  that suggests the impact of  
53  
54  
55 hydrogen bonding on the  $\text{NH}_2$  group. This is agreeable with the peak shifting in the  
56  
57  
58  
59  
60

wavenumber range from 3000 to 3600  $\text{cm}^{-1}$  to higher wavenumber. The absorption peak at 1590  $\text{cm}^{-1}$  is indicated for the asymmetry stretching mode vibration of the COO group which insignificantly modifies in the nanocomposite. In summary, the  $\text{NH}_2$  group of the  $\text{OOC-CH}_2\text{-NH}_2$  anion is predicted to create the hydrogen bonding with the OH or  $\text{H}_2\text{O}$  apical ligands of the  $\text{Mo}_6$  cluster and freely adsorbed  $\text{H}_2\text{O}$  molecules while the  $\text{COO}^-$  group will neutralize positive charges on the metal hydroxide surface of the LDH. The addition of the glycine in the base LDH medium will increase the charged  $\text{OOC-CH}_2\text{-NH}_2$  anions which could generate ionic and/or covalent interactions with the positively charged LDH, resulting in the decreased positive zeta potential value.

Table 1. Average zeta potential values of the CMI cluster compound, glycine, CGx, and CGx@ZAG suspensions in formamide.

	Zeta potential (mV)	
CMI:Gly (wt%)	CGx	CGx@ZAG
1:0 (x=0)	-47.0±0.9	-
1:1 (x=1)	-29.0±1.2	27.5±0.8
1:5 (x=2)	-20.8±0.8	26.2±1.1

3  
4  
5  
6 Nevertheless, the presence of the Mo<sub>6</sub> cluster units in LDH is also demonstrated by the  
7  
8  
9 UV-Vis absorption (in formamide solution) and reflectance (with powder) measurements  
10  
11  
12 as shows in Figures S4a and 1c, respectively. Figure 1c illustrates a weak reflectance as  
13  
14  
15 well as a strong absorption below the 370-nm wavelength caused by LDH, while it is  
16  
17  
18 below the 600-nm wavelength observed for the CMI cluster compound. However, the  
19  
20  
21 optical adsorbing characteristic of the CG1@ZAG in formamide slightly shifts to a higher  
22  
23  
24 wavelength in comparison to that of the ZAG and CG1 compositions (Fig. S4a). In  
25  
26  
27 comparison to the ZA and ZAG powders, a strong red-shifted absorption of the  
28  
29  
30 CG1@ZAG nanocomposite due to the Mo<sub>6</sub> cluster compound is visible with a peak  
31  
32  
33 centered at 690 nm upon the  $\lambda_{ex.}$  of 365 nm (Fig. 1d). For the solution, the most important  
34  
35  
36 modification is a shift in the maximum emission peaks for the different samples. It  
37  
38  
39 appears as an emission peak centered at 673 nm for the Mo<sub>6</sub> cluster-dissolved formamide,  
40  
41  
42 663 nm for the CG1@ZAG-dissolved formamide, and 700 nm for the CG1-dissolved  
43  
44  
45 formamide upon the  $\lambda_{ex.}$  of 400 nm (Fig. S4b). These shifts are significant and could be  
46  
47  
48 explained by the different interactions between glycine and LDH with the Mo<sub>6</sub> clusters.  
49  
50  
51 It is agreeable with a previous discussion about the reasonable change in the zeta potential.  
52  
53  
54 Indeed, the specific nature of the exchanged apical ligand is well known to affect the  
55  
56  
57 length of the Mo-Mo bonding that intervenes in the geometries.<sup>33</sup>  
58  
59  
60

1  
2  
3  
4  
5  
6 Regarding the optical properties, several points discussed above were confirmed: i) the  
7  
8  
9 ZA, ZAG, and CMI cluster powders do not show any luminescent-characterizing peak  
10  
11  
12 during light irradiation at 365 nm (Fig. 1d); ii) the Mo<sub>6</sub> cluster-dispersed formamide  
13  
14  
15 solution presents a strong red emission which is slightly modified by the addition of  
16  
17  
18 glycine during excitation at 400 nm (Fig. S4b); iii) the CGx@ZAG powder and solution  
19  
20  
21 exhibit a strong red emission upon excitation by UV light (Fig. S4b and 1d); iv) the nano-  
22  
23  
24 scaled CG1@ZAG sheets in formamide were proved though the Tyndall effect exhibits a  
25  
26  
27 strong photoluminescence characterized by a red-emitting light upon UV irradiation at  
28  
29  
30 365 nm (Fig. S4b).  
31  
32

33  
34 As already proposed, the Mo<sub>6</sub> clusters were possibly immobilized on graphene oxide  
35  
36  
37 nanosheets by covalent linking<sup>59</sup> or to a silica matrix by hydrogen bonds and/or by Mo-  
38  
39  
40 O-Si covalent linking<sup>60</sup> that modify the photoluminescent property of the cluster. In the  
41  
42  
43 previous work, the Mo-O-LDH chemical bonding was suggested between the  
44  
45  
46  $[\text{Mo}_6\text{Cl}_8\text{Cl}_{6-x-y}(\text{H}_2\text{O})_x(\text{OH})_y]^{x-2}$  ( $x = 0, 1$  or  $2$  and  $y = 0, 1, 2, 3$ ;  $x + y = 3$ ) cluster and  
47  
48  
49 Zn-Al LDH that was revealed on the basic result of X-ray photoelectron spectroscopy.<sup>61</sup>  
50

51  
52 In this study, one similarly suggested a hypothesis that the iodide Mo<sub>6</sub> cluster units would  
53  
54  
55 react with OH on the LDH surface to form Mo-O-LDH bonding and reduce the OH  
56  
57  
58 groups. Therefore, the interactions between the Mo<sub>6</sub> clusters and the metal-OH of LDH  
59  
60

1  
2  
3  
4  
5  
6 is possible to stabilize the  $[\text{Mo}_6\text{I}_8\text{I}_6^{a-x-y}(\text{OH})_x(\text{H}_2\text{O})_y]^{y-2}$  units on the surface of LDH.

8  
9 This leads to the modification of the molecular orbital diagram compared to that of the  
10 starting  $[\text{Mo}_6\text{I}_8\text{I}_6]^{2-}$  unit, meanwhile inducing some change in the photoluminescence  
11 properties.<sup>51, 52</sup>

### 12 13 14 15 16 17 18 19 3.2. Characterization of the ZAG and CGx@ZAG Nanocomposite Films

20  
21 Figure 2 shows the XRD patterns of the ZAG and CG<sub>1-4</sub>@ZAG films prepared by EPD.

22  
23 It is realized that a series of peaks located at the  $2\theta$  angles of  $7.21^\circ$ ,  $13.44^\circ$ , and  $21.19^\circ$   
24 appear with the same peak position indicated in the pattern of the ZAG powder as seen in  
25 Figure 1a. The  $d_{003}$  value is about 1.22 nm which means a 1.2 nm-sized  $\text{Mo}_6$  cluster unit  
26 is unable to occupy in the 0.74 nm-sized basal space between the host layers (0.48 nm).<sup>45</sup>

27  
28 In order to identify the compositions of the deposited film, the particle size distribution  
29 dissolved in the MEK/formamide medium as a suspension used for the EPD process was  
30 investigated and displayed in Figure S5. The ZAG suspension produced a uniform  
31 nanosheet size (0.54  $\mu\text{m}$ ) with a small size distribution (0.26  $\mu\text{m}$ ). When the mixture of  
32 the  $\text{Mo}_6$  cluster and glycine (CG1-4) was introduced in the ZAG-dispersed MEK  
33 suspension, the coagulation occurred to form big particles with the size distribution in the  
34 range from 1 to 6  $\mu\text{m}$ . Remarkably, CG<sub>3</sub>@ZAG shows a high volume of big particles  
35 with the obtained size of around 2  $\mu\text{m}$ . Under an electric field, the small and uniform  
36

47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 nanosheets will preferentially move to the electrode with the same moment and the bigger  
7  
8  
9 particles will slowly arrive. The uniformity of the ZAG nanosheets of around 0.54  $\mu\text{m}$  is  
10  
11  
12 an optimistic advantage to load a high intensity of the characteristic peak assigned to the  
13  
14  
15 glycine-LDH composition of ZAG as presented in Figure 1a. The treatment of formamide  
16  
17  
18 and glycine plays an extremely efficient role in the delamination of LDH. The CG1-  
19  
20  
21 3@ZAG films show insignificantly different patterns with a clearly lower intensity in  
22  
23  
24 comparison to that of ZAG. The existence of the CG during the delamination process  
25  
26  
27 produces the big coagulated LDH particles due to the hydrogen bondings and covalent-  
28  
29  
30 linkages between the added glycine and interspacing-adsorbed glycine or between the  
31  
32  
33  $\text{Mo}_6$  cluster and LDH as already suggested. When the higher concentration of glycine is  
34  
35  
36 added, the bigger the coagulated particles are obtained, resulting in a decrease of the  
37  
38  
39 delaminated LDH species with a small size (Fig. S5). As a result, the CG4@ZAG  
40  
41  
42 nanocomposite film contains a small amount of the delaminated glycine-LDH species and  
43  
44  
45 the majority of coagulated anion-typed LDH species. It is suggested that glycine existing  
46  
47  
48 in the original glycine-LDH species is removed by the strong interaction of a large amount  
49  
50  
51 of added glycine and formamide to reform the anion-typed LDH species then an  
52  
53  
54 agglomeration occurs. For this reason, the CG4@ZAG film shows a peak located at the  
55  
56  
57  $2\theta$  angle of  $11.5^\circ$  which is assigned to the anion-typed LDH. It means that the  
58  
59  
60

delamination of the ZAG in the formamide medium containing CG4 is not successful.

Figure 2. Thin-film XRD patterns of the ZAG, CG1-4@ZAG films prepared by the EPD.

The thin-film XRD pattern agrees with the lamellar structure observed in the cross-section FE-SEM images of the ZAG and CG1-2@ZAG films corresponding to the excellent transparency under visible light (Figs. 3a-c). A good condensing (see the cross-section) and homogeneous morphology of the ZAG film were obtained (Fig. 3a). Similarly, the CG1@ZAG and CG2@ZAG films also consist of a dense-layered structure and smooth

1  
2  
3  
4  
5  
6 morphology (Fig. 3b and 3c). For the CG3@ZAG and CG4@ZAG samples,  
7  
8  
9 corresponding to the highest glycine concentrations, the transparency of the film  
10  
11  
12 decreased. This can be explained by the high number of defects observed in the layer as  
13  
14  
15 seen at the cross-section surface images, following the increase in the light scattering  
16  
17  
18 (Figs. 3d and 3e). It is understood that the interaction between glycine and formamide  
19  
20  
21 was extremely efficient to exfoliate the LDH nanosheets as provided in the ZAG film.  
22  
23  
24 However, not only the existence of the Mo<sub>6</sub> cluster but also the loaded glycine in the  
25  
26  
27 formamide medium leads to the formation of the nonhomogeneity of the particle size as  
28  
29  
30 seen in Figure S5. That indicates the reformation of the anion-typed LDH due to the  
31  
32  
33 removal of interspacing adsorbed glycine and then agglomeration occurs. Therefore, the  
34  
35  
36 optimal concentration of added glycine needs to be investigated. The glycine  
37  
38  
39 concentration in the CG3-4@ZAG films starts to show a random arrangement of the  
40  
41  
42 nanosheets intercalated with big particles creating a porosity on the surface and inside the  
43  
44  
45 layer. On the other hand, the high concentration of glycine could create a hydrophilic  
46  
47  
48 effect on Mo<sub>6</sub>@ZAG and increase the miscibility between it and MEK that also limits the  
49  
50  
51 lamellar-structured reconstruction during the EPD. The red emission, at the exciting  
52  
53  
54 wavelength of 365 nm, was visually confirmed for all the CG1-4@ZAG films. This  
55  
56  
57 behavior indicates that EPD did not destroy the Mo<sub>6</sub> octahedron.  
58  
59  
60

1  
2  
3  
4  
5  
6 The HR-TEM and STEM images show the nano-scaled thin layer containing the  
7 agglomerated cluster units in the CG1@ZAG film prepared by the EPD (Figs. S6a, b, and  
8  
9 c). The proof of the constituting elemental components of the nanocomposite was  
10 repeatedly provided by the STEM-EDX mapping. The energy spectrum completely  
11 confirms the existence of Zn, Al, Mo, I, and N atoms, followed by a weak sign of Cs  
12 atoms (Fig. S6d).  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23

24 All these results are in agreement with the optical studies. As seen in Figures 3f and 3g,  
25 the optical properties are affected by the lamella structure of the nanocomposite films. As  
26 expected, the transmittance of the ZAG, CG1@ZAG and CG2@ZAG films is higher than  
27 50% and agree with the transparency of the observed film photos taken by the camera  
28 under visible light (Fig. 3f). Additionally, the absorption characteristic of the hexanuclear  
29 iodide clusters indicated at wavelengths under 550 nm<sup>52</sup> is recognized as a fingerprint for  
30 the CGx@ZAG films while as it does not appear for the ZAG film. The absorption at the  
31 wavelengths over 1200 nm is assigned to the absorption of the indium tin oxide layer  
32 coated on glass. Figure 3g demonstrates, without a doubt, the red emission due to the Mo<sub>6</sub>  
33 atom clusters. In summary, the structure of the film should be composed of the [Mo<sub>6</sub>I<sub>8</sub>I<sup>a</sup>·

7  
8  
9 At room temperature, the ZAG and CG2@ZAG films show a hydrophilic property with  
10 a contact angle less than 90 degrees, followed by insignificant damage on the surface after  
11 they are in contact with water (Fig. 4a and 4b). Both the ZAG and CG2@ZAG films were  
12 cut 1 mm apart and eleven cuts made to form the patterns on the surface as shown in  
13 Figures 4c and 4d for the adhesion measurement with tape. It can be seen that the film  
14 surface was slightly destroyed after testing the adhesion with tape. Based on the result of  
15 the 4B~5B classification of the ASTM D3359-97 standard test method, it can be  
16 concluded that the ZAG and CG2@ZAG films obtained an encouraging adhesion  
17 property as well as dense and strong interlayer interactions that positively affect the  
18 conductivity of the film.

### 22 3.3 Photocurrent Response of the ZAG and CG2@ZAG Nanocomposite Films

23  
24  
25 The EIS measurement illustrated in Figure S1 was applied for the optimally thick, dense,  
26  
27 and homogeneous ZAG and CG2@ZAG films prepared by EPD at 25 V for 2 minutes.

28  
29  
30 The quality and thickness of the films were controlled by the EPD parameters and the  
31  
32 stability of the EPD suspension that is distributed by the amount of glycine, wet powder  
33  
34 concentration, and the ratio between MEK and formamide. The thicknesses of the ZAG  
35  
36 film and CG2@ZAG film are about  $3.0 \pm 0.2 \mu\text{m}$  and  $3.4 \pm 0.3 \mu\text{m}$ , respectively, prepared  
37  
38 by the same EPD parameters. The light energy is transferred by an optical fiber through  
39  
40 the ITO-coated glass to the deposited film. Based on Figure 3f, the absorption of the ITO-  
41  
42 coated glass was about 60% at 320 nm, 30% at 370 nm, and 20% in the visible light range.  
43  
44  
45

46  
47  
48 As a result, the real intensity of the photon energy arriving at the surface of the material  
49  
50 film corresponded to 40% at 320 nm, 70% at 370 nm, and 80% in the visible light range  
51  
52  
53  
54  
55  
56  
57  
58 (400 nm – 600 nm). For this reason, we selected the excitation wavelengths with the peaks  
59  
60

1  
2  
3  
4  
5  
6 centered at 320, 350, 370, 410, 440, 540, and 580 nm followed by the bandwidth of the  
7  
8  
9 light of about 10 nm. EIS of the films was measured in the humidity and temperature-  
10  
11  
12 controlled chamber.  
13

14  
15 Figure 5a shows the thin film photos and illustrates the sample-testing model for the DC  
16  
17 and AC impedance (EIS) measurements with two ITO-coated glass electrodes connected  
18  
19 to the source. The interlayer galleries of LDH contain hydroxyl ions, water, and  
20  
21 exchanged anions for balancing the positively charged surface. The ionic conductivity is  
22  
23 explained by the Grotthus mechanism and the hydroxyl ions will transport along with the  
24  
25 adsorbed water molecules and hydroxyl groups of the host layer through covalent linking  
26  
27 and hydrogen bonding.<sup>62</sup> The illustration scheme in Figure 5a suggests the possibly  
28  
29 layered structure of the film and the transportation of the hydroxyl ions from the cathode  
30  
31 to the anode when applying a bias. Besides the available absorbed hydroxyl anions on the  
32  
33 host layer, they might be provided by the water hydrolysis reaction on the cathodic  
34  
35 electrode during the EPD process.  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47

48 Figure S7 shows the Nyquist plots of the ZAG film at the relative humidity (RH) of 50 %,  
49  
50 ZAG film at the relative humidity (RH) of 80 %, and CG2@ZAG film at the relative  
51  
52 humidity (RH) of 80 % measured by EIS at different temperatures. The Nyquist curve  
53  
54 measured for the CG2@ZAG films at 303K and RH of 80% shows the compositions of  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6 the solution resistance ( $R_s$ ), charge transfer resistance ( $R_{ct}$ ), and diffusional impedance or  
7  
8  
9 so-called Warburg Element ( $Z_w$ ) (Fig. 5b). The Nyquist diagram was fitted by using a  
10  
11  
12 Randles equivalent circuit as depicted in Figure 5b. The R-value of the electrical  
13  
14  
15 conductivity in Eq.1 was calculated from the total resistance of the charge transfer  
16  
17  
18 resistance ( $R_{ct}$ ) and the solution resistance ( $R_s$ ) measured by Zview software. Generally,  
19  
20  
21 the semicircular arc becomes smaller corresponding to the decrease in the impedance  
22  
23  
24 versus the temperature increase. The decrease in the electrical resistance corresponds to  
25  
26  
27 the increase in the electrical conductivity as calculated by Eq. 1. The dependence of the  
28  
29  
30 electrical conductivity on the temperature of the films stored at RH 50% and RH 80% is  
31  
32  
33 illustrated in Figure 5c. The calculated electrical conductivities of ZAG at RH 50%, ZAG  
34  
35  
36 at RH 80%, and CG2@ZAG at RH 80% are  $6.7 \times 10^{-8}$ ,  $36.1 \times 10^{-8}$ , and  $4.1 \times 10^{-8}$  S cm<sup>-1</sup>,  
37  
38  
39 respectively. As already suggested, the Mo<sub>6</sub> cluster could react with the OH group on  
40  
41  
42 the LDH surface to form a covalent linkage and hydrogen bonding. These interactions  
43  
44  
45 cause a reduction of the free hydroxyl anion concentration in the film. Moreover, the  
46  
47  
48 water carrier was also kept by hydrogen bonding with the cluster and limits the anion  
49  
50  
51 diffusion in the film through the water carrier. These points lead to the result of the inferior  
52  
53  
54 ionic conductivity in the CG2@ZAG film ( $3.4 \pm 0.3$   $\mu\text{m}$ ) in comparison to the ZAG film  
55  
56  
57 ( $3.0 \pm 0.2$   $\mu\text{m}$ ). The electrical conductivity of the ZAG film increases with increased  
58  
59  
60

1  
2  
3  
4  
5  
6 relative humidity from 50% to 80%. In parallel, a linear rising tendency of the  
7  
8 conductivity versus the temperature increase was observed. Simultaneously, the  
9  
10 CG2@ZAG film stored at RH 80% displays a low electrical conductivity in comparison  
11  
12 to the ZAG film under the same condition with a faster-increasing speed.  
13  
14  
15  
16

17  
18 In general, the energy activation ( $E_a$ ) was calculated from the relation with the electrical  
19  
20 conductivity by the following equation:  
21  
22

$$\sigma T = A \cdot \exp(-E_a/RT) \quad (2)$$

23  
24  
25  
26  
27 where A is a constant, T is the temperature, R is the gas constant, and  $E_a$  is the activation  
28  
29 energy. The activation energy of the film was calculated from the slope of the fitted  
30  
31 Arrhenius plots wherein the value of the natural logarithm of ( $\sigma T$ ) is linear versus the  
32  
33 temperature (1/K). The activation energies of the ZAG (RH 50%), ZAG (RH 80%) and  
34  
35 CG2@ZAG (RH 80%) films are 0.904 eV, 0.757 eV and 1.108 eV, respectively shown in  
36  
37  
38  
39

56  
57  
58  
59  
60  
Figure 5d. The  $E_a$  values agree with the Arrhenius equation (Eq. 2). This illustrates that a  
low  $E_a$  value corresponds to a higher electrical conductivity. With the reasonably  
calculated activation energy, the anionic conduction mechanism is suggested for all the  
films.<sup>63</sup> This result agrees with many previous studies for the LDH materials.<sup>13-16</sup> In  
summary, the existence of the  $Mo_6$  cluster present on the metal hydroxide surface does  
not only not affect the anionic conduction mechanism of the LDH film but also shows a

1  
2  
3  
4  
5  
6 similar tendency during the increasing temperature. Generally, the anionic conductivity  
7  
8  
9 is created by the transportation of the hydroxyl ions through water molecules as an  
10  
11  
12 important carrier by using the hydrogen bonding pathway. The Mo<sub>6</sub> cluster is suggested  
13  
14  
15 to create hydrogen bonding with the OH group and water adsorbed on the metal hydroxide  
16  
17  
18 surface and limits the diffusion of the hydroxyl anions, resulting in a reduction of the  
19  
20  
21 ionic conductivity. As a result, the conductivity of the Mo<sub>6</sub>@LDH film is lower than that  
22  
23  
24 of the LDH film. This agrees with a higher E<sub>a</sub> value for the Mo<sub>6</sub>@LDH film. At a high  
25  
26  
27 temperature, the movement of the hydroxyl ions seems to be a priority in the cluster-  
28  
29  
30 modified space. This interesting point should be further investigated in the future.

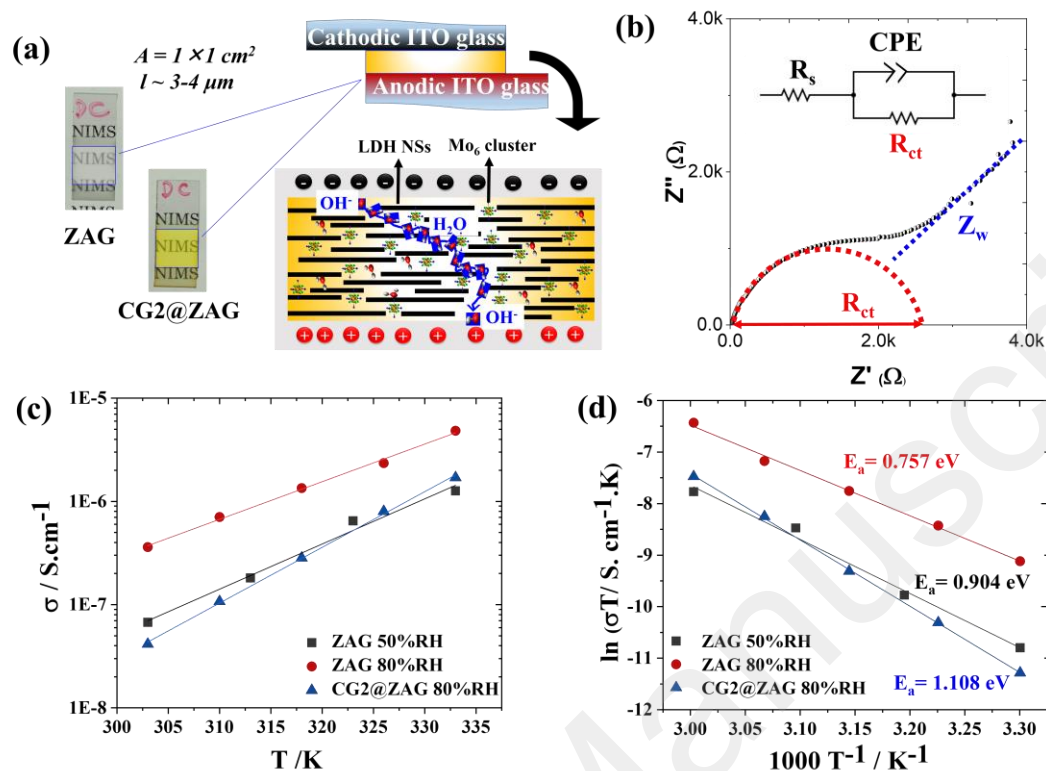

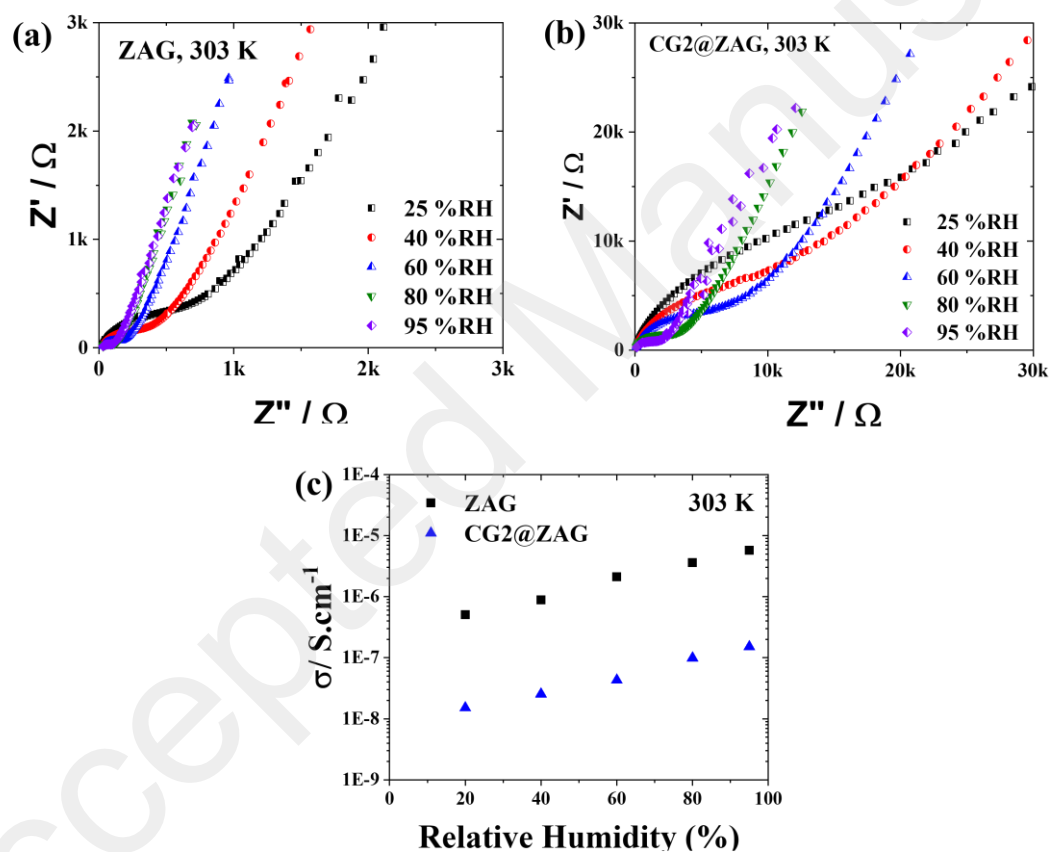

Figure 5. a) Photos of the ZAG and CG2@ZAG thin films under visible light and the transferring model of the proton through the film, b) Randles equivalent circuit for the electrochemical cell, Nyquist diagram and its fitting curve of CG2@ZAG at 303K and RH 80%, c) The dependence of the electrical conductivity vs. the temperatures, and d) Linear fits of the plots of  $\ln(\sigma T)$  versus  $T^{-1}$  of the ZAG and CG2@ZAG thin films at different temperatures and humidity.

The detailed investigation of the ionic conductivity versus the humidity is presented in Figure 6. Similarly, the reduction of the semicircular arc is observed that corresponds to the increase in the relative humidity from 25, 40, 60, 80, and 95% at 303 K (Fig. 6a and

1  
2  
3  
4  
5  
6  
7 b). The ZAG and CG2@ZAG films show a linear dependence of the ionic conductivity  
8  
9 vs. the relative humidity (Figure 6c). The introduction of the Mo<sub>6</sub> cluster does not affect  
10  
11 the proportionally increasing tendency of the ionic conductivity vs. the relative humidity.  
12  
13 At high humidity, the increase of the water concentration adsorbed in the LDH forces an  
14  
15 enhancement of ionic conductivity.

2  
3  
4  
5  
6 The photocurrent of the CG2@ZAG film was evaluated by DC measurements in the dark  
7  
8  
9 and under light illumination at various wavelengths. The applied bias was 1 V generated  
10  
11  
12 by a DC Keithley Model 2400 source. Figure 7a shows that the fluorescence peak in the  
13  
14  
15 wavelength range from 410 to 450 nm was caused by the metal hydroxide layers of the  
16  
17  
18 ZA and ZAG powders upon excitation at 370 nm. This result supports the  
19  
20  
21 photosensitization occurring in the LDH-based films upon excitation by UV light (Fig.  
22  
23  
24 7b). The ZAG and CG2@ZAG films at the temperature of 303 K and RH of 50% and  
25  
26  
27 80% result in the photocurrent response that proportionally fluctuates with the incident  
28  
29  
30 photon energy and reaches a higher intensity corresponding to the UV light range (Fig.  
31  
32  
33 7b). However, the optical absorption of the ITO-coated glass at 320 nm obtains about  
34  
35  
36 60% that limits the photon energy arriving at the material surface causing a reduction of  
37  
38  
39 the conductivity. For this reason, the photocurrent excited at 320 nm is observed to be  
40  
41  
42 more inferior than that excited at 350 nm. The small difference in the wavelength intensity  
43  
44  
45 does not affect the photocurrent result. The light adsorption and possible excitation during  
46  
47  
48 irradiation at specific wavelengths of the material mostly contribute to the photocurrent  
49  
50  
51 response. In the visible light range, the CG2@ZAG film displays a photosensitization  
52  
53  
54 possibility higher than that of the ZAG film due to the visible light absorption of the Mo<sub>6</sub>  
55  
56  
57 cluster.

Figure 7c illustrates a variation in the photocurrent responses under on –and -off switching of the continual UV-Vis light illumination at the fixed wavelengths centered at 320, 350, 370, 410, 440, 540 and 580 nm versus time. In the beginning, the films were applied a voltage for several minutes to gain a stable current value. At this stage, most of the hydroxyl ions are almostally transported from the cathode to anode under the electric field impact and a stable current is indicated for the electronic conductivity. Under illumination, the photocurrent responses are then characterized by a rapid enhancement during the first minutes before reaching saturation at 5 minutes. When the light was turned off, the current suddenly dropped to the original current value. Moreover, it can be seen in Figure 7c that the photocurrent intensity depends on the relative humidity following a directly proportional gradient. The fluctuating tendency of the photocurrent value is the same for the film controlled at the relative humidity of 50% and 80% at 303K. To confirm this tendency, an extra irradiation experiment for the ZAG film was performed at the excitation wavelengths from 580 nm to 320 nm versus time as seen in Figure S8, confirming a similar tendency of the photocurrent intensity in Figure 7c. Three interesting points are concluded in Figure 7c such as i) the ZAG film having a thinner thickness showed a photocurrent response higher than that of the CG2@ZAG upon irradiation below 440 nm, ii) the ZAG and CG2@ZAG films showing a linear dependence of the

1  
2  
3  
4  
5  
6 photocurrent response vs. the humidity, and iii) only the CG2@ZAG film exhibited a  
7  
8  
9 photocurrent sensitization at  $\lambda_{\text{ex.}} = 540$  nm.  
10

11  
12  
13 Reproducibility and stabilization of the photocurrent response is an important key for the  
14  
15  
16 photodetector application. For this reason, the repeatability of the photocurrent on the  
17  
18  
19 CG2@ZAG film with various thicknesses was performed at the  $\lambda_{\text{ex.}}$  of 370 nm (Fig. 7d).  
20

21  
22 The photocurrent from the on/off light switching operation always remains a constant  
23  
24  
25 value after the procedure is repeated several times. The basic electrical conductivity and  
26  
27  
28 the photocurrent response consistently depend on the film thickness. As illustrated here,  
29  
30  
31 the thicker film provides a higher current value and the fluctuation of the current is  
32  
33  
34 repeated with the same tendency.  
35

36  
37  
38 As is known, the blank LDH could produce a photoconductive response with the light  
39  
40  
41 illumination from 350 nm to 420 nm.<sup>28</sup> In this study, the photosensitization of the blank  
42  
43  
44 LDH was extended in the visible light range of 440 nm as clearly observed in Figure 7c.  
45

46  
47 However, only the CG2@ZAG film shows photosensitization in the visible light at the  
48  
49  
50  $\lambda_{\text{ex.}}$  of 540 nm as seen in Figure 7e. The optical absorbing characteristic of the cluster in  
51  
52  
53 the visible light range below 600 nm has produced the visible photosensitization for the  
54  
55  
56 CG2@ZAG film.  
57

58  
59 In general, the UV light irradiation could enhance the photocurrent of the LDH due to the  
60

1  
2  
3  
4  
5  
6 incident photon energy ( $h\nu$ ) promoting the excitation of the electron ( $e_{CB}^-$ ) from the  
7  
8  
9 valence band to a conducting band and leave a hole ( $h_{VB}^+$ ) as seen in Eq. 1.<sup>64</sup> The electron  
10  
11  
12 created on the photoexcited LDH from Eq. 1 will enlarge the electronic flow on the metal  
13  
14  
15 hydroxide layer to increase the electrical conductivity. Besides, the hydroxyl radicals  
16  
17  
18 ( $\cdot OH$ ) generated from Eq. 2 are highly unstable due to their electron spin configuration is  
19  
20  
21 unpaired. The unpaired spin configuration forces the hydroxyl radical immediately  
22  
23  
24 capturing the free electron ( $e_{CB}^-$ ) to form  $OH^-$  anion (Eq. 3) or missing electron  
25  
26  
27 from another hydroxyl radical ( $\cdot OH$ ) to form hydrogen peroxide ( $H_2O_2$ ) (Eq. 4). The  
28  
29  
30 proton is also created from Eq. 2, however, the hydroxyl anion mobility is more dominant  
31  
32  
33 than the proton in LDH.<sup>14</sup> The immediate transport of the hydroxyl anions results in the  
34  
35  
36 enhancement of the total photocurrent. When the irradiation is off, the electron ( $e_{CB}^-$ ) will  
37  
38  
39 immediately couple with the hole ( $h_{VB}^+$ ) and the generation of the hydroxyl anions is  
40  
41  
42 simultaneously stopped, resulting in the disappearance of the photocurrent. As a result,  
43  
44  
45 the adsorbed water concentration at the different humidities will affect the generated  
46  
47  
48 hydroxyl concentration that causes an anionic conductivity when applying a bias. It could  
49  
50  
51 be suggested that the generated photoconductivity is produced by the electronic and  
52  
53  
54 anionic conductivities. The deep discussion about the role of the major conductivity  
55  
56  
57 mechanism during the irradiation should be performed in the future.  
58  
59  
60

This suggestion is also used to explain the linear dependence of the photoconductivity on the humidity for the CG2@ZAG film during light excitation at 540 nm. In this case, only the Mo<sub>6</sub> cluster plays an important role as an electron-supplying source during irradiation.

When the Mo<sub>6</sub> cluster is excited by visible light ( $\lambda = 540$  nm), the hole and electron pair are generated on the photoexcited cluster unit (Eq. 5).<sup>59, 65</sup> Similarly, the photocurrent value increases due to not only the electron generated from Eq. 5 but also the hydroxyl anion formed from Eq. 6 and Eq. 3. The photocurrent is therefore composed of electronic and anionic conductivities, which linearly depend on the humidity.

The smooth movement of the electron in the nanocomposite needs strong support from the homogeneously dense lamella structure, chemical bonding between the elemental

1  
2  
3  
4  
5  
6 compositions, and homogeneous distribution of the Mo<sub>6</sub> cluster in the LDH matrix. For  
7  
8  
9 this result, the unique chemical interaction existing between the metal oxide layer and the  
10  
11  
12 cluster plays an important role in the transportation of the electron through the interspace.

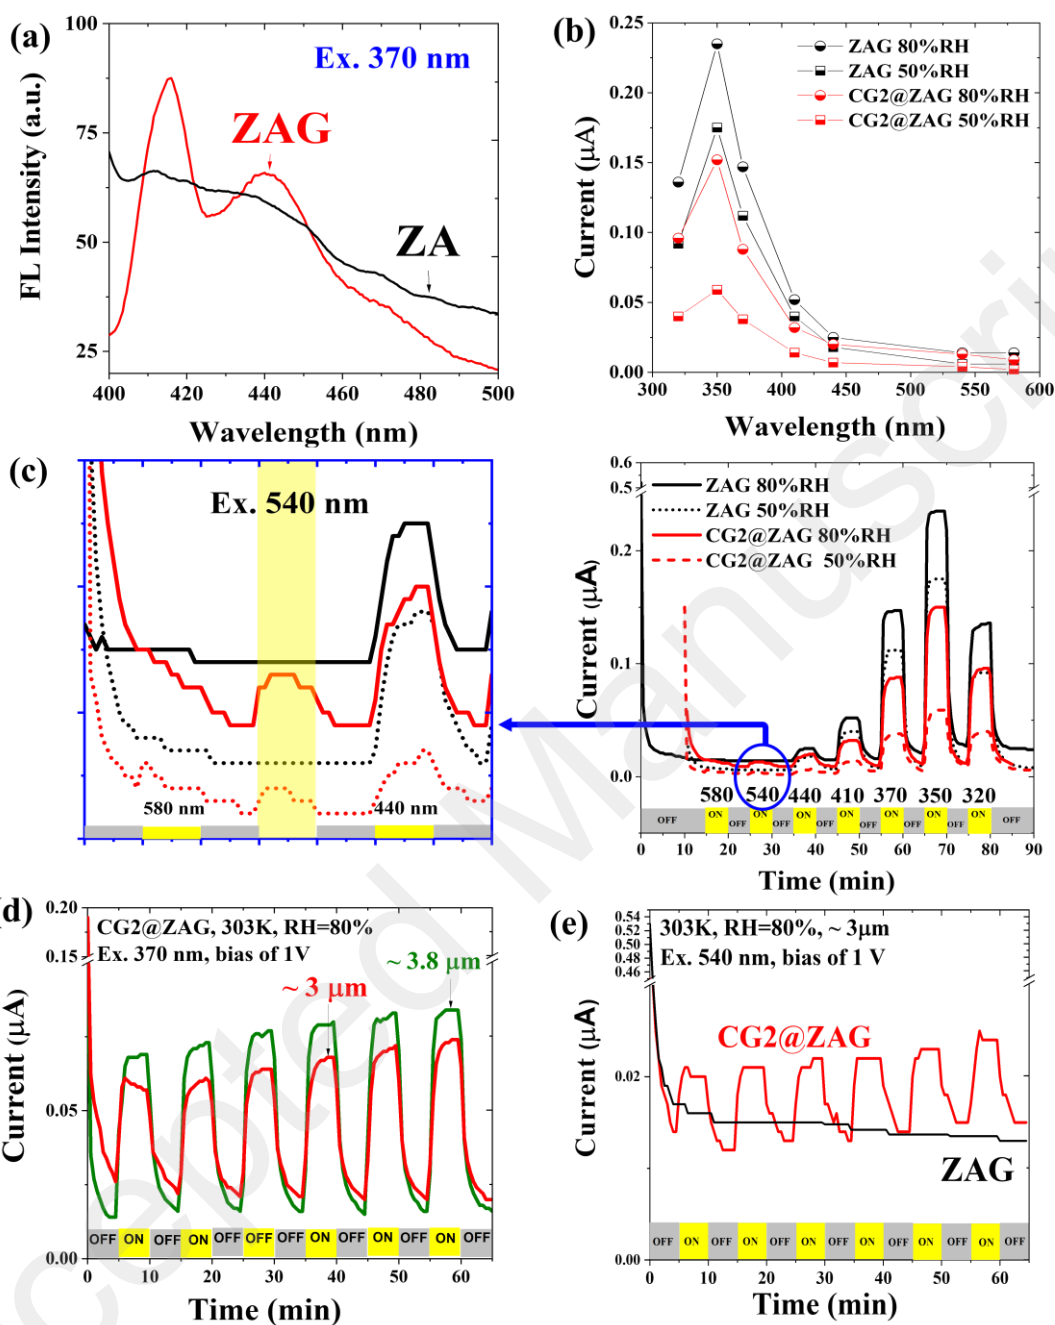

Figure 7. a) The fluorescence spectra of the ZA and ZAG powder under excitation of 370 nm, b) The dependence of the photocurrent intensity versus the exciting wavelength, c) The photocurrent controlled by on-off switching procedure under the illumination by

1  
2  
3  
4  
5  
6 different light wavelengths of the ZAG and CG2@ZAG films measured at RH of 50%  
7  
8  
9 and RH of 80 % and 303 K versus the time. d) The repeatability of the photocurrent  
10  
11  
12 responses repeated versus the time of the CG2@ZAG films at  $\lambda_{\text{ex.}} = 540$  nm for different  
13  
14  
15 thicknesses. e) The repeatability of the photocurrent responses of the ZAG and  
16  
17  
18 CG2@ZAG films versus the on-off switching time with  $\lambda_{\text{ex.}} = 540$  nm.  
19  
20  
21  
22  
23

24  
25 Figure 8a shows the electrical property versus the temperature of the ZAG and  
26  
27  
28 CG2@ZAG films measured by EIS. These results were calculated from the impedance  
29  
30  
31 semicircular arc presented in Figure S9. The impedance of the films controlled at 80%  
32  
33  
34 RH was measured in the dark and at  $\lambda_{\text{ex.}}$  of 370 or 440 nm. Both the ZAG and CG2@ZAG  
35  
36  
37 films present a small increase in the conductivity during irradiation with a slightly  
38  
39  
40 preferential value for the excitation wavelength of 370 nm. The results are in agreement  
41  
42  
43 with the increasing tendency of the photocurrent intensity measured by DC (Figure 7b).  
44  
45  
46 The activation energies ( $E_a$ ) of the ZAG and CG2@ZAG films at different irradiation  
47  
48  
49 conditions calculated from the Arrhenius plots in Figure 8b result in  $0.75 \pm 0.01$  eV and  
50  
51  
52  $1.12 \pm 0.01$  eV, respectively. The  $E_a$  of the CG2@ZAG films is higher than that of the  
53  
54  
55 ZAG film in all cases. As mentioned in the previous discussion, the Mo<sub>6</sub> cluster reduces  
56  
57  
58 the diffusion of the hydroxyl anion resulting in a decrease of the conductivity and increase  
59  
60

in the activation energy. The  $E_a$  value of the CG2@ZAG and ZAG films presents an insignificant modification with and without irradiation.

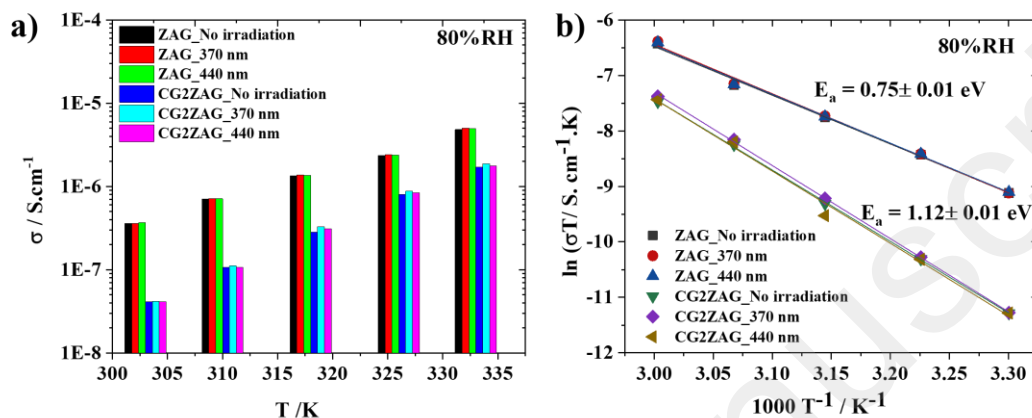

Figure 8. a) The dependence of the electrical conductivity on the temperature and b) Linear fits of the plots of  $\ln(\sigma T)$  versus  $T^{-1}$  of the ZAG and CG2@ZAG films stored at RH 80% in the dark and at  $\lambda_{\text{ex.}} = 370, 440$  nm.

In summary, for the first time, the photochemical behavior of the molybdenum halide cluster was combined with the electrical property of LDH aiming to create a material exhibiting a photocurrent response upon visible light irradiation. Its photo-electrical property stabilization is valid for the development of an optical sensing device. Many reasonable hypothesizes have discussed the origin of the redox, photophysical, and photochemical properties of the  $\text{Mo}_6$  cluster based on the molecular structure, chemical compositions, and their intrinsic interactions.<sup>33,37,38,51</sup> Moreover, the proton-conducting properties of the  $(\text{H})_2[\text{Mo}_6\text{X}_8(\text{OH})_6]\cdot 12\text{H}_2\text{O}$  ( $\text{X} = \text{Cl}, \text{Br}$ ) have been clarified through the

1  
2  
3  
4  
5  
6 hydrogen-bond network that develops between apical hydroxyl groups and the adsorbed  
7  
8  
9 water molecules.<sup>66</sup> Kuttipillai et al. also suggested that the counter cations can play an  
10  
11  
12 important role in charge injection, transport, recombination, and exciton formation in the  
13  
14  
15 electrically pumped devices fabricated from the core cluster.<sup>67</sup> The interaction between  
16  
17  
18 the neighboring clusters and electrical pumped host material is an important key to impact  
19  
20  
21 the tunneling, recombination dynamics, and exciton formation. These ideas could be used  
22  
23  
24 to explain in this study that the covalent bonding, ionic interaction, or hydrogen bonding  
25  
26  
27 possibly occurring between the OH or H<sub>2</sub>O groups induced the Mo<sub>6</sub> clusters and metal  
28  
29  
30 hydroxide layers to play a role as the closed bridges for the unique electron transportation.  
31  
32  
33 A uniquely closed network is the essential parameter to assure the continually occurring  
34  
35  
36 electrical transportation that results in a high photo-electrical sensitization, stabilization,  
37  
38  
39 reproducibility, and utilizing for a device-developing strategy.  
40

#### 41 42 4. CONCLUSION 43

44  
45 For the first time, thin and transparent Mo<sub>6</sub> cluster-functionalized LDH films, CG<sub>x</sub>@ZAG  
46  
47  
48 (x=1-4), were successfully prepared by EPD. The morphology, the dense lamellar  
49  
50  
51 structure, and the elemental composition of the films were fully characterized by utilizing  
52  
53  
54 SEM/HR-TEM/EDX analyses, and XRD measurements. The optical properties and  
55  
56  
57 photocurrent responses were fully measured. The CG1-2@ZAG films display a strong  
58  
59  
60

1  
2  
3  
4  
5  
6 UV-Vis absorption under 550 nm and red emission light at the wavelength of 690 nm  
7  
8  
9 when excited by the UV-Vis lights. The obtained conductivity value of the CG2@ZAG  
10  
11  
12 was about  $4.1 \times 10^{-8} \text{ S} \cdot \text{cm}^{-1}$  at RH 80% and 303K with the activation energies ( $E_a$ ) about  
13  
14  
15 1.108 eV indicating an ionic conduction mechanism. The CG2@ZAG film conductivity  
16  
17  
18 can be controlled by the relative humidity and temperature. Remarkably, the films present  
19  
20  
21 very good photocurrent responses, measured by both DC and AC impedance  
22  
23  
24 measurements, during excitation in the UV light range, and visible light from 410 to 540  
25  
26  
27 nm due to the visible light adsorbing  $\text{Mo}_6$  clusters. The reproducibility and stabilization  
28  
29  
30 of the sample's photocurrent response were established. The excellent properties obtained  
31  
32  
33 from the CGx@ZAG films prepared by the EPD process make them be considered as  
34  
35  
36 promising candidates for photo-humidity sensing and a photodetector.  
37  
38  
39
