| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| 0.39±0.14 | [2] BARATE | 99R | ALEP | 1991–1995 LEP runs |

[1] ASNER 00B assume $\tau^- \to K^-\pi^+\pi^-\nu_\tau$ (ex. $K^0$) decays proceed only through $K\rho$ and $K^*\pi$ intermediate states. They assume the resonance structure of $\tau^- \to K^-\pi^+\pi^-\nu_\tau$ (ex. $K^0$) decays is dominated by $K_1(1270)^-$ and $K_1(1400)^-$ resonances, and assume $B(K_1(1270) \to K^*(892)\pi) = (16 \pm 5)\%$, $B(K_1(1270) \to K\rho) = (42 \pm 6)\%$, and $B(K_1(1400) \to K\rho) = 0$.

[2] BARATE 99R assume $\tau^- \to K^-\pi^+\pi^-\nu_\tau$ (ex. $K^0$) decays proceed only through $K\rho$ and $K^*\pi$ intermediate states. The quoted error is statistical only.

[1] LEES 12X obtain this value by dividing their B($\tau^-\to f_1(1285)\pi^-\nu_\tau\to 3\pi^-2\pi^+\nu_\tau$) measurement by the PDG 12 value of B($f_1(1285)\to 2\pi^+2\pi^-$) = $0.111^{+0.007}_{-0.006}$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[2] LEES 12X obtain this value by dividing their $B(\tau^- \to f_1(1285)\pi^-\nu_\tau \to \eta\pi^-\pi^+\pi^-\nu_\tau)$ measurement by 2/3 of the PDG 12 value of $B(f_1(1285) \to \eta\pi\pi) = 0.524^{+0.019}_{-0.021}$.

[3] AUBERT 08AE obtain this value by dividing their $B(\tau^- \to f_1(1285)\pi^-\nu_\tau \to \eta\pi^-\pi^+\pi^-\nu_\tau)$ measurement by the PDG 06 value of $B(f_1(1285) \to \eta\pi^-\pi^+) = 0.35 \pm 0.11$. The quote $(3.19 \pm 0.18 \pm 0.16 \pm 0.99) \times 10^{-4}$ where the final error is due to the uncertainty on $B(f_1(1285) \to \eta\pi^-\pi^+)$. We combine the two systematic errors in quadrature.

[4] AUBERT,B 05W use the $f_1(1285) \to 2\pi^+2\pi^-$ decay mode and the PDG 04 value of $B(f_1(1285) \to 2\pi^+2\pi^-) = 0.110^{+0.007}_{-0.006}$.

[5] BERGFELD 97 use the $f_1(1285) \to \eta\pi^+\pi^-$ decay mode.

[1] Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E. ALBRECHT 98 use tau pair events of the type $\tau^-\tau^+\to(\ell^-\overline{\nu}_\ell\nu_\tau)(\pi^+\pi^0\overline{\nu}_\tau)$, and their charged conjugates.
[2] ABE 97O assume $\eta=0$ in their fit. Letting $\eta$ vary in the fit gives a $\rho$ value of 0.69 ± 0.13 ± 0.05.
[3] Value is from a simultaneous fit for the $\rho$ and $\eta$ decay parameters to the lepton energy spectrum. Not independent of ALBRECHT 90E $\rho$($e$ or $\mu$) value which assumes $\eta=0$. Result is strongly correlated with ALBRECHT 95C.
[4] Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E.

# Heavy Charged Lepton Searches

## Charged Heavy Lepton MASS LIMITS

### Sequential Charged Heavy Lepton ($L^{\pm}$) MASS LIMITS

These experiments assumed that a fourth generation $L^{\pm}$ decayed to a fourth generation $\nu_L$ (or $L^0$) where $\nu_L$ was stable, or that $L^{\pm}$ decays to a light $\nu_\ell$ via mixing.

See the "Quark and Lepton Compositeness, Searches for" Listings for limits on radiatively decaying excited leptons, *i.e.* $\ell^* \to \ell\gamma$. See the "WIMPs and other Particle Searches" section for heavy charged particle search limits in which the charged particle could be a lepton.

[1] ACCIARRI 96G assumes LEP result that the associated neutral heavy lepton mass > 40 GeV.

[2] The AHMED 94 limits are from a search for neutral and charged sequential heavy leptons at HERA via the decay channels $L^- \to e\gamma$, $L^- \to \nu W^-$, $L^- \to eZ$; and $L^0 \to \nu\gamma$, $L^0 \to e^- W^+$, $L^- \to \nu Z$, where the $W$ decays to $\ell\nu_\ell$, or to jets, and $Z$ decays to $\ell^+\ell^-$ or jets.

[3] RILES 90 limits were the result of a special analysis of the data in the case where the mass difference $m_{L^-} - m_{L^0}$ was allowed to be quite small, where $L^0$ denotes the neutrino into which the sequential charged lepton decays. With a slightly reduced $m_{L^\pm}$ range, the mass difference extends to about 4 GeV.

[4] STOKER 89 (Mark II at PEP) gives bounds on charged heavy lepton ($L^+$) mass for the generalized case in which the corresponding neutral heavy lepton ($L^0$) in the SU(2) doublet is not of negligible mass.

[5] ABE 88 search for $L^+$ and $L^- \to$ hadrons looking for acoplanar jets. The bound is valid for $m_\nu < 10$ GeV.

[6] ADACHI 88B search for hadronic decays giving acoplanar events with large missing energy. $E_{cm}{}^{ee} = 52$ GeV.

[7] Assumes associated neutrino is approximately massless.

[8] ADEVA 85 analyze one-isolated-muon data and sensitive to $\tau$ <10 nanosec. Assume B(lepton) = 0.30. $E_{cm}$ = 40–47 GeV.

[9] BARTEL 83 limit is from PETRA $e^+e^-$ experiment with average $E_{cm}$ = 34.2 GeV.

[10] BERGER 81B is DESY DORIS and PETRA experiment. Looking for $e^+e^- \to L^+L^-$.

[11] BRANDELIK 81 is DESY-PETRA experiment. Looking for $e^+e^- \to L^+L^-$.

[12] AZIMOV 80 estimated probabilities for $M + N$ type events in $e^+e^- \to L^+L^-$ deducing semi-hadronic decay multiplicities of $L$ from $e^+e^-$ annihilation data at $E_{cm} = (2/3)m_L$. Obtained above limit comparing these with $e^+e^-$ data (BRANDELIK 80).

[13] BARBER 80B looked for $e^+e^- \to L^+L^-$, $L \to \nu_L^+ X$ with MARK-J at DESY-PETRA.

[14] ROTHE 69 examines previous data on $\mu$ pair production and $\pi$ and $K$ decays.

# Neutrino Properties

## NEUTRINO PROPERTIES

Revised August 2019 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

The Neutrino Properties Listings concern measurements of various properties of neutrinos. Nearly all of the measurements, so far only limits, actually concern superpositions of the mass eigenstates $\nu_i$, which are in turn related to the weak eigenstates $\nu_\ell$, via the neutrino mixing matrix

$$|\nu_\ell\rangle = \sum_i U_{\ell i}\,|\nu_i\rangle\ .$$

In the analogous case of quark mixing via the CKM matrix, the smallness of the off-diagonal terms (small mixing angles) permits a "dominant eigenstate" approximation. However, the results of neutrino oscillation searches show that the mixing matrix contains two large mixing angles and a third angle that is not exceedingly small. We cannot therefore associate any particular state $|\nu_i\rangle$ with any particular lepton label $e, \mu$ or $\tau$. Nevertheless, note that in the standard labeling the $|\nu_1\rangle$ has the largest $|\nu_e\rangle$ component ($\sim 2/3$), $|\nu_2\rangle$ contains $\sim 1/3$ of the $|\nu_e\rangle$ component and $|\nu_3\rangle$ contains only a small $\sim 2.5\%$ $|\nu_e\rangle$ component.

Neutrinos are produced in weak decays with a definite lepton flavor, and are typically detected by the charged current weak interaction again associated with a specific lepton flavor. Hence, the listings for the neutrino mass that follow are separated into the three associated charged lepton categories. Other properties (mean lifetime, magnetic moment, charge and charge radius) are no longer separated this way. If needed, the associated lepton flavor is reported in the footnotes.

Measured quantities (mass-squared, magnetic moments, mean lifetimes, *etc.*) all depend upon the mixing parameters $|U_{\ell i}|^2$, but to some extent also on experimental conditions (e.g., on energy resolution). Many of these observables, in particular mass-squared, cannot distinguish between Dirac and Majorana neutrinos and are unaffected by $CP$ phases.

Direct neutrino mass measurements are usually based on the analysis of the kinematics of charged particles (leptons, pions) emitted together with neutrinos (flavor states) in various weak decays. The most sensitive neutrino mass measurement to date, involving electron type antineutrinos, is based on fitting the shape of the beta spectrum. The quantity $m^{2(eff)}_{\nu_e} = \sum_i |U_{ei}|^2 m^2_{\nu_i}$ is determined or constrained, where the sum is over all mass eigenvalues $m_{\nu_i}$ that are too close together to be resolved experimentally. (The quantity $m^{eff}_{\nu_e} \equiv \sqrt{m^{2(eff)}_{\nu_e}}$ is often denoted $\langle m_\beta \rangle$ in the literature.) If the energy resolution is better than $\Delta m^2_{ij} \equiv m^2_{\nu_i} - m^2_{\nu_j}$, the corresponding heavier $m_{\nu_i}$ and mixing parameter could be determined by fitting the resulting spectral anomaly (step or kink).

The dependence of $m_{\nu_e}$ on the mass of the lightest neutrino is shown in Fig. 14.11 of the *Neutrino Masses, Mixing, and Oscillations* review. In the case of inverted ordering there is a minimum possible value of $m^{eff}_{\nu_e}$, approximately $\sqrt{(}\Delta m^2_{32}) \sim 50$ meV. If $m^{eff}_{\nu_e}$ is found to be larger than this value, it is impossible, based on this information only, to decide which ordering is realized in nature. On the other hand, if the $m^{eff}_{\nu_e}$ is less than ∼50 meV, only the normal mass ordering is possible.

A limit on $m^{2(eff)}_{\nu_e}$ implies an upper limit on the minimum value $m^2_{min}$ of $m^2_{\nu_i}$, independent of the mixing parameters $U_{ei}$: $m^2_{min} \leq m^{2(eff)}_{\nu_e}$. However, if and when the value of $m^{2(eff)}_{\nu_e}$ is determined then its combination with the results derived from neutrino oscillations that give us the values of the neutrino mass-squared differences $\Delta m^2_{ij} \equiv m^2_i - m^2_j$, including eventually also their signs, and the mixing parameters $|U_{ei}|^2$, the individual neutrino mass squares $m^2_{\nu_j} = m^{2(eff)}_{\nu_e} - \sum_i |U_{ei}|^2 \Delta m^2_{ij}$ can be determined.

So far solar, reactor, atmospheric and accelerator neutrino oscillation experiments can be consistently described using three active neutrino flavors, i.e. two mass splittings and three mixing angles. However, several experiments with radioactive sources, reactors, and accelerators imply the possible existence of one or more non-interacting, i.e. sterile, neutrino species that might be observable since they couple, albeit weakly, to the flavor neutrinos $|\nu_l\rangle$. In that case, the neutrino mixing matrix would be $n \times n$ unitary matrix with $n > 3$.

Combined three neutrino analyses determine the squared mass differences and all three mixing angles to within reasonable accuracy. For given $|\Delta m^2_{ij}|$ a limit on $m^{2(eff)}_{\nu_e}$ from beta decay defines an upper limit on the maximum value $m_{max}$ of $m_{\nu_i}$: $m^2_{max} \leq m^{2(eff)}_{\nu_e} + \sum_{i<j} |\Delta m^2_{ij}|$. The analysis of the low energy beta decay of tritium, combined with the oscillation results, thus limits *all* active neutrino masses. Traditionally, experimental neutrino mass limits obtained from pion decay $\pi^+ \to \mu^+ + \nu_\mu$ or the shape of the spectrum of decay products of the $\tau$ lepton did not distinguish between flavor and mass eigenstates. These results are reported as limits of the $\mu$ and $\tau$ based neutrino

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

mass. After the determination of the $|\Delta m^2_{ij}|$'s and the mixing angles $\theta_{ij}$, the corresponding neutrino mass limits are no longer competitive with those derived from low energy beta decays.

The spread of arrival times of the neutrinos from SN1987A, coupled with the measured neutrino energies, provided a time-of-flight limit on a quantity similar to $\langle m_\beta \rangle \equiv \sqrt{m^{2(eff)}_{\nu_e}}$. This statement, clothed in various degrees of sophistication, has been the basis for a very large number of papers. The resulting limits, however, are no longer comparable with the limits from tritium beta decay.

Constraint, or eventually a value, of the sum of the neutrino masses $m_{tot}$ can be determined from the analysis of the cosmic microwave background anisotropy, combined with the galaxy redshift surveys and other data. These limits are reported in a separate table ( Sum of Neutrino Masses, $m_{tot}$). Obviously, $m_{tot}$ represents an upper limit for all $m_i$ values. Note that many reported $m_{tot}$ limits are considerably more stringent than the listed $m^{eff}_{\nu_e}$ limits. Discussion concerning the model dependence of the $m_{tot}$ limit is continuing.

## $\overline{\nu}$ MASS (electron based)

Those limits given below are for the square root of $m^{2(\text{eff})}_{\nu_e} \equiv \sum_i |U_{ei}|^2\ m^2_{\nu_i}$. Limits that come from the kinematics of $^3\text{H}\ \beta^-\overline{\nu}$ decay are the square roots of the limits for $m^{2(\text{eff})}_{\nu_e}$. Obtained from the measurements reported in the Listings for "$\overline{\nu}$ Mass Squared," below.

[1] AKER 19 report a neutrino mass limit, derived from the first month of data collected by the KATRIN tritium endpoint experiment. The analysis of the electron kinematics shows no evidence for neutrino mass.

[2] ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002 (some of the earlier runs were rejected), using a windowless gaseous tritium source. The fitted value of $m_\nu$, based on the method of Feldman and Cousins, is obtained from the upper limit of the fit for $m^2_\nu$. Previous analysis problems were resolved by careful monitoring of the tritium gas column density. Supersedes LOBASHEV 99 and BELESEV 95.

[3] PAGLIAROLI 10 is critical of the likelihood method used by LOREDO 02.

[4] KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Various sources of systematic uncertainties have been identified and quantified. The background has been reduced compared to the initial running period. A spectral anomaly at the endpoint, reported in LOBASHEV 99, was not observed.

[5] ARNABOLDI 03A *et al.* report kinematical neutrino mass limit using $\beta$-decay of $^{187}$Re. Bolometric $AgReO_4$ micro-calorimeters are used. Mass bound is substantially weaker than those derived from tritium $\beta$-decays but has different systematic uncertainties.

[6] LOREDO 02 updates LOREDO 89.

[7] LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. This limit depends on phenomenological fit parameters used to derive their best fit to $m^2_\nu$, making unambiguous interpretation difficult. See the footnote under "$\overline{\nu}$ Mass Squared."

[8] WEINHEIMER 99 presents two analyses which exclude the spectral anomaly and result in an acceptable $m^2_\nu$. We report the most conservative limit, but the other is nearly the same. See the footnote under "$\overline{\nu}$ Mass Squared."

[9] BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. A fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly) plus a monochromatic line 7–15 eV below the endpoint yields $m^2_\nu = -4.1 \pm 10.9\ \text{eV}^2$, leading to this Bayesian limit.

[10] CHING 95 quotes results previously given by SUN 93; no experimental details are given. A possible explanation for consistently negative values of $m^2_\nu$ is given.

[11] HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. Bayesian limit calculated from the weighted mean $m^2_\nu = 221 \pm 4244\ \text{eV}^2$ from the two runs listed below.

[12] STOEFFL 95 (LLNL) result is the Bayesian limit obtained from the $m^2_\nu$ errors given below but with $m^2_\nu$ set equal to 0. The anomalous endpoint accumulation leads to a value of $m^2_\nu$ which is negative by more than 5 standard deviations.

[13] WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium $\beta$ spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.

[14] HOLZSCHUH 92B (Zurich) result is obtained from the measurement $m^2_\nu = -24 \pm 48 \pm 61$ ($1\sigma$ errors), in $\text{eV}^2$, using the PDG prescription for conversion to a limit in $m_\nu$.

[15] KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid. This result is the Bayesian limit obtained from the $m^2_\nu$ limit with the errors combined in quadrature. This was also done in ROBERTSON 91, although the authors report a different procedure.

[16] ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that $m_\nu$ lies between 17 and 40 eV. However, the probability of a positive $m^2$ is only 3% if statistical and systematic error are combined in quadrature.

[17] See also comment in BORIS 87B and erratum in BORIS 88.

## $\overline{\nu}$ MASS SQUARED (electron based)

Given troubling systematics which result in improbably negative estimators of $m^{2(\text{eff})}_{\nu_e} \equiv \sum_i |U_{ei}|^2\ m^2_{\nu_i}$, in many experiments, we use only KRAUS 05, LOBASHEV 99, and AKER 19 for our average.

[1] AKER 19 use the first month of data collected by the KATRIN experiment to determine $m^2_\nu$. The result is consistent with a neutrino mass of zero and is used to place a limit on $m_\nu$.

[2] ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002, using a windowless gaseous tritium source. The analysis does not use the two additional fit parameters (see LOBASHEV 99) for a step-like structure near the endpoint. Using only the runs where the tritium gas column density was carefully monitored the need for such parameters was eliminated. Supersedes LOBASHEV 99 and BELESEV 95.

[3] KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Problems with significantly negative squared neutrino masses, observed in some earlier experiments, have been resolved in this work.

[4] LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. The data were corrected for electron trapping effects in the source, eliminating the dependence of the fitted neutrino mass on the fit interval. The analysis assuming a pure beta spectrum yields significantly negative fitted $m^2_\nu \approx -(20\text{–}10)\ \text{eV}^2$. This problem is attributed to a discrete spectral anomaly of about $6 \times 10^{-11}$ intensity with a time-dependent energy of 5–15 eV below the endpoint. The data analysis accounts for this anomaly by introducing two extra phenomenological fit parameters resulting in a best fit of $m^2_\nu = -1.9 \pm 3.4 \pm 2.2\ \text{eV}^2$ which is used to derive a neutrino mass limit. However, the introduction of phenomenological fit parameters which are correlated with the derived $m^2_\nu$ limit makes unambiguous interpretation of this result difficult.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[5] WEINHEIMER 99 is a continuation of the work reported in WEINHEIMER 93 . Using a lower temperature of the frozen tritium source eliminated the dewetting of the $T_2$ film, which introduced a dependence of the fitted neutrino mass on the fit interval in the earlier work. An indication for a spectral anomaly reported in LOBASHEV 99 has been seen, but its time dependence does not agree with LOBASHEV 99. Two analyses, which exclude the spectral anomaly either by choice of the analysis interval or by using a particular data set which does not exhibit the anomaly, result in acceptable $m_\nu^2$ fits and are used to derive the neutrino mass limit published by the authors. We list the most conservative of the two.

[6] BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. This value comes from a fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly), including the effects of an apparent peak 7–15 eV below the endpoint.

[7] HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. They quote measurements from two data sets.

[8] STOEFFL 95 (LLNL) uses a gaseous source of molecular tritium. An anomalous pileup of events at the endpoint leads to the negative value for $m_\nu^2$. The authors acknowledge that "the negative value for the best fit of $m_\nu^2$ has no physical meaning" and discuss possible explanations for this effect.

[9] SUN 93 uses a tritiated hydrocarbon source. See also CHING 95.

[10] WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium $\beta$ spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.

[11] HOLZSCHUH 92B (Zurich) source is a monolayer of tritiated hydrocarbon.

[12] KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid.

[13] ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that $m_\nu$ lies between 17 and 40 eV. However, the probability of a positive $m_\nu^2$ is only 3% if statistical and systematic error are combined in quadrature.

## $\nu$ MASS (electron based)

These are measurement of $m_\nu$ (in contrast to $m_{\overline{\nu}}$, given above). The masses can be different for a Dirac neutrino in the absence of $CPT$ invariance. The possible distinction between $\nu$ and $\overline{\nu}$ properties is usually ignored elsewhere in these Listings.

## $\nu$ MASS (muon based)

Limits given below are for the square root of $m_{\nu_\mu}^{2(\mathrm{eff})} \equiv \sum_i |U_{\mu i}|^2\ m_{\nu_i}^2$.

In some of the COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

OUR EVALUATION is based on OUR AVERAGE for the $\pi^\pm$ mass and the ASSAMAGAN 96 value for the muon momentum for the $\pi^+$ decay at rest. The limit is calculated using the unified classical analysis of FELDMAN 98 for a Gaussian distribution near a physical boundary. WARNING: since $m_{\nu_\mu}^{2(\mathrm{eff})}$ is calculated from the differences of large numbers, it and the corresponding limits are extraordinarily sensitive to small changes in the pion mass, the decay muon momentum, and their errors. For example, the limits obtained using JECKELMANN 94, LENZ 98, and the weighted averages are 0.15, 0.29, and 0.19 MeV, respectively.

| <0.65 | 90 | CLARK | 74 | ASPK | $K_{\mu 3}$ decay |

[1] ASSAMAGAN 96 measurement of $p_\mu$ from $\pi^+ \to \mu^+\nu$ at rest combined with JECKELMANN 94 Solution B pion mass yields $m_\nu^2 = -0.016 \pm 0.023$ with corresponding Bayesian limit listed above. If Solution A is used, $m_\nu^2 = -0.143 \pm 0.024$ MeV$^2$. Replaces ASSAMAGAN 94.

[2] DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below $T_{\mathrm{QCD}}$ for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits.

[3] ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, $\sim 1$ s.

[4] Assumes neutrino lifetime >1 s. For Dirac neutrinos only. See also ENQVIST 93.

[5] ANDERHUB 82 kinematics is insensitive to the pion mass.

## $\nu$ MASS (tau based)

The limits given below are the square roots of limits for $m_{\nu_\tau}^{2(\mathrm{eff})} \equiv \sum_i |U_{\tau i}|^2\ m_{\nu_i}^2$.

In some of the ASTR and COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

[1] BARATE 98F result based on kinematics of 2939 $\tau^- \to 2\pi^-\pi^+\nu_\tau$ and 52 $\tau^- \to 3\pi^-2\pi^+(\pi^0)\nu_\tau$ decays. If possible 2.5% excited $a_1$ decay is included in 3-prong sample analysis, limit increases to 19.2 MeV.

[2] ATHANAS 00 bound comes from analysis of $\tau^- \to \pi^-\pi^+\pi^-\pi^0\nu_\tau$ decays.

[3] ACKERSTAFF 98T use $\tau \to 5\pi^\pm\nu_\tau$ decays to obtain a limit of 43.2 MeV (95%CL). They combine this with ALEXANDER 96M value using $\tau \to 3h^\pm\nu_\tau$ decays to obtain quoted limit.

[4] AMMAR 98 limit comes from analysis of $\tau^- \to 3\pi^-2\pi^+\nu_\tau$ and $\tau^- \to 2\pi^-\pi^+2\pi^0\nu_\tau$ decay modes.

[5] ANASTASSOV 97 derive limit by comparing their $m_\tau$ measurement (which depends on $m_{\nu_\tau}$) to BAI 96 $m_\tau$ threshold measurement.

[6] FIELDS 97 limit for a Dirac neutrino. For a Majorana neutrino the mass region < 0.93 or >31 MeV is excluded. These bounds assume $N_\nu$ <4 from nucleosynthesis; a wider excluded region occurs with a smaller $N_\nu$ upper limit.

[7] SWAIN 97 derive their limit from the Standard Model relationships between the tau mass, lifetime, branching fractions for $\tau^- \to e^-\overline{\nu}_e\nu_\tau$, $\tau^- \to \mu^-\overline{\nu}_\mu\nu_\tau$, $\tau^- \to \pi^-\nu_\tau$, and $\tau^- \to K^-\nu_\tau$, and the muon mass and lifetime by assuming lepton universality and using world average values. Limit is reduced to 48 MeV when the CLEO $\tau$ mass measurement (BALEST 93) is included; see CLEO's more recent $m_{\nu_\tau}$ limit (ANASTASSOV 97). Consideration of mixing with a fourth generation heavy neutrino yields $\sin^2\theta_L < 0.016$ (95%CL).

[8] ALEXANDER 96M bound comes from analyses of $\tau^- \to 3\pi^-2\pi^+\nu_\tau$ and $\tau^- \to h^-h^-h^+\nu_\tau$ decays.

[9] BOTTINO 96 assumes three generations of neutrinos with mixing, finds consistency with massless neutrinos with no mixing based on 1995 data for masses, lifetimes, and leptonic partial widths.

[10] HANNESTAD 96C limit is on the mass of a Majorana neutrino. This bound assumes $N_\nu < 4$ from nucleosynthesis. A wider excluded region occurs with a smaller $N_\nu$ upper limit. This paper is the corrected version of HANNESTAD 96; see the erratum: HANNESTAD 96B.

[11] SOBIE 96 derive their limit from the Standard Model relationship between the tau mass, lifetime, and leptonic branching fraction, and the muon mass and lifetime, by assuming lepton universality and using world average values.

[12] BUSKULIC 95H bound comes from a two-dimensional fit of the visible energy and invariant mass distribution of $\tau \to 5\pi(\pi^0)\nu_\tau$ decays. Replaced by BARATE 98F.

[13] DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below $T_{\mathrm{QCD}}$ for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits. DOLGOV 96 argues that a possible window near 20 MeV is excluded.

[14] SIGL 95 exclude massive Dirac or Majorana neutrinos with lifetimes between $10^{-3}$ and $10^8$ seconds if the decay products are predominantly $\gamma$ or $e^+e^-$.

[15] DODELSON 94 calculate constraints on $\nu_\tau$ mass and lifetime from nucleosynthesis for 4 generic decay modes. Limits depend strongly on decay mode. Quoted limit is valid for

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

all decay modes of Majorana neutrinos with lifetime greater than about 300 s. For Dirac neutrinos limits change to $< 0.3$ or $> 33$.

[16] KAWASAKI 94 excluded region is for Majorana neutrino with lifetime >1000 s. Other limits are given as a function of $\nu_\tau$ lifetime for decays of the type $\nu_\tau \to \nu_\mu \phi$ where $\phi$ is a Nambu-Goldstone boson.

[17] PERES 94 used PDG 92 values for parameters to obtain a value consistent with mixing. Reexamination by BOTTINO 96 which included radiative corrections and 1995 PDG parameters resulted in two allowed regions, $m_3 < 70$ MeV and 140 MeV $m_3 < 149$ MeV.

[18] CINABRO 93 bound comes from analysis of $\tau^- \to 3\pi^- 2\pi^+ \nu_\tau$ and $\tau^- \to 2\pi^- \pi^+ 2\pi^0 \nu_\tau$ decay modes.

[19] DOLGOV 93 assumes neutrino lifetime >100 s. For Majorana neutrinos, the low mass limit is 0.5 MeV. KAWANO 92 points out that these bounds can be overcome for a Dirac neutrino if it possesses a magnetic moment. See also DOLGOV 96.

[20] ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, $\sim 1$ s.

[21] ALBRECHT 92M reports measurement of a slightly lower $\tau$ mass, which has the effect of reducing the $\nu_\tau$ mass reported in ALBRECHT 88B. Bound is from analysis of $\tau^- \to 3\pi^- 2\pi^+ \nu_\tau$ mode.

[22] Assumes neutrino lifetime >1 s. For Dirac neutrinos. See also ENQVIST 93.

[23] KOLB 91 exclusion region is for Dirac neutrino with lifetime >1 s; other limits are given.

Revised September 2019 by K.A. Olive (University of Minnesota).

Neutrinos decouple from thermal equilibrium in the early universe at temperatures $\mathcal{O}(1)$ MeV. The limits on low mass ($m_\nu \lesssim 1$ MeV) neutrinos apply to $m_{\rm tot}$ given by

$$m_{\rm tot} = \sum_\nu m_\nu \ .$$

Stable neutrinos in this mass range decouple from the thermal bath while still relativistic and make a contribution to the total energy density of the Universe which is given by

$$\rho_\nu = m_{\rm tot} n_\nu \simeq m_{\rm tot}(3/11)(3.045/3)^{3/4} n_\gamma \ ,$$

where the factor 3/11 is the ratio of (light) neutrinos to photons and the factor $(3.045/3)^{3/4}$ corrects for the fact that the effective number of neutrinos in the standard model is 3.045 when taking into account $e^+e^-$ annihilation during neutrino decoupling. Writing $\Omega_\nu = \rho_\nu/\rho_c$, where $\rho_c$ is the critical energy density of the Universe, and using $n_\gamma = 410.7$ cm$^{-3}$, we have

$$\Omega_\nu h^2 \simeq m_{\rm tot}/(93 \text{ eV}) \ .$$

While an upper limit to the matter density of $\Omega_m h^2 < 0.12$ would constrain $m_{\rm tot} < 11$ eV, much stronger constraints are obtained from a combination of observations of the CMB, the amplitude of density fluctuations on smaller scales from the clustering of galaxies and the Lyman-$\alpha$ forest, baryon acoustic oscillations, and new Hubble parameter data. These combine to give an upper limit of around 0.15 eV, and may, in the near future, be able to provide a lower bound on the sum of the neutrino masses. The current lower bound of $m_{\rm tot} > 0.06$ eV implies a lower limit of $\Omega_\nu h^2 > 6 \times 10^{-4}$. See our review on "Neutrinos in Cosmology" for more details.

## SUM OF THE NEUTRINO MASSES, $m_{\rm tot}$

This is a sum of the neutrino masses, $m_{\rm tot}$, as defined in the above note, of effectively stable neutrinos, i.e. those with mean lifetimes on cosmological scales. When necessary, we have generalized the results reported so they apply to $m_{\rm tot}$. For other limits, see SZALAY 76, VYSOTSKY 77, BERNSTEIN 81, FREESE 84, SCHRAMM 84, and COWSIK 85. For more information see a note on "Neutrinos in Cosmology" in this *Review*.

[1] LOUREIRO 19 combines data from large scale structure, cosmic microwave background, type Ia supernovae and big bang nucleosynthesis using physically motivated neutrino mass models.

[2] UPADHYE 19 uses the shape of the BOSS redshift-space galaxy power spectrum in combination with the CMB, and supernovae data. Limit weakens to $< 0.54$ eV if the dark energy equation of state is allowed to vary.

[3] CHOUDHURY 18 combines 2015 Planck CMB temperature data, information from the optical depth to reionization from Planck 2016 intermediate results together with baryon acoustic oscillation data from BOSS, MGS, and 6dFGS as well as supernovae Type Ia data from the Pantheon Sample. The limit is strengthened to 0.118 eV when high-$l$ CMB polarization data is also included.

[4] SIMPSON 17 uses a combination of laboratory and cosmological measurements to determine the light neutrino masses and argue that there is strong evidence for the normal mass ordering.

[5] Combines temperature anisotropies of the CMB from Planck with data on baryon acoustic oscillations and the optical depth to reionization. Limit is strengthened to 0.118 when high multipole polarization data is included. Updates GIUSARMA 16.

[6] Constrains the total mass of neutrinos using the Lyman-alpha forest power spectrum with BOSS (mid-resolution), XQ-100 (high-resolution) and CMB. Without the CMB data, the limit relaxes to 0.8 eV. Supersedes PALANQUE-DELABROUILLE 15A.

[7] Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation and Planck cluster data.

[8] Constrains the total mass of neutrinos from BAO data from SDSS-III/BOSS combined with CMB data from Planck. Limit quoted for normal mass hierarchy. The limit for the inverted mass hierarchy is 0.20 eV and for the degenerate mass hierarchy it is 0.15 eV.

[9] ROSSI 15 sets limits on the sum of neutrino masses using BOSS Lyman alpha forest data combined with Planck CMB data and baryon acoustic oscillations.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[10] Constrains the total mass of neutrinos from Planck CMB data along with WMAP polarization, high L, and BAO data.

[11] Finite neutrino mass fit to resolve discrepancy between CMB and lensing measurements.

[12] Fit to the total mass of neutrinos from BOSS data along with WMAP CMB data and data from other BAO constraints and weak lensing.

[13] Fit to the total mass of neutrinos from Planck CMB data along with BAO.

[14] Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation data from BOSS and HST data on the Hubble parameter.

[15] Fit based on the SPT-SZ survey combined with CMB, BAO, and $H_0$ data.

[16] Constraints the total mass of neutrinos (marginalizing over the effective number of neutrino species) from CMB, CMB lensing, BAO, and galaxy clustering data.

[17] Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation data from BOSS, 6dFGS, SDSS, WiggleZ data on the galaxy power spectrum, and HST data on the Hubble parameter. The limit is increased to 0.25 eV if a lower bound to the sum of neutrino masses of 0.04 eV is assumed.

[18] Constrains the total mass of neutrinos from observational Hubble parameter data with seven-year WMAP data and the most recent estimate of $H_0$.

[19] Constrains the total mass of neutrinos from the CFHTLS combined with seven-year WMAP data and a prior on the Hubble parameter. Limit is relaxed to 0.41 eV when small scales affected by non-linearities are removed.

[20] Constrains the total mass of neutrinos from the Sloan Digital Sky Survey and the five-year WMAP data.

[21] Constrains the total mass of neutrinos from the 7-year WMAP data including SDSS and HST data. Limit relaxes to 1.19 eV when CMB data is used alone. Supersedes HANNESTAD 06.

[22] Constrains the total mass of neutrinos from a combination of CMB data, a recent measurement of $H_0$ (SHOES), and baryon acoustic oscillation data from SDSS.

[23] Constrains the total mass of neutrinos from SDSS MegaZ LRG DR7 galaxy clustering data combined with CMB, HST, supernovae and baryon acoustic oscillation data. Limit relaxes to 0.47 eV when the equation of state parameter, $w \neq 1$.

[24] Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to 0.54 eV when supernovae and baryon acoustic oscillation observations are included. Assumes ΛCDM model.

[25] Constrains the total mass of neutrinos from five-year WMAP data. Limit improves to 0.67 eV when supernovae and baryon acoustic oscillation observations are included. Limits quoted assume the ΛCDM model. Supersedes SPERGEL 07.

[26] Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to $0.03 < \Sigma m_\nu < 0.54$ eV when supernovae and baryon acoustic oscillation observations are included. The slight preference for massive neutrinos at the two-sigma level disappears when systematic errors are taken into account. Assumes ΛCDM model.

[27] Constrains the total mass of neutrinos from recent Chandra X-ray observations of galaxy clusters when combined with CMB, supernovae, and baryon acoustic oscillation measurements. Assumes flat universe and constant dark-energy equation of state, $w$.

[28] Constraints the total mass of neutrinos from recent CMB and SOSS LRG power spectrum data along with bias mass relations from SDSS, DEEP2, and Lyman-Break Galaxies. It assumes ΛCDM model. Limit degrades to 0.59 eV in a more general wCDM model.

[29] Constrains the total mass of neutrinos from neutrino oscillation experiments and cosmological data. The most conservative limit uses only WMAP three-year data, while the most stringent limit includes CMB, large-scale structure, supernova, and Lyman-alpha data.

[30] Constrains the total mass of neutrinos from recent CMB, large scale structure, SN1a, and baryon acoustic oscillation data. The limit relaxes to 1.75 when WMAP data alone is used with no prior. Paper shows results with several combinations of data sets. Supersedes KRISTIANSEN 06.

[31] Constrains the total mass of neutrinos from the CMB and the large scale structure data. The most conservative limit is obtained when generic initial conditions are allowed.

[32] Constrains the total mass of neutrinos from recent CMB, large scale structure, Lyman-alpha forest, and SN1a data.

[33] Constrains the total mass of neutrinos from recent CMB and large scale structure data. See also GOOBAR 06. Superseded by HANNESTAD 10.

[34] Constrains the total mass of neutrinos from the CMB and the final 2dF Galaxy Redshift Survey.

[35] Constrains the total mass of neutrinos from the CMB experiments alone, assuming ΛCDM Universe. FUKUGITA 06 show that this result is unchanged by the 3-year WMAP data.

[36] Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey and the 2dF galaxy redshift survey, WMAP and 27 other CMB experiments and measurements by the HST Key project.

[37] Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey, the 2dF galaxy redshift survey, WMAP and ACBAR. The limit is strengthened to 0.6 eV when measurements by the HST Key project and supernovae data are included.

[38] Constrains the fractional contribution of neutrinos to the total matter density in the Universe from WMAP data combined with other CMB measurements, the 2dfGRS data, and Lyman $\alpha$ data. The limit does not noticeably change if the Lyman $\alpha$ data are not used.

[39] LEWIS 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB, HST Key project, 2dF galaxy redshift survey, supernovae type Ia, and BBN.

[40] WANG 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB and other cosmological data sets such as galaxy clustering and the Lyman $\alpha$ forest.

[41] FUKUGITA 00 is a limit on neutrino masses from structure formation. The constraint is based on the clustering scale $\sigma_8$ and the COBE normalization and leads to a conservative limit of 0.9 eV assuming 3 nearly degenerate neutrinos. The quoted limit is on the sum of the light neutrino masses.

[42] CROFT 99 result based on the power spectrum of the Ly $\alpha$ forest. If $\Omega_{\text{matter}} < 0.5$, the limit is improved to $m_\nu < 2.4\ (\Omega_{\text{matter}}/0.17\text{–}1)$ eV.

### Limits on MASSES of Light Stable Right-Handed ν (with necessarily suppressed interaction strengths)

| VALUE (eV) | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| <100–200 | [1] OLIVE | 82 | COSM | Dirac $\nu$ |
| <200–2000 | [1] OLIVE | 82 | COSM | Majorana $\nu$ |

[1] Depending on interaction strength $G_R$ where $G_R < G_F$.

### Limits on MASSES of Heavy Stable Right-Handed ν (with necessarily suppressed interaction strengths)

| VALUE (GeV) | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| > 10 | [1] OLIVE | 82 | COSM | $G_R/G_F$ <0.1 |
| >100 | [1] OLIVE | 82 | COSM | $G_R/G_F$ <0.01 |

[1] These results apply to heavy Majorana neutrinos and are summarized by the equation: $m_\nu$ >1.2 GeV $(G_F/G_R)$. The bound saturates, and if $G_R$ is too small no mass range is allowed.

## ν CHARGE

$e$ = electron charge is the unit of values listed below.

[1] CAPRINI 05 limit derived from the lack of a charge asymmetry in the universe. Limit assumes that charge asymmetries between particles are not anti-correlated.

[2] DELLA-VALLE 16 obtain a limit on the charge of neutrinos valid for masses of less than 10 meV. For heavier neutrinos the limit increases as a power of mass, reaching $10^{-6}$ $e$ for $m = 100$ meV.

[3] CHEN 14A use the Multi-Configuration RRPA method to analyze reactor $\overline{\nu}_e$ scattering on Ge atoms with 300 eV recoil energy threshold to obtain this limit.

[4] STUDENIKIN 14 uses the limit on $\mu_\nu$ from BEDA 13 and the 2.8 keV threshold of the electron recoil energy to obtain this limit.

[5] GNINENKO 07 use limit on $\overline{\nu}_e$ magnetic moment from LI 03B to derive this result. The limit is considerably weaker than the limits on the charge of $\nu_e$ and $\overline{\nu}_e$ from various astrophysics considerations.

[6] This RAFFELT 99 limit applies to all neutrino flavors which are light enough (<5 keV) to be emitted from globular-cluster red giants.

[7] This RAFFELT 99 limit is derived from the helioseismological limit on a new energy-loss channel of the Sun, and applies to all neutrino flavors which are light enough (<1 keV) to be emitted from the sun.

[8] BABU 94 use COOPER-SARKAR 92 limit on $\nu$ magnetic moment to derive quoted result. It applies to $\nu_\tau$.

[9] DAVIDSON 91 use data from early SLAC electron beam dump experiment to derive charge limit as a function of neutrino mass. It applies to $\nu_\tau$.

[10] Exact BARBIELLINI 87 limit depends on assumptions about the intergalactic or galactic magnetic fields and about the direct distance and time through the field. It applies to $\nu_e$.

[11] The limit applies to all flavors.

## ν (MEAN LIFE) / MASS

Measures $\left[\sum |U_{\ell j}|^2\, \Gamma_j\, m_j\right]^{-1}$, where the sum is over mass eigenstates which cannot be resolved experimentally. Some of the limits constrain the radiative decay and are based on the limit of the corresponding photon flux. Other apply to the decay of a heavier neutrino into the lighter one and a Majoron or other invisible particle. Many of these limits apply to any $\nu$ within the indicated mass range.

Limits on the radiative decay are either directly based on the limits of the corresponding photon flux, or are derived from the limits on the neutrino magnetic moments. In the later case the transition rate for $\nu_i \to \nu_j + \gamma$ is constrained by $\Gamma_{ij} = \frac{1}{\tau_{ij}} = \frac{(m_i^2 - m_j^2)^3}{m_i^3}\, \mu_{ij}^2$ where $\mu_{ij}$ is the neutrino transition moment in the mass eigenstates basis. Typically, the limits on lifetime based on the magnetic moments are many orders of magnitude more restrictive than limits based on the nonobservation of photons.

[1] KRAKAUER 91 quotes the limit $\tau/m_{\nu_1} > (0.75a^2 + 21.65a + 26.3)$ s/eV, where $a$ is a parameter describing the asymmetry in the neutrino decay defined as $dN_\gamma/d\cos\theta = (1/2)(1 + a\cos\theta)$ The parameter $a = 0$ for a Majorana neutrino, but can vary from $-1$ to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).

[2] RAFFELT 85 limit on the radiative decay is from solar x- and $\gamma$-ray fluxes. Limit depends on $\nu$ flux from $pp$, now established from GALLEX and SAGE to be > 0.5 of expectation.

[3] REINES 74 looked for $\nu$ of nonzero mass decaying radiatively to a neutral of lesser mass + $\gamma$. Used liquid scintillator detector near fission reactor. Finds lab lifetime $6 \times 10^7$ s or more. Above value of (mean life)/mass assumes average effective neutrino energy of 0.2 MeV. To obtain the limit $6 \times 10^7$ s REINES 74 assumed that the full $\overline{\nu}_e$ reactor flux could be responsible for yielding decays with photon energies in the interval 0.1 MeV – 0.5 MeV. This represents some overestimate so their lower limit is an over-estimate of the lab lifetime (VOGEL 84). If so, OBERAUER 87 may be comparable or better.

[4] AHARMIM 19 quotes the limit $\tau/m_{\nu_2}$ for invisible nonradiative decay of $\nu_2$. They obtained this result by analyzing the entire SNO dataset, allowing for the decay of $\nu_2$ which would cause an energy-dependent distortion of the survival probability of electron-type solar neutrinos.

[5] AHARMIM 19 quotes the limit $\tau/m_{\nu_2}$ for invisible nonradiative decay of $\nu_2$. They obtained this result by combining the $\tau/m_{\nu_2}$ measurements from SNO and other solar neutrino experiments (Super-Kamiokande, KamLAND, and Borexino $^8$B results; Borexino and KamLAND $^7$Be results; the combined gallium interaction rate from GNO, GALLEX, and SAGE; and the chlorine interaction rate from Homestake). The quoted limit at 99% CL is $> 1.04 \times 10^{-3}$.

[6] ESCUDERO 19 sets limits on invisible neutrino decays using Planck 2018 data of $\tau > 1.3–0.3 \times 10^9$ s at 95% C.L. Values in the range $\tau = 2–16 \times 10^9$ s are preferred at 95% C.L. when Planck polarization data is included. Limits scale as $(m_\nu/0.05 \text{ eV})^3$.

[7] CECCHINI 11 search for radiative decays of solar neutrinos into visible photons during the 2006 total solar eclipse. The range of (mean life)/mass values corresponds to a range of $\nu_1$ masses between $10^{-4}$ and 0.1 eV.

[8] MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the maximum allowed distortion of the CMB spectrum as measured by the COBE/FIRAS. For the decay $\nu_2 \rightarrow \nu_1$ the lifetime limit is $\lesssim 4 \times 10^{20}$ s for $m_{min} \lesssim 0.14$ eV. For transition with the $|\Delta m_{31}|$ mass difference the lifetime limit is $\sim 2 \times 10^{19}$ s for $m_{min} \lesssim 0.14$ eV and $\sim 5 \times 10^{20}$ s for $m_{min} \gtrsim 0.14$ eV.

[9] MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the cosmic infrared background (CIB) using the Spitzer Observatory data. For transition with the $|\Delta m_{31}|$ mass difference they obtain the lifetime limit $\sim 10^{20}$ s for $m_{min} \lesssim 0.14$ eV.

[10] WONG 07 use their limit on the neutrino magnetic moment together with the assumed experimental value of $\Delta m^2_{13} \sim 2 \times 10^{-3}$ eV$^2$ to obtain $\tau_{13}/m_1^3 > 3.2 \times 10^{27}$ s/eV$^3$ for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for $\tau_{23}$ and $\tau_{21}$.

[11] XIN 05 search for the $\gamma$ from radiative decay of $\nu_e$ produced by the electron capture on $^{51}$Cr. No events were seen and the limit on $\tau/m_\nu$ was derived. This is a weaker limit on the decay of $\nu_e$ than KRAKAUER 91.

[12] XIN 05 use their limit on the neutrino magnetic moment of $\nu_e$ together with the assumed experimental value of $\Delta m^2_{1,3} \sim 2 \times 10^{-3}$ eV$^2$ to obtain $\tau_{13}/m_1^3 > 1 \times 10^{23}$ s/eV$^3$ for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for $\tau_{23}$ and $\tau_{21}$. Again, this limit is specific for $\nu_e$.

[13] AHARMIM 04 obtained these results from the solar $\overline{\nu}_e$ flux limit set by the SNO measurement assuming $\nu_2$ decay through nonradiative process $\nu_2 \rightarrow \overline{\nu}_1 X$, where $X$ is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.

[14] CECCHINI 04 obtained this bound through the observations performed on the occasion of the 21 June 2001 total solar eclipse, looking for visible photons from radiative decays of solar neutrinos. Limit is a $\tau/m_{\nu_2}$ in $\nu_2 \rightarrow \nu_1\gamma$. Limit ranges from ~ 100 to $10^7$ s/eV for $0.01 < m_{\nu_1} < 0.1$ eV.

[15] EGUCHI 04 obtained these results from the solar $\overline{\nu}_e$ flux limit set by the KamLAND measurement assuming $\nu_2$ decay through nonradiative process $\nu_2 \rightarrow \overline{\nu}_1 X$, where $X$ is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.

[16] The ratio of the lifetime over the mass derived by BANDYOPADHYAY 03 is for $\nu_2$. They obtained this result using the following solar-neutrino data: total rates measured in Cl and Ga experiments, the Super-Kamiokande's zenith-angle spectra, and SNO's day and night spectra. They assumed that $\nu_1$ is the lowest mass, stable or nearly stable neutrino state and $\nu_2$ decays through nonradiative Majoron emission process, $\nu_2 \rightarrow \overline{\nu}_1 + J$, or through nonradiative process with all the final state particles being sterile. The best fit is obtained in the region of the LMA solution.

[17] DERBIN 02B (also BACK 03B) obtained this bound for the radiative decay from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). The laboratory gamma spectrum is given as $dN_\gamma/d\cos\theta = (1/2)(1 + \alpha\cos\theta)$ with $\alpha$=0 for a Majorana neutrino, and $\alpha$ varying to $-1$ to 1 for a Dirac neutrino. The listed bound is for the case of $\alpha$=0. The most conservative bound $1.5 \times 10^3$ s eV$^{-1}$ is obtained for the case of $\alpha$=$-1$.

[18] The ratio of the lifetime over the mass derived by JOSHIPURA 02B is for $\nu_2$. They obtained this result from the total rates measured in all solar neutrino experiments. They assumed that $\nu_1$ is the lowest mass, stable or nearly stable neutrino state and $\nu_2$ decays through nonradiative process like Majoron emission decay, $\nu_2 \rightarrow \nu_1' + J$ where $\nu_1'$ state is sterile. The exact limit depends on the specific solution of the solar neutrino problem. The quoted limit is for the LMA solution.

[19] DOLGOV 99 places limits in the (Majorana) $\tau$-associated $\nu$ mass-lifetime plane based on nucleosynthesis. Results would be considerably modified if neutrino oscillations exist.

[20] BILLER 98 use the observed TeV $\gamma$-ray spectra to set limits on the mean life of any radiatively decaying neutrino between 0.05 and 1 eV. Curve shows $\tau_\nu/B_\gamma > 0.15 \times 10^{21}$ s at 0.05 eV, $> 1.2 \times 10^{21}$ s at 0.17 eV, $> 3 \times 10^{21}$ s at 1 eV, where $B_\gamma$ is the branching ratio to photons.

[21] BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.

[22] Limit on the radiative decay based on nonobservation of $\gamma$'s in coincidence with $\nu$'s from SN 1987A.

[23] DODELSON 92 range is for wrong-helicity keV mass Dirac $\nu$'s from the core of neutron star in SN 1987A decaying to $\nu$'s that would have interacted in KAM2 or IMB detectors.

[24] GRANEK 91 considers heavy neutrino decays to $\gamma\nu_L$ and $3\nu_L$, where $m_{\nu_L}$ <100 keV. Lifetime is calculated as a function of heavy neutrino mass, branching ratio into $\gamma\nu_L$, and $m_{\nu_L}$.

[25] KRAKAUER 91 quotes the limit for $\nu_e$, $\tau/m_\nu > (0.3a^2 + 9.8a + 15.9)$ s/eV, where $a$ is a parameter describing the asymmetry in the radiative neutrino decay defined as $dN_\gamma/d\cos\theta = (1/2)(1 + a\cos\theta)$ $a = 0$ for a Majorana neutrino, but can vary from $-1$ to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).

[26] WALKER 90 uses SN 1987A $\gamma$ flux limits after 289 days.

[27] CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.

[28] RAFFELT 89 uses KYULDJIEV 84 to obtain $\tau m^3 > 3 \times 10^{18}$ s eV$^3$ (based on $\overline{\nu}_e e^-$ cross sections). The bound for the radiative decay is not valid if electric and magnetic transition moments are equal for Dirac neutrinos.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[29] RAFFELT 89B analyze stellar evolution and exclude the region $3 \times 10^{12} < \tau m^3 < 3 \times 10^{21}$ s eV$^3$.

[30] Model-dependent theoretical analysis of SN1987A neutrinos. Quoted limit is for $\left[\sum_j |U_{\ell j}|^2 \Gamma_j m_j\right]^{-1}$, where $\ell = \mu, \tau$. Limit is $3.3 \times 10^{14}$ s/eV for $\ell = e$.

[31] OBERAUER 87 looks for photons and $e^+e^-$ pairs from radiative decays of reactor neutrinos.

[32] BINETRUY 84 finds $\tau < 10^8$ s for neutrinos in a radiation-dominated universe.

[33] These experiments look for $\nu_k \to \nu_j\gamma$ or $\overline{\nu}_k \to \overline{\nu}_j\gamma$.

[34] STECKER 80 limit based on UV background; result given is $\tau > 4\times10^{22}$ s at $m_\nu$=20 eV.

[35] FALK 78 finds lifetime constraints based on supernova energetics.

[36] COWSIK 77 considers variety of scenarios. For neutrinos produced in the big bang, present limits on optical photon flux require $\tau > 10^{23}$ s for $m_\nu \sim 1$ eV. See also COWSIK 79 and GOLDMAN 79.

## $\nu$ MAGNETIC MOMENT

The coupling of neutrinos to an electromagnetic field is a characterized by a 3×3 matrix $\lambda$ of the magnetic ($\mu$) and electric ($d$) dipole moments ($\lambda = \mu - id$). For Majorana neutrinos the matrix $\lambda$ is antisymmetric and only transition moments are allowed, while for Dirac neutrinos $\lambda$ is a general 3×3 matrix. In the standard electroweak theory extended to include neutrino masses (see FUJIKAWA 80) $\mu_\nu = 3eG_F m_\nu/(8\pi^2\sqrt{2}) = 3.2 \times 10^{-19}(m_\nu/\text{eV})\mu_B$, i.e. it is unobservably small given the known small neutrino masses. In more general models there is no longer a proportionality between neutrino mass and its magnetic moment, even though only massive neutrinos have nonvanishing magnetic moments without fine tuning.

Laboratory bounds on $\lambda$ are obtained via elastic $\nu$-$e$ scattering, where the scattered neutrino is not observed. The combinations of matrix elements of $\lambda$ that are constrained by various experiments depend on the initial neutrino flavor and on its propagation between source and detector (e.g., solar $\nu_e$ and reactor $\overline{\nu}_e$ do not constrain the same combinations). The listings below therefore identify the initial neutrino flavor.

Other limits, e.g. from various stellar cooling processes, apply to all neutrino flavors. Analogous flavor independent, but weaker, limits are obtained from the analysis of $e^+e^- \to \nu\overline{\nu}\gamma$ collider experiments.

[1] AGOSTINI 17A obtained this limit using the shape of the recoil electron energy spectrum from the Borexino Phase-II 1291.5 live days of solar neutrino data and the constraints on the sum of the solar neutrino fluxes from the radiochemical gallium experiments SAGE, Gallex, and GNO. Without radiochemical constraints, the 90% C.L. limit of $< 4.0 \times 10^{-11} \mu_B$ is obtained.

[2] BEDA 13 report $\overline{\nu}_e e^-$ scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.5 and 55 keV. Supersedes BEDA 07. Supersedes BEDA 10. This is the most stringent limit on the magnetic moment of reactor $\overline{\nu}_e$.

[3] AUERBACH 01 limit is based on the LSND $\nu_e$ and $\nu_\mu$ electron scattering measurements. The limit is slightly more stringent than KRAKAUER 90.

[4] SCHWIENHORST 01 quote an experimental sensitivity of $4.9 \times 10^{-7}$.

[5] ARCEO-DIAZ 15 constrains the neutrino magnetic moment from observation of the tip of the red giant branch in the globular cluster $\omega$-Centauri.

[6] CORSICO 14 constrains the neutrino magnetic moment from observations of white drarf pulsations.

[7] MILLER-BERTOLAMI 14B constrains the neutrino magnetic moment from observations of the white dwarf luminosity function of the Galactic disk.

[8] VIAUX 13A constrains the neutrino magnetic moment from observations of the globular cluster M5.

[9] BEDA 10 report $\overline{\nu}_e e^-$ scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.9 and 45 keV. Supersedes BEDA 07. Superseded by BEDA 13.

[10] DENIZ 10 observe reactor $\overline{\nu}_e e$ scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on $\overline{\nu}_e$ magnetic moment.

[11] KUZNETSOV 09 obtain a limit on the flavor averaged magnetic moment of Dirac neutrinos from the time averaged neutrino signal of SN1987A. Improves and supersedes the analysis of BARBIERI 88 and AYALA 99.

[12] ARPESELLA 08A obtained this limit using the shape of the recoil electron energy spectrum from the Borexino 192 live days of solar neutrino data.

[13] BEDA 07 performed search for electromagnetic $\overline{\nu}_e$-$e$ scattering at Kalininskaya nuclear reactor. A Ge detector with active and passive shield was used and the electron recoil spectrum between 3.0 and 61.3 keV analyzed. Superseded by BEDA 10.

[14] WONG 07 performed search for non-standard $\overline{\nu}_e$-$e$ scattering at the Kuo-Sheng nuclear reactor. Ge detector equipped with active anti-Compton shield is used. Most stringent laboratory limit on magnetic moment of reactor $\overline{\nu}_e$. Supersedes LI 03B.

[15] DARAKTCHIEVA 05 present the final analysis of the search for non-standard $\overline{\nu}_e$-$e$ scattering component at Bugey nuclear reactor. Full kinematical event reconstruction of both the kinetic energy above 700 keV and scattering angle of the recoil electron, by use of TPC. Most stringent laboratory limit on magnetic moment. Supersedes DARAKTCHIEVA 03.

[16] XIN 05 evaluated the $\nu_e$ flux at the Kuo-Sheng nuclear reactor and searched for non-standard $\nu_e$-$e$ scattering. Ge detector equipped with active anti-Compton shield was used. This laboratory limit on magnetic moment is considerably less stringent than the limits for reactor $\overline{\nu}_e$, but is specific to $\nu_e$.

[17] GRIFOLS 04 obtained this bound using the SNO data of the solar $^8$B neutrino flux measured with deuteron breakup. This bound applies to $\mu_{\text{eff}} = (\mu_{21}^2 + \mu_{22}^2 + \mu_{23}^2)^{1/2}$.

[18] LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 days of solar neutrino data. Neutrinos are assumed to have only diagonal magnetic moments, $\mu_{\nu 1} = \mu_{\nu 2}$. This limit corresponds to the oscillation parameters in the vacuum oscillation region.

[19] LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 live-day solar neutrino data, by limiting the oscillation parameter region in the LMA region allowed by solar neutrino experiments plus KamLAND. $\mu_{\nu 1} = \mu_{\nu 2}$ is assumed. In the LMA region, the same limit would be obtained even if neutrinos have off-diagonal magnetic moments.

[20] BACK 03B obtained this bound from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). Standard Solar Model flux was assumed. This $\mu_\nu$ can be different from the reactor $\mu_\nu$ in certain oscillation scenarios (see BEACOM 99).

[21] DARAKTCHIEVA 03 searched for non-standard $\overline{\nu}_e$-$e$ scattering component at Bugey nuclear reactor. Full kinematical event reconstruction by use of TPC. Superseded by DARAKTCHIEVA 05.

[22] LI 03B used Ge detector in active shield near nuclear reactor to test for nonstandard $\overline{\nu}_e$-$e$ scattering.

[23] GRIMUS 02 obtain stringent bounds on all Majorana neutrino transition moments from a simultaneous fit of LMA-MSW oscillation parameters and transition moments to global

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

solar neutrino data + reactor data. Using only solar neutrino data, a 90% CL bound of $6.3 \times 10^{-10} \mu_B$ is obtained.

[24] TANIMOTO 00 combined $e^+ e^- \to \nu\overline{\nu}\gamma$ data from VENUS, TOPAZ, and AMY.

[25] AYALA 99 improves the limit of BARBIERI 88.

[26] BEACOM 99 obtain the limit using the shape, but not the absolute magnitude which is affected by oscillations, of the solar neutrino spectrum obtained by Superkamiokande (825 days). This $\mu_\nu$ can be different from the reactor $\mu_\nu$ in certain oscillation scenarios.

[27] RAFFELT 99 is an update of RAFFELT 90. This limit applies to all neutrino flavors which are light enough ($< 5$ keV) to be emitted from globular-cluster red giants. This limit pertains equally to electric dipole moments and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.

[28] RAFFELT 99 is essentially an update of BERNSTEIN 63, but is derived from the helioseismological limit on a new energy-loss channel of the Sun. This limit applies to all neutrino flavors which are light enough ($<$1 keV) to be emitted from the Sun. This limit pertains equally to electric dipole and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.

[29] ACCIARRI 97Q result applies to both direct and transition magnetic moments and for $q^2$=0.

[30] ELMFORS 97 calculate the rate of depolarization in a plasma for neutrinos with a magnetic moment and use the constraints from a big-bang nucleosynthesis on additional degrees of freedom.

[31] Applies to absolute value of magnetic moment.

[32] DERBIN 93 determine the cross section for 0.6–2.0 MeV electron energy as $(1.28 \pm 0.63) \times \sigma_{\text{weak}}$. However, the (reactor on – reactor off)/(reactor off) is only $\sim 1/100$.

[33] COOPER-SARKAR 92 assume $f_{D_s}/f_\pi = 2$ and $D_s$, $\overline{D}_s$ production cross section = 2.6 $\mu$b to calculate $\nu$ flux.

[34] VIDYAKIN 92 limit is from a $e\overline{\nu}_e$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2\theta_W = 0.23$ as input.

[35] DORENBOSCH 91 corrects an incorrect statement in DORENBOSCH 89 that the $\nu$ magnetic moment is $< 1 \times 10^{-9}$ at the 95%CL. DORENBOSCH 89 measures both $\nu_\mu e$ and $\overline{\nu}e$ elastic scattering and assume $\mu(\nu) = \mu(\overline{\nu})$.

[36] KRAKAUER 90 experiment fully reported in ALLEN 93.

[37] RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives $< 1.4 \times 10^{-12}$. Limit at 95%CL obtained from $\delta M_C$.

[38] Significant dependence on details of stellar models.

[39] FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by $\mu < 10^{-16}$ $[10^{-9}\ G/B_0]$ where $B_0$ is the present-day intergalactic field strength.

[40] GROTCH 88 combined data from MAC, ASP, CELLO, and Mark J.

[41] For $m_\nu$ = 8–200 eV. NUSSINOV 87 examines transition magnetic moments for $\nu_\mu \to \nu_e$ and obtain $< 3 \times 10^{-15}$ for $m_\nu > 16$ eV and $< 6 \times 10^{-14}$ for $m_\nu > 4$ eV.

[42] We obtain above limit from SUTHERLAND 76 using their limit $f < 1/3$.

[43] KIM 74 is a theoretical analysis of $\overline{\nu}_\mu$ reaction data.

## NEUTRINO CHARGE RADIUS SQUARED

We report limits on the so-called neutrino charge radius squared. While the straight-forward definition of a neutrino charge radius has been proven to be gauge-dependent and, hence, unphysical (LEE 77C), there have been recent attempts to define a physically observable neutrino charge radius (BERNABEU 00, BERNABEU 02). The issue is still controversial (FUJIKAWA 03, BERNABEU 03). A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

[1] DENIZ 10 observe reactor $\overline{\nu}_e e$ scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on $\overline{\nu}_e$ charge radius.

[2] CADEDDU 18 use the data of the COHERENT experiment, AKIMOV 18. The limit is $\langle r^2_\nu \rangle$ for $\nu_\mu$ obtained from the time-dependent data. Weaker limits were obtained for charge radii of $\nu_e$ and for transition charge radii. The published value was divided by 2 to conform to the convention of this table.

[3] Based on analysis of CCFR 98 results. Limit is on $\langle r^2_V \rangle + \langle r^2_A \rangle$. The CHARM II and E734 at BNL results are reanalyzed, and weaker bounds on the charge radius squared than previously published are obtained. The NuTeV result is discussed; when tentatively interpreted as $\nu_\mu$ charge radius it implies $\langle r^2_V \rangle + \langle r^2_A \rangle = (4.20 \pm 1.64) \times 10^{-33}$ cm$^2$.

[4] Results of LEP-2 are interpreted as limits on the axial-vector charge radius squared of a Majorana $\nu_\tau$. Slightly weaker limits for both vector and axial-vector charge radius squared are obtained for the Dirac case, and somewhat weaker limits are obtained from the analysis of lower energy data (LEP-1.5 and TRISTAN).

[5] AUERBACH 01 measure $\nu_e e$ elastic scattering with LSND detector. The cross section agrees with the Standard Model expectation, including the charge and neutral current interference. The 90% CL applies to the range shown.

[6] VIDYAKIN 92 limit is from a $e\overline{\nu}$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2\theta_W = 0.23$ as input.

[7] Result is obtained from reanalysis given in ALLEN 91, followed by our reduction to obtain $1\,\sigma$ errors.

[8] GRIFOLS 89B sets a limit of $\langle r^2 \rangle < 0.2 \times 10^{-32}$ cm$^2$ for right-handed neutrinos.

## Number of Neutrino Types

The neutrinos referred to in this section are those of the Standard SU(2)×U(1) Electroweak Model possibly extended to allow nonzero neutrino masses. Light neutrinos are those with $m < m_Z/2$. The limits are on the number of neutrino mass eigenstates, including $\nu_1$, $\nu_2$, and $\nu_3$.

### THE NUMBER OF LIGHT NEUTRINO TYPES FROM COLLIDER EXPERIMENTS

Revised June 2020 by C.-J. Lin (LBNL). Written by D. Karlen (University of Victoria and TRIUMF).

The most precise measurements of the number of light neutrino types, $N_\nu$, come from studies of $Z$ production in $e^+e^-$ collisions. The invisible partial width, $\Gamma_{\rm inv}$, is determined by subtracting the measured visible partial widths, corresponding to $Z$ decays into quarks and charged leptons, from the total $Z$ width. The invisible width is assumed to be due to $N_\nu$ light neutrino species each contributing the neutrino partial width $\Gamma_\nu$ as given by the Standard Model. In order to reduce the model dependence, the Standard Model value for the ratio of the neutrino to charged leptonic partial widths, $(\Gamma_\nu/\Gamma_\ell)_{\rm SM} = 1.991 \pm 0.001$, is used instead of $(\Gamma_\nu)_{\rm SM}$ to determine the number of light neutrino types:

$$N_\nu = \frac{\Gamma_{\rm inv}}{\Gamma_\ell}\left(\frac{\Gamma_\ell}{\Gamma_\nu}\right)_{\rm SM} . \qquad (1)$$

The combined result from the four LEP experiments is $N_\nu = 2.984 \pm 0.008$ [1]. Recent analyses applied corrections to the LEP result [1] by including the effect of correlated luminosity systematics and also using an improved Bhabha cross section calculation [2,3] to obtain $N_\nu = 2.9963 \pm 0.0074$.

In the past, when only small samples of $Z$ decays had been recorded by the LEP experiments and by the Mark II at SLC, the uncertainty in $N_\nu$ was reduced by using Standard Model fits to the measured hadronic cross sections at several center-of-mass energies near the $Z$ resonance. Since this method is

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

much more dependent on the Standard Model, the approach described above is favored.

Before SLC and LEP, limits on the number of neutrino generations were placed by experiments at lower-energy $e^+e^-$ colliders by measuring the cross section of the process $e^+e^- \to \nu\overline{\nu}\gamma$. The ASP, CELLO, MAC, MARK J, and VENUS experiments observed a total of 3.9 events above background [4], leading to a 95% CL limit of $N_\nu < 4.8$. This process has a much larger cross section at center-of-mass energies near the $Z$ mass and has been measured at LEP by the ALEPH, DELPHI, L3, and OPAL experiments [5]. These experiments have observed several thousand such events, and the combined result is $N_\nu = 3.00 \pm 0.08$. The same process has also been measured by the LEP experiments at much higher center-of-mass energies, between 130 and 208 GeV, in searches for new physics [6]. Combined with the lower energy data, the result is $N_\nu = 2.92 \pm 0.05$.

Experiments at $p\overline{p}$ colliders also placed limits on $N_\nu$ by determining the total $Z$ width from the observed ratio of $W^\pm \to \ell^\pm\nu$ to $Z \to \ell^+\ell^-$ events [7]. This involved a calculation that assumed Standard Model values for the total $W$ width and the ratio of $W$ and $Z$ leptonic partial widths, and used an estimate of the ratio of $Z$ to $W$ production cross sections. Now that the $Z$ width is very precisely known from the LEP experiments, the approach is now one of those used to determine the $W$ width.

# Double-$\beta$ Decay

OMITTED FROM SUMMARY TABLE

## NEUTRINOLESS DOUBLE-$\beta$ DECAY

Revised August 2019 by A. Piepke (University of Alabama) and P. Vogel (Caltech) .

Observation of neutrinoless double-beta ($0\nu\beta\beta$) decay would signal violation of total lepton number conservation. The process can be mediated by an exchange of a light Majorana neutrino, or by an exchange of other particles. However, the existence of $0\nu\beta\beta$-decay requires a nonvanishing Majorana neutrino mass, no matter what the actual mechanism is. As long as only a limit on the lifetime is available, limits on the effective Majorana neutrino mass, on the lepton-number violating right-handed current or other possible mechanisms mediating $0\nu\beta\beta$ decay can be obtained, independently of the actual mechanism, by assuming that one of these "new physics" possibilities dominates. These limits are listed in the Double-$\beta$ Decay Listings of the experimental measurements.

In the following we assume that the exchange of light Majorana neutrinos ($m_{\nu_i} \leq 10$ MeV) contributes dominantly to the decay rate. Besides a dependence on the phase space ($G^{0\nu}$) and the nuclear matrix element ($M^{0\nu}$), the observable $0\nu\beta\beta$-decay rate is proportional then to the square of the effective Majorana mass $m_{ee}$, $(T^{0\nu}_{1/2})^{-1} = G^{0\nu} \cdot |M^{0\nu}|^2 \cdot m^2_{ee}$, with $m^2_{ee} = |\sum_i U^2_{ei} m_{\nu_i}|^2$. The sum contains, in general, complex CP-phases in $U^2_{ei}$, i.e., cancellations may occur. For three neutrino flavors there are two physical phases for Majorana neutrinos ($\eta_1, \eta_2$) and one for Dirac neutrinos ($\delta_{CP}$). The relevant Majorana phases affect only processes to which lepton-number changing amplitudes contribute. Given the general $3 \times 3$ mixing matrix for Majorana neutrinos, one can construct other analogous lepton number violating quantities, $m_{\ell\ell'} = \sum_i U_{\ell i} U_{\ell' i} m_{\nu_i} (\ell$ or $\ell' \neq e)$. However, these are currently much less constrained than $m_{ee}$.

Nuclear structure calculations are needed to deduce $m_{ee}$ from the decay rate. While $G^{0\nu}$ can be calculated accurately, the computation of $M^{0\nu}$ is subject to uncertainty. Comparing different nuclear model evaluations indicates a factor ∼2-3 spread in the calculated nuclear matrix elements. Nuclear structure calculation consistently overestimate Gamow-Teller (axial current) matrix elements. This inability of the nuclear models to reproduce Gamow-Teller decay rates is often parametrized in form of a modified coupling constant $g_A$. Many nuclear theorists interpret this shortcoming as evidence that important physics is missing in the modeling of weak nuclear transitions. It is not clear how these observed uncertainties impact $0\nu\beta\beta$-matrix elements. Nevertheless, this constitutes an additional element of uncertainty. Recent work, [1] shows how the discrepancy between experimental and theoretical axial current matrix elements might be resolved. However, application of this approach to the $0\nu\beta\beta$ decay remains to be accomplished. The particle physics quantities to be determined are thus nuclear model-dependent, so the half-life measurements are listed first. Where possible, we reference the nuclear matrix elements used in the subsequent analysis. Since rates for the conventional $2\nu\beta\beta$ decay serve to constrain the nuclear theory models, results for this process are also given.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

Oscillation experiments utilizing atmospheric, accelerator, solar, and reactor produced neutrinos and anti-neutrinos show that at least some neutrinos are massive. However, so far the inverted mass ordering (i.e., whether $\Delta m^2_{31} < 0$) is disfavored only by 2-3 $\sigma$ compared to the normal mass ordering (when $\Delta m^2_{31} > 0$), while the absolute neutrino mass values or the properties of neutrinos under CPT-conjugation (Dirac or Majorana) remain undetermined. All confirmed oscillation experiments can be consistently described using three interacting neutrino species with two mass splittings and three mixing angles. (For values of the mixing angles and mass square differences see the corresponding tables.)

Based on the 3-neutrino analysis:
$m^2_{ee} = |\cos^2\theta_{13}\cos^2\theta_{12}m_1 + e^{2i(\eta_2-\eta_1)}\cos^2\theta_{13}\sin^2\theta_{12}m_2 + e^{-2i(\eta_1+\delta_{CP})}\sin^2\theta_{13}m_3|^2$, valid for both mass orderings. Given the present knowledge of the neutrino oscillation parameters one can derive a relation between the effective Majorana mass and the mass of the lightest neutrino, as illustrated in Figure 14.11 in the Neutrino Masses, Mixing and Oscillations review. The three mass orderings allowed by the oscillation data: normal ($m_1 < m_2 \ll m_3$), inverted ($m_3 \ll m_1 < m_2$), and degenerate ($m_1 \approx m_2 \approx m_3$), result in different projections. The width of the colored bands reflects the uncertainty introduced by the unknown Majorana and Dirac phases as well as the experimental errors of the oscillation parameters. The latter causes only minor broadening of the bands. Because of the overlap of the different mass scenarios, a measurement of $m_{ee}$ would not reveal which mass ordering is applicable, provided the value of $m_{ee}$ is in the overlapping range.

Analogous plots depict the relation of $m_{ee}$ with the summed neutrino mass $m_{tot} = m_1 + m_2 + m_3$, constrained by observational cosmology, and $m_{ee}$ as a function of the average mass $m^{eff}_{\nu_e} = [\Sigma|U_{ei}|^2 m^2_{\nu_i}]^{1/2}$ determined through the analysis of the electron energy distribution in low energy beta decays. (See Fig. 1 of [2]. ) The oscillation data thus allow to test whether observed values of $m_{ee}$ and $m_{tot}$ or $m^{eff}_{\nu_e}$ are consistent within the 3 neutrino framework. The rather large intrinsic width of the $\beta\beta$-decay constraints essentially does not allow to positively identify the mass ordering, and thus the sign of $\Delta m^2_{31}$, even in combination with these other observables. Naturally, if a value of $0 < m_{ee} \leq 0.01$ eV is ever established, then the normal mass ordering becomes the only possible scenario.

It should be noted that systematic uncertainties of the nuclear matrix elements and possible quenching of the axial current matrix elements are sometimes not folded into the mass limits reported by $\beta\beta$-decay experiments. Taking this additional uncertainty into account would further widen the projections. The plots are based on a 3-neutrino analysis. If it turns out that additional, i.e. sterile light neutrinos exist, the allowed regions would be modified substantially.

If neutrinoless double-beta decay is observed, it will be possible to fix a range of absolute values of the masses $m_{\nu_i}$. Unlike the direct neutrino mass measurements, however, a limit on $m_{ee}$ does not allow one to constrain the individual mass values $m_{\nu_i}$ even when the mass differences $\Delta m^2_{ij}$ are known.

Neutrino oscillation data imply the existence of a lower limit $\sim 0.014$ eV for the Majorana neutrino mass for the inverted mass ordering pattern, while $m_{ee}$ could, by fine tuning, vanish in the case of the normal mass ordering. Several new double-beta searches have been proposed to probe the interesting $m_{ee}$ mass range, with the prospect of full coverage of the inverted mass ordering region within the next decade.

The $0\nu\beta\beta$ decay mechanism discussed so far is not the only way in which the decay can occur. Numerous other possible scenarios have been proposed, however, all of them requiring new physics. It will be a challenging task to decide which mechanism was responsible once $0\nu\beta\beta$ decay is observed. LHC experiments may reveal corresponding signatures for new physics of lepton number violation. If lepton-number violating right-handed weak current interactions exist, its strength can be characterized by the phenomenological coupling constants $\eta$ and $\lambda$ ($\eta$ describes the coupling between the right-handed lepton current and left-handed quark current while $\lambda$ describes the coupling when both currents are right-handed). The $0\nu\beta\beta$ decay rate then depends on $\langle\eta\rangle = \eta\sum_i U_{ei}V_{ei}$ and $\langle\lambda\rangle = \lambda\sum_i U_{ei}V_{ei}$ that vanish for massless or unmixed neutrinos ($V_{\ell j}$ is a matrix analogous to $U_{\ell j}$ but describing the mixing with the hypothetical right-handed neutrinos). The observation of the single electron spectra could, in principle, allow to distinguish this mechanism of $0\nu\beta\beta$ from the light Majorana neutrino exchange driven mode. The limits on $\langle\eta\rangle$ and $\langle\lambda\rangle$ are listed in a separate table. The reader is cautioned that a number of earlier experiments did not distinguish between $\eta$ and $\lambda$. In addition, see the section on Majoron searches for additional limits set by these experiments.

### Half-life $0\nu$ double-$\beta$ decay

In most cases the transitions (Z,A) $\rightarrow$ (Z+2,A) + $2e^-$ to the $0^+$ ground state of the final nucleus are listed. We also list transitions that decrease the nuclear charge ($2e^+$, $e^+$ CC and double EC) and transitions to an excited state of the final nucleus ($0^+_i$, $2^+$, and $2^+_i$). In the following Listings only the best or comparable limits for the half-lives of each transition are reported and only those with about $T_{1/2} > 10^{23}$ years that are relevant for particle physics.

[1] AGOSTINI 19 use 82.4 kg·yr of data, collected by the GERDA experiment, to search for the $0\nu\,\beta\beta$ decay of $^{76}$Ge. High resolution Ge-calorimeters, made from isotopically enriched Ge, are used. A median sensitivity of $1.1 \times 10^{26}$ yr is reported. Supersedes AGOSTINI 18.

[2] ALDUINO 19 use the combined data of the CUORICINO and CUORE-0 experiments to place a lower limit on the half life of the $0\nu\,\beta\beta$ decay of $^{130}$Te to the first excited $0^+$ state of $^{130}$Xe. Supersedes ANDREOTTI 12.

[3] ALENKOV 19 report the $0\nu\,\beta\beta$ decay half-life limit based on the 52.1 kg·d exposure of $^{100}$Mo, of a a cryogenic dual heat and light detector in the Yangyang underground laboratory. The median sensitivity is $1.1 \times 10^{23}$ years.

[4] ALVIS 19 use the MAJORANA Demonstrator with enriched in $^{76}$Ge detectors to set this limit on $0\nu\,\beta\beta$ half-life of $^{76}$Ge. The exposure is 26.0 kg yr. The sensitivity is $4.8 \times 10^{25}$ yr.

[5] ANTON 19 uses he complete dataset of the EXO-200 detector to search for the $0\nu\,\beta\beta$ decay. The exposure is 234.1 kg yr. The median sensitivity is $5.0 \times 10^{25}$ yr. Supersedes ALBERT 18 and ALBERT 14B.

[6] AZZOLINI 19 use the CPID-0 scintillating cryogenic bolometer to set this limit on $0\nu\,\beta\beta$ half-life of $^{82}$Se. The exposure is 5.29 kg yr. The sensitivity is $5 \times 10^{24}$ yr.

[7] NI 19 use the PandaX-II dual phase TPC at CJPL to search for the $0\nu\,\beta\beta$ decay of $^{136}$Xe. The half-life limit $2.4 \times 10^{23}$ yr is obtained from 22.2 kg yr exposure with a sensitivity of $1.9 \times 10^{23}$ yr.

[8] AALSETH 18 uses the MAJORANA Demonstrator to search for the $0\nu\,\beta\beta$ decay. The exposure is 9.95 kg-year. The median sensitivity is $2.1 \times 10^{25}$ yr.

[9] AGOSTINI 18 uses the GERDA detector to search for the $0\nu\,\beta\beta$ decay. The exposure is 46.7 kg-year. The median sensitivity is $5.8 \times 10^{25}$ yr. Supersedes AGOSTINI 17.

[10] ALBERT 18 uses the EXO-200 detector to search for the $0\nu\,\beta\beta$ decay. The exposure is 177.6 kg-year. The median sensitivity is $3.7 \times 10^{25}$ years.

[11] ALDUINO 18 uses the CUORE detector to search for the $0\nu\,\beta\beta$ decay of $^{130}$Te. The exposure is 86.3 kg-year of natural $TeO_2$ corresponding to 24.0 kg-year for $^{130}$Te. The median sensitivity is $0.7 \times 10^{25}$ yr. The limit is obtained combining the new data from CUORE with those of CUORE0 (9.8 kg-year of $^{130}$Te) and Cuoricino (19.8 kg-year of $^{130}$Te).

[12] ARNOLD 18 use the NEMO-3 tracking detector to place a limit on the $0\nu\beta\beta$ decay of $^{82}$Se. This is a slightly weaker limit than in BARABASH 11A, using the same detector. Supersedes ARNOLD 05A.

[13] AZZOLINI 18 uses CUPID-0 detector, a novel scintillating cryogenic calorimeter, operated in the LNGS. This results replaces BARABASH 11A (NEMO-3) as the most stringent limit on the $0\nu\,\beta\beta$-decay of $^{82}$Se.

[14] AZZOLINI 18A data collected by CUPID-0 based on scintillating bolometers is used to derive a new most stringent limit on the $0\nu\beta\beta$-decay of $^{82}$Se to the $0^+_1$ state of $^{82}$Kr.

[15] BARABASH 18 use 1.162 kg of $^{116}CdWO_4$ scintillating crystals to obtain this limit. Supersedes DANEVICH 03 with analogous source and is more sensitive than ARNOLD 17.

[16] AGOSTINI 17 result corresponds to data collected with GERDA phase 1 and first release of phase 2 for a total of 343 mol-yr exposure. Supersedes AGOSTINI 13A. The median sensitivity is $4.0\ 10^{25}$ yr.

[17] ALBERT 17C uses the EXO-200 detector that contains $19.098 \pm 0.014\%$ admixture of $^{134}$Xe to search for the $0\nu$ and $2\nu\,\beta\beta$ decay modes. The exposure is 29.6 kg-year. The median sensitivity is $1.9 \times 10^{21}$ years.

[18] ARNOLD 17 use the NEMO-3 tracking calorimeter, containing 410 g of enriched $^{116}$Cd exposed for 5.26 yr, to determine the half-life limit. Supersedes BARABASH 11A.

[19] ALDUINO 16 report result obtained with 9.8 kg y of data collected with the CUORE-0 bolometer, combined with data from the CUORICINO. Supersedes ALFONSO 15.

[20] ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter ($^{136}$Xe 89.5 kg yr) to place a limit on the $0\nu\beta\beta$-decay into the first excited state of the daughter nuclide.

[21] ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter ($^{136}$Xe 89.5 kg yr) to place a limit on the $0\nu\beta\beta$-decay into the second excited state of the daughter nuclide.

[22] ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter ($^{136}$Xe 89.5 kg yr) to place a limit on the $0\nu\beta\beta$-decay into the third excited state of the daughter nuclide.

[23] GANDO 16 use the the KamLAND detector to search for the $0\nu$ decay of $^{136}$Xe. With a significant background reduction, the combination of results of the first (270.7 days) and the second phase (263.8 days) of the experiment leads to about six fold improvement over the previous limit. Supersedes GANDO 13A. The sensitivity is $5.6\ 10^{25}$ yr.

[24] ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the limit of $0\nu\beta\beta$-half life of $^{100}$Mo. Supersedes ARNOLD 2005A and BARABASH 11A.

[25] ALBERT 14B use 100 kg yr of exposure of the EXO-200 tracking calorimeter to place a lower limit on the $0\nu\beta\beta$-half life of $^{136}$Xe. Supersedes AUGER 12.

[26] ANDREOTTI 12 use high resolution $TeO_2$ bolometric calorimeter to search for the $0\nu\beta\beta$ decay of $^{130}$Te leading to the excited $0^+_1$ state at 1793.5 keV.

[27] BARABASH 11A use the NEMO-3 detector to measure $2\nu\beta\beta$ rates and place limits on $0\nu\beta\beta$ half lives for various nuclides. Supersedes ARNOLD 05A, ARNOLD 04, ARNOLD 98, and ELLIOTT 92.

[28] Supersedes ARNABOLDI 04. Bolometric $TeO_2$ detector array CUORICINO is used for high resolution search for $0\nu\beta\beta$ decay. The half-life limit is derived from 3.09 kg yr $^{130}$Te exposure.

[29] UMEHARA 08 use $CaF_2$ scintillation calorimeter to search for double beta decay of $^{48}$Ca. Limit is significantly more stringent than quoted sensitivity: $18 \times 10^{21}$ years.

[30] Limit on $0\nu$-decay to the first excited $0^+_1$-state of daughter nucleus using NEMO-3 tracking calorimeter. Supersedes DASSIE 95.

[31] Limit on $0\nu$-decay to the first excited $2^+$-state of daughter nucleus using NEMO-3 tracking calorimeter.

[32] NEMO-3 tracking calorimeter is used in ARNOLD 05A to place limit on $0\nu\beta\beta$ half-life of $^{82}$Se. Detector contains 0.93 kg of enriched $^{82}$Se. Supersedes ARNOLD 04.

[33] Supersedes ALESSANDRELLO 00. Array of $TeO_2$ crystals in high resolution cryogenic calorimeter. Some enriched in $^{128}$Te. Ground state to ground state decay.

[34] Limit on $0\nu\beta\beta$ decay of $^{116}$Cd using enriched $CdWO_4$ scintillators. Supersedes DANEVICH 00.

[35] AALSETH 02B limit is based on 117 mol-yr of data using enriched Ge detectors. Background reduction by means of pulse shape analysis is applied to part of the data set. Reported limit is slightly less restrictive than that in KLAPDOR-KLEINGROTHAUS 01 However, it excludes part of the allowed half-life range reported in KLAPDOR-KLEINGROTHAUS 01B for the same nuclide. The analysis has been criticized in KLAPDOR-KLEINGROTHAUS 04B. The criticism was addressed and disputed in AALSETH 04.

[36] KLAPDOR-KLEINGROTHAUS 01 is a continuation of the work published in BAUDIS 99. Isotopically enriched Ge detectors are used in calorimetric measurement. The most stringent bound is derived from the data set in which pulse-shape analysis has been used to reduce background. Exposure time is 35.5 kg y. Supersedes BAUDIS 99 as most stringent result.

## Half-life measurements of the two-neutrino double-$\beta$ decay

The measured half-life values for the transitions (Z,A) $\rightarrow$ (Z+2,A) + $2e^- + 2\overline{\nu}_e$ to the $0^+$ ground state of the final nucleus are listed. We also list the transitions to an excited state of the final nucleus ($0^+_i$, etc.). We report only the measuremetnts with the smallest (or comparable) uncertainty for each transition.

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| 0.096 | $\pm 0.003$ | $\pm 0.010$ | $^{82}$Se | NEMO-3 | [20] ARNOLD | 05A |
| 0.029 | $^{+0.004}_{-0.003}$ | | $^{116}$Cd | $^{116}CdWO_4$ scint. | [21] DANEVICH | 03 |

[1] APRILE 19E report first measurement of two-neutrino double electron capture in $^{124}$Xe using the XENON1T detector with a 0.73 t-yr exposure. An excess of 126 $\pm$ 29 events is observed at 64.3 $\pm$ 0.6 keV decay energy, corresponding to $\sqrt{\Delta\chi^2} = 4.4$ with respect to the background-only hypothesis.

[2] ARNOLD 19 use the NEMO-3 tracking calorimeter with 34.3 kg y exposure to determine the $2\nu\ \beta\beta$ half-life of $^{100}$Mo. Supersedes ARNOLD 15.

[3] ARNOLD 18 use the NEMO-3 tracking detector to determine the $2\nu\beta\beta$ half-life of $^{82}$Se. 0.93 kg of $^{82}$Se was observed for 5.25 y. The half-life value was obtained based on the single-state-dominance (SSD) hypothesis, preferred in this case by about 2 $\sigma$. Supersedes ARNOLD 05A.

[4] BARABASH 18 use 1.162 kg of $^{116}CdWO_4$ scintillating crystals to obtain this value. Supersedes DANEVICH 03 with analogous source and agrees with ARNOLD 17 with the NEMO-3 detector.

[5] ALBERT 17C uses the EXO-200 detector that contains 19.098 $\pm$ 0.014% admixture of $^{134}$Xe to search for the $2\nu\ \beta\beta$ decay mode. The exposure is 29.6 kg·year. The median sensitivity is $1.2 \times 10^{21}$ years.

[6] ALDUINO 17 use the CUORE-0 detector containing 10.8 kg of $^{130}$Te in 52 crystals of $TeO_2$. The exposure was 9.3 kg yr of $^{130}$Te. This is a more accurate rate determination than in ARNOLD 11 and BARABASH 11A.

[7] ARMENGAUD 17 use 185.9 $\pm$ 0.1 g crystal of $Li_2{}^{100}MoO_4$ to determine the $^{100}$Mo $2\nu\ \beta\beta$ half-life. The exposure was of 1303 $\pm$ 26 hours only, using novel technique.

[8] ARNOLD 17 use the NEMO-3 tracking calorimeter, containing 410 grams of enriched $^{116}$Cd exposed for 5.26 years, to determine the half-life value.

[9] ARNOLD 16 use the NEMO-3 detector and a source of 6.99 g of $^{48}$Ca. The half-life is based on 36.7 g year exposure. It is consistent, although somewhat longer, than the previous determinations of the half-life. Supersedes BARABASH 11A.

[10] ARNOLD 16A use the NEMO-3 tracking calorimeter, containing 36.6 g of $^{150}$Nd exposed for 1918.5 days, to determine the half-life. Supersedes ARGYRIADES 09.

[11] AGOSTINI 15A use 17.9 kg yr exposure of the GERDA calorimeter to derive an improved measurement of the $2\nu\beta\beta$ decay half life of $^{76}$Ge.

[12] ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the $2\nu\beta\beta$-half life of $^{100}$Mo. Supersedes ARNOLD 05A and ARNOLD 04.

[13] ALBERT 14 use the EXO-200 tracking detector for a re-measurement of the $2\nu\beta\beta$-half life of $^{136}$Xe. A nuclear matrix element of 0.0218 $\pm$ 0.0003 MeV$^{-1}$ is derived from this data. Supersedes ACKERMAN 11.

[14] GAVRILYAK 13 use a proportional counter filled with Kr gas to search for the $2\nu$2K decay of $^{78}$Kr. Data with the enriched and depleted Kr were used to determine signal and background. A 2.5$\sigma$ excess of events obtained with the enriched sample is interpreted as an indication for the presence of this decay.

[15] GANDO 12A use a modification of the existing KamLAND detector. The $\beta\beta$ decay source/detector is 13 tons of enriched $^{136}$Xe-loaded scintillator contained in an inner balloon. The $2\nu\beta\beta$ decay rate is derived from the fit to the spectrum between 0.5 and 4.8 MeV. This result is in agreement with ACKERMAN 11.

[16] ARNOLD 11 use enriched $^{130}$Te in the NEMO-3 detector to measure the $2\nu\ \beta\beta$ decay rate. This result is in agreement with, but more accurate than ARNABOLDI 03.

[17] ARGYRIADES 10 use 9.4 $\pm$ 0.2 g of $^{96}$Zr in NEMO-3 detector and identify its $2\nu\beta\beta$ decay. The result is in agreement and supersedes ARNOLD 99.

[18] BELLI 10 use enriched $^{100}$Mo with 4 HP Ge detectors to record the 590.8 and 539.5 keV $\gamma$ rays from the decay of the $0^+_1$ state in $^{100}$Ru both in singles and coincidences. This result confirms the measurement of KIDD 09 and ARNOLD 07 and supersedes them.

[19] First exclusive measurement of $2\nu$-decay to the first excited $0^+_1$-state of daughter nucleus. ARNOLD 07 use the NEMO-3 tracking calorimeter to detect all particles emitted in decay. Result agrees with the inclusive ($0\nu + 2\nu$) measurement of DEBRAECKELEER 01.

[20] ARNOLD 05A use the NEMO-3 tracking detector to determine the $2\nu\beta\beta$ half-life of $^{82}$Se with high statistics and low background (389 days of data taking). Supersedes ARNOLD 04.

[21] Calorimetric measurement of $2\nu\beta\beta$ ground state decay of $^{116}$Cd using enriched $CdWO_4$ scintillators. Agrees with EJIRI 95 and ARNOLD 96. Supersedes DANEVICH 00.

## $\langle m_{ee}\rangle$, The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double-$\beta$ Decay

$\langle m_{ee}\rangle = |\Sigma U^2_{ei} m_{\nu_i}|$, $i$ = 1,2,3. It is assumed that $\nu_i$ are Majorana particles and that the transition is dominated by the known (light) neutrinos. Note that $U^2_{ei}$ and not $|U_{ei}|^2$ occur in the sum, and that consequently cancellations are possible. The experiments obtain the limits on $\langle m_\nu\rangle$ from the measured ones on $T_{1/2}$ using a range of nuclear matrix elements (NME), which is reflected in the spread of $\langle m_\nu\rangle$. Different experiments may choose different NME. All assume $g_A = 1.27$. In the following Listings, only the best or comparable limits for each isotope are reported. When not mentioned explicitly the transition is between ground states, but transitions between excited states are also reported.

[1] AGOSTINI 19 use 82.4 kg-yr of data collected by the isotopically enriched $^{76}$Ge detectors of the GERDA experiment to derive an upper limit for $\langle m_{\beta\beta}\rangle$. The range reflects the variability of the theoretically calculated nuclear matrix elements. Supersedes AGOSTINI 18.

[2] ALENKOV 19 report the range of the effective masses $\langle m_{\beta\beta}\rangle$ corresponding to the $0\nu\ \beta\beta$ decay half-life limit. It is based on the 52.1 kg·d exposure of $^{100}$Mo, in the Yangyang underground laboratory. The median sensitivity is $1.1 \times 10^{23}$ years. The range of $\langle m_{\beta\beta}\rangle$ reflects the uncertainty of nuclear matrix elements.

[3] ALVIS 19 use the MAJORANA Demonstrator with enriched in $^{76}$Ge detectors to set this limit. The exposure is 26.0 kg yr. The sensitivity is $4.8 \times 10^{25}$ yr.

[4] ANTON 19 uses the complete dataset of the EXO-200 experiment to obtain these limits. The spread reflect the uncertainty in the nuclear matrix elements. Supersedes ALBERT 18 and ALBERT 14B.

[5] AZZOLINI 19 use the CPID-0 scintillating cryogenic bolometer to set this limit. The exposure is 5.29 kg yr. The sensitivity is $5 \times 10^{24}$ yr.

[6] NI 19 use the PandaX-II dual phase TPC at CJPL to search for the $0\nu\ \beta\beta$ decay of $^{136}$Xe with 22.2 kg yr exposure. The range in the $m_{\beta\beta}$ limit of 1.3–3.5 eV reflects the range of the calculated nuclear matrix elements. The sensitivity is $1.9 \times 10^{23}$ yr.

[7] AALSETH 18 uses the MAJORANA Demonstrator detector to establish this limit.

[8] AGOSTINI 18 uses the GERDA detector to establish this limit.

[9] ALBERT 18 uses the EXO-200 experiment to obtain this limit.

[10] ALDUINO 18 use the combined data of CUORE, CUORE0, and Cuoricino to obtain this limit.

[11] ARNOLD 18 use the NEMO-3 tracking detector to constrain the $0\nu\beta\beta$ decay of $^{82}$Se. The limit on $\langle m_{\beta\beta}\rangle$ is obtained assuming light neutrino exchange; the range reflects different calculations of the nuclear matrix elements. This is a somewhat weaker limit than in BARABASH 11A using the same detector.

[12] AZZOLINI 18 uses data collected by the CUPID-0 scintillating cryogenic calorimeter, operated in the LNGS, to derive a range of limits on $\langle m_\nu\rangle$. The reported range reflects the spread of the nuclear matrix element calculations considered in this work. Use $g_A$ = 1.269.

[13] BARABASH 18 use 1.162 kg of $^{116}CdWO_4$ scintillating crystals to obtain these limits. The spread reflects the estimated uncertainty in the nuclear matrix element. Supersedes DANEVICH 03.

[14] AGOSTINI 17 is based on 343 mol yr of data from GERDA phase 1 and phase 2 first part and the corresponding limit on $T_{1/2}$ using the different nuclear matrix elements mentioned by the authors. Supersedes AGOSTINI 13A.

[15] ARNOLD 17 utilize NEMO-3 data, taken with enriched $^{116}$Cd to limit the effective Majorana neutrino mass. The reported range results from the use of different nuclear matrix elements. Supersedes BARABASH 11A.

[16] ALDUINO 16 place a limit on the effective Majorana neutrino mass using the combined data of the CUORE-0 and CUORICINO experiments. The range reflects the authors' evaluation of the variability of the nuclear matrix elements. Supersededs ALFONSO 15.

[17] ARNOLD 16A limit is derived from data taken with the NEMO-3 detector and $^{150}$Nd. A range of nuclear matrix elements that include the effect of nuclear deformation have been used. Supersedes ARGYRIADES 09.

[18] GANDO 16 result is based on the 2016 KamLAND-Zen half-life limit. The stated range reflects different nuclear matrix elements, an unquenched $g_A = 1.27$ is used. Supersedes GANDO 13A.

[19] ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the neutrino mass limit based on the $0\nu\beta\beta$-half life of $^{100}$Mo. The spread range reflects different nuclear matrix elements. Supersedes ARNOLD 14 and BARABASH 11A.

[20] ALBERT 14B is based on 100 kg yr of exposure of the EXO-200 tracking calorimeter. The mass range reflects the nuclear matrix element calculations. Supersedes AUGER 12.

[21] BARABASH 11A limit is based on NEMO-3 data for $^{82}$Se. The reported range reflects different nuclear matrix elements. Supersedes ARNOLD 05A and ARNOLD 04.

[22] ARGYRIADES 10 use $^{96}$Zr and the NEMO-3 tracking detector to obtain the reported mass limit. The range reflects the fluctuation of the nuclear matrix elements considered.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[23] Limit was obtained using $CaF_2$ scintillation calorimeter to search for double beta decay of $^{48}$Ca. Reported range of limits reflects spread of QRPA and SM matrix element calculations used. Supersedes OGAWA 04.

[24] Supersedes ARNABOLDI 04. Reported range of limits due to use of different nuclear matrix element calculations.

[25] Supersedes ARNABOLDI 03. Reported range of limits due to use of different nuclear matrix element calculations.

[26] Limit for $\langle m_\nu \rangle$ is based on the nuclear matrix elements of STAUDT 90 and ARNOLD 96. Supersedes DANEVICH 00.

[27] KLAPDOR-KLEINGROTHAUS 01 uses the calculation by STAUDT 90. Using several other models in the literature could worsen the limit up to 1.2eV. This is the most stringent experimental bound on $m_\nu$. It supersedes BAUDIS 99B.

### Limits on Lepton-Number Violating ($V+A$) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later. $\langle\lambda\rangle = \lambda\sum U_{ej} V_{ej}$ and $\langle\eta\rangle = \eta\sum U_{ej} V_{ej}$, where the sum is over the number of neutrino generations. This sum vanishes for massless or unmixed neutrinos. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

| $\langle\lambda\rangle$ ($10^{-6}$) | CL% | $\langle\eta\rangle$ ($10^{-8}$) | CL% | ISOTOPE | METHOD | DOCUMENT ID | |
|---|---|---|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | | | |
| $< 2.2$–$2.6$ | 90 | $< 1.7$–$2.1$ | 90 | $^{82}$Se | NEMO-3 | [1] ARNOLD | 18 |
| $< 1.8$–$22$ | 90 | $< 1.6$–$21$ | 90 | $^{116}$Cd | AURORA | [2] BARABASH | 18 |

| $< 1.6$–$2.4$ | 90 | $< 0.9$–$5.3$ | 90 | $^{130}$Te | Cryog. det. | [10] ARNABOLDI | 03 |
| $< 2.2$ | 90 | $<2.5$ | 90 | $^{116}$Cd | $^{116}CdWO_4$ scint. | [11] DANEVICH | 03 |
| $< 3.2$–$4.7$ | 90 | $< 2.4$–$2.7$ | 90 | $^{100}$Mo | ELEGANT V | [12] EJIRI | 01 |
| $< 1.1$ | 90 | $<0.64$ | 90 | $^{76}$Ge | Enriched HPGe | [13] GUENTHER | 97 |
| $< 4.4$ | 90 | $<2.3$ | 90 | $^{136}$Xe | TPC | [14] VUILLEUMIER | 93 |
| | | $<5.3$ | | $^{128}$Te | Geochem | [15] BERNATOW... | 92 |

[1] ARNOLD 18 use the NEMO03 tracking detector, with 0.93 kg of $^{82}$Se mass and 5.25 y exposure to obtain the limits for the hypothetical right-handed currents. Supersedes ARNOLD 05A.

[2] BARABASH 18 use 1.162 kg of $^{116}CdWO_4$ scintillating crystals to obtain this limits for the hypothetical right-handed currents in the $0\nu\beta\beta$ decay of $^{116}$Cd.

[3] ARNOLD 14 is based on 34.7 kg yr of exposure of the NEMO-3 tracking calorimeter. The reported range limit on $\langle\lambda\rangle$ and $\langle\eta\rangle$ reflects the nuclear matrix element uncertainty in $^{100}$Mo.

[4] ARNOLD 07 use NEMO-3 half life limit for $0\nu$-decay of $^{100}$Mo to the first excited $2^+$-state of daughter nucleus to limit the right-right handed admixture of weak currents $\langle\lambda\rangle$. This limit is not competitive when compared to the decay to the ground state.

[5] Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim $6\sigma$ statistical evidence for observation of $0\nu$-decay. Authors use matrix element of MUTO 89 to determine $\langle\lambda\rangle$ and $\langle\eta\rangle$. Uncertainty of nuclear matrix element is not reflected in stated errors.

[6] ARNOLD 05A derive limit for $\langle\lambda\rangle$ based on $^{100}$Mo data collected with NEMO-3 detector. No limit for $\langle\eta\rangle$ is given. Supersedes ARNOLD 04.

[7] ARNOLD 05A derive limit for $\langle\lambda\rangle$ based on $^{82}$Se data collected with NEMO-3 detector. No limit for $\langle\eta\rangle$ is given. Supersedes ARNOLD 04.

[8] ARNOLD 04 use the matrix elements of SUHONEN 94 to obtain a limit for $\langle\lambda\rangle$, no limit for $\langle\eta\rangle$ is given. This limit is more stringent than the limit in EJIRI 01 for the same nucleus.

[9] ARNOLD 04 use the matrix elements of TOMODA 91 and SUHONEN 91 to obtain a limit for $\langle\lambda\rangle$, no limit for $\langle\eta\rangle$ is given.

[10] Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.

[11] Limits for $\langle\lambda\rangle$ and $\langle\eta\rangle$ are based on nuclear matrix elements of STAUDT 90. Supersedes DANEVICH 00.

[12] The range of the reported $\langle\lambda\rangle$ and $\langle\eta\rangle$ values reflects the spread of the nuclear matrix elements. On axis value assuming $\langle m_\nu\rangle$=0 and $\langle\lambda\rangle$=$\langle\eta\rangle$=0, respectively.

[13] GUENTHER 97 limits use the matrix elements of STAUDT 90. Supersedes BALYSH 95 and BALYSH 92.

[14] VUILLEUMIER 93 uses the matrix elements of MUTO 89. Based on a half-life limit $2.6 \times 10^{23}$ y at 90%CL.

[15] BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the $0\nu$ width, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on $\eta$. Further details of the experiment are given in BERNATOWICZ 93.

## Neutrino Mixing

With the possible exceptions of "short-baseline anomalies," such as LSND, all neutrino data can be described within the framework of a 3×3 mixing matrix between the mass eigenstates $\nu_1$, $\nu_2$, and $\nu_3$, leading to the flavor eigenstates $\nu_e$, $\nu_\mu$, and $\nu_\tau$, as described in the review *"Neutrino masses, mixing and oscillations."*

The Listings are divided in the following sections:

**(A) Neutrino fluxes and event ratios:** shows measurements which correspond to various oscillation tests for Accelerator, Reactor, Atmospheric, and Solar neutrino experiments. Typically, ratios involve a measurement in a realm sensitive to oscillations compared to one for which no oscillation effect is expected.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

**(B) Neutrino mixing parameters:** shows measurements of $\sin^2(\theta_{12})$, $\sin^2(\theta_{23})$, $\sin^2(\theta_{13})$, $\Delta m^2_{21}$, $\Delta m^2_{32}$, and $\delta_{CP}$ as extracted from the measured data in the quoted publications in the frame of the three-neutrino mixing scheme. The quoted averages are not the result of a global fit, as in the review *"Neutrino masses, mixing, and oscillations,"* and, as a consequence, might slightly differ from them. In some cases, measurements depend on the mass order (normal when $\Delta m^2_{32} > 0$ or inverted when $\Delta m^2_{32} < 0$) or octant of $\theta_{23}$ (lower when $\theta_{23} < 45°$ or upper when $\theta_{23} > 45°$).

**(C) Other neutrino mixing results:**

The LSND anomaly [AGUILAR 01], reported a signal which is consistent with $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillations. In a three neutrino framework, this would be a measurement of $\theta_{12}$ and $\Delta m^2_{21}$. This does not appear to be consistent with the interpretation of other neutrino data. It has been interpreted as evidence for a 4th "sterile" neutrino. The following listings include results which might be relevant towards understanding this observation. They include searches for $\nu_\mu \to \nu_e$, $\overline{\nu}_\mu \to \overline{\nu}_e$, sterile neutrino oscillations, and others.

## (A) Neutrino fluxes and event ratios

### Events (observed/expected) from accelerator $\nu_\mu$ experiments.

Some neutrino oscillation experiments compare the flux in two or more detectors. This is usually quoted as the ratio of the event rate in the far detector to the expected rate based on an extrapolation from the near detector in the absence of oscillations.

| VALUE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| $1.01 \pm 0.10$ | [1] ABE | 14B | T2K | $\nu_e$ rate in T2K near detect. |
| $0.71 \pm 0.08$ | [2] AHN | 06A | K2K | K2K to Super-K |
| $0.64 \pm 0.05$ | [3] MICHAEL | 06 | MINS | All charged current events |
| $0.71^{+0.08}_{-0.09}$ | [4] ALIU | 05 | K2K | KEK to Super-K |
| $0.70^{+0.10}_{-0.11}$ | [5] AHN | 03 | K2K | KEK to Super-K |

[1] The rate of $\nu_e$ from $\mu$ decay was measured to be $0.68 \pm 0.30$ compared to the predicted flux. From $K$ decay $1.10 \pm 0.14$ compared to the predicted flux.

[2] Based on the observation of 112 events when $158.1^{+9.2}_{-8.6}$ were expected without oscillations. Including not only the number of events but also the shape of the energy distribution, the evidence for oscillation is at the level of about 4.3 $\sigma$. Supersedes ALIU 05.

[3] This ratio is based on the observation of 215 events compared to an expectation of $336 \pm 14$ without oscillations. See also ADAMSON 08.

[4] This ratio is based on the observation of 107 events at the far detector 250 km away from KEK, and an expectation of $151^{+12}_{-10}$.

[5] This ratio is based on the observation of 56 events with an expectation of $80.1^{+6.2}_{-5.4}$.

### Events (observed/expected) from reactor $\overline{\nu}_e$ experiments.

The quoted values are the ratios of the measured reactor $\overline{\nu}_e$ event rate at the quoted distances, and the rate expected without oscillations. The expected rate is based on the experimental data for the most significant reactor fuels ($^{235}$U, $^{239}$Pu, $^{241}$Pu) and on calculations for $^{238}$U.

A recent re-evaluation of the spectral conversion of electron to $\overline{\nu}_e$ in MUELLER 11 results in an upward shift of the reactor $\overline{\nu}_e$ spectrum by 3% and, thus, might require revisions to the ratios listed in this table.

[1] ADEY 19 present a re-analysis of 1230 days of Daya Bay near detector data with reduced systematic uncertainties on the neutron detection efficiency. Note that ADEY 19 report the measured to predicted antineutrino ratio using the reactor model of MUELLER 11 (Huber-Mueller model). The ratio using the older ILL-Vogel model is $1.001 \pm 0.015 \pm 0.027$.

[2] AN 16 use 217 days of data (338k events) to determine the neutrino flux ratio relative to the prediction of Mueller-Huber and ILL-Vogel models (see AN 16 for details). The reported flux ratios were corrected for $\theta_{13}$ oscillation effect. The flux measurement is consistent with results from previous short-baseline reactor experiments. The measured inverse beta decay yield is $(1.55 \pm 0.04) \times 10^{-18}$ cm$^2$/(GW day) or $\sigma_f = (5.92 \pm 0.14) \times 10^{-43}$ cm$^2$/fission. About $4\sigma$ excess of events was observed in the 4–6 MeV prompt energy region.

[3] DENIZ 10 observe reactor $\overline{\nu}_e e$ scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate is consistent with the Standard Model prediction, leading to a constraint on $\sin^2\theta_W = 0.251 \pm 0.031(\text{stat}) \pm 0.024(\text{sys})$.

[4] Updated result of KamLAND, including the data used in EGUCHI 03. Note that the survival probabilities for different periods are not directly comparable because the effective baseline varies with power output of the reactor sources involved, and there were large variations in the reactor power production in Japan in 2003.

[5] EGUCHI 03 observe reactor neutrino disappearance at $\sim$ 180 km baseline to various Japanese nuclear power reactors.

[6] BOEHM 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors.

[7] APOLLONIO 99, APOLLONIO 98 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use $\overline{\nu}_e p \to e^+ n$ in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98. See also APOLLONIO 03 for detailed description.

[8] GREENWOOD 96 search for neutrino oscillations at 18 m and 24 m from the reactor at Savannah River.

[9] DECLAIS 94 result based on integral measurement of neutrons only. Result is ratio of measured cross section to that expected in standard *V-A* theory. Replaced by ACHKAR 95.

[10] KWON 81 represents an analysis of a larger set of data from the same experiment as BOEHM 80.

### Atmospheric neutrinos

Neutrinos and antineutrinos produced in the atmosphere induce $\mu$-like and $e$-like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as $\mu/e$. It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The "ratio of the ratios" of experimental to theoretical $\mu/e$, $R(\mu/e)$, or that of experimental to theoretical $\mu$/total, $R(\mu/\text{total})$ with total $= \mu + e$, is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions. In addition, the measured "up-down asymmetry" for $\mu$ ($N_{up}(\mu)/N_{down}(\mu)$) or $e$ ($N_{up}(e)/N_{down}(e)$) is reported. The expected "up-down asymmetry" is nearly unity if there is no neutrino oscillation.

### R($\mu/e$) = (Measured Ratio $\mu/e$) / (Expected Ratio $\mu/e$)

[1] ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring $e$-like events with 0.1 GeV/c $< p_e$ and $\mu$-like events 0.2 GeV/c $< p_\mu$, both having a visible energy $< 1.33$ GeV. These criteria match the definition used by FUKUDA 94.

[2] ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring events with visible energy $> 1.33$ GeV and partially-contained events. All partially-contained events are classified as $\mu$-like.

[3] SANCHEZ 03 result is based on an exposure of 5.9 kton yr, and updates ALLISON 99 result. The analyzed data sample consists of fully-contained $e$-flavor and $\mu$-flavor events having lepton momentum $> 0.3$ GeV/c.

[4] FUKUDA 96B studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.

[5] DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90B. This ratio is for the contained and semicontained events. DAUM 95

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

also report $R(\mu/e) = 0.99 \pm 0.13 \pm 0.08$ for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.

[6] FUKUDA 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained $e$-like events with $0.1 < p_e < 1.33$ GeV/$c$ and fully-contained $\mu$-like events with $0.2 < p_\mu < 1.5$ GeV/$c$.

[7] FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy $> 1.33$ GeV and partially contained $\mu$-like events.

[8] BECKER-SZENDY 92B reports the fraction of nonshowering events (mostly muons from atmospheric neutrinos) as $0.36 \pm 0.02 \pm 0.02$, as compared with expected fraction $0.51 \pm 0.01 \pm 0.05$. After cutting the energy range to the Kamiokande limits, BEIER 92 finds $R(\mu/e)$ very close to the Kamiokande value.

### R($\nu_\mu$) = (Measured Flux of $\nu_\mu$) / (Expected Flux of $\nu_\mu$)

[1] ADAMSON 06 uses a measurement of 107 total neutrinos compared to an expected rate of $127 \pm 13$ without oscillations.

[2] AMBROSIO 01 result is based on the upward through-going muon tracks with $E_\mu > 1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The first error is the statistical error, the second is the systematic error, dominated by the theoretical error in the predicted flux.

[3] AMBROSIO 00 result is based on the upgoing partially contained event sample. It came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

[4] AMBROSIO 00 result is based on the combined samples of downgoing partially contained events and upgoing stopping events. These two subsamples could not be distinguished due to the lack of timing information. The result came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

[5] AMBROSIO 98 result is for all nadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of $\pm 0.13$. With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields $\sin^2 2\theta = 1.0$ and $\Delta(m^2) \sim$ a few times $10^{-3}$ eV$^2$. However, the fit to the observed zenith distribution gives a maximum probability for $\chi^2$ of only 5% for the best oscillation hypothesis.

[6] CASPER 91 correlates showering/nonshowering signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowering ($\approx \nu_\mu$ induced) fraction is $0.41 \pm 0.03 \pm 0.02$, as compared with expected $0.51 \pm 0.05$ (syst).

[7] AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define $\rho$ = (measured number of $\nu_e$'s)/(measured number of $\nu_\mu$'s). They report $\rho(\text{measured}) = \rho(\text{expected}) = 0.96^{+0.32}_{-0.28}$.

[8] From this data BOLIEV 81 obtain the limit $\Delta(m^2) \leq 6 \times 10^{-3}$ eV$^2$ for maximal mixing, $\nu_\mu \not\to \nu_\mu$ type oscillation.

| $0.96^{+0.38}_{-0.27} \pm 0.15$ | [6] ADAMSON | 06 | MINS | atmospheric $\nu$ with far detector |

[1] ADAMSON 12B reports the atmospheric neutrino results obtained with MINOS far detector in 2,553 live days (an exposure of 37.9 kton-yr). The muon charge ratio $N(\mu^+)/N(\mu^-)$ represents the $\overline{\nu}_\mu/\nu_\mu$ ratio. As far as the same oscillation parameters are used for $\nu$s and $\overline{\nu}$s, the expected $\overline{\nu}_\mu/\nu_\mu$ ratio is almost entirely independent of any input oscillations.

[2] This result is obtained with a charge-separated sample of high resolution contained-vertex muons.

[3] This result is obtained with a charge-separated sample of high resolution neutrino-induced rock-muons.

[4] The charge-separated samples of high resolution contained-vertex muons and neutrino-induced rock-muons are combined to obtain this result which is consistent with unity.

[5] ADAMSON 07 result is obtained with the MINOS far detector in 854.24 live days, based on neutrino-induced upward-going and horizontal muons. This result is consistent with $CPT$ conservation.

[6] ADAMSON 06 result is obtained with the MINOS far detector with an exposure of 4.54 kton yr, based on contained events. The expected ratio is calculated by assuming the same oscillation parameters for neutrinos and antineutrinos.

## Solar neutrinos

Solar neutrinos are produced by thermonuclear fusion reactions in the Sun. Radiochemical experiments measure particular combinations of fluxes from various neutrino-producing reactions, whereas water-Cherenkov experiments mainly measure a flux of neutrinos from decay of $^8$B. Solar neutrino fluxes are composed of all active neutrino species, $\nu_e$, $\nu_\mu$, and $\nu_\tau$. In addition, some other mechanisms may cause antineutrino components in solar neutrino fluxes. Each measurement method is sensitive to

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

a particular component or a combination of components of solar neutrino fluxes.

### $\nu_e$ Capture Rates from Radiochemical Experiments

1 SNU (Solar Neutrino Unit) = $10^{-36}$ captures per atom per second.

| VALUE (SNU) | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| $73.4\ ^{+6.1}_{-6.0}\ ^{+3.7}_{-4.1}$ | [1] KAETHER | 10 | | GALX reanalysis |
| $67.6 \pm 4.0 \pm 3.2$ | [2] KAETHER | 10 | | GNO+GALX reanalysis combined |

[1] KAETHER 10 reports the reanalysis results of a complete GALLEX data (GALLEX I+II+III+IV, reported in HAMPEL 99) based on the event selection with a new pulse shape analysis, which provides a better background reduction than the rise time analysis adopted in HAMPEL 99.

[2] Combined result of GALLEX I+II+III+IV reanalysis and GNO I+II+III (ALTMANN 05).

[3] ABDURASHITOV 09 reports a combined analysis of 168 extractions of the SAGE solar neutrino experiment during the period January 1990 through December 2007, and updates the ABDURASHITOV 02 result. The data are consistent with the assumption that the solar neutrino production rate is constant in time. Note that a $\sim 15\%$ systematic uncertainty in the overall normalization may be added to the ABDURASHITOV 09 result, because calibration experiments for gallium solar neutrino measurements using intense $^{51}Cr$ (twice by GALLEX and once by SAGE) and $^{37}Ar$ (by SAGE) result in an average ratio of $0.87 \pm 0.05$ of the observed to calculated rates.

[4] ALTMANN 05 reports the complete result from the GNO solar neutrino experiment (GNO I+II+III), which is the successor project of GALLEX. Experimental technique of GNO is essentially the same as that of GALLEX. The run data cover the period 20 May 1998 through 9 April 2003.

[5] Combined result of GALLEX I+II+III+IV (HAMPEL 99) and GNO I+II+III.

[6] HAMPEL 99 report the combined result for GALLEX I+II+III+IV (65 runs in total), which update the HAMPEL 96 result. The GALLEX IV result (12 runs) is $118.4 \pm 17.8 \pm 6.6$ SNU. (HAMPEL 99 discuss the consistency of partial results with the mean.) The GALLEX experimental program has been completed with these runs. The total run data cover the period 14 May 1991 through 23 January 1997. A total of 300 $^{71}Ge$ events were observed. Note that a $\sim 15\%$ systematic uncertainty in the overall normalization may be added to the HAMPEL 99 result, because calibration experiments for gallium solar neutrino measurements using intense $^{51}Cr$ (twice by GALLEX and once by SAGE) and $^{37}Ar$ (by SAGE) result in an average ratio of $0.87 \pm 0.05$ of the observed to calculated rates.

[7] CLEVELAND 98 is a detailed report of the $^{37}Cl$ experiment at the Homestake Mine. The average solar neutrino-induced $^{37}Ar$ production rate from 108 runs between 1970 and 1994 updates the DAVIS 89 result.

### $\phi_{ES}$ ($^8$B)

$^8$B solar-neutrino flux measured via $\nu e$ elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to $\nu_\mu$, $\nu_\tau$ due to the cross-section difference, $\sigma(\nu_{\mu,\tau} e) \sim 0.16\sigma(\nu_e e)$. If the $^8$B solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is $\sim 0.16$ times of $\nu_e$.

[1] ANDERSON 19 reports this result from the $\nu_e e$ elastic scattering rate using a 69.2 kton·day (or 114.7 days) of exposure from May through December, 2017 during the SNO+ detector's water commissioning phase. The events over the reconstructed electron kinetic energy range of 5–15 MeV were analyzed.

[2] AGOSTINI 18B obtained this result from the $\nu_e e$ elastic scattering rate over the period between January 2008 and December 2016.

[3] ABE 16C reports the combined results of the four phases of the Super-Kamiokande average flux measurements. Here the revised Super-Kamiokande-III result is used.

[4] ABE 16C reports the Super-Kamiokande-IV results for 1664 live days from September 2008 to February 2014. The analysis threshold is total electron energy of 4.0 MeV.

[5] ABE 16C revised the Super-Kamiokande-III average flux value reported in ABE 11. Super-Kamiokande-III results are for 548 live days from August 4, 2006 to August 18, 2008. The analysis threshold is 5.0 MeV, but the event sample in the 5.0–6.5 MeV total electron energy range has a total live time of 298 days.

[6] ABE 11 recalculated the Super-Kamiokande-II results using $^8$B spectrum of WINTER 06A.

[7] ABE 11 recalculated the Super-Kamiokande-I results using $^8$B spectrum of WINTER 06A.

[8] ABE 11B use a 123 kton·day exposure of the KamLAND liquid scintillation detector to measure the $^8$B solar neutrino flux. They utilize $\nu - e$ elastic scattering above a reconstructed-energy threshold of 5.5 MeV, corresponding to 5 MeV electron recoil energy. 299 electron recoil candidate events are reported, of which $157 \pm 23.6$ are assigned to background.

[9] BELLINI 10A reports the Borexino result with 3 MeV energy threshold for scattered electrons. The data correspond to 345.3 live days with a target mass of 100 t, between July 15, 2007 and August 23, 2009.

[10] AHARMIM 08 reports the results from SNO Phase III measurement using an array of $^3$He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the $^8$B shape.

[11] CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the average flux is 7 MeV.

[12] HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

[13] AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The *CC*, *ES*, and *NC* events were statistically separated. In one method, the $^8$B energy spectrum was not constrained. In the other method, the constraint of an undistorted $^8$B energy spectrum was added for comparison with AHMAD 02 results.

[14] AHMAD 02 reports the $^8$B solar-neutrino flux measured via $\nu e$ elastic scattering above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results.

[15] AHMAD 01 reports the $^8$B solar-neutrino flux measured via $\nu e$ elastic scattering above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.

[16] FUKUDA 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold $E_e > 9.3$ MeV (first 449 days), $> 7.5$ MeV (middle 794 days), and $> 7.0$ MeV (last 836 days). These results update the HIRATA 90 result for the average $^8$B solar-neutrino flux and HIRATA 91 result for the day-night variation in the $^8$B solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.

### $\phi_{CC}$ ($^8$B)

$^8$B solar-neutrino flux measured with charged-current reaction which is sensitive exclusively to $\nu_e$.

[1] AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the $^8$B flux mostly comes from the NC signal, however, CC contribution is included in the fit.

[2] AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with a "binned-histogram unconstrained fit" where binned probability distribution functions of the neutrino signal observables were used without any model constraints on the shape of the neutrino spectrum.

[3] AHARMIM 08 reports the results from SNO Phase III measurement using an array of $^3$He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the $^8$B shape.

[4] AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The *CC*, *ES*, and *NC* events were statistically separated. In one method, the $^8$B energy spectrum was not constrained. In the other method, the constraint of an undistorted $^8$B energy spectrum was added for comparison with AHMAD 02 results.

[5] AHMAD 02 reports the first SNO result of the $^8$B solar-neutrino flux measured with the neutral-current reaction on deuterium, $\nu_\ell d \rightarrow np\nu_\ell$, above the neutral-current reaction threshold of 2.2 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001. The complete description of the SNO Phase I data set is given in AHARMIM 07.

## $\phi_{\nu_\mu+\nu_\tau}$ ($^8$B)

Nonelectron-flavor active neutrino component ($\nu_\mu$ and $\nu_\tau$) in the $^8$B solar-neutrino flux.

[1] ANDERSON 19 reports this result from the measured $\nu_e e$ elastic scattering rate using a 69.2 kton-day (or 114.7 days) of exposure from May through December, 2017 during the SNO+ detector's water commissioning phase, assuming the neutrino mixing parameters given in PDG 16 and a standard solar model given in BAHCALL 05.

[2] AGOSTINI 18B obtained this result from the measured $\nu_e e$ elastic scattering rate over the period between January 2008 and December 2016, assuming the MSW-LMA oscillation parameters derived by ESTEBAN 17. Assuming a high-metalicity standard solar model, the electron neutrino survival probability for the $^8$B solar neutrino is calculated to be 0.37 ± 0.08.

[3] AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the $^8$B flux mostly comes from the NC signal, however, CC contribution is included in the fit.

[4] AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with the assumption of unitarity, which relates the NC, CC, and ES rates. The data were fit with the free parameters directly describing the total $^8$B neutrino flux and the energy-dependent $\nu_e$ survival probability.

[5] AHARMIM 08 reports the results from SNO Phase III measurement using an array of $^3$He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the $^8$B shape.

[6] AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the $^8$B energy spectrum was not constrained. In the other method, the constraint of an undistorted $^8$B energy spectrum was added for comparison with AHMAD 02 results.

[7] AHMAD 02 determined the total flux of active $^8$B solar neutrinos by directly measuring the neutral-current reaction, $\nu_\ell d \rightarrow np\nu_\ell$, which is equally sensitive to $\nu_e$, $\nu_\mu$, and $\nu_\tau$. The complete description of the SNO Phase I data set is given in AHARMIM 07.

[8] AHMAD 01 deduced the total flux of active $^8$B solar neutrinos by combining the SNO charged-current result (AHMAD 01) and the Super-Kamiokande $\nu e$ elastic-scattering result (FUKUDA 01).

[1] ABE 16C reports the combined day-night flux asymmetry results of the four phases of the Super-Kamiokande measurements. Amplitude fit method is used. See footnote to RENSHAW 14.

[2] ABE 16C reports the Super-Kamiokande-IV results for 1664 live days from September 2008 to February 2014. The analysis threshold for day-night flux asymmetry is recoil electron energy of 4.49 MeV (total electron energy of 5.0 MeV). Amplitude fit method is used. See footnote to RENSHAW 14.

[3] RENSHAW 14 obtains this result by using the "amplitude fit" introduced in SMY 04. The data from the Super-Kamiokande(SK)-I, -II, -III, and 1306 live days of the SK-IV measurements are used. The analysis threshold is recoil-electron kinetic energy of 4.5 MeV for SK-III, and SK-IV except for 250 live days in SK-III (6.0 MeV). The analysis threshold for SK-I and SK-II is the same as in the previous reports. (Note that in the previous SK solar-neutrino results, the analysis threshold is quoted as recoil-electron total energy.) This day-night asymmetry result is consistent with neutrino oscillations for $4\times10^{-5}$ eV$^2$ $< \Delta m^2_{21} < 7\times10^{-5}$ eV$^2$ and large mixing values of $\theta_{12}$ at the 68% CL.

[4] CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the day and night fluxes is 7.5 MeV except for the first 159 live days (8.0 MeV).

[5] HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

[6] This result with reduced statistical uncertainty is obtained by assuming two-neutrino oscillations within the LMA (large mixing angle) region and by fitting the time variation of the solar neutrino flux measured via $\nu_e$ elastic scattering to the variations expected from neutrino oscillations. For details, see SMY 04. There is an additional small systematic error of ±0.0004 coming from uncertainty of oscillation parameters.

[7] AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, with 176.5 days of the live time recorded during the day and 214.9 days during the night. This result is obtained with the spectral distribution of the CC events not constrained to the $^8$B shape.

[8] AHMAD 02B results are based on the charged-current interactions recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

[9] AHMAD 02B results are derived from the charged-current interactions, neutral-current interactions, and $\nu e$ elastic scattering, with the total flux of active neutrinos constrained to have no asymmetry. The data were recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

### $\phi_{ES}$ ($^7$Be)

$^7$Be solar-neutrino flux measured via $\nu_e$ elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to $\nu_\mu$, $\nu_\tau$ due to the cross-section difference, $\sigma(\nu_{\mu,\tau} e) \sim 0.2\ \sigma(\nu_e e)$. If the $^7$Be solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is ∼ 0.2 times that of $\nu_e$.

[1] GANDO 15 uses 165.4 kton·day exposure of the KamLAND liquid scintillator detector to measure the 862 keV $^7$Be solar neutrino flux via $\nu - e$ elastic scattering

[2] BELLINI 11A reports the $^7$Be solar neutrino flux measured via $\nu - e$ elastic scattering. The data correspond to 740.7 live days between May 16, 2007 and May 8, 2010, and also correspond to 153.6 ton·year fiducial exposure. BELLINI 11A measured the 862 keV $^7$Be solar neutrino flux, which is an 89.6% branch of the $^7$Be solar neutrino flux, to be $(2.78\pm0.13)\times10^9$ cm$^{-2}$s$^{-1}$. Supercedes ARPESELLA 08A.

### $\phi_{ES}$ ($pep$)

$pep$ solar-neutrino flux measured via $\nu_e$ elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to $\nu_\mu$, $\nu_\tau$ due to the cross section difference, $\sigma(\nu_{\mu,\tau} e) \sim 0.2\ \sigma(\nu_e e)$. If the $pep$ solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is ∼ 0.2 times that of $\nu_e$.

[1] BELLINI 12A reports 1.44 MeV $pep$ solar-neutrino flux measured via $\nu_e$ elastic scattering. The data were collected between January 13, 2008 and May 9, 2010, corresponding to 20,4009 ton·day fiducial exposure. The listed flux value is calculated from the observed rate of $pep$ solar neutrino interactions in Borexino (3.1 ± 0.6 ± 0.3 counts/(day·100 ton)) and the corresponding rate expected for no neutrino flavor oscillations (4.47 ± 0.05 counts/(day·100 ton)), using the SSM prediction for the $pep$ solar neutrino flux of $(1.441\pm0.012)\times10^8$ cm$^{-2}$s$^{-1}$.

### $\phi_{ES}$ (CNO)

CNO solar-neutrino flux measured via $\nu_e$ elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to $\nu_\mu$, $\nu_\tau$ due to the cross section difference, $\sigma(\nu_{\mu,\tau} e) \sim 0.2\ \sigma(\nu_e e)$. If the CNO solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is ∼ 0.2 times that of $\nu_e$.

[1] BALATA 06 obtained this result from the search for $\overline{\nu}_e$ interactions with Counting Test Facility (the prototype of the Borexino detector).

## (B) Three-neutrino mixing parameters

## THREE-NEUTRINO MIXING PARAMETERS

Updated July 2019 by M. Goodman (ANL).

***Introduction and Notation:*** With the exception of possible short-baseline anomalies (such as LSND), current accelerator, reactor, solar and atmospheric neutrino data can be described within the framework of a $3 \times 3$ mixing matrix between the flavor states $\nu_e$, $\nu_\mu$ and $\nu_\tau$ and mass eigenstates $\nu_1$, $\nu_2$ and $\nu_3$. (See equation 14.34 of the review "Neutrino Mass, Mixing and Oscillations" by M.C. Gonzalez-Garcia and M. Yokoyama.) Whether or not this is the ultimately correct framework, it is currently widely used to parametrize neutrino mixing data and to plan new experiments.

The mass differences are called $\Delta m^2_{21} \equiv m_2^2 - m_1^2$ and $\Delta m^2_{32} \equiv m_3^2 - m_2^2$. Until recently, we assumed

$$\Delta m^2_{32} \sim \Delta m^2_{31}. \quad (1)$$

But the experimental error is comparable to the difference $\Delta m^2_{31} - \Delta m^2_{32} = \Delta m^2_{21}$, so we quote them separately when appropriate. The measurements made by $\nu_\mu$ disappearance at accelerators and by $\nu_e$ disappearance at reactors are slightly different mixtures of $\Delta m^2_{32}$ and $\Delta m^2_{31}$. The angles are labeled $\theta_{12}$, $\theta_{23}$ and $\theta_{13}$. The CP violating phase is called $\delta_{CP}$.

The familiar two neutrino form for oscillations is

$$P(\nu_a \to \nu_b; a \neq b) = \sin^2(2\theta)\sin^2(\Delta m^2 L/4E). \quad (2)$$

Despite the fact that the mixing angles have been measured to be much larger than in the quark sector, the two neutrino form is often a very good approximation and is used in many situations.

The angles appear in the equations below in many forms. They often appear as $\sin^2(2\theta)$. The listings currently now use $\sin^2(\theta)$ because this distinguishes the octant, i.e. whether $\theta_{23}$ is larger or smaller than 45°.

***Accelerator neutrino experiments:*** Ignoring $\Delta m^2_{21}$, *CP* violation, and matter effects, the equations for the probability of appearance in an accelerator oscillation experiment are:

$$P(\nu_\mu \to \nu_\tau) = \sin^2(2\theta_{23})\cos^4(\theta_{13})\sin^2(\Delta m^2_{32} L/4E) \quad (3)$$
$$P(\nu_\mu \to \nu_e) = \sin^2(2\theta_{13})\sin^2(\theta_{23})\sin^2(\Delta m^2_{32} L/4E) \quad (4)$$
$$P(\nu_e \to \nu_\mu) = \sin^2(2\theta_{13})\sin^2(\theta_{23})\sin^2(\Delta m^2_{32} L/4E) \quad (5)$$
$$P(\nu_e \to \nu_\tau) = \sin^2(2\theta_{13})\cos^2(\theta_{23})\sin^2(\Delta m^2_{32} L/4E)\ . \quad (6)$$

Current and future long-baseline accelerator experiments are studying non-zero $\theta_{13}$ through $P(\nu_\mu \to \nu_e)$. Including the CP terms and low mass scale, the equation for neutrino oscillation in vacuum is:

$$\begin{aligned} P(\nu_\mu \to \nu_e) &= P1 + P2 + P3 + P4 \\ P1 &= \sin^2(\theta_{23})\sin^2(2\theta_{13})\sin^2(\Delta m^2_{32} L/4E) \\ P2 &= \cos^2(\theta_{23})\sin^2(2\theta_{13})\sin^2(\Delta m^2_{21} L/4E) \\ P3 &= -/+ J\sin(\delta_{CP})\sin(\Delta m^2_{32} L/4E) \\ P4 &= J\cos(\delta_{CP})\cos(\Delta m^2_{32} L/4E) \end{aligned} \quad (7)$$

where

$$\begin{aligned} J = &\cos(\theta_{13})\sin(2\theta_{12})\sin(2\theta_{13})\sin(2\theta_{23})\times \\ &\sin(\Delta m^2_{32} L/4E)\sin(\Delta m^2_{21} L/4E) \end{aligned} \quad (8)$$

and the sign in P3 is negative for neutrinos and positive for antineutrinos respectively. For most new long-baseline accelerator experiments, P2 can safely be neglected. Also, depending on the distance and the mass order, matter effects need to be included.

***Reactor neutrino experiments:*** Nuclear reactors are prolific sources of $\bar{\nu}_e$ with an energy near 4 MeV. The oscillation probability can be expressed

$$\begin{aligned} P(\bar{\nu}_e \to \bar{\nu}_e) = 1 &- \cos^4(\theta_{13})\sin^2(2\theta_{12})\sin^2(\Delta m^2_{21} L/4E) \\ &- \cos^2(\theta_{12})\sin^2(2\theta_{13})\sin^2(\Delta m^2_{31} L/4E) \\ &- \sin^2(\theta_{12})\sin^2(2\theta_{13})\sin^2(\Delta m^2_{32} L/4E) \end{aligned} \quad (9)$$

not using the approximation in Eq. (1). For short distances (L<5 km) we can ignore the second term on the right and can reimpose approximation Eq. (1). This takes the familiar two neutrino form with $\theta_{13}$ and $\Delta m^2_{32}$:

$$P(\bar{\nu}_e \to \bar{\nu}_e) = 1 - \sin^2(2\theta_{13})\sin^2(\Delta m^2_{32} L/4E). \quad (10)$$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

***Solar and Atmospheric neutrino experiments:*** Solar neutrino experiments are sensitive to $\nu_e$ disappearance and have allowed the measurement of $\theta_{12}$ and $\Delta m^2_{21}$. They are also sensitive to $\theta_{13}$. We identify $\Delta m^2_{\odot} = \Delta m^2_{21}$ and $\theta_{\odot} = \theta_{12}$.

Atmospheric neutrino experiments are primarily sensitive to $\nu_\mu$ disappearance through $\nu_\mu \to \nu_\tau$ oscillations, and have allowed the measurement of $\theta_{23}$ and $\Delta m^2_{32}$. We identify $\Delta m^2_A = \Delta m^2_{32}$ and $\theta_A = \theta_{23}$. Despite the large $\nu_e$ component of the atmospheric neutrino flux, it is difficult to measure $\Delta m^2_{21}$ effects. This is because of a cancellation between $\nu_\mu \to \nu_e$ and $\nu_e \to \nu_\mu$ together with the fact that the ratio of $\nu_\mu$ and $\nu_e$ atmospheric fluxes, which arise from sequential $\pi$ and $\mu$ decay, is near 2.

***Oscillation Parameter Listings:*** In Section (B) we encode the three mixing angles $\theta_{12}$, $\theta_{23}$, $\theta_{13}$, $\delta_{CP}$, and two mass squared differences $\Delta m^2_{21}$ and $\Delta m^2_{32}$. Our knowledge of $\theta_{12}$ and $\Delta m^2_{21}$ comes from the KamLAND reactor neutrino experiment together with solar neutrino experiments. Our knowledge of $\theta_{23}$ and $\Delta m^2_{32}$ comes from atmospheric, reactor and long-baseline accelerator neutrino experiments. For the earlier experiments, we identified the large mass splitting as $\Delta m^2_{32}$. Now that $\sigma(\Delta m^2_{32}) \approx \Delta m^2_{21}$, some experiments report separate values for the two mass orders. Results on $\theta_{13}$ come from reactor antineutrino disappearance experiments. There are also results from long-baseline accelerator experiments looking for $\nu_e$ appearance. The interpretation of both kinds of results depends on $\Delta m^2_{32}$, and the accelerator results also depend on the mass order, $\theta_{23}$ and the CP violating phase $\delta_{CP}$.

Accelerator and atmospheric experiments have some sensitivity to the CP violation phase $\delta_{CP}$ through Eq. (7). Note that P3 depends on the sign of $\Delta m^2_{32}$ so the sensitivity depends on the mass order. For non-maximal $\theta_{23}$ mixing, it also depends on the octant of $\theta_{23}$, i.e. whether $\theta_{23} > \pi/4$ or $\theta_{23} < \pi/4$.

## $\sin^2(\theta_{12})$

If an experiment reports $\sin^2(2\theta_{12})$ we convert the value to $\sin^2(\theta_{12})$.

[1] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using all solar data and KamLAND data. *CPT* invariance is assumed.

[2] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using Super-Kamiokande (I+II+III+IV) and SNO data.

[3] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, by combining the four phases of the Super-Kamiokande solar data.

[4] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using the Super-Kamiokande-IV data.

[5] FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

[6] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $0.304^{+0.013}_{-0.012}$ for normal and $0.305^{+0.012}_{-0.013}$ for inverted mass ordering.

[7] AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

[8] AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active $^8$B neutrino flux and energy-dependent $\nu_e$ survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and $^7$Be (BELLINI 11A) rates, and $^8$B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

[9] AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{32}$ fixed to $2.45 \times 10^{-3}$ eV$^2$, using global solar neutrino data.

[10] AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{32}$ fixed to $2.45 \times 10^{-3}$ eV$^2$, using global solar neutrino and KamLAND (GANDO 11) data. CPT invariance is assumed.

[11] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming *CPT* invariance. Supersedes GANDO 11.

[12] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming CPT invariance. Supersedes GANDO 11.

[13] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

[14] ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.

[15] ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[16] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{32}$ fixed to $2.4 \times 10^{-3}$ eV$^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and CPT invariance are assumed.

[17] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{32}$ fixed to $2.4 \times 10^{-3}$ eV$^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

[18] BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the $^8$B flux was left free. CPT invariance is assumed.

[19] BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the $^8$B flux was left free.

[20] GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.

[21] GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Superseded by GANDO 13.

[22] AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

[23] AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[24] AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

[25] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{31}$ fixed to $2.3 \times 10^{-3}$ eV$^2$, using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[26] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{31}$ fixed to $2.3 \times 10^{-3}$ eV$^2$, using global solar neutrino data.

[27] ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for $\Delta m^2_{21}$ and $\tan^2\theta_{12}$, using KamLAND data only. Superseded by GANDO 11.

[28] ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO $\chi^2$-map, and solar flux data. *CPT* invariance is assumed. Superseded by GANDO 11.

[29] The result given by AHARMIM 08 is $\theta = (34.4^{+1.3}_{-1.2})^\circ$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[30] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using SK $\nu_e$ data, CC data from other solar neutrino experiments, and KamLAND data (ARAKI 05). *CPT* invariance is assumed.

[31] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. *CPT* invariance is assumed.

[32] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.

[33] The result given by AHARMIM 05A is $\theta = (33.9 \pm 1.6)^\circ$. This result is obtained by a two-neutrino oscillation analysis using SNO pure deuteron and salt phase data, SK $\nu_e$ data, Cl and Ga CC data, and KamLAND data (ARAKI 05). *CPT* invariance is assumed. AHARMIM 05A also quotes $\theta = (33.9^{+2.4}_{-2.2})^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.86^{+0.05}_{-0.06}$.

[34] AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes $\tan^2\theta = 0.45^{+0.09}_{-0.08}$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.86^{+0.05}_{-0.07}$.

[35] ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. *CPT* invariance is assumed. The $1\sigma$ error shown here is translated from the number provided by the KamLAND collaboration, $\tan^2\theta = 0.40^{+0.07}_{-0.05}$. The corresponding number quoted in ARAKI 05 is $\tan^2\theta = 0.40^{+0.10}_{-0.07}$ ($\sin^2 2\theta = 0.82 \pm 0.07$), which envelops the 68% CL two-dimensional region.

[36] The result given by AHMED 04A is $\theta = (32.5^{+1.7}_{-1.6})^\circ$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04A also quotes $\theta = (32.5^{+2.4}_{-2.3})^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.82 \pm 0.06$.

[37] AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is $\Delta(m^2) = 6.5 \times 10^{-5}$ eV$^2$, $\tan^2\theta = 0.40$ ($\sin^2 2\theta = 0.82$).

[38] The result given by SMY 04 is $\tan^2\theta = 0.44 \pm 0.08$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.

[39] SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The $1\sigma$ errors are read from Fig. 6(a) of SMY 04.

[40] SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The $1\sigma$ errors are read from Fig. 6(a) of SMY 04.

[41] AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is $\Delta(m^2) = 5.0 \times 10^{-5}$ eV$^2$ and $\tan\theta = 0.34$ ($\sin^2 2\theta = 0.76$).

[42] FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2) = 6.9 \times 10^{-5}$ eV$^2$ and $\tan^2\theta = 0.38$ ($\sin^2 2\theta = 0.80$).

[1] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming CPT invariance. Supersedes GANDO 11.

[2] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using all solar data and KamLAND data. *CPT* invariance is assumed.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[3] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using Super-Kamiokande (I+II+III+IV) and SNO data.

[4] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, by combining the four phases of the Super-Kamiokande solar data.

[5] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using the Super-Kamiokande-IV data.

[6] FORERO 14 performs a global fit to $\Delta m^2_{21}$ using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

[7] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(7.50^{+0.19}_{-0.17}) \times 10^{-5}$ eV$^2$ for normal and $(7.50^{+0.18}_{-0.17}) \times 10^{-5}$ eV$^2$ for inverted mass ordering.

[8] AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

[9] AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active $^8$B neutrino flux and energy-dependent $\nu_e$ survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and $^7$Be (BELLINI 11A) rates, and $^8$B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08), and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

[10] AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{31}$ fixed to $2.45 \times 10^{-3}$ eV$^2$, using global solar neutrino data.

[11] AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{31}$ fixed to $2.45 \times 10^{-3}$ eV$^2$, using global solar neutrino and KamLAND data (GANDO 11). CPT invariance is assumed.

[12] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming CPT invariance. Supersedes GANDO 11.

[13] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

[14] ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.

[15] ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

[16] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{32}$ fixed to $2.4 \times 10^{-3}$ eV$^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and CPT invariance are assumed.

[17] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{32}$ fixed to $2.4 \times 10^{-3}$ eV$^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

[18] BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the $^8$B flux was left free. CPT invariance is assumed.

[19] BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the $^8$B flux was left free.

[20] GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.

[21] GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Supersedes ABE 08A.

[22] AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

[23] AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[24] AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

[25] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{31}$ fixed to $2.3 \times 10^{-3}$ eV$^2$, using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[26] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{31}$ fixed to $2.3 \times 10^{-3}$ eV$^2$, using global solar neutrino data.

[27] ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for $\Delta m^2_{21}$ and $\tan^2\theta_{12}$, using KamLAND data only. Superseded by GANDO 11.

[28] ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO $\chi^2$-map, and solar flux data. *CPT* invariance is assumed. Superseded by GANDO 11.

[29] AHARMIM 08 obtained this result by a two-neutrino oscillation analysis using all solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[30] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed.

[31] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. *CPT* invariance is assumed.

[32] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.

[33] HOSAKA 06 obtained this result from the consistency between the observed and expected day-night flux asymmetry amplitude. The listed 68% CL range is derived from the $1\sigma$ boundary of the amplitude fit to the data. Oscillation parameters are constrained to be in the LMA region. The mixing angle is fixed at $\tan^2\theta = 0.44$ because the fit depends only very weekly on it.

[34] AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed. AHARMIM 05A also quotes $\Delta(m^2) = (8.0^{+0.6}_{-0.4}) \times 10^{-5}$ eV$^2$ as the error enveloping the 68% CL two-dimensional region.

[35] AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes $\Delta(m^2) = (6.5^{+4.4}_{-2.3}) \times 10^{-5}$ eV$^2$ as the error enveloping the 68% CL two-dimensional region.

[36] ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. *CPT* invariance is assumed. The $1\sigma$ error shown here is provided by the KamLAND collaboration. The error quoted in ARAKI 05, $\Delta(m^2) = (7.9^{+0.6}_{-0.5}) \times 10^{-5}$, envelops the 68% CL two-dimensional region.

[37] AHMED 04A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04A also quotes $\Delta(m^2) = (7.1^{+1.2}_{-0.6}) \times 10^{-5}$ eV$^2$ as the error enveloping the 68% CL two-dimensional region.

[38] AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is $\Delta(m^2) = 6.5 \times 10^{-5}$ eV$^2$, $\tan^2\theta = 0.40$ ($\sin^2 2\theta = 0.82$).

[39] SMY 04 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.

[40] SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The $1\sigma$ errors are read from Fig. 6(a) of SMY 04.

[41] SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The $1\sigma$ errors are read from Fig. 6(a) of SMY 04.

[42] AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is $\Delta(m^2) = 5.0 \times 10^{-5}$ eV$^2$ and $\tan\theta = 0.34$ ($\sin^2 2\theta = 0.76$).

[43] FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2) = 6.9 \times 10^{-5}$ eV$^2$ and $\tan^2\theta = 0.38$ ($\sin^2 2\theta = 0.80$).

## $\sin^2(\theta_{23})$

The reported limits below correspond to the projection onto the $\sin^2(\theta_{23})$ axis of the 90% CL contours in the $\sin^2(\theta_{23}) - \Delta m^2_{32}$ plane presented by the authors. Unless otherwise specified, the limits are 90% CL and the reported uncertainties are 68% CL.

If an experiment reports $\sin^2(2\theta_{23})$ we convert the value to $\sin^2(\theta_{23})$.

[1] ACERO 19 is based on a sample size of $12.33\times10^{20}$ protons on target. The fit combines both antineutrino and neutrino data to extract the oscillation parameters. The results favor the normal mass ordering by 1.9 $\sigma$ and $\theta_{23}$ values in octant II by 1.6 $\sigma$. Supersedes ACERO 18.

[2] Errors are from normal mass ordering and $\theta_{13}$ octant II fits.

[3] AARTSEN 18A uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 18A also reports the best fit result for the inverted mass ordering as $\Delta m^2_{32} = -2.32\times10^{-3}$ eV$^2$ and $\sin^2(\theta_{23}) = 0.51$. Uncertainties for the inverted mass ordering fits were not provided. Supersedes AARTSEN 15A.

[4] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, $\Delta m^2_{32}$, $\sin^2(\theta_{23})$, and $\delta$, while the solar parameters and $\sin^2(\theta_{13})$ are fixed to $\Delta m^2_{21} = (7.53\pm0.18)\times10^{-5}$ eV$^2$, $\sin^2(\theta_{12}) = 0.304\pm0.014$, and $\sin^2(\theta_{13}) = 0.0219\pm0.0012$.

[5] ABE 18G data prefers normal mass ordering is with a posterior probability of 87%. Supersedes ABE 17F.

[6] ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the $\nu_\mu$ disappearance and $\nu_e$ appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions. The best fit is for first $\theta_{23}$ octant and inverted mass ordering.

[7] AARTSEN 20 uses the data taken between May 2012 and April 2014 with the low-energy subdetector DeepCore of the IceCube neutrino telescope. The reconstructed energy range is between 4 (5) and 90 (80) GeV for the main (confirmatory) analysis. Though the observed best-fit is in the lower octant for both mass orderings, a substantial range of $\sin^2(\theta_{23}) > 0.5$ is still compatible with the observed data for both mass orderings.

[8] AARTSEN 19C uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 19C adopts looser event selection criteria to prioritize the efficiency of selecting neutrino events, different from tighter event selection criteria which closely follow the criteria used by AARTSEN 18A to measure the $\nu_\mu$ disappearance.

[9] ALBERT 19 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2016 (2830 days of total live time). Supersedes ADRIAN-MARTINEZ 12.

[10] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, $\Delta m^2_{32}$, $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and $\delta$, while the solar parameters are fixed to $\Delta m^2_{21} = (7.53\pm0.18)\times10^{-5}$ eV$^2$ and $\sin^2\theta_{12} = 0.304\pm0.014$.

[11] ACERO 18 performs a joint fit to the data for $\nu_\mu$ disappearance and $\nu_e$ appearance. The overall best fit favors normal mass ordering and $\theta_{23}$ in octant II. No 1$\sigma$ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.

[12] Errors are from the projections of the 68% contour on 2D plot of $\Delta m^2$ versus $\sin^2(\theta_{23})$. ABE 17F supersedes ABE 17A. Superseded by ABE 18G.

[13] Superseded by ACERO 18.

[14] ABE 16D reports oscillation results using $\overline{\nu}_\mu$ disappearance in an off-axis beam.

[15] ADAMSON 16A obtains $\sin^2(\theta_{23})$ in the 68% C.L. range [0.38, 0.65] ([0.37, 0.64]), with two statistically degenerate best-fit values of 0.44 and 0.59 (0.44 and 0.59) for normal (inverted) mass ordering. Superseded by ADAMSON 17A.

[16] AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Superseded by AARTSEN 18A.

[17] ABE 14 results are based on $\nu_\mu$ disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. Superseded by ABE 17A.

[18] FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

[19] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 0.433–0.496 or 0.530–0.594 for normal and 0.514–0.612 for inverted mass ordering.

[20] AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.

[21] The best fit value is $\sin^2(\theta_{23}) = 0.514\pm0.082$. Superseded by ABE 14.

[22] ADAMSON 13B obtained this result from $\nu_\mu$ and $\overline{\nu}_\mu$ disappearance using $\nu_\mu$ ($10.71\times10^{20}$ POT) and $\overline{\nu}_\mu$ ($3.36\times10^{20}$ POT) beams, and atmospheric (37.88kton-years) data from MINOS The fit assumed two-flavor neutrino hypothesis and identical $\nu_\mu$ and $\overline{\nu}_\mu$ oscillation parameters. Superseded by ADAMSON 14.

[23] ABE 12A obtained this result by a two-neutrino oscillation analysis. The best-fit point is $\sin^2(2\theta_{23}) = 0.98$.

[24] ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos. The best fit value is $\sin^2(2\theta_{23}) = 0.95^{+0.10}_{-0.11}\pm0.01$.

[25] ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton·yr atmospheric neutrino data with the MINOS far detector.

[26] The best fit point is $\Delta m^2 = 0.0019$ eV$^2$ and $\sin^2 2\theta = 0.99$. The 90% single-parameter confidence interval at the best fit point is $\sin^2 2\theta > 0.86$.

[27] The data are separated into pure samples of $\nu$s and $\overline{\nu}$s, and separate oscillation parameters for $\nu$s and $\overline{\nu}$s are fit to the data. The best fit point is ($\Delta m^2$, $\sin^2 2\theta$) = (0.0022 eV$^2$, 0.99) and ($\Delta\overline{m}^2$, $\sin^2 2\overline{\theta}$) = (0.0016 eV$^2$, 1.00). The quoted result is taken from the

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

90% C.L. contour in the ($\Delta m^2$, $\sin^2 2\theta$) plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.

[28] ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time). Superseded by ALBERT 19.

[29] ABE 11C obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data. ABE 11C also reported results under a two-neutrino disappearance model with separate mixing parameters between $\nu$ and $\overline{\nu}$, and obtained $\sin^2 2\theta > 0.93$ for $\nu$ and $\sin^2 2\theta > 0.83$ for $\overline{\nu}$ at 90% C.L.

[30] ADAMSON 11B obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with $1.71 \times 10^{20}$ protons on target. This results is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.

[31] WENDELL 10 obtained this result ($\sin^2\theta_{23} = 0.407$–$0.583$) by a three-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data, assuming $\theta_{13} = 0$ but including the solar oscillation parameters $\Delta m^2_{21}$ and $\sin^2\theta_{12}$ in the fit.

[32] WENDELL 10 obtained this result ($\sin^2\theta_{23} = 0.43$–$0.61$) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m^2_{21} = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

[33] WENDELL 10 obtained this result ($\sin^2\theta_{23} = 0.44$–$0.63$) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m^2_{21} = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

[34] ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.

[35] Supercedes ALIU 05.

[36] MICHAEL 06 best fit is for maximal mixing. See also ADAMSON 08.

[37] The best fit is for maximal mixing.

[38] ALLISON 05 result is based upon atmospheric neutrino interactions including upward-stopping muons, with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017$ eV$^2$ and $\sin^2(2\theta) = 0.97$.

[39] ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period.

[40] AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_\mu > 1$ GeV, $N_{low}$ and $N_{high}$, and the numbers of InDown + UpStop and InUp events. Here, $N_{low}$ and $N_{high}$ are the number of events with reconstructed neutrino energies $< 30$ GeV and $> 130$ GeV, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for maximal mixing.

[41] ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of $\nu_\mu$ disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data.

[42] There are several islands of allowed region from this K2K analysis, extending to high values of $\Delta m^2$. We only include the one that overlaps atmospheric neutrino analyses. The best fit is for maximal mixing.

[43] AMBROSIO 03 obtained this result on the basis of the ratio $R = N_{low}/N_{high}$, where $N_{low}$ and $N_{high}$ are the number of upward through-going muon events with reconstructed neutrino energy $< 30$ GeV and $> 130$ GeV, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits.

[44] AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is to maximal mixing.

[45] SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection $\mu$ flavor sample while the $e$-flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is $\sin^2(2\theta) = 0.97$.

[46] AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_\mu > 1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits. The best fit is for maximal mixing.

[47] AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_\mu > 1$ GeV. See the previous footnote.

[48] FUKUDA 99C obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_\mu > 1.6$ GeV, the observed flux is $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. The best fit is $\sin^2(2\theta) = 0.95$.

[49] FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. This is compared to the expected flux of $(0.73 \pm 0.16$ (theoretical error)$) \times 10^{-13}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. The best fit is to maximal mixing.

[50] FUKUDA 99D obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is to maximal mixing.

[51] FUKUDA 98C obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for maximal mixing.

[52] HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_\mu > 1.6$ GeV, the observed flux of upward through-going muons is $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. This is compared to the expected flux of $(2.46 \pm 0.54$ (theoretical error)$) \times 10^{-13}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. The best fit is for maximal mixing.

[53] HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is $\sin^2(2\theta) = 0.95$.

[54] FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for maximal mixing.

## $\Delta m^2_{32}$

The sign of $\Delta m^2_{32}$ is not known at this time. If given, values are shown separately for the normal and inverted mass ordering. Unless otherwise specified, the ranges below correspond to the projection onto the $\Delta m^2_{32}$ axis of the 90% CL contours in the $\sin^2(2\theta_{23}) - \Delta m^2_{32}$ plane presented by the authors. If uncertainties are reported with the value, they correspond to one standard deviation uncertainty.

[1] ACERO 19 is based on a sample size of $12.33\times10^{20}$ protons on target. The fit combines both antineutrino and neutrino data to extract the oscillation parameters. The results favor the normal mass ordering by 1.9 $\sigma$ and $\theta_{23}$ values in octant II by 1.6 $\sigma$. Supersedes ACERO 18.

[2] AARTSEN 18A uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 18A also reports the best fit values for the inverted mass ordering as $\Delta m^2_{32} = -2.32\times10^{-3}$ eV$^2$ and $\sin^2(\theta_{23}) = 0.51$. Uncertainties for the inverted mass ordering fits were not provided. Supersedes AARTSEN 15A.

[3] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, $\Delta m^2_{32}$, $\sin^2(\theta_{23})$, and $\delta$, while the solar parameters and $\sin^2(\theta_{13})$ are fixed to $\Delta m^2_{21} = (7.53\pm0.18)\times10^{-5}$ eV$^2$, $\sin^2(\theta_{12}) = 0.304\pm0.014$, and $\sin^2(\theta_{13}) = 0.0219\pm0.0012$.

[4] ABE 18G data prefers normal ordering with a posterior probability of 87%. Supersedes ABE 17F.

[5] ABE 18G reports $\Delta m^2_{13}=(2.432\pm0.070)\times10^{-3}$ eV$^2$ for inverted mass ordering. We convert to $\Delta m^2_{32}$ using PDG 18 value of $\Delta m^2_{21}=(7.53\pm0.18)\times10^{-5}$ eV$^2$.

[6] ADEY 18A reports results from analysis of 1958 days of data taking with the Daya-Bay experiment, with $3.9\times10^6$ $\overline{\nu}_e$ candidates. The fit to the data gives $\Delta m^2_{ee} = (2.522^{+0.068}_{-0.070})\times10^{-3}$ eV$^2$. Solar oscillation parameters are fixed in the analysis using the global averages, $\sin^2(\theta_{12}) = 0.307^{+0.013}_{-0.012}$, $\Delta m^2_{21} = (7.53\pm0.18)\times10^{-5}$ eV$^2$, from PDG 18. Supersedes AN 17A.

[7] BAK 18 reports results of the RENO experiment using about 2200 live-days of data taken with detectors placed at 410.6 and 1445.7 m from reactors of the Hanbit Nuclear Power Plant. We convert the results to $\Delta m^2_{32}$ using the PDG 18 values of $\sin^2\theta_{12} = 0.307^{+0.013}_{-0.012}$ and $\Delta m^2_{21} = (7.53\pm0.18)\times10^{-5}$ eV$^2$. Supersedes SEO 18.

[8] ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines The analysis combines the $\nu_\mu$ disappearance and $\nu_e$ appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions.

[9] AARTSEN 19C uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy sub-detector DeepCore of the IceCube neutrino telescope. AARTSEN 19C adopts looser event selection criteria to prioritize the efficiency of selecting neutrino events, different from tighter event selection criteria which closely follow the criteria used by AARTSEN 18A to measure the $\nu_\mu$ disappearance.

[10] ALBERT 19 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2016 (2830 days of total live time). Supersedes ADRIAN-MARTINEZ 12.

[11] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, $\Delta m^2_{32}$, $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and $\delta$, while the solar parameters are fixed to $\Delta m^2_{21}= (7.53\pm0.18)\times10^{-5}$ eV$^2$ and $\sin^2\theta_{12} = 0.304\pm0.014$.

[12] ACERO 18 performs a joint fit to the data for $\nu_\mu$ disappearance and $\nu_e$ appearance. The overall best fit favors normal mass ordering and $\theta_{23}$ in octant II. No 1$\sigma$ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.

[13] The error for octant I is taken from the result for octant II.

[14] AGAFONOVA 18 assumes maximal $\theta_{23}$ mixing.

[15] SEO 18 reports result of the RENO experiment from a rate and shape analysis of 500 days of data. A simultaneous fit to $\theta_{13}$ and $\Delta m^2_{ee}$ yields $\Delta m^2_{ee} = (2.62^{+0.21+0.12}_{-0.23-0.13})\times10^{-3}$ eV$^2$. We convert the results to $\Delta m^2_{32}$ using the PDG 18 values of $\sin^2\theta_{12}$ and $\Delta m^2_{21}$. SEO 18 is a detailed description of the results published in CHOI 16, which it supersedes. Superseded by BAK 18

[16] ABE 17F confidence intervals are obtained using a frequentist analysis including $\theta_{13}$ constraint from reactor experiments. Bayesian intervals based on Markov Chain Monte Carlo method are also provided by the authors. Superseded by ABE 18G.

[17] Superseded by ACERO 18.

[18] AN 17A report results from combined rate and spectral shape analysis of 1230 days of data taken with the Daya Bay reactor experiment. The data set contains more than $2.5\times10^6$ inverse beta-decay events with neutron capture on Gd. The fit to the data gives $\Delta^2_{ee}$=$(2.50\pm0.06\pm0.06)\times10^{-3}$ eV. Superseded by ADEY 18A.

[19] ABE 16D reports oscillation results using $\overline{\nu}_\mu$ disappearance in an off-axis beam.

[20] Superseded by ADAMSON 17A.

[21] CHOI 16 reports result of the RENO experiment from a rate and shape analysis of 500 days of data. A simultaneous fit to $\theta_{13}$ and $\Delta m^2_{ee}$ yields $\Delta m^2_{ee} = (2.62^{+0.21+0.12}_{-0.23-0.13})\times10^{-3}$ eV. We convert the results to $\Delta m^2_{32}$ using PDG 18 values of $\sin^2(\theta_{12})$ and $\Delta m^2_{21}$.

[22] AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurements with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Superseded by AARTSEN 18A.

[23] AGAFONOVA 15A result is based on 5 $\nu_\mu\to\nu_\tau$ appearance candidates with an expected background of $0.25\pm0.05$ events. The best fit is for $\Delta m^2_{32}$=$3.3\times10^{-3}$ eV$^2$.

[24] AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine prompt energy spectra. The results correspond to the exposure of $6.9\times10^5$ GW$_{th}$-ton-days. They derive $\Delta m^2_{ee} = (2.42\pm0.11)\times10^{-3}$ eV$^2$. Assuming the normal (inverted) ordering, the fitted $\Delta m^2_{32} = (2.37\pm0.11)\times10^{-3}$ ($(2.47\pm0.11)\times10^{-3}$) eV$^2$. Superseded by AN 17A.

[25] ABE 14 results are based on $\nu_\mu$ disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. In ABE 14 the inverted mass ordering result is reported as $\Delta m^2_{13} = (2.48\pm0.10)\times10^{-3}$ eV$^2$ which we converted to $\Delta m^2_{32}$ by adding PDG 14 value of $\Delta m^2_{21} = (7.53\pm0.18)\times10^{-5}$ eV$^2$. Superseded by ABE 17C.

[26] AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine prompt energy spectra and derive $\Delta m^2_{ee} = (2.59^{+0.19}_{-0.20})\times10^{-3}$ eV$^2$. Assuming the normal (inverted) ordering, the fitted $\Delta m^2_{32} = (2.54^{+0.19}_{-0.20})\times10^{-3}$ ($(2.64^{+0.19}_{-0.20})\times10^{-3}$) eV$^2$. Superseded by AN 15.

[27] FORERO 14 performs a global fit to $\Delta m^2_{31}$ using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

[28] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(2.460\pm0.046)\times10^{-3}$ eV$^2$ for normal and $(2.445^{+0.047}_{-0.045})\times10^{-3}$ eV$^2$ for inverted mass ordering.

[29] The value for normal mass ordering is actually a measurement of $\Delta m^2_{31}$ which differs from $\Delta m^2_{32}$ by a much smaller value of $\Delta m^2_{12}$.

[30] AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[31] Based on the observation of 58 $\nu_\mu$ events with 205 ± 17(syst) expected in the absence of neutrino oscillations. Superseded by ABE 14.

[32] ADAMSON 13B obtained this result from $\nu_\mu$ and $\overline{\nu}_\mu$ disappearance using $\nu_\mu$ ($10.71 \times 10^{20}$ POT) and $\overline{\nu}_\mu$ ($3.36 \times 10^{20}$ POT) beams, and atmospheric (37.88 kton-years) data from MINOS. The fit assumed two-flavor neutrino hypothesis and identical $\nu_\mu$ and $\overline{\nu}_\mu$ oscillation parameters.

[33] ABE 12A obtained this result by a two-neutrino oscillation analysis. The best-fit point is $\Delta m^2_{32} = 2.65 \times 10^{-3}$ eV$^2$.

[34] ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos.

[35] ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.

[36] The 90% single-parameter confidence interval at the best fit point is $\Delta m^2 = 0.0019 \pm 0.0004$ eV$^2$.

[37] The data are separated into pure samples of $\nu$s and $\overline{\nu}$s, and separate oscillation parameters for $\nu$s and $\overline{\nu}$s are fit to the data. The best fit point is ($\Delta m^2$, $\sin^2 2\theta$) = (0.0022 eV$^2$, 0.99) and ($\Delta\overline{m}^2$, $\sin^2 2\overline{\theta}$) = (0.0016 eV$^2$, 1.00). The quoted result is taken from the 90% C.L. contour in the ($\Delta m^2$, $\sin^2 2\theta$) plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.

[38] ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time). Superseded by ALBERT 19

[39] ABE 11C obtained this result by a two-neutrino oscillation analysis with separate mixing parameters between neutrinos and antineutrinos, using the Super-Kamiokande-I+II+III atmospheric neutrino data. The corresponding 90% CL neutrino oscillation parameter range obtained from this analysis is $\Delta m^2 = 1.7$–$3.0 \times 10^{-3}$ eV$^2$.

[40] ADAMSON 11B obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with $1.71 \times 10^{20}$ protons on target. This results is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.

[41] ADAMSON 11C obtains this result based on a study of antineutrinos in a neutrino beam and assumes maximal mixing in the two-flavor approximation.

[42] WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m^2_{21} = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

[43] ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.

[44] The best fit in the physical region is for $\Delta m^2 = 2.8 \times 10^{-3}$ eV$^2$.

[45] Supercedes ALIU 05.

[46] MICHAEL 06 best fit is $2.74 \times 10^{-3}$ eV$^2$. See also ADAMSON 08.

[47] ALLISON 05 result is based on an atmospheric neutrino observation with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017$ eV$^2$ and $\sin^2 2\,\theta = 0.97$.

[48] ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period. The best fit is for $\Delta m^2 = 2.1 \times 10^{-3}$ eV$^2$.

[49] AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_\mu > 1$ GeV, $N_{low}$ and $N_{high}$, and the numbers of InDown + UpStop and InUp events. Here, $N_{low}$ and $N_{high}$ are the number of events with reconstructed neutrino energies $< 30$ GeV and $> 130$ GeV, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for $\Delta m^2 = 2.3 \times 10^{-3}$ eV$^2$.

[50] ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of $\nu_\mu$ disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data. The best fit is for $\Delta m^2 = 2.4 \times 10^{-3}$ eV$^2$.

[51] There are several islands of allowed region from this K2K analysis, extending to high values of $\Delta m^2$. We only include the one that overlaps atmospheric neutrino analyses. The best fit is for $\Delta m^2 = 2.8 \times 10^{-3}$ eV$^2$.

[52] AMBROSIO 03 obtained this result on the basis of the ratio $R = N_{low}/N_{high}$, where $N_{low}$ and $N_{high}$ are the number of upward through-going muon events with reconstructed neutrino energy $< 30$ GeV and $> 130$ GeV, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3}$ eV$^2$.

[53] AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3}$ eV$^2$.

[54] SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection $\mu$ flavor sample while the $e$-flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is for $\Delta m^2 = 5.2 \times 10^{-3}$ eV$^2$.

[55] AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_\mu > 1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.

[56] AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_\mu > 1$ GeV. See the previous footnote.

[57] FUKUDA 99C obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_\mu > 1.6$ GeV, the observed flux is $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. The best fit is for $\Delta m^2 = 5.9 \times 10^{-3}$ eV$^2$.

[58] FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. This is compared to the expected flux of $(0.73 \pm 0.16$ (theoretical error)$) \times 10^{-13}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. The best fit is for $\Delta m^2 = 3.9 \times 10^{-3}$ eV$^2$.

[59] FUKUDA 99D obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is for $\Delta m^2 = 3.1 \times 10^{-3}$ eV$^2$.

[60] FUKUDA 98C obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for $\Delta m^2 = 2.2 \times 10^{-3}$ eV$^2$.

[61] HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_\mu > 1.6$ GeV, the observed flux of upward through-going muons is $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. This is compared to the expected flux of $(2.46 \pm 0.54$ (theoretical error)$) \times 10^{-13}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. The best fit is for $\Delta m^2 = 2.2 \times 10^{-3}$ eV$^2$.

[62] HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is for $\Delta m^2 = 13 \times 10^{-3}$ eV$^2$.

[63] FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for $\Delta m^2 = 16 \times 10^{-3}$ eV$^2$.

## $\sin^2(\theta_{13})$

At present time direct measurements of $\sin^2(\theta_{13})$ are derived from the reactor $\overline{\nu}_e$ disappearance at distances corresponding to the $\Delta m^2_{32}$ value, i.e. L $\sim$ 1km. Alternatively, limits can also be obtained from the analysis of the solar neutrino data and accelerator-based $\nu_\mu \to \nu_e$ experiments.

If an experiment reports $\sin^2(2\theta_{13})$ we convert the value to $\sin^2(\theta_{13})$.

[1] ADEY 18A reports results from analysis of 1958 days of data taking with the Daya-Bay experiment, with $3.9 \times 10^6$ $\overline{\nu}_e$ candidates. The fit to the data gives $\Delta m^2_{ee} = (2.522^{+0.068}_{-0.070}) \times 10^{-3}$ eV$^2$. Solar oscillation parameters are fixed in the analysis using the global averages, $\sin^2(\theta_{12}) = 0.307^{+0.013}_{-0.012}$, $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV$^2$, from PDG 18. Supersedes AN 17A.

[2] BAK 18 reports results of the RENO experiment using about 2200 live-days of data taken with detectors placed at 410.6 and 1445.7 m from reactors of the Hanbit Nuclear Power Plant. Supersedes SEO 18.

[3] ABE 16B uses 455.57 live days of data from a detector 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2\theta_{13})$. This analysis uses 7.15 reactor-off days for constraining backgrounds. A rate and shape analysis is performed on combined neutron captures on H and Gd. Supersedes ABE 14H and ABE 13C.

[4] AN 16A uses data from the eight antineutrino detectors (404 days) and six antineutrino detectors (217 days) runs to determine the mixing parameter $\sin^2(2\theta_{13})$ using the neutron capture on H only. Supersedes AN 14B.

[5] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, $\Delta m^2_{32}$, $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and $\delta$, while the solar parameters are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV$^2$ and $\sin^2\theta_{12} = 0.304 \pm 0.014$.

[6] AGAFONOVA 18A reports $\sin^2(2\theta_{13}) < 0.43$ at 90% C.L. The result on the sterile neutrino search in the context of 3+1 model is also reported. A 90% C.L. upper limit on $\sin^2(2\theta_{\mu e}) = 0.021$ for $\Delta m^2_{41} \geq 0.1$ eV$^2$ is set.

[7] SEO 18 reports results of the RENO experiment using about 500 days of data, performing a rate and shape analysis. Compared to AHN 12, a significant reduction of the systematic uncertainties is reported. A 3% excess of events near 5 MeV of the prompt energy is observed. SEO 18 is a detailed description of the results published in CHOI 16, which it supersedes. Superseded by BAK 18.

[8] Using T2K data only. For inverted mass ordering, all values of $\theta_{13}$ are ruled out at 68% CL.

[9] AN 17A reports results from combined rate and spectral shape analysis of 1230 days of data taken with the Daya Bay reactor experiment. The data set contains more than $2.5 \times 10^6$ inverse beta-decay events with neutron capture on Gd. A simultaneous fit to $\theta_{13}$ and $\Delta m^2_{ee}$ is performed. Superseded by ADEY 18A.

[10] CHOI 16 reports results of the RENO experiment using about 500 days of data, performing a rate and shape analysis. Compared to AHN 12, a significant reduction of the systematic uncertainties is reported. A 3% excess of events near 5 MeV of the prompt energy is observed. Supersedes AHN 12.

[11] AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine the mixing angle $\theta_{13}$ using the $\overline{\nu}_e$ observed interaction rates with neutron capture on Gd and energy spectra. The result corresponds to the exposure of $6.9 \times 10^5$ GW$_{th}$-ton-days. Superseded by AN 17A.

[12] ABE 14A uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2\,\theta_{13})$. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A "rate-modulation" analysis is performed. Supercedes ABE 12B.

[13] ABE 14C result is for $\nu_e$ appearance and assumes $\Delta m^2_{32} = 2.4 \times 10^{-3}$ eV$^2$, $\sin^2(\,\theta_{23}) = 0.5$, and $\delta = 0$.

[14] ABE 14H uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2\,\theta_{13})$. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A rate and shape analysis is performed. Superceded by ABE 16B.

[15] AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine the mixing angle $\theta_{13}$ using the $\overline{\nu}_e$ observed interaction rates with neutron capture on Gd and energy spectra. Supersedes AN 13 and superseded by AN 15.

[16] AN 14B uses six identical anti-neutrino detectors with flux-weighted baselines of $\sim 500$ m and $\sim 1.6$ km to six power reactors. This rate analysis uses a 217-day data set and neutron capture on protons (not Gd) only. $\Delta m^2_{31} = 2.32 \times 10^{-3}$ eV$^2$ is assumed. Superseded by AN 16A.

[17] FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

[18] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(2.18^{+0.10}_{-0.11}) \times 10^{-2}$ eV$^2$ for normal and $(2.19^{+0.12}_{-0.10}) \times 10^{-2}$ eV$^2$ for inverted mass ordering.

[19] ABE 13C uses delayed neutron capture on hydrogen instead of on Gd used previously. The physical volume is thus three times larger. The fit is based on the rate and shape analysis as in ABE 12B. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 16B.

[20] ABE 13E assumes maximal $\theta_{23}$ mixing and $CP$ phase $\delta = 0$.

[21] ADAMSON 13A results obtained from $\nu_e$ appearance, assuming $\delta = 0$, and $\sin^2(2\,\theta_{23}) = 0.957$.

[22] AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{32}$ fixed to $2.45 \times 10^{-3}$ eV$^2$, using global solar neutrino data. AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active $^8$B neutrino flux and energy-dependent $\nu_e$ survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and $^7$Be (BELLINI 11A) rates, and $^8$B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra. AHARMIM 13 also reported a result combining global solar and KamLAND data, which is $\sin^2(2\,\theta_{13}) = (9.1^{+2.9}_{-3.1}) \times 10^{-2}$.

[23] AN 13 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 498 and 555 m) and the remaining three at the far hall (at the flux averaged distance of 1628 m from all six reactor cores) to determine the $\overline{\nu}_e$ interaction rate ratios. Superseded by AN 14.

[24] ABE 12 determines the $\overline{\nu}_e$ interaction rate in a single detector, located 1050 m from the cores of two reactors. A rate and shape analysis is performed. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations. The value of $\Delta m^2_{31} = 2.4 \times 10^{-3}$ eV$^2$ is used in the analysis. Superseded by ABE 12B.

[25] ABE 12B determines the neutrino mixing angle $\theta_{13}$ using a single detector, located 1050 m from the cores of two reactors. This result is based on a spectral shape and rate analysis. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 14A.

[26] AHN 12 uses two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99 m from six reactor cores, to determine the mixing angle $\theta_{13}$. This rate-only analysis excludes the no-oscillation hypothesis at 4.9 standard deviations. The value of $\Delta m^2_{31} = (2.32^{+0.12}_{-0.08}) \times 10^{-3}$ eV$^2$ was assumed in the analysis. Superseded by CHOI 16.

[27] AN 12 uses six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle $\theta_{13}$ using the $\overline{\nu}_e$ observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 5.2 standard deviations. The value of $\Delta m^2_{31} = (2.32^{+0.12}_{-0.08}) \times 10^{-3}$ eV$^2$ was assumed in the analysis. Superseded by AN 13.

[28] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{32}$ fixed to $2.4 \times 10^{-3}$ eV$^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. This result implies an upper bound of $\sin^2\theta_{13} < 0.059$ (95% CL) or $\sin^2 2\theta_{13} < 0.22$ (95% CL). The normal neutrino mass ordering and CPT invariance are assumed.

[29] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{32}$ fixed to $2.4 \times 10^{-3}$ eV$^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

[30] The quoted limit is for $\Delta m^2_{32} = 2.4 \times 10^{-3}$ eV$^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the normal mass ordering. For other values of $\delta$, the 68% region spans from 0.03 to 0.25, and the 90% region from 0.02 to 0.32.

[31] The quoted limit is for $\Delta m^2_{32} = 2.4 \times 10^{-3}$ eV$^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the inverted mass ordering. For other values of $\delta$, the 68% region spans from 0.04 to 0.30, and the 90% region from 0.02 to 0.39.

[32] The quoted limit is for $\Delta m^2_{32} = 2.32 \times 10^{-3}$ eV$^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the normal mass ordering. For other values of $\delta$, the 68% region spans from 0.02 to 0.12, and the 90% region from 0 to 0.16.

[33] The quoted limit is for $\Delta m^2_{32} = 2.32 \times 10^{-3}$ eV$^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the inverted mass ordering. For other values of $\delta$, the 68% region spans from 0.02 to 0.16, and the 90% region from 0 to 0.21.

[34] FOGLI 11 obtained this result from an analysis using the atmospheric, accelerator long baseline, CHOOZ, solar, and KamLAND data. Recently, MUELLER 11 suggested an

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

average increase of about 3.5% in normalization of the reactor $\overline{\nu}_e$ fluxess, and using these fluxes, the fitted result becomes $0.10 \pm 0.03$.

[35] GANDO 11 report $\sin^2\theta_{13} = 0.020 \pm 0.016$. This result was obtained with three-neutrino fit using the KamLAND + solar data.

[36] GANDO 11 report $\sin^2\theta_{13} = 0.032 \pm 0.037$. This result was obtained with three-neutrino fit using the KamLAND data only.

[37] This result corresponds to the limit of $<0.12$ at 90% CL for $\Delta m^2_{32} = 2.43 \times 10^{-3}$ eV$^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of $\delta$, the 90% CL region spans from 0 to 0.16.

[38] This result corresponds to the limit of $<0.20$ at 90% CL for $\Delta m^2_{32} = 2.43 \times 10^{-3}$ eV$^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of $\delta$, the 90% CL region spans from 0 to 0.21.

[39] AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

[40] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{31}$ fixed to $2.3 \times 10^{-3}$ eV$^2$, using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed. This result implies an upper bound of $\sin^2\theta_{13} < 0.057$ (95% CL) or $\sin^2 2\theta_{13} < 0.22$ (95% CL).

[41] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of $\Delta m^2_{31}$ fixed to $2.3 \times 10^{-3}$ eV$^2$, using global solar neutrino data.

[42] WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m^2_{21} = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

[43] The quoted limit is for $\Delta m^2_{32} = 2.43 \times 10^{-3}$ eV$^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of $\delta$, the 68% CL region spans from 0.02 to 0.26.

[44] The quoted limit is for $\Delta m^2_{32} = 2.43 \times 10^{-3}$ eV$^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of $\delta$, the 68% CL region spans from 0.04 to 0.34.

[45] FOGLI 08 obtained this result from a global analysis of all neutrino oscillation data, that is, solar + KamLAND + atmospheric + accelerator long baseline + CHOOZ.

[46] FOGLI 08 obtained this result from an analysis using the solar and KamLAND neutrino oscillation data.

[47] FOGLI 08 obtained this result from an analysis using the atmospheric, accelerator long baseline, and CHOOZ neutrino oscillation data.

[48] YAMAMOTO 06 searched for $\nu_\mu \to \nu_e$ appearance. Assumes $2\sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$. The quoted limit is for $\Delta m^2_{32} = 1.9 \times 10^{-3}$ eV$^2$. That value of $\Delta m^2_{32}$ is the one-$\sigma$ low value for AHN 06A. For the AHN 06A best fit value of $2.8 \times 10^{-3}$ eV$^2$, the $\sin^2(2\theta_{13})$ limit is $< 0.26$. Supersedes AHN 04.

[49] AHN 04 searched for $\nu_\mu \to \nu_e$ appearance. Assuming $2\sin^2(2\theta_{\mu_e}) = \sin^2(2\theta_{13})$, a limit on $\sin^2(2\theta_{\mu_e})$ is converted to a limit on $\sin^2(2\theta_{13})$.The quoted limit is for $\Delta m^2_{32} = 1.9 \times 10^{-3}$ eV$^2$. That value of $\Delta m^2_{32}$ is the one-$\sigma$ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3}$ eV$^2$, the $\sin^2(2\theta_{13})$ limit is $< 0.30$.

[50] The quoted limit is for $\Delta m^2_{32} = 1.9 \times 10^{-3}$ eV$^2$. That value of $\Delta m^2_{32}$ is the 1-$\sigma$ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3}$ eV$^2$, the $\sin^2 2\theta_{13}$ limit is $< 0.19$. In this range, the $\theta_{13}$ limit is larger for lower values of $\Delta m^2_{32}$, and smaller for higher values of $\Delta m^2_{32}$.

[51] The quoted limit is for $\Delta m^2_{32} = 1.9 \times 10^{-3}$ eV$^2$. That value of $\Delta m^2_{32}$ is the 1-$\sigma$ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3}$ eV$^2$, the $\sin^2 2\theta_{13}$ limit is $< 0.23$.

[52] The quoted limit is for $\Delta m^2_{32} = 2.43 \times 10^{-3}$ eV$^2$. That value of $\Delta m^2_{32}$ is the central value for ADAMSON 08. For the ADAMSON 08 1-$\sigma$ low value of $2.30 \times 10^{-3}$ eV$^2$, the $\sin^2 2\theta_{13}$ limit is $< 0.16$. See also APOLLONIO 03 for a detailed description of the experiment.

## *CP* violating phase

### $\delta$, *CP* violating phase

Measurements of $\delta$ come from atmospheric and accelerator experiments looking at $\nu_e$ appearance. We encode values between 0 and $2\pi$, though it is equivalent to use $-\pi$ to $\pi$.

[1] ACERO 19 is based on a sample size of $1.33 \times 10^{20}$ protons on target with combined antineutrino and neutrino data. Supersedes ACERO 18.

[2] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, $\Delta m^2_{32}$, $\sin^2\theta_{23}$, and $\delta$, while the solar parameters and $\sin^2\theta_{23}$ are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV$^2$, $\sin^2\theta_{12} = 0.304 \pm 0.014$, and $\sin^2\theta_{13} = 0.0219 \pm 0.0012$.

[3] ABE 18G confidence intervals are marginalized over both mass orderings. Normal order preferred with a posterior probability of 87%. The 1-sigma result for normal mass ordering used in the average was provided by the experiment via private communications. Supersedes ABE 17F.

[4] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, $\Delta m^2_{32}$, $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and $\delta$, while the solar parameters are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV$^2$ and $\sin^2\theta_{12} = 0.304 \pm 0.014$.

[5] ACERO 18 performs a joint fit to the data for $\nu_\mu$ disappearance and $\nu_e$ appearance. The overall best fit favors normal mass ordering and $\theta_{23}$ in octant II. No $1\sigma$ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.

[6] ABE 17F confidence intervals are obtained using a frequentist analysis including $\theta_{13}$ constraint from reactor experiments. Bayesian intervals based on Markov Chain Monte Carlo method are also provided by the authors. Superseded by ABE 18G.

[7] Errors are projections of 68% C.L. curve of $\delta_{CP}$ vs. $\sin^2\theta_{23}$.

[8] ADAMSON 16 result is based on a data sample with $2.74 \times 10^{20}$ protons on target. The likelihood-based analysis observed 6 $\nu_e$ events with an expected background of $0.99 \pm 0.11$ events.

[9] ADAMSON 14 result is based on three-flavor formalism and $\theta_{23} > \pi/4$. Likelihood as a function of $\delta$ is also shown for the other three combinations of hierarchy and $\theta_{23}$ octants; all values of $\delta$ are allowed at 90% C.L.

[10] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 1.24–1.94 for normal and 1.15–1.77 for inverted mass ordering.

[11] ADAMSON 13A result is based on $\nu_e$ appearance in MINOS and the calculated $\sin^2(2\theta_{23}) = 0.957, \theta_{23} > \pi/4$, and normal mass hierarchy. Likelihood as a function of $\delta$ is also shown for the other three combinations of hierarchy and $\theta_{23}$ octants; all values of $\delta$ are allowed at 90% C.L.

## (C) Other neutrino mixing results

The LSND collaboration reported in AGUILAR 01 a signal which is consistent with $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillations. In a three neutrino framework, this would be a measurement of $\theta_{12}$ and $\Delta m^2_{21}$. This does not appear to be consistent with most of the other neutrino data. The following listings include results from $\nu_\mu \to \nu_e$, $\overline{\nu}_\mu \to \overline{\nu}_e$ appearance and $\nu_\mu$, $\overline{\nu}_\mu$, $\nu_e$, and $\overline{\nu}_e$ disappearance experiments, and searches for *CPT* violation.

[1] AGUILAR-AREVALO 18C result is based on $\nu_\mu \to \nu_e$ appearance of $460.5 \pm 99.0$ events; The best fit value is $\Delta m^2 = 0.041$ eV$^2$.

[2] AGUILAR-AREVALO 13A result is based on $\nu_\mu \to \nu_e$ appearance of $162.0 \pm 47.8$ events; marginally compatible with twoneutrino oscillations. The best fit value is $\Delta m^2 = 3.14$ eV$^2$.

[3] MAHN 12 is a combined spectral fit of MiniBooNE and SciBooNE neutrino data with the range of $\Delta m^2$ up to 25 eV$^2$. The best limit is 0.04 at 7 eV$^2$.

[4] AGUILAR 01 is the final analysis of the LSND full data set. Search is made for the $\nu_\mu \to \nu_e$ oscillations using $\nu_\mu$ from $\pi^+$ decay in flight by observing beam-on electron events from $\nu_e C \to e^- X$. Present analysis results in $8.1 \pm 12.2 \pm 1.7$ excess events in the $60 < E_e < 200$ MeV energy range, corresponding to oscillation probability of $0.10 \pm 0.16 \pm 0.04\%$. This is consistent, though less significant, with the previous result of ATHANASSOPOULOS 98, which it supersedes. The present analysis uses selection criteria developed for the decay at rest region, and is less effective in removing the background above 60 MeV than ATHANASSOPOULOS 98.

[5] ATHANASSOPOULOS 98 is a search for the $\nu_\mu \to \nu_e$ oscillations using $\nu_\mu$ from $\pi^+$ decay in flight. The 40 observed beam-on electron events are consistent with $\nu_e C \to e^- X$; the expected background is $21.9 \pm 2.1$. Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability $(0.26 \pm 0.10 \pm 0.05)\%$. Although the significance is only 2.3 $\sigma$, this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillations from $\mu^+$ decay at rest. See also ATHANASSOPOULOS 98B.

[6] LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

[1] AGUILAR-AREVALO 18C result is based on $\nu_\mu \to \nu_e$ appearance of $460.5 \pm 99.0$ events; The best fit value is $\sin^2(2\theta) = 0.92$. The quoted limit for the two-neutrino mixing angle $\theta$ is valid above $\Delta m^2 = 0.59$ eV$^2$.

[2] AGUILAR-AREVALO 13A result is based on $\nu_\mu \to \nu_e$ appearance of $162.0 \pm 47.8$ events; marginally compatible with two neutrino oscillations. The best fit value is $\sin^2(2\theta) = 0.002$.

[3] ANTONELLO 13 use the ICARUS T600 detector at LNGS and $\sim 20$ GeV beam of $\nu_\mu$ from CERN 730 km away to search for an excess of $\nu_e$ events. Two events are found with $3.7 \pm 0.6$ expected from conventional sources. This result excludes some parts of the parameter space expected by LSND. Superseded by ANTONELLO 13A.

[4] Based on four events with a background of $6.4 \pm 0.9$ from conventional sources with an average energy of 20 GeV and 730 km from the source of $\nu_\mu$.

[5] MAHN 12 is a combined fit of MiniBooNE and SciBooNE neutrino data.

[6] The limit is $\sin^2 2\theta < 0.9 \times 10^{-3}$ at $\Delta m^2 = 2$ eV$^2$. That value of $\Delta m^2$ corresponds to the smallest mixing angle consistent with the reported signal from LSND in AGUILAR 01.

[7] The limit becomes $\sin^2 2\theta < 0.15$ at $\Delta m^2 = 2.8 \times 10^{-3}$ eV$^2$, the bets-fit value of the $\nu_\mu$ disappearance analysis in K2K.

[8] AGUILAR 01 is the final analysis of the LSND full data set of the search for the $\nu_\mu \to \nu_e$ oscillations. See footnote in preceding table for further details.

[9] ATHANASSOPOULOS 98 report $(0.26 \pm 0.10 \pm 0.05)\%$ for the oscillation probability; the value of $\sin^2 2\theta$ for large $\Delta m^2$ is deduced from this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate $\sin^2 2\theta$ and $\Delta m^2$. See also ATHANASSOPOULOS 98B.

[10] LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

[11] VILAIN 94C limit derived by combining the $\nu_\mu$ and $\overline{\nu}_\mu$ data assuming $CP$ conservation.

[1] Based on $\overline{\nu}_\mu \to \overline{\nu}_e$ appearance of $78.4 \pm 28.5$ events. The best fit values are $\Delta m^2 = 0.043$ eV$^2$ and $\sin^2 2\theta = 0.88$.

[2] CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

[3] This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 475$ MeV. The best fit is at 0.07. The allowed region is consistent with LSND reported by AGUILAR 01. Supercedes AGUILAR-AREVALO 09B.

[4] This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 200$ MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. The best fit value is 0.007 for $\Delta(m^2) = 4.4$ eV$^2$.

[5] ARMBRUSTER 02 is the final analysis of the KARMEN 2 data for 17.7 m distance from the ISIS stopped pion and muon neutrino source. It is a search for $\overline{\nu}_e$, detected by the inverse $\beta$-decay reaction on protons and $^{12}$C. 15 candidate events are observed, and $15.8 \pm 0.5$ background events are expected, hence no oscillation signal is detected. The results exclude large regions of the parameter area favored by the LSND experiment.

[6] AGUILAR 01 is the final analysis of the LSND full data set. It is a search for $\overline{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly for $\pi^+$ decay at rest. $\overline{\nu}_e$ are detected through $\overline{\nu}_e p \to e^+ n$ ($20 < E_{e^+} < 60$ MeV) in delayed coincidence with $np \to d\gamma$. Authors observe $87.9 \pm 22.4 \pm 6.0$ total excess events. The observation is attributed to $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillations with the oscillation probability of $0.264 \pm 0.067 \pm 0.045\%$, consistent with the previously published result. Taking into account all constraints, the most favored allowed region of oscillation parameters is a band of $\Delta(m^2)$ from 0.2–2.0 eV$^2$. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

[7] ATHANASSOPOULOS 96 is a search for $\overline{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly from $\pi^+$ decay at rest. $\overline{\nu}_e$ could come from either $\overline{\nu}_\mu \to \overline{\nu}_e$ or $\nu_e \to \overline{\nu}_e$; our entry assumes the first interpretation. They are detected through $\overline{\nu}_e p \to e^+ n$ (20 MeV $< E_{e^+} <$ 60 MeV) in delayed coincidence with $np \to d\gamma$. Authors observe $51 \pm 20 \pm 8$ total excess events over an estimated background $12.5 \pm 2.9$. ATHANASSOPOULOS 96B is a shorter version of this paper.

[8] ATHANASSOPOULOS 95 error corresponds to the $1.6\sigma$ band in the plot. The expected background is $2.7 \pm 0.4$ events. Corresponds to an oscillation probability of $(0.34^{+0.20}_{-0.18} \pm 0.07)\%$. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

[9] HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\overline{\nu}_\mu \to \overline{\nu}_e$ and obtains only upper limits.

[10] FREEDMAN 93 is a search at LAMPF for $\overline{\nu}_e$ generated from any of the three neutrino types $\nu_\mu$, $\overline{\nu}_\mu$, and $\nu_e$ which come from the beam stop. The $\overline{\nu}_e$'s would be detected by the reaction $\overline{\nu}_e p \to e^+ n$. FREEDMAN 93 replaces DURKIN 88.

## $\sin^2(2\theta)$ for "Large" $\Delta(m^2)$ $(\overline{\nu}_\mu \to \overline{\nu}_e)$

[1] ANTONELLO 13A obtained the limit by assuming $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillation from the $\sim 2\%$ of $\overline{\nu}_\mu$ evnets contamination in the CNGS beam.

[2] CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

[3] This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 475$ MeV. At 90% CL there is no solution at high $\Delta(m^2)$. The best fit is at maximal mixing. The allowed region is consistent with LSND reported by AGUILAR 01. Supercedes AGUILAR-AREVALO 09B.

[4] This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 200$ MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. At 90% CL there is no solution at high $\Delta(m^2)$. The best fit value is 0.007 for $\Delta(m^2) = 4.4$ eV$^2$.

[5] This result is inconclusive with respect to small amplitude mixing suggested by LSND.

[6] ARMBRUSTER 02 is the final analysis of the KARMEN2 data. See footnote in the preceding table for further details, and the paper for the exclusion plot.

[7] AGUILAR 01 is the final analysis of the LSND full data set. The deduced oscillation probability is $0.264 \pm 0.067 \pm 0.045\%$; the value of $\sin^2 2\theta$ for large $\Delta(m^2)$ is twice this probability (although these values are excluded by other constraints). See footnote in preceding table for further details, and the paper for a plot showing allowed regions. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

[8] ATHANASSOPOULOS 96 reports $(0.31 \pm 0.12 \pm 0.05)\%$ for the oscillation probability; the value of $\sin^2 2\theta$ for large $\Delta(m^2)$ should be twice this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions.

[9] ATHANASSOPOULOS 95 error corresponds to the $1.6\sigma$ band in the plot. The expected background is $2.7 \pm 0.4$ events. Corresponds to an oscillation probability of $(0.34^{+0.20}_{-0.18} \pm 0.07)\%$. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

[10] HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\overline{\nu}_\mu \to \overline{\nu}_e$ and obtains only upper limits.

[1] SEREBROV 19 searches for $\overline{\nu}_e \to \overline{\nu}_s$ oscillations with baseline 6–12 m with SM-3 research reactor that uses highly enriched $^{235}$U fuel. The spectrum is well described by the $1/L^2$ dependence. However, the shape differs from the theoretical expectations, with the best fit corresponding to $\Delta m^2_{41} = 7.34 \pm 0.1$ eV$^2$ and $\sin^2(2\theta_{14}) = 0.39 \pm 0.12$ at $3\sigma$ significance.

[2] ALEKSEEV 18 searches for $\overline{\nu}_e \to \overline{\nu}_s$ oscillations using the DANSS detector at 10.7, 11.2, and 12.7 m from the 3.1 GW$_{th}$ power reactor. The DANSS detector is highly segmented and moveable; the positions are changed usually 3 times a week. The analysis is based on the ratio of the events at top and bottom position; the middle position is used for checks of consistency. The best fit point is at $\Delta m^2_{41} = 1.4$ eV$^2$ and $\sin^2(2\theta_{14}) = 0.05$ with $\Delta\chi^2 = 13.1$ (statistical errors only) compared to the fit with 3 active neutrinos only. The quoted limit of 0.01 for $\sin^2(2\theta_{14})$ corresponds to $\Delta m^2_{41} \sim 1.0$ eV$^2$.

[3] ALMAZAN 18 searches for the $\overline{\nu}_e \to \overline{\nu}_s$ oscillations with baseline from 9.4 to 11.1 m from the ILL research reactor with highly enriched $^{235}$U fuel. The STEREO detector consists of six separated cells with Gd loaded scintillator, with 15 m water equivalent overburden. The detected rate is $396.3 \pm 4.7$ $\overline{\nu}_e$/day with signal to background ratio of about 0.9. The reported results corresponds to 66 days of reactor-on. The analysis uses the relative rates normalized to the cell number 1. No indication of the oscillation to the sterile neutrinos is found, the stated limit on $\sin^2(2\theta_{14})$ correspond to $\Delta m^2_{41} \sim 3.5$ eV$^2$ where the exclusion is maximal.

[4] ASHENFELTER 18 searches for the $\overline{\nu}_e \to \overline{\nu}_s$ oscillations at baseline from 6.7 to 9.2 m from the 85 MW research reactor with pure $^{235}$U core. The segmented 4 ton $^6$Li-doped liquid scintillator is operated with about 1 m water equivalent overburden and recorded $25461 \pm 283$ IBD events. No indication of oscillations into sterile neutrinos was observed. The stated limit for $\sin^2(2\theta_{14})$ is for $\Delta m^2_{41} \sim 2$ eV$^2$ where the sensitivity is maximal.

[5] SEREBROV 18A searches for the $\overline{\nu}_e \to \overline{\nu}_s$ oscillation with baseline 6–12 m from the core of the SM-3 research reactor that uses highly enriched $^{235}$U. They find that oscillations with $\Delta m^2_{41} \sim 0.7\text{–}0.8$ eV$^2$ and $\sin^2(2\theta_{14}) \sim 0.10\text{–}0.15$ give better fit to the $L$ and $E$ dependence than the no oscillation scenario. The significance of this is about $2\sigma$.

[6] AARTSEN 17B uses three years of upward-going atmospheric neutrino data in the energy range of 10-60 GeV to constrain their disappearance into light sterile neutrinos. The reported limit $\sin^2\theta_{24} < 0.11$ at 90% C.L. is for $\Delta m^2_{41} = 1.0$ eV$^2$. We convert the result to $\sin^2 2\theta_{24}$ for the listing. AARTSEN 17B also reports $\cos^2\theta_{24} \cdot \sin^2\theta_{34} < 0.15$ at 90% C.L. for $\Delta m^2_{41} = 1.0$ eV$^2$.

[7] ABDURASHITOV 17 use the Troitsk nu-mass experiment to search for sterile neutrinos with mass 0.1 - 2 keV. We convert the reported limit from $U^2_{e4} < 0.002$ to $\sin^2 2\theta_{14} < 0.008$ assume $U_{e4} \sim \sin\theta_{14}$. The stated limit corresponds to the smallest $U^2_{e4}$. The exclusion curve begins at $U^2_{e4}$ of 0.02 for $m_4 = 0.1$ keV.

[8] KO 17 reports on short baseline reactor oscillation search ($\overline{\nu}_e \to \overline{\nu}_s$), motivated be the so-called "reactor antineutrino anomaly". The experiment is conducted at 23.7 m from the core of unit 5 of the Hanbit Nuclear Power Complex in Korea. the reported limited on $\sin^2(2\theta_{41})$ for sterile neutrinos was determined using the reactor antineutrino spectrum determined by the Daya Bay experiment for $\Delta m^2_{14}$ around 0.55 eV$^2$ where the sensitivity is maximal. A fraction of the parameter space derived from the "reactor antineutrino anomaly" is excluded by this work. Compared to reactor models an event excess is observed at about 5 MeV, in agreement with other experiments.

[9] AARTSEN 16 use one year of upward-going atmospheric muon neutrino data in the energy range of 320 GeV to 20 TeV to constrain their disappearance into light sterile neutrinos. Sterile neutrinos are expected to produce distinctive zenith distribution for these energies for $0.01 \leq \Delta m^2 \leq 10$ eV$^2$. The stated limit is for $\sin^2 2\theta_{24}$ at $\Delta m^2$ around 0.3 eV$^2$.

[10] ADAMSON 16B combine the results of AN 16B, ADAMSON 16C, and Bugey-3 reactor experiments to constrain $\nu_\mu$ to $\nu_e$ mixing through oscillations into light sterile neutrinos. The stated limit for $\sin^2 2\theta_{\mu e}$ is at $|\Delta m^2_{41}| = 1.2$ eV$^2$.

[11] ADAMSON 16C use the NuMI beam and exposure of $10.56 \times 10^{20}$ protons on target to search for the oscillation of $\nu_\mu$ dominated beam into light sterile neutrinos with detectors at 1.04 and 735 km. The reported limit $\sin^2(\theta_{24}) < 0.022$ at 95% C.L. is for $|\Delta m^2_{41}| = 0.5$ eV$^2$. We convert the result to $\sin^2(2\theta_{24})$ for the listing.

[12] AN 16B utilize 621 days of data to place limits on the $\overline{\nu}_e$ disappearance into a light sterile neutrino. The stated limit corresponds to the smallest $\sin^2(2\theta_{14})$ at $|\Delta m^2_{41}| \sim 3 \times 10^{-2}$ eV$^2$ (obtained from Figure 3 in AN 16B). The exclusion curve begins at $|\Delta m^2_{41}| \sim 1.5 \times 10^{-4}$ eV$^2$ and extends to $\sim 0.25$ eV$^2$. The analysis assumes $\sin^2(2\theta_{12})$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

$= 0.846 \pm 0.021$, $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV$^2$, and $|\Delta m^2_{32}| = (2.44 \pm 0.06) \times 10^{-3}$ eV$^2$.

[13] AMBROSIO 01 tested the pure 2-flavor $\nu_\mu \to \nu_s$ hypothesis using matter effects which change the shape of the zenith-angle distribution of upward through-going muons. With maximum mixing and $\Delta m^2$around 0.0024 eV$^2$, the $\nu_\mu \to \nu_s$ oscillation isdisfavored with 99% confidence level with respect to the $\nu_\mu \to \nu_\tau$ hypothesis.

[14] FUKUDA 00 tested the pure 2-flavor $\nu_\mu \to \nu_s$ hypothesis using three complementary atmospheric-neutrino data samples. With this hypothesis, zenith-angle distributions are expected to show characteristic behavior due to neutral currents and matter effects. In the $\Delta m^2$ and $\sin^2 2\theta$region preferred by the Super-Kamiokande data, the $\nu_\mu \to \nu_s$ hypothesis isrejected at the 99% confidence level, while the $\nu_\mu \to \nu_\tau$hypothesis consistently fits all of the data sample.

# Heavy Neutral Leptons, Searches for

OMITTED FROM SUMMARY TABLE

We define searches for Heavy Neutral Leptons (HNLs) as searches for Dirac or Majorana fermions with sterile neutrino quantum numbers, that are heavy enough to not disrupt the simplest Big Bang Nucleosynthesis bounds and/or unstable on cosmological timescales: Typically HNLs have mass $\sim$ MeV or higher.

Searches for these particles generically set bounds on the mixing between the HNL and the active neutrinos, as parametrized by the extended 3×4 PMNS matrix elements $U_{\ell x}$ (see the "Neutrino mass, mixing and oscillations" review) where $\ell = e$, $\mu$ or $\tau$, and we denote the HNL as $\nu_x$. While many measurements may be interpreted to place bounds on various combinations of these matrix elements, we quote below limits only for those cases in which one matrix element is assumed to be much larger than the other two, i.e. $|U_{\ell x}| \gg |U_{\ell' x}|$ for $\ell' \neq \ell$.

Experimental searches make use of various different strategies, including e.g. resonance searches in missing mass decay distributions or specific final states, searches for lepton number violating decays, and trilepton signatures. The resulting bounds on $U_{\ell x}$ are typically dependent on the HNL mass. The quoted limits below are either the best limit near an experimental kinematic threshold, or a characteristic value in the mass range of the experimental sensitivity.

### Limits on heavy neutral lepton mixing parameters

#### Limits on $|U_{ex}|^2$

Quoted limits are either the best limit near the kinematic threshold of the experiment, or a characteristic value in the mass range of the experimental sensitivity

Quark Masses

## $u$

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass $m = 2.16^{+0.49}_{-0.26}$ MeV  Charge $= \frac{2}{3}\ e$  $I_z = +\frac{1}{2}$

$m_u/m_d = 0.47^{+0.06}_{-0.07}$

## $d$

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass $m = 4.67^{+0.48}_{-0.17}$ MeV  Charge $= -\frac{1}{3}\ e$  $I_z = -\frac{1}{2}$

$m_s/m_d = 17$–$22$

$\overline{m} = (m_u + m_d)/2 = 3.45^{+0.55}_{-0.15}$ MeV

## $s$

$I(J^P) = 0(\frac{1}{2}^+)$

Mass $m = 93^{+11}_{-5}$ MeV  Charge $= -\frac{1}{3}\ e$  Strangeness $= -1$

$(m_s - (m_u + m_d)/2)/(m_d - m_u) = 27.3^{+0.7}_{-1.3}$

# Light Quarks ($u$, $d$, $s$)

OMITTED FROM SUMMARY TABLE

### $u$-QUARK MASS

The $u$-, $d$-, and $s$-quark masses are estimates of so-called "current-quark masses," in a mass- independent subtraction scheme such as $\overline{\text{MS}}$. The ratios $m_u/m_d$ and $m_s/m_d$ are extracted from pion and kaon masses using chiral symmetry. The estimates of $d$ and $u$ masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the $u$ quark could be essentially massless. The $s$-quark mass is estimated from SU(3) splittings in hadron masses.

We have normalized the $\overline{\text{MS}}$ masses at a renormalization scale of $\mu = 2$ GeV. Results quoted in the literature at $\mu = 1$ GeV have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 1 and 2.

[1] DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.

[2] BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.

[3] FODOR 16 is a lattice simulation with $N_f = 2 + 1$ dynamical flavors and includes partially quenched QED effects.

[4] CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The $u$ and $d$ quark masses are obtained separately by using the $K$ meson mass splittings and lattice results for the electromagnetic contributions.

[5] AOKI 12 is a lattice computation using $1 + 1 + 1$ dynamical quark flavors.

[6] BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.

[7] DAVIES 10 and MCNEILE 10 determine $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $N_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass $m_u$ is obtained from this using the value of $m_c$ from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratios, $m_s/\overline{m}$ and $m_u/m_d$.

[8] DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed. The individual $m_u$, $m_d$ values are obtained using the lattice determination of the average mass $m_{ud}$ and of the ratio $m_s/m_{ud}$ and the value of $Q = (m_s^2 - m_{ud}^2)\ /\ (m_d^2 - m_u^2)$ as determined from $\eta \to 3\pi$ decays.

[9] BAZAVOV 10 is a lattice computation using 2+1 dynamical quark flavors.

[10] DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order $\alpha_s^4$.

[11] DEANDREA 08 determine $m_u - m_d$ from $\eta \to 3\pi^0$, and combine with the PDG 06 lattice average value of $m_u + m_d = 7.6 \pm 1.6$ to determine $m_u$ and $m_d$.

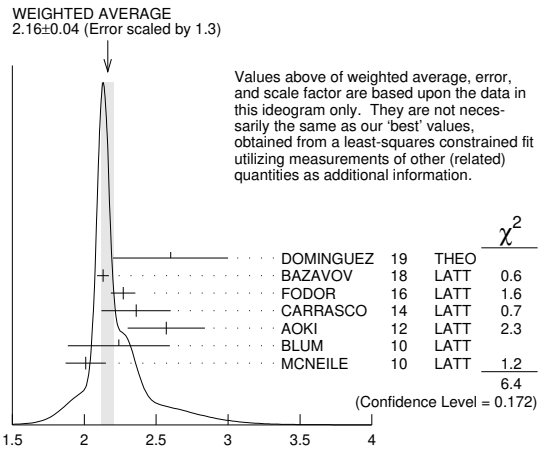
[12] BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

[13] JAMIN 06 determine $m_u$(2 GeV) by combining the value of $m_s$ obtained from the spectral function for the scalar $K\pi$ form factor with other determinations of the quark mass ratios.

[14] MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate $u$ and $d$ quarks. Perturbative corrections were included at NNLO order. The quark masses $m_u$ and $m_d$ were determined from their $(m_u + m_d)/2$ measurement and AUBIN 04A $m_u/m_d$ value.

[15] NARISON 06 uses sum rules for $e^+e^- \to$ hadrons to order $\alpha_s^3$ to determine $m_s$ combined with other determinations of the quark mass ratios.

[16] AUBIN 04A employ a partially quenched lattice calculation of the pseudoscalar meson masses.



### $d$-QUARK MASS

See the comment for the $u$ quark above.

We have normalized the $\overline{\text{MS}}$ masses at a renormalization scale of $\mu = 2$ GeV. Results quoted in the literature at $\mu = 1$ GeV have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 1 and 2.

## Light Quarks ($u$, $d$, $s$)

[1] DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.

[2] BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.

[3] FODOR 16 is a lattice simulation with $N_f = 2 + 1$ dynamical flavors and includes partially quenched QED effects.

[4] CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The $u$ and $d$ quark masses are obtained separately by using the $K$ meson mass splittings and lattice results for the electromagnetic contributions.

[5] AOKI 12 is a lattice computation using $1 + 1 + 1$ dynamical quark flavors.

[6] BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.

[7] DAVIES 10 and MCNEILE 10 determine $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $N_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass $m_d$ is obtained from this using the value of $m_c$ from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratios, $m_s/\overline{m}$ and $m_u/m_d$.

[8] DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed. The individual $m_u$, $m_d$ values are obtained using the lattice determination of the average mass $m_{ud}$ and of the ratio $m_s/m_{ud}$ and the value of $Q = (m_s^2 - m_{ud}^2) / (m_d^2 - m_u^2)$ as determined from $\eta \to 3\pi$ decays.

[9] BAZAVOV 10 is a lattice computation using 2+1 dynamical quark flavors.

[10] DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order $\alpha_s^4$.

[11] DEANDREA 08 determine $m_u - m_d$ from $\eta \to 3\pi^0$, and combine with the PDG 06 lattice average value of $m_u + m_d = 7.6 \pm 1.6$ to determine $m_u$ and $m_d$.

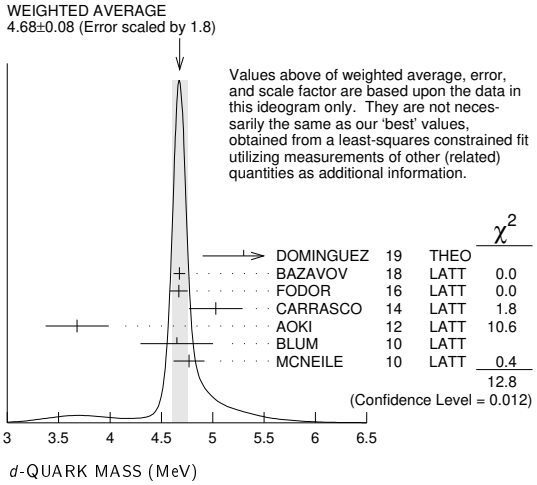
[12] BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

[13] JAMIN 06 determine $m_d$(2 GeV) by combining the value of $m_s$ obtained from the spectral function for the scalar $K\pi$ form factor with other determinations of the quark mass ratios.

[14] MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate $u$ and $d$ quarks. Perturbative corrections were included at NNLO order. The quark masses $m_u$ and $m_d$ were determined from their $(m_u + m_d)/2$ measurement and AUBIN 04A $m_u/m_d$ value.

[15] NARISON 06 uses sum rules for $e^+e^- \to$ hadrons to order $\alpha_s^3$ to determine $m_s$ combined with other determinations of the quark mass ratios.

[16] AUBIN 04A perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with continuum estimate of electromagnetic effects in the kaon masses, and one-loop perturbative renormalization constant.



## $\overline{m} = (m_u + m_d)/2$

See the comments for the $u$ quark above.

We have normalized the $\overline{\text{MS}}$ masses at a renormalization scale of $\mu = 2$ GeV. Results quoted in the literature at $\mu = 1$ GeV have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 1 and 2.

[1] DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.

[2] YUAN 17 determine $\overline{m}$ using QCD sum rules in the isospin $I=0$ scalar channel. At the end of the "Numerical Results" section of YUAN 17 the authors discuss the significance of their larger value of the light quark mass compared to previous determinations.

[3] CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The $u$ and $d$ quark masses are obtained separately by using the $K$ meson mass splittings and lattice results for the electromagnetic contributions.

[4] ARTHUR 13 is a lattice computation using 2+1 dynamical domain wall fermions. Masses at $\mu = 3$ GeV have been converted to $\mu = 2$ GeV using conversion factors given in their paper.

[5] DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.

[6] BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f$=2 dynamical twisted-mass Wilson fermions.

[7] DAVIES 10 and MCNEILE 10 determine $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $N_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass $\overline{m}$ is obtained from this using the value of $m_c$ from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratio, $m_s/\overline{m}$.

[8] AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using $N_f = 2 + 1$ dynamical flavors of domain wall fermions.

[9] DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order $\alpha_s^4$.

[10] ALLTON 08 use a lattice computation of the $\pi$, $K$, and $\Omega$ masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.

[11] BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.

[12] DOMINGUEZ-CLARIMON 08B obtain an inequality from sum rules for the scalar two-point correlator.

[13] ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of $\mathcal{O}(a)$ improved Wilson quarks, and one-loop perturbative renormalization.

[14] NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.

[15] BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

[16] GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization, to obtain $\overline{m}(2\text{ GeV}) = 4.08 \pm 0.25 \pm 0.19 \pm 0.23$ MeV, where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.

[17] GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[18] MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate $u$ and $d$ quarks. Perturbative corrections were included at NNLO order.

[19] NARISON 06 uses sum rules for $e^+e^- \to$ hadrons to order $\alpha_s^3$ to determine $m_s$ combined with other determinations of the quark mass ratios.

[20] AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.

[21] AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory.

[22] The errors given in AOKI 03B were $^{+0.046}_{-0.069}$. We changed them to $\pm 0.3$ for calculating the overall best values. AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the $\mathcal{O}(a)$ improved Wilson action.

[23] BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses $\mathcal{O}(a)$ improved Wilson action and nonperturbative renormalization.

[24] CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.

[1] FODOR 16 is a lattice simulation with $N_f = 2 + 1$ dynamical flavors and includes partially quenched QED effects.

[2] BASAK 15 is a lattice computation using 2+1 dynamical quark flavors.

[3] CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The $u$ and $d$ quark masses are obtained separately by using the $K$ meson mass splittings and lattice results for the electromagnetic contributions.

[4] AOKI 12 is a lattice computation using $1 + 1 + 1$ dynamical quark flavors.

[5] BAZAVOV 10 is a lattice computation using 2+1 dynamical quark flavors.

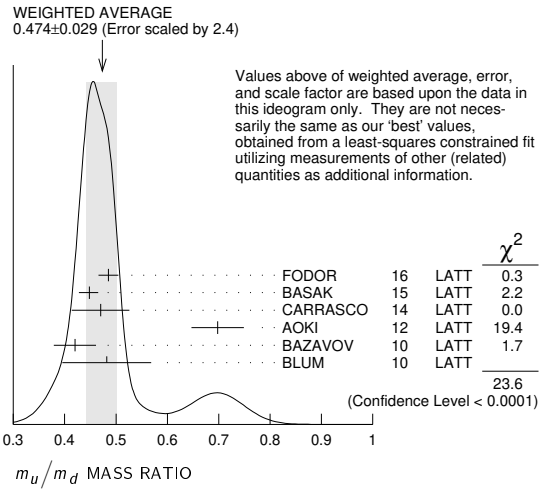
[6] BLUM 10 is a lattice computation using 2+1 dynamical quark flavors.

[7] BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

[8] AUBIN 04A perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with continuum estimate of electromagnetic effects in the kaon masses.

[9] NELSON 03 computes coefficients in the order $p^4$ chiral Lagrangian using a lattice calculation with three dynamical flavors. The ratio $m_u/m_d$ is obtained by combining this with the chiral perturbation theory computation of the meson masses to order $p^4$.

[10] LEUTWYLER 96 uses a combined fit to $\eta \to 3\pi$ and $\psi' \to J/\psi\,(\pi,\eta)$ decay rates, and the electromagnetic mass differences of the $\pi$ and $K$.



## $s$-QUARK MASS

See the comment for the $u$ quark above.

We have normalized the $\overline{\text{MS}}$ masses at a renormalization scale of $\mu = 2$ GeV. Results quoted in the literature at $\mu = 1$ GeV have been rescaled by dividing by 1.35.

[1] BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.

[2] LYTLE 18 combined with CHAKRABORTY 2015 determine $\overline{m}_s(3\text{ GeV}) = 84.78 \pm 0.65$ MeV from a lattice simulation with $n_f = 2+1+1$ flavors. They also determine the quoted value $\overline{m}_s(2\text{ GeV})$ for $n_f = 4$ dynamical flavors.

[3] ANANTHANARAYAN 16 determine $\overline{m}_s(2\text{ GeV}) = 106.70 \pm 9.36$ MeV and $74.47 \pm 7.77$ MeV from fits to ALEPH and OPAL $\tau$ decay data, respectively. We have used the weighted average of the two.

[4] CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The $u$ and $d$ quark masses are obtained separately by using the $K$ meson mass splittings and lattice results for the electromagnetic contributions.

[5] ARTHUR 13 is a lattice computation using 2+1 dynamical domain wall fermions. Masses at $\mu = 3$ GeV have been converted to $\mu = 2$ GeV using conversion factors given in their paper.

[6] BODENSTEIN 13 determines $m_s$ from QCD finite energy sum rules, and the perturbative computation of the pseudoscalar correlator to five-loop order.

[7] FRITZSCH 12 determine $m_s$ using a lattice computation with $N_f = 2$ dynamical flavors.

[8] DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.

[9] CHAKRABORTY 15 is a lattice QCD computation that determines $m_c$ and $m_c/m_s$ using pseudoscalar mesons masses tuned on gluon field configurations with 2+1+1 dynamical flavors of HISQ quarks with $u/d$ masses down to the physical value.

[10] AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using $N_f = 2 + 1$ dynamical flavors of domain wall fermions.

[11] BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f$=2 dynamical twisted-mass Wilson fermions.

[12] BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.

[13] DAVIES 10 and MCNEILE 10 determine $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $N_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass $m_s$ is obtained from this using the value of $m_c$ from ALLISON 08 or MCNEILE 10.

[14] ALLTON 08 use a lattice computation of the $\pi$, $K$, and $\Omega$ masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.

[15] BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.

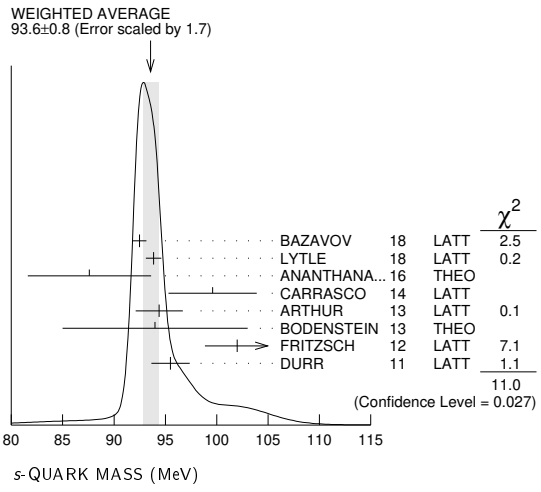
[16] DOMINGUEZ 08A make determination from QCD finite energy sum rules for the pseudoscalar two-point function computed to order $\alpha_s^4$.

[17] ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of $\mathcal{O}(a)$ improved Wilson quarks, and one-loop perturbative renormalization.

[18] NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[19] BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
[20] CHETYRKIN 06 use QCD sum rules in the pseudoscalar channel to order $\alpha_s^4$.
[21] GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization, to obtain $\overline{m}_s(2\text{ GeV}) = 111 \pm 6 \pm 4 \pm 6$ MeV, where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
[22] GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization.
[23] JAMIN 06 determine $\overline{m}_s(2\text{ GeV})$ from the spectral function for the scalar $K\pi$ form factor.
[24] MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate $u$ and $d$ quarks. Perturbative corrections were included at NNLO order.
[25] NARISON 06 uses sum rules for $e^+e^- \to$ hadrons to order $\alpha_s^3$.
[26] NARISON 06 obtains the quoted range from positivity of the spectral functions.
[27] BAIKOV 05 determines $\overline{m}_s(M_\tau) = 100^{+5}_{-3}{}^{+17}_{-19}$ from sum rules using the strange spectral function in $\tau$ decay. The computations were done to order $\alpha_s^3$, with an estimate of the $\alpha_s^4$ terms. We have converted the result to $\mu = 2$ GeV.
[28] GAMIZ 05 determines $\overline{m}_s(2\text{ GeV})$ from sum rules using the strange spectral function in $\tau$ decay. The computations were done to order $\alpha_s^2$, with an estimate of the $\alpha_s^3$ terms.
[29] GORBUNOV 05 use hadronic tau decays to N3LO, including power corrections.
[30] NARISON 05 determines $\overline{m}_s(2\text{ GeV})$ from sum rules using the strange spectral function in $\tau$ decay. The computations were done to order $\alpha_s^3$.
[31] AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
[32] AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory. Determines $m_s$=113.8 $\pm$ 2.3 $^{+5.8}_{-2.9}$ using $K$ mass as input and $m_s$=142.3 $\pm$ 5.8 $^{+22}_{-0}$ using $\phi$ mass as input. We have performed a weighted average of these values.
[33] AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the $\mathcal{O}(a)$ improved Wilson action.
[34] BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses $\mathcal{O}(a)$ improved Wilson action and nonperturbative renormalization. They also quote $\overline{m}/m_s$=24.3 $\pm$ 0.2 $\pm$ 0.6.
[35] CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.
[36] GAMIZ 03 determines $m_s$ from SU(3) breaking in the $\tau$ hadronic width. The value of $V_{us}$ is chosen to satisfy CKM unitarity.
[37] GAMIZ 03 determines $m_s$ from SU(3) breaking in the $\tau$ hadronic width. The value of $V_{us}$ is taken from the PDG.



## OTHER LIGHT QUARK MASS RATIOS

### $m_s/m_d$ MASS RATIO

## $c$-QUARK MASS

The $c$-quark mass corresponds to the "running" mass $m_c$ ($\mu = m_c$) in the $\overline{\text{MS}}$ scheme. We have converted masses in other schemes to the $\overline{\text{MS}}$ scheme using two-loop QCD perturbation theory with $\alpha_s(\mu{=}m_c) = 0.38 \pm 0.03$. The value $1.27 \pm 0.02$ GeV for the $\overline{\text{MS}}$ mass corresponds to $1.67 \pm 0.07$ GeV for the pole mass (see the "Note on Quark Masses").

[1] NARISON 20 determines the quark mass using QCD Laplace sum rules from the $B_c$ mass, combined with previous determinations of the QCD condensates and $c$ and $b$ masses.

[2] ABRAMOWICZ 18 determine $\overline{m}_c(\overline{m}_c) = 1.290^{+0.046}_{-0.041}{}^{+0.062}_{-0.014}{}^{+0.003}_{-0.031}$ from the production of $c$ quarks in $ep$ collisions at HERA using combined H1 and ZEUS data. The experimental/fitting errors, and those from modeling and parameterization have been combined in quadrature.

[3] BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.

[4] LYTLE 18 combined with CHAKRABORTY 15 determine $\overline{m}_c(3\text{ GeV}) = 0.9874(48)$ GeV from a lattice simulation with $n_f = 2{+}1{+}1$ flavors. They also determine the quoted value $\overline{m}_c(\overline{m}_c)$ for $n_f = 4$ dynamical flavors.

[5] PESET 18 determine $\overline{m}_c(\overline{m}_c)$ and $\overline{m}_b(\overline{m}_b)$ using an N3LO calculation of the $\eta_c$, $\eta_b$ and $B_c$ masses.

[6] CHETYRKIN 17 determine $\overline{m}_c(\mu = 3\text{ GeV}) = 0.993 \pm 0.008$ GeV and $\overline{m}_c(\overline{m}_c)$ from a four-loop sum-rule computation of the cross-section for $e^+e^- \to$ hadrons in the charm threshold region.

[7] ERLER 17 determine $\overline{m}_c(\overline{m}_c) = 1.272 \pm 0.008$ GeV from a three-loop QCD sum-rule computation of the vector current correlator. This result is for fixed $\alpha_s(M_Z) = 0.1182$. Including an $\alpha_s$ uncertainty of $\pm 0.0016$, the charm mass error increases from 8 to 9 MeV.

[8] KIYO 16 determine $\overline{m}_c(\overline{m}_c)$ from the $J/\psi(1S)$ mass at order $\alpha_s^3$ (N3LO).

[9] DEHNADI 15 determine $\overline{m}_c(\overline{m}_c)$ using sum rules for $e^+e^- \to$ hadrons at order $\alpha_s^3$ (N3LO), and fitting to both experimental data and lattice results.

[10] CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The $u$ and $d$ quark masses are obtained separately by using the $K$ meson mass splittings and lattice results for the electromagnetic contributions.

[11] ALEKHIN 13 determines $m_c$ from charm production in deep inelastic scattering at HERA using approximate NNLO QCD.

[12] SAMOYLOV 13 determines $m_c$ from a study of charm dimuon production in neutrino-iron scattering using the NLO QCD result for the charm quark production cross section.

[13] BODENSTEIN 11 determine $\overline{m}_c(3\text{ GeV}) = 0.987 \pm 0.009$ GeV and $\overline{m}_c(\overline{m}_c) = 1.278 \pm 0.009$ GeV using QCD sum rules for the charm quark vector current correlator.

[14] LASCHKA 11 determine the $c$ mass from the charmonium spectrum. The theoretical computation uses the heavy $Q\overline{Q}$ potential to order $1/m_Q$ obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.

[15] AUBERT 10A determine the $b$- and $c$-quark masses from a fit to the inclusive decay spectra in semileptonic $B$ decays in the kinetic scheme (and convert it to the $\overline{\text{MS}}$ scheme).

[16] SIGNER 09 determines the $c$-quark mass using non-relativistic sum rules to analyze the $e^+e^- \to c\overline{c}$ cross-section near threshold. Also determine the PS mass $m_{PS}(\mu_F = 0.7\text{ GeV}) = 1.50 \pm 0.04$ GeV.

[17] NARISON 18A determines simultaneously $\overline{m}_c(\overline{m}_c)$ and the 4-dimension gluon condensate using QCD exponential sum rules and their ratios evaluated at the optimal scale $\mu = 2.85$ GeV at N2LO-N3LO of perturbative QCD and including condensates up to dimension 6–8 in the (axial-)vector and (pseudo-)scalar charmonium channels.

[18] NARISON 18B determines $\overline{m}_c(\overline{m}_c)$ using QCD vector moment sum rules and their ratios at N2LO-N3LO of perturbative QCD and including condensates up to dimension 8.

[19] BERTONE 16 determine $\overline{m}_c(\overline{m}_c)$ from HERA deep inelastic scattering data using the FONLL scheme. Also determine $\overline{m}_c(\overline{m}_c) = 1.318 \pm 0.054^{+0.490}_{-0.022}$ using the fixed flavor number scheme.

[20] CHAKRABORTY 15 is a lattice QCD computation using $2{+}1{+}1$ dynamical flavors. Moments of pseudoscalar current-current correlators are matched to $\alpha_s^3$-accurate QCD perturbation theory with the $\eta_c$ meson mass tuned to experiment.

[21] ABRAMOWICZ 13C determines $m_c$ from charm production in deep inelastic $ep$ scattering, using the QCD prediction at NLO order. The uncertainties from model and parameterization assumptions, and the value of $\alpha_s$, of $\pm 0.03$, $\pm 0.02$, and $\pm 0.02$ respectively, have been combined in quadrature.

[22] DEHNADI 13 determines $m_c$ using QCD sum rules for the charmonium spectrum and charm continuum to order $\alpha_s^3$ (N3LO). The statistical and systematic experimental errors of $\pm 0.006$ and $\pm 0.009$ have been combined in quadrature. The theoretical uncertainties $\pm 0.019$ from truncation of the perturbation series, $\pm 0.010$ from $\alpha_s$, and $\pm 0.002$ from the gluon condensate have been combined in quadrature.

[23] NARISON 13 determines $m_c$ using QCD spectral sum rules to order $\alpha_s^2$ (NNLO) and including condensates up to dimension 6.

[24] ALEKHIN 12 determines $m_c$ from heavy quark production in deep inelastic scattering at HERA using approximate NNLO QCD.

[25] NARISON 12A determines $m_c$ using sum rules for the vector current correlator to order $\alpha_s^3$, including the effect of gluon condensates up to dimension eight.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[26] ALEKHIN 11 determines $m_c$ from heavy quark production in deep inelastic scattering using fixed target and HERA data, and approximate NNLO QCD.
[27] BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f$=2 dynamical twisted-mass Wilson fermions.
[28] BODENSTEIN 10 determines $\overline{m}_c(3\ \text{GeV}) = 1.008 \pm 0.026$ GeV using finite energy sum rules for the vector current correlator. The authors have converted this to $\overline{m}_c(\overline{m}_c)$ using $\alpha_s(M_Z) = 0.1189 \pm 0.0020$.
[29] MCNEILE 10 determines $m_c$ by comparing the order $\alpha_s^3$ perturbative results for the pseudo-scalar current to lattice simulations with $N_f = 2{+}1$ sea-quarks by the HPQCD collaboration.
[30] NARISON 10 determines $m_c$ from ratios of moments of vector current correlators computed to order $\alpha_s^3$ and including the dimension-six gluon condensate.
[31] CHETYRKIN 09 determine $m_c$ and $m_b$ from the $e^+e^- \to Q\overline{Q}$ cross-section and sum rules, using an order $\alpha_s^3$ computation of the heavy quark vacuum polarization. They also determine $m_c(3\ \text{GeV}) = 0.986 \pm 0.013$GeV.
[32] ALLISON 08 determine $m_c$ by comparing four-loop perturbative results for the pseudo-scalar current correlator to lattice simulations by the HPQCD collaboration. The result has been updated in MCNEILE 10.
[33] KUHN 07 determine $\overline{m}_c(\mu = 3\ \text{GeV}) = 0.986 \pm 0.013$ GeV and $\overline{m}_c(\overline{m}_c)$ from a four-loop sum-rule computation of the cross-section for $e^+e^- \to$ hadrons in the charm threshold region.
[34] BOUGHEZAL 06 result comes from the first moment of the hadronic production cross-section to order $\alpha_s^3$.
[35] BUCHMUELLER 06 determine $m_b$ and $m_c$ by a global fit to inclusive $B$ decay spectra.
[36] HOANG 06 determines $\overline{m}_c(\overline{m}_c)$ from a global fit to inclusive $B$ decay data. The $B$ decay distributions were computed to order $\alpha_s^2\beta_0$, and the conversion between different $m_c$ mass schemes to order $\alpha_s^3$.
[37] AUBERT 04X obtain $m_c$ from a fit to the hadron mass and lepton energy distributions in semileptonic $B$ decay. The paper quotes values in the kinetic scheme. The $\overline{\text{MS}}$ value has been provided by the BABAR collaboration.
[38] HOANG 04 determines $\overline{m}_c(\overline{m}_c)$ from moments at order $\alpha_s^2$ of the charm production cross-section in $e^+e^-$ annihilation.
[39] DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.
[40] EIDEMULLER 03 determines $m_b$ and $m_c$ using QCD sum rules.
[41] ERLER 03 determines $m_b$ and $m_c$ using QCD sum rules. Includes recent BES data.
[42] ZYABLYUK 03 determines $m_c$ by using QCD sum rules in the pseudoscalar channel and comparing with the $\eta_c$ mass.

[1] BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
[2] CHAKRABORTY 15 is a lattice QCD computation on gluon field configurations with 2+1+1 dynamical flavors of HISQ quarks with u/d masses down to the physical value. $m_c$ and $m_s$ are tuned from pseudoscalar meson masses.
[3] CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The $u$ and $d$ quark masses are obtained separately by using the $K$ meson mass splittings and lattice results for the electromagnetic contributions.
[4] DURR 12 determine $m_c/m_s$ using a lattice computation with $N_f = 2$ dynamical fermions. The result is combined with other determinations of $m_c$ to obtain $m_s(2\ \text{GeV}) = 97.0 \pm 2.6 \pm 2.5$ MeV.
[5] DAVIES 10 determine $m_c/m_s$ from meson masses calculated on gluon fields including $u$, $d$, and $s$ sea quarks with lattice spacing down to 0.045 fm. The Highly Improved Staggered quark formalism is used for the valence quarks.
[6] BAZAVOV 14A is a lattice computation using 4 dynamical flavors of HISQ fermions.
[7] BLOSSIER 10 determine $m_c/m_s$ from a computation of the hadron spectrum using $N_f$ = 2 dynamical twisted-mass Wilson fermions.

## *b*-QUARK MASS

*b*-quark mass corresponds to the "running mass" $\overline{m}_b(\mu = \overline{m}_b)$ in the $\overline{\text{MS}}$ scheme. We have converted masses in other schemes to the $\overline{\text{MS}}$ mass using two-loop QCD perturbation theory with $\alpha_s(\mu = \overline{m}_b) = 0.223 \pm 0.008$. The value $4.18^{+0.04}_{-0.03}$ GeV for the $\overline{\text{MS}}$ mass corresponds to $4.78 \pm 0.06$ GeV for the pole mass, using the two-loop conversion formula. A discussion of masses in different schemes can be found in the "Note on Quark Masses."

[1] NARISON 20 determines the quark mass using QCD Laplace sum rules from the $B_c$ mass, combined with previous determinations of the QCD condensates and $c$ and $b$ masses.

[2] ABRAMOWICZ 18 determine $\overline{m}_b(\overline{m}_b) = 4.049^{+0.104}_{-0.109} {}^{+0.090}_{-0.032} {}^{+0.001}_{-0.031}$ from the production of $b$ quarks in $ep$ collisions at HERA using combined H1 and ZEUS data. The experimental/fitting errors, and those from modeling and parameterization have been combined in quadrature.

[3] BAZAVOV 18 determine the $b$ mass using a lattice computation with staggered fermions and five active quark flavors.

[4] PESET 18 determine $\overline{m}_c(\overline{m}_c)$ and $\overline{m}_b(\overline{m}_b)$ using an N3LO calculation of the $\eta_c$, $\eta_b$ and $B_c$ masses.

[5] KIYO 16 determine $\overline{m}_b(\overline{m}_b)$ from the $\Upsilon(1S)$ mass at order $\alpha_s^3$ (N3LO).

[6] ALBERTI 15 determine $\overline{m}_b(\overline{m}_b)$ from fits to inclusive $B \to X_c e \overline{\nu}$ decay. They also find $m_b^{\text{kin}}(1\text{ GeV}) = 4.553 \pm 0.020$ GeV.

[7] BENEKE 15 determine $\overline{m}_b(\overline{m}_b)$ using sum rules for $e^+e^- \to$ hadrons at order N3LO including finite $m_c$ effects. They find $m_b^{\text{PS}}(2\text{ GeV}) = 4.532^{+0.013}_{-0.039}$ GeV, and $\overline{m}_b(\overline{m}_b) = 4.193^{+0.022}_{-0.035}$ GeV. The value quoted is obtained using the four-loop conversion given in BENEKE 16.

[8] COLQUHOUN 15 determine $\overline{m}_b(\overline{m}_b)$ from moments of the vector current correlator computed with a lattice simulation using the NRQCD action.

[9] DEHNADI 15 determine $\overline{m}_b(\overline{m}_b)$ using sum rules for $e^+e^- \to$ hadrons at order $\alpha_s^3$ (N3LO), and fitting to both experimental data and lattice results.

[10] BERNARDONI 14 determine $m_b$ from $N_f = 2$ lattice calculations using heavy quark effective theory non-perturbatively renormalized and matched to QCD at $1/m$ order.

[11] PENIN 14 determine $\overline{m}_b(\overline{m}_b) = 4.169 \pm 0.008 \pm 0.002 \pm 0.002$ using an estimate of the order $\alpha_s^3$ $b$-quark vacuum polarization function in the threshold region, including finite $m_c$ effects. The errors of $\pm 0.008$ from theoretical uncertainties, and $\pm 0.002$ from $\alpha_s$ have been combined in quadrature.

[12] LEE 13O determines $m_b$ using lattice calculations of the $\Upsilon$ and $B_s$ binding energies in NRQCD, including three light dynamical quark flavors. The quark mass shift in NRQCD is determined to order $\alpha_s^2$, with partial $\alpha_s^3$ contributions.

[13] LUCHA 13 determines $m_b$ from QCD sum rules for heavy-light currents using the lattice value for $f_B$ of 191.5 ± 7.3 GeV.

[14] BODENSTEIN 12 determine $m_b$ using sum rules for the vector current correlator and the $e^+e^- \to Q\overline{Q}$ total cross-section.

[15] DIMOPOULOS 12 determine quark masses from a lattice computation using $N_f = 2$ dynamical flavors of twisted mass fermions.

[16] LASCHKA 11 determine the $b$ mass from the charmonium spectrum. The theoretical computation uses the heavy $Q\overline{Q}$ potential to order $1/m_Q$ obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.

[17] AUBERT 10A determine the $b$- and $c$-quark masses from a fit to the inclusive decay spectra in semileptonic $B$ decays in the kinetic scheme (and convert it to the $\overline{\text{MS}}$ scheme).

[18] CHETYRKIN 09 determine $m_c$ and $m_b$ from the $e^+e^- \to Q\overline{Q}$ cross-section and sum rules, using an order $\alpha_s^3$ (N3LO) computation of the heavy quark vacuum polarization.

[19] SCHWANDA 08 measure moments of the inclusive photon spectrum in $B \to X_s\gamma$ decay to determine $m_b^{1S}$. We have converted this to $\overline{\text{MS}}$ scheme.

[20] NARISON 18A determines $\overline{m}_b(\overline{m}_b)$ as a function of $\alpha_s$ using QCD exponential sum rules and their ratios evaluated at the optimal scale $\mu = 9.5$ GeV at N2LO-N3LO of perturbative QCD and including condensates up to dimension 6–8 in the (axial-)vector and (pseudo-)scalar bottomonium channels.

[21] NARISON 18B determines $\overline{m}_b(\overline{m}_b)$ using QCD vector moment sum rules and their ratios at N2LO-N3LO of perturbative QCD and including condensates up to dimension 8.

[22] ABRAMOWICZ 14A determine $\overline{m}_b(\overline{m}_b) = 4.07 \pm 0.14^{+0.01}_{-0.07} {}^{+0.05}_{-0.00} {}^{+0.08}_{-0.05}$ from the production of $b$ quarks in $ep$ collisions at HERA. The errors due to fitting, modeling, PDF parameterization, and theoretical QCD uncertainties due to the values of $\alpha_s$, $m_c$, and the renormalization scale $\mu$ have been combined in quadrature.

[23] AYALA 14A determine $\overline{m}_b(\overline{m}_b)$ from the $\Upsilon(1S)$ mass computed to N3LO order in perturbation theory using a renormalon subtracted scheme.

[24] NARISON 13 determines $m_b$ using QCD spectral sum rules to order $\alpha_s^2$ (NNLO) and including condensates up to dimension 6.

[25] NARISON 13A determines $m_b$ using HQET sum rules to order $\alpha_s^2$ (NNLO) and the $B$ meson mass and decay constant.

[26] HOANG 12 determine $m_b$ using non-relativistic sum rules for the $\Upsilon$ system at order $\alpha_s^2$ (NNLO) with renormalization group improvement.

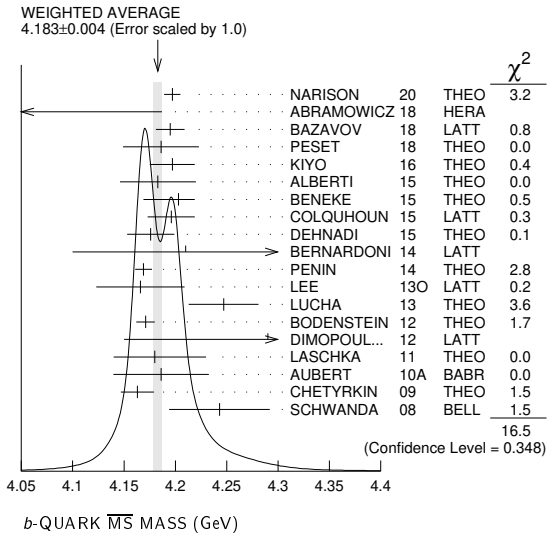
[27] NARISON 12 determines $m_b$ using exponential sum rules for the vector current correlator to order $\alpha_s^3$, including the effect of gluon condensates up to dimension eight.

[28] Determines $m_b$ to order $\alpha_s^3$ (N3LO), including the effect of gluon condensates up to dimension eight combining the methods of NARISON 12 and NARISON 12A.

[29] NARISON 12A determines $m_b$ using sum rules for the vector current correlator to order $\alpha_s^3$, including the effect of gluon condensates up to dimension eight.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[30] MCNEILE 10 determines $m_b$ by comparing order $\alpha_s^3$ (N3LO) perturbative results for the pseudo-scalar current to lattice simulations with $N_f = 2{+}1$ sea-quarks by the HPQCD collaboration.
[31] NARISON 10 determines $m_b$ from ratios of moments of vector current correlators computed to order $\alpha_s^3$ and including the dimension-six gluon condensate. These values are taken from the erratum to that reference.
[32] ABDALLAH 08D determine $\overline{m}_b(M_Z) = 3.76 \pm 1.0$ GeV from a leading order study of four-jet rates at LEP.
[33] GUAZZINI 08 determine $\overline{m}_b(\overline{m}_b)$ from a quenched lattice simulation of heavy meson masses. The $\pm 0.08$ is an estimate of the quenching error.
[34] DELLA-MORTE 07 determine $\overline{m}_b(\overline{m}_b)$ from a computation of the spin-averaged $B$ meson mass using quenched lattice HQET at order $1/m$. The $\pm 0.08$ is an estimate of the quenching error.
[35] KUHN 07 determine $\overline{m}_b(\mu = 10\ \text{GeV}) = 3.609 \pm 0.025$ GeV and $\overline{m}_b(\overline{m}_b)$ from a four-loop sum-rule computation of the cross-section for $e^+e^- \to$ hadrons in the bottom threshold region.
[36] ABDALLAH 06D determine $m_b(M_Z) = 2.85 \pm 0.32$ GeV from $Z$-decay three-jet events containing a $b$-quark.
[37] BOUGHEZAL 06 $\overline{\text{MS}}$ scheme result comes from the first moment of the hadronic production cross-section to order $\alpha_s^3$.
[38] BUCHMUELLER 06 determine $m_b$ and $m_c$ by a global fit to inclusive $B$ decay spectra.
[39] PINEDA 06 $\overline{\text{MS}}$ scheme result comes from a partial NNLL evaluation (complete at order $\alpha_s^2$ (NNLO)) of sum rules of the bottom production cross-section in $e^+e^-$ annihilation.
[40] GRAY 05 determines $\overline{m}_b(\overline{m}_b)$ from a lattice computation of the $\Upsilon$ spectrum. The simulations have $2{+}1$ dynamical light flavors. The $b$ quark is implemented using NRQCD.
[41] AUBERT 04X obtain $m_b$ from a fit to the hadron mass and lepton energy distributions in semileptonic $B$ decay. The paper quotes values in the kinetic scheme. The $\overline{\text{MS}}$ value has been provided by the BABAR collaboration.
[42] BAUER 04 determine $m_b$, $m_c$ and $m_b - m_c$ by a global fit to inclusive $B$ decay spectra.
[43] HOANG 04 determines $\overline{m}_b(\overline{m}_b)$ from moments at order $\alpha_s^2$ of the bottom production cross-section in $e^+e^-$ annihilation.
[44] MCNEILE 04 use lattice QCD with dynamical light quarks and a static heavy quark to compute the masses of heavy-light mesons.
[45] BAUER 03 determine the b quark mass by a global fit to $B$ decay observables. The experimental data includes lepton energy and hadron invariant mass moments in semileptonic $B \to X_c \ell \nu_\ell$ decay, and the inclusive photon spectrum in $B \to X_s \gamma$ decay. The theoretical expressions used are of order $1/m^3$, and $\alpha_s^2 \beta_0$.
[46] BORDES 03 determines $m_b$ using QCD finite energy sum rules to order $\alpha_s^2$.
[47] CORCELLA 03 determines $\overline{m}_b$ using sum rules computed to order $\alpha_s^2$. Includes charm quark mass effects.
[48] DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.
[49] EIDEMULLER 03 determines $\overline{m}_b$ and $\overline{m}_c$ using QCD sum rules.
[50] ERLER 03 determines $\overline{m}_b$ and $\overline{m}_c$ using QCD sum rules. Includes recent BES data.
[51] MAHMOOD 03 determines $m_b^{1S}$ by a fit to the lepton energy moments in $B \to X_c \ell \nu_\ell$ decay. The theoretical expressions used are of order $1/m^3$ and $\alpha_s^2 \beta_0$. We have converted their result to the $\overline{\text{MS}}$ scheme.
[52] BRAMBILLA 02 determine $\overline{m}_b(\overline{m}_b)$ from a computation of the $\Upsilon(1S)$ mass to order $\alpha_s^4$, including finite $m_c$ corrections.
[53] PENIN 02 determines $\overline{m}_b$ from the spectrum of the $\Upsilon$ system.



### $m_b/m_s$ MASS RATIO

| VALUE | DOCUMENT ID | | TECN |
|---|---|---|---|
| **53.94±0.12** | [1] BAZAVOV | 18 | LATT |

[1] BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors for the $u$, $d$, $s$, $c$ quarks and five active flavors for the $b$ quark.

Top Quark

## *t*-QUARK MASS

We first list the direct measurements of the top quark mass which employ the event kinematics and then list the measurements which extract a top quark mass from the measured $t\bar{t}$ cross-section using theory calculations. A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."

For earlier search limits see PDG 96, Physical Review **D54** 1 (1996). We no longer include a compilation of indirect top mass determinations from Standard Model Electroweak fits in the Listings (our last compilation can be found in the Listings of the 2007 partial update). For a discussion of current results see the reviews "The Top Quark" and "Electroweak Model and Constraints on New Physics."

### *t*-Quark Mass (Direct Measurements)

The following measurements extract a $t$-quark mass from the kinematics of $t\bar{t}$ events. They are sensitive to the top quark mass used in the MC generator that is usually interpreted as the pole mass, but the theoretical uncertainty in this interpretation is hard to quantify. See the review "The Top Quark" and references therein for more information.

OUR AVERAGE of 172.76 ± 0.30 GeV is an average of top mass measurements from LHC and Tevatron Runs. The latest Tevatron average, 174.30 ± 0.35 ± 0.54 GeV, was provided by the Tevatron Electroweak Working Group (TEVEWWG).

| VALUE (GeV) | | DOCUMENT ID | | TECN | COMMENT |

[1] AABOUD 19AC is an ATLAS combination of 7 and 8 TeV top-quark mass determination in the dilepton, lepton + jets, and all jets channels.

[2] SIRUNYAN 19AP based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. A combined measurement using the lepton+jets and all-jets channels through a single likelihood function. See SIRUNYAN 18DE and SIRUNYAN 19AP below.

[3] SIRUNYAN 19AR based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. Obtained from a simultaneous fit of the cross section and the top quark mass in the POWHEG simulation. The cross section is used also to extract the $\overline{\text{MS}}$ mass and the strong coupling constant for different PDF sets.

[4] SIRUNYAN 17L based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. $m_t$ is reconstructed from a fit to the invariant mass distribution of $\mu\nu b$, where $p_T^{miss}$ and $W$ mass constraint are used to reconstruct $\nu$ momentum. The number of events for various contributions, except for the $t$-channel single top one, are fixed to the values extracted from simulation.

[5] KHACHATRYAN 16AK based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Combination of the three top mass measurements in KHACHATRYAN 16AK and with the CMS results at $\sqrt{s} = 7$ TeV.

[6] TEVEWWG 16 is the latest Tevatron average (July 2016) provided by the Tevatron Electroweak Working Group. It takes correlated uncertainties into account and has a $\chi^2$ of 10.8 for 11 degrees of freedom.

[7] AABOUD 19AC based on 20.2 fb$^{-1}$ in $pp$ collisions at $\sqrt{s} = 8$ TeV. Uses optimized event selection to suppress less-well-reconstructed events and template fits to determine $m_t$ together with a global jet energy scale factor and a relative $b$-to-light-jet energy scale factor.

[8] SIRUNYAN 19AP based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. A kinematical fit is applied to each event assuming the signal event topology. $m_t$ is determined simultaneously with a jet energy scale factor (JSF). The second error represents stat.+JSF. Modeling uncertainties are larger than in the measurements at $\sqrt{s} = 7$ and 8 TeV because of the use of new alternative color reconnection models.

[9] SIRUNYAN 18DE based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. $m_t$ is determined simultaneously with an overall jet energy scale factor constrained by the mass of the hadronically decayed $W$. Compared to the Run 1 analysis a more advanced treatment of modeling uncertainties are employed, in particular concerning color-reconnection models.

[10] AABOUD 17AH based on 20.2 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Uses template fits to the ratio of the masses of three-jets (from $t$ candidate) and dijets (from $W$ candidate), to suppress jet energy scale uncertainty. Large QCD background is modelled using a data-driven method.

[11] ABAZOV 17B is a combination of measurements of the top quark mass by D0 in the lepton+jets and dilepton channels, using all data collected in Run I (1992–1996) at $\sqrt{s}$ = 1.8 TeV and Run II (2001–2011) at $\sqrt{s} = 1.96$ TeV of the Tevatron, corresponding to integrated luminosities of 0.1 fb$^{-1}$ and 9.7 fb$^{-1}$, respectively.

[12] SIRUNYAN 17N based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. The fully hadronic decay of a highly-boosted $t$ is reconstructed in the $\ell$+jets channel and unfolded at the particle level. The sensitivity of the peak position of the $m_{jet}$ distribution is used to test quality of the modelling by the simulation.

[13] SIRUNYAN 17O based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Analysis is based on the kinematical observables $M(b\ell)$, $M_{T2}$ and $M(b\ell\nu)$. A fit is performed to determine $m_t$ and an overall jet energy scale factor simultaneously.

[14] AABOUD 16T based on 20.2 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. The analysis is refined using the $p_T$ and invariant mass distributions of $\ell$+$b$-jet system. A combination with measurements from $\sqrt{s} = 7$ TeV data in the dilepton and lepton+jets channels gives $172.84 \pm 0.34 \pm 0.61$ GeV.

[15] AABOUD 16T is an ATLAS combination of 8 TeV top-quark mass in the dilepton channel with previous measurements from $\sqrt{s} = 7$ TeV data in the dilepton and lepton + jets channels.

[16] ABAZOV 16 based on 9.7 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. Employs improved fit to minimize statistical errors and improved jet energy calibration, using lepton + jets mode, which reduces error of jet energy scale. Based on previous determination in ABAZOV 12AB with increased integrated luminosity and improved fit and calibrations.

[17] ABAZOV 16D based on 9.7 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV, using the matrix element technique. Based on previous determination in ABAZOV 11R with increased integrated luminosity. There is a strong correlation with the determination in ABAZOV 16. (See ABAZOV 17B.)

[18] KHACHATRYAN 16AK based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Combination of the three top mass measurements in KHACHATRYAN 16AK and with the CMS results at $\sqrt{s} = 7$ TeV gives $172.44 \pm 0.13 \pm 0.47$ GeV.

[19] The top mass and jet energy scale factor are determined by a fit.

[20] Uses the analytical matrix weighting technique method.

[21] KHACHATRYAN 16AL based on 19.7 fb$^{-1}$ in $pp$ collisions at $\sqrt{s} = 8$ TeV. Determined from the invariant mass distribution of leptons and reconstructed secondary vertices from $b$ decays using only charged particles. The uncertainty is dominated by modeling of $b$ fragmentation and top $p_T$ distribution.

[22] KHACHATRYAN 16CB based on 666 candidate reconstructed events corresponding to 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. The measurement exploits correlation of $m_t$ with M($J/\psi\ell$) in the same top quark decay, using a high-purity event sample. A study on modeling of $b$-quark fragmentation is given in Sec. 3.3.

[23] AAD 15AW based on 4.6 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. Uses template fits to the ratio of the masses of three-jets (from $t$ candidate) and dijets (from $W$ candidate). Large background from multijet production is modeled with data-driven methods.

[24] AAD 15BF based on 4.6 fb$^{-1}$ in $pp$ collisions at $\sqrt{s} = 7$ TeV. Using a three-dimensional template likelihood technique the lepton plus jets ($\geq 1b$-tagged) channel gives $172.33 \pm 0.75 \pm 1.02$ GeV, while exploiting a one dimensional template method using $m_{\ell b}$ the dilepton channel (1 or 2$b$-tags) gives $173.79 \pm 0.54 \pm 1.30$ GeV. The results are combined.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[25] AALTONEN 15D based on 9.1 fb$^{-1}$ of $p\overline{p}$ data at $\sqrt{s}$ = 1.96 TeV. Uses a template technique to fit a distribution of a variable defined by a linear combination of variables sensitive and insensitive to jet energy scale to optimize reduction of systematic errors. $b$-tagged and non-$b$-tagged events are separately analyzed and combined.

[26] Based on 9.3 fb$^{-1}$ of $p\overline{p}$ data at $\sqrt{s}$ = 1.96 TeV. Multivariate algorithm is used to discriminate signal from backgrounds, and templates are used to measure $m_t$.

[27] Based on 9.7 fb$^{-1}$ of $p\overline{p}$ data at $\sqrt{s}$ = 1.96 TeV. A matrix element method is used to calculate the probability of an event to be signal or background, and the overall jet energy scale is constrained *in situ* by $m_W$. See ABAZOV 15G for further details.

[28] Based on 3.54 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. The mass is reconstructed for each event employing a kinematic fit of the jets to a ttbar hypothesis. The combination with the pervious CMS measurements in the dilepton and the lepton+jets channels gives 173.54 ± 0.33 ± 0.96 GeV.

[29] Based on 8.7 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Events with an identified charged lepton or small $\not\!\!E_T$ are rejected from the event sample, so that the measurement is statistically independent from those in the $\ell$ + jets and all hadronic channels while being sensitive to those events with a $\tau$ lepton in the final state.

[30] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 13S studied events with di-lepton + $\not\!\!E_T$ + ≥ 2 $b$-jets, and looked for kinematical endpoints of MT2, MT2$_T$, and subsystem variables.

[31] AAD 12I based on 1.04 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. Uses 2d-template analysis (MT) with $m_t$ and jet energy scale factor (JSF) from $m_W$ mass fit.

[32] Based on 8.7 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV. The JES is calibrated by using the dijet mass from the $W$ boson decay.

[33] Use the ME method based on 2.2 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV.

[34] Combination based on up to 5.8 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV.

[35] Based on 5.8 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV the quoted value is $m_t$ = 172.5 ± 1.4(stat)±1.0(JES)±1.1(syst) GeV. The measurement is performed with a liklihood fit technique which simultaneously determines $m_t$ and JES (Jet Energy Scale).

[36] Based on 4.3 fb$^{-1}$ of data in p-pbar collisions at 1.96 TeV. The measurement reduces the JES uncertainty by using the single lepton channel study of ABAZOV 11P.

[37] Combination with the result in 1 fb$^{-1}$ of preceding data reported in ABAZOV 09AH as well as the MWT result of ABAZOV 11R with a statistical correlation of 60%.

[38] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. Uses an analytical matrix weighting technique (AMWT) and full kinematic analysis (KIN).

[39] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. The first error is statistical and JES combined, and the second is systematic. Ideogram method is used to obtain 2D liklihood for the kinematical fit with two parameters mtop and JES.

[40] Based on 3.2 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The first error is from statistics and JES combined, and the latter is from the other systematic uncertainties. The result is obtained using an unbinned maximum likelihood method where the top quark mass and the JES are measured simultaneously, with $\Delta_{JES} = 0.3 \pm 0.3$(stat).

[41] Based on 5.7 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Events with an identified charged lepton or small $\not\!\!E_T$ are rejected from the event sample, so that the measurement is statistically independent from those in the $\ell$ + jets and all hadronic channels while being sensitive to those events with a $\tau$ lepton in the final state. Supersedes AALTONEN 07B.

[42] AALTONEN 11E based on 5.6 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Employs a multi-dimensional template likelihood technique where the lepton plus jets (one or two $b$-tags) channel gives 172.2 ± 1.2 ± 0.9 GeV while the dilepton channel yields 170.3 ± 2.0 ± 3.1 GeV. The results are combined. OUR EVALUATION includes the measurement in the dilepton channel only.

[43] Uses a likelihood fit of the lepton $p_T$ distribution based on 2.7 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[44] Based on 3.6 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. ABAZOV 11P reports 174.94 ± 0.83±0.78±0.96 GeV, where the first uncertainty is from statistics, the second from JES, and the last from other systematic uncertainties. We combine the JES and systematic uncertainties. A matrix-element method is used where the JES uncertainty is constrained by the $W$ mass. ABAZOV 11P describes a measurement based on 2.6 fb$^{-1}$ that is combined with ABAZOV 08AH, which employs an independent 1 fb$^{-1}$ of data.

[45] Based on a matrix-element method which employs 5.4 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Superseded by ABAZOV 12AB.

[46] Based on 36 pb$^{-1}$ of $pp$ collisions at $\sqrt{s}$ = 7 TeV. A Kinematic Method using $b$-tagging and an analytical Matrix Weighting Technique give consistent results and are combined. Superseded by CHATRCHYAN 12BA.

[47] Based on 5.6 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The likelihood calculated using a matrix element method gives $m_t$ = 173.0 ± 0.7(stat)±0.6( JES)±0.9(syst) GeV, for a total uncertainty of 1.2 GeV.

[48] Based on 3.4 fb$^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The result is obtained by combining the MT2 variable method and the NWA (Neutrino Weighting Algorithm). The MT2 method alone gives $m_t = 168.0^{+4.8}_{-4.0}$(stat)±2.9(syst) GeV with smaller systematic error due to small JES uncertainty.

[49] Based on 1.9 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The result is from the measurement using the transverse decay length of $b$-hadrons and that using the transverse momentum of the $W$ decay muons, which are both insensitive to the JES (jet energy scale) uncertainty. OUR EVALUATION uses only the measurement exploiting the decay length significance which yields $166.9^{+9.5}_{-8.5}$(stat)±2.9 (syst) GeV. The measurement that uses the lepton transverse momentum is excluded from the average because of a statistical correlation with other samples.

[50] Based on 2.9 fb$^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The first error is from statistics and JES uncertainty, and the latter is from the other systematics. Neural-network-based kinematical selection of 6 highest $E_T$ jets with a vtx $b$-tag is used to distinguish signal from background. Superseded by AALTONEN 12G.

[51] Based on 2 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. The top mass is obtained from the measurement of the invariant mass of the lepton ($e$ or $\mu$) from $W$ decays and the soft $\mu$ in $b$-jet. The result is insensitive to jet energy scaling.

[52] Based on 1.9 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics. Matrix element method with effective propagators.

[53] Based on 943 pb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. The first error is from statistical and jet-energy-scale uncertainties, and the latter is from other systematics. AALTONEN 09K selected 6 jet events with one or more vertex $b$-tags and used the tree-level matrix element to construct template models of signal and background.

[54] Based on 1.9 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. The first error is from statistical and jet-energy-scale (JES) uncertainties, and the second is from other systematics. Events with lepton + jets and those with dilepton + jets were simultaneously fit to constrain $m_t$ and JES. Lepton + jets data only give $m_t$ = 171.8 ± 2.2 GeV, and dilepton data only give $m_t = 171.2^{+5.3}_{-5.1}$ GeV.

[55] Based on 2 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. Matrix Element method. Optimal selection criteria for candidate events with two high $p_T$ leptons, high $\not\!\!E_T$, and two or more jets with and without $b$-tag are obtained by neural network with neuroevolution technique to minimize the statistical error of $m_t$.

[56] Based on 2.9 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. Mass $m_t$ is estimated from the likelihood for the eight-fold kinematical solutions in the plane of the azimuthal angles of the two neutrino momenta.

[57] Based on 1 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. Events with two identified leptons, and those with one lepton plus one isolated track and a $b$-tag were used to constrain $m_t$. The result is a combination of the $\nu$WT ($\nu$ Weighting Technique) result of 176.2 ± 4.8 ± 2.1 GeV and the MWT (Matrix-element Weighting Technique) result of 173.2 ± 4.9 ± 2.0 GeV.

[58] Reports measurement of $170.7^{+4.2}_{-3.9}$ ± 2.6 ± 2.4 GeV based on 1.2 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. The last error is due to the theoretical uncertainty on $\sigma_{t\overline{t}}$. Without the cross-section constraint a top mass of $169.7^{+5.2}_{-4.9}$ ± 3.1 GeV is obtained.

[59] Template method.

[60] Result is based on 1 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics.

[61] Based on 310 pb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV.

[62] Ideogram method.

[63] Based on 311 pb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. Events with 4 or more jets with $E_T$ > 15 GeV, significant missing $E_T$, and secondary vertex $b$-tag are used in the fit. About 44% of the signal acceptance is from $\tau\nu$ + 4 jets. Events with identified $e$ or $\mu$ are vetoed to provide a statistically independent measurement.

[64] Based on 1.02 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. Superseded by AALTONEN 12G.

[65] Based on 955 pb$^{-1}$ of data $\sqrt{s}$ = 1.96 TeV. $m_t$ and JES (Jet Energy Scale) are fitted simultaneously, and the first error contains the JES contribution of 1.5 GeV.

[66] Matrix element method.

[67] Based on 425 pb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. The first error is a combination of statistics and JES ( Jet Energy Scale) uncertainty, which has been measured simultaneously to give JES = 0.989 ± 0.029(stat).

[68] Based on 370 pb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. Combined result of MWT (Matrix-element Weighting Technique) and $\nu$WT ($\nu$ Weighting Technique) analyses is 178.1 ± 6.7 ± 4.8 GeV.

[69] Based on 1.0 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. ABULENCIA 07D improves the matrix element description by including the effects of initial-state radiation.

[70] Based on 695 pb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. The transverse decay length of the $b$ hadron is used to determine $m_t$, and the result is free from the JES (jet energy scale) uncertainty.

[71] Based on ∼ 400 pb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. The first error includes statistical and systematic jet energy scale uncertainties, the second error is from the other systematics. The result is obtained with the $b$-tagging information. The result without $b$-tagging is $169.2^{+5.0}_{-7.4}{}^{+1.5}_{-1.4}$ GeV. Superseded by ABAZOV 08AH.

[72] Based on 318 pb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV.

[73] Dynamical likelihood method.

[74] Based on 340 pb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV.

[75] Based on 360 pb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV.

[76] Based on 110.2 ± 5.8 pb$^{-1}$ at $\sqrt{s}$ = 1.8 TeV.

[77] Based on the all hadronic decays of $t\overline{t}$ pairs. Single $b$-quark tagging via the decay chain $b \to c \to \mu$ was used to select signal enriched multijet events. The result was obtained by the maximum likelihood method after bias correction.

[78] Obtained by re-analysis of the lepton + jets candidate events that led to ABBOTT 98F. It is based upon the maximum likelihood method which makes use of the leading order matrix elements.

[79] Based on 125 ± 7 pb$^{-1}$ of data at $\sqrt{s}$ = 1.8 TeV.

[80] Based on ∼ 106 pb$^{-1}$ of data at $\sqrt{s}$= 1.8 TeV.

[81] Obtained by combining the measurements in the lepton + jets [AFFOLDER 01], all-jets [ABE 97R, ABE 99B], and dilepton [ABE 99B] decay topologies.

[82] Obtained by combining the D0 result $m_t$ (GeV) = 168.4 ± 12.3 ± 3.6 from 6 di-lepton events (see also ABBOTT 98D) and $m_t$ (GeV) = 173.3 ± 5.6 ± 5.5 from lepton+jet events (ABBOTT 98F).

[83] Obtained by combining the CDF results of $m_t$ (GeV)=167.4 ± 10.3 ± 4.8 from 8 dilepton events, $m_t$ (GeV)=175.9 ± 4.8 ± 5.3 from lepton+jet events (ABE 98E), and $m_t$ (GeV)=186.0 ± 10.0 ± 5.7 from all-jet events (ABE 97R). The systematic errors in the latter two measurements are changed in this paper.

[84] See AFFOLDER 01 for details of systematic error re-evaluation.

[85] Based on 109 ± 7 pb$^{-1}$ of data at $\sqrt{s}$ = 1.8 TeV.

[86] See ABAZOV 04G.

[87] The updated systematic error is listed. See AFFOLDER 01, appendix C.

[88] Obtained by combining the DØ results of $m_t$(GeV)=168.4 ± 12.3 ± 3.6 from 6 dilepton events and $m_t$(GeV)=173.3 ± 5.6 ± 5.5 from 77 lepton+jet events.

[89] Obtained by combining the DØ results from dilepton and lepton+jet events, and the CDF results (ABE 99B) from dilepton, lepton+jet events, and all-jet events.

[90] Based on the first observation of all hadronic decays of $t\overline{t}$ pairs. Single $b$-quark tagging with jet-shape variable constraints was used to select signal enriched multi-jet events. The updated systematic error is listed. See AFFOLDER 01, appendix C.

### $t$-Quark Mass from Cross-Section Measurements

The top quark $\overline{\text{MS}}$ or pole mass can be extracted from a measurement of $\sigma(t\overline{t})$ by using theory calculations. We quote below the $\overline{\text{MS}}$ mass. See the review "The Top Quark" and references therein for more information.

[1] AAD 19G based on 20.2 fb$^{-1}$ of data in $pp$ collisions at $\sqrt{s}$ = 8 TeV. Normalized $t\bar{t}$ + 1-jet differential cross section as a function of $t\bar{t}j$ invariant mass is measured in the $\ell$ + jets mode. The unfolded parton-level distribution is compared with the NLO QCD prediction. The three errors are from statitics, systematics, and theory.

[2] Based on 5.3 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. ABAZOV 11S uses the measured $t\bar{t}$ production cross section of $8.13^{+1.02}_{-0.90}$ pb [ABAZOV 11E] in the lepton plus jets channel to obtain the top quark $\overline{\text{MS}}$ mass by using an approximate NNLO computation (MOCH 08, LANGENFELD 09). The corresponding top quark pole mass is $167.5^{+5.4}_{-4.9}$ GeV. A different theory calculation (AHRENS 10, AHRENS 10A) is also used and yields $m_t^{\overline{\text{MS}}} = 154.5^{+5.0}_{-4.3}$ GeV.

[3] Based on 1 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. Uses the $\ell$ + jets, $\ell\ell$, and $\ell\tau$ + jets channels. ABAZOV 09AG extract the pole mass of the top quark using two different calculations that yield $169.1^{+5.9}_{-5.2}$ GeV (MOCH 08, LANGENFELD 09) and $168.2^{+5.9}_{-5.4}$ GeV (KIDONAKIS 08).

[4] Based on 1 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. Uses the $\ell\ell$ and $\ell\tau$ + jets channels. ABAZOV 09R extract the pole mass of the top quark using two different calculations that yield $173.3^{+9.8}_{-8.6}$ GeV (MOCH 08, LANGENFELD 09) and $171.5^{+9.9}_{-8.8}$ GeV (CACCIARI 08).

[1] AAD 19G based on 20.2 fb$^{-1}$ of data in $pp$ collisions at $\sqrt{s}$ = 8 TeV. Normalized $t\bar{t}$ + 1-jet differential cross section as a function of $t\bar{t}j$ invariant mass is measured in the $\ell$ + jets mode. The unfolded parton-level distribution is compared with the NLO QCD prediction. The three errors are from statitics, systematics, and theory.

[2] AABOUD 17BC based on 20.2 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. The pole mass is extracted from a fit of NLO predictions to eight single lepton and dilepton differential distributions, while simultaneously constraining uncertainties due to PDFs and QCD scales. The three reported uncertainties come from statistics, experimental systematics, and theoretical sources.

[3] SIRUNYAN 17W based on 2.2 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. Events are categorized according to the jet multiplicity and the number of $b$-tagged jets. The pole mass is obtained from the inclusive cross section measurement and the NNLO prediction.

[4] ABAZOV 16F based on 9.7 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The result is obtained from the inclusive cross section measurement and the NNLO+NNLL prediction.

[5] KHACHATRYAN 16AW based on 5.0 fb$^{-1}$ of $pp$ collisions at 7 TeV and 19.7 fb$^{-1}$ at 8 TeV. The 7 TeV data include those used in CHATRCHYAN 14. The result is obtained from the inclusive cross sections.

[6] AAD 15BW based on 4.6 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. Uses normalized differential cross section for $t\bar{t}$ + 1 jet as a function of the inverse of the invariant mass of the $t\bar{t}$ + 1 jet system. The measured cross section is corrected to the parton level. Then a fit to the data using NLO + parton shower prediction is performed.

[7] AAD 14AY used $\sigma(t\bar{t})$ for $e\mu$ events. The result is a combination of the measurements $m_t$ = 171.4 ± 2.6 GeV based on 4.6 fb$^{-1}$ of data at 7 TeV and $m_t$ = 174.1 ± 2.6 GeV based on 20.3 fb$^{-1}$ of data at 8 TeV.

[8] CHATRCHYAN 14 used $\sigma(t\bar{t})$ from $pp$ collisions at $\sqrt{s}$ = 7 TeV measured in CHATRCHYAN 12AX to obtain $m_t$(pole) for $\alpha_s(m_Z)$ = 0.1184 ± 0.0007. The errors have been corrected in KHACHATRYAN 14K.

### $m_t - m_{\overline{t}}$

Test of $CPT$ conservation. OUR AVERAGE assumes that the systematic uncertainties are uncorrelated.

| <13.1 | 95 | [7] AALTONEN | 09M | CDF | $m_t$(rec) distribution |

[1] Based on 20.2 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. $\Gamma_t$ is measured using a template fit to the reconstructed invariant mass of the $b$-jet of the semileptonically decaying top quark and the corresponding lepton, and the angular distance between $j_b$ and $j_l$ in hadronic top decay. Signal templates are generated by reweighting events at parton-level to Breit-Wigner distribution with different $\Gamma_t$ hypotheses for $m_t$ = 172.5 GeV. The result is consistent with the NNLO SM prediction of 1.322 GeV.

[2] Based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. The result is obtained by combining the measurement of $R = \Gamma(t\to Wb)/\Gamma(t\to Wq\ (q$=$b,s,d))$ and a previous CMS measurement of the $t$-channel single top production cross section of CHATRCHYAN 12BQ, by using the theoretical calculation of $\Gamma(t\to Wb)$ for $m_t$ = 172.5 GeV.

[3] Based on 5.4 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV. $\Gamma(t\to bW) = 1.87^{+0.44}_{-0.40}$ GeV is obtained from the observed $t$-channel single top quark production cross section, whereas $\mathrm{B}(t\to bW) = 0.90\pm0.04$ is used assuming $\sum_q \mathrm{B}(t\to qW) = 1$. The result is valid for $m_t$ = 172.5 GeV. See the paper for the values for $m_t$ = 170 or 175 GeV.

[4] Based on 8.7 fb$^{-1}$ of data. The two sided 68% CL interval is 1.10 GeV < $\Gamma_t$ < 4.05 GeV for $m_t$ = 172.5 GeV.

[5] Based on 2.3 fb$^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. ABAZOV 11B extracted $\Gamma_t$ from the partial width $\Gamma(t\to Wb) = 1.92^{+0.58}_{-0.51}$ GeV measured using the $t$-channel single top production cross section, and the branching fraction $\mathrm{br}t\to Wb = 0.962^{+0.068}_{-0.066}(\mathrm{stat})^{+0.064}_{-0.052}(\mathrm{syst})$. The $\Gamma(t\to Wb)$ measurement gives the 95% CL lowerbound of $\Gamma(t\to Wb)$ and hence that of $\Gamma_t$.

[6] Results are based on 4.3 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The top quark mass and the hadronically decaying $W$ boson mass are reconstructed for each candidate events and compared with templates of different top quark width. The two sided 68% CL interval is 0.3 GeV< $\Gamma_t$ < 4.4 GeV for $m_t$ = 172.5 GeV.

[7] Based on 955 pb$^{-1}$ of $p\overline{p}$ collision data at $\sqrt{s}$ = 1.96 TeV. AALTONEN 09M selected $t\bar{t}$ candidate events for the $\ell$ + $\not\!\!E_T$ + jets channel with one or two $b$-tags, and examine the decay width dependence of the reconstructed $m_t$ distribution. The result is for $m_t$ =175 GeV, whereas the upper limit is lower for smaller $m_t$.

### $t$ DECAY MODES

| | Mode | Fraction ($\Gamma_i/\Gamma$) | Confidence level |
|---|---|---|---|
| $\Gamma_1$ | $Wq\ (q=b,s,d)$ | | |

## $t$

• • • We do not use the following data for averages, fits, limits, etc. • • •

| | | | | | |
|---|---|---|---|---|---|
| $0.97\ ^{+0.09}_{-0.08}$ | | [5] ABAZOV | 08M | D0 | $\ell$ + n jets with 0,1,2 $b$-tag |
| $1.03\ ^{+0.19}_{-0.17}$ | | [6] ABAZOV | 06K | D0 | |
| $1.12\ ^{+0.21}_{-0.19}$ | $^{+0.17}_{-0.13}$ | [7] ACOSTA | 05A | CDF | Repl. by AALTONEN 13G |
| $0.94\ ^{+0.26}_{-0.21}$ | $^{+0.17}_{-0.12}$ | [8] AFFOLDER | 01C | CDF | |

[1] Based on 8.7 fb$^{-1}$ of data. This measurement gives $|V_{tb}| = 0.93 \pm 0.04$ and $|V_{tb}| > 0.85$ (95% CL) in the SM.

[2] Based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. The result is obtained by counting the number of $b$ jets per $t\bar{t}$ signal events in the dilepton channel. The $t\bar{t}$ production cross section is measured to be $\sigma(t\bar{t}) = 238 \pm 1 \pm 15$ pb, in good agreement with the SM prediction and the latest CMS measurement of CHATRCHYAN 14F. The measurement gives $R > 0.995$ (95% CL), or $|V_{tb}| > 0.975$ (95% CL) in the SM, requiring $R \leq 1$.

[3] Based on 8.7 fb$^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. Measure the fraction of $t \to Wb$ decays simultaneously with the $t\bar{t}$ cross section. The correlation coefficient between those two measurements is $-0.434$. Assume unitarity of the 3×3 CKM matrix and set $|V_{tb}| > 0.89$ at 95% CL.

[4] Based on 5.4 fb$^{-1}$ of data. The error is statistical and systematic combined. The result is a combination of $0.95 \pm 0.07$ from $\ell$ + jets channel and $0.86 \pm 0.05$ from $\ell\ell$ channel. $|V^{tb}| = 0.95 \pm 0.02$ follows from the result by assuming unitarity of the 3x3 CKM matrix.

[5] Result is based on 0.9 fb$^{-1}$ of data. The 95% CL lower bound R > 0.79 gives $|V_{tb}| > 0.89$ (95% CL).

[6] ABAZOV 06K result is from the analysis of $t\bar{t} \to \ell\nu + \geq 3$ jets with 230 pb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV. It gives R > 0.61 and $|V_{tb}| > 0.78$ at 95% CL. Superseded by ABAZOV 08M.

[7] ACOSTA 05A result is from the analysis of lepton + jets and di-lepton + jets final states of $t\bar{t}$ candidate events with $\sim 162$ pb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV. The first error is statistical and the second systematic. It gives R > 0.61, or $|V_{tb}| > 0.78$ at 95% CL.

[8] AFFOLDER 01C measures the top-quark decay width ratio $R = \Gamma(Wb)/\Gamma(Wq)$, where $q$ is a $d$, $s$, or $b$ quark, by using the number of events with multiple $b$ tags. The first error is statistical and the second systematic. A numerical integration of the likelihood function gives $R > 0.61$ (0.56) at 90% (95%) CL. By assuming three generation unitarity, $|V_{tb}| = 0.97^{+0.16}_{-0.12}$ or $|V_{tb}| > 0.78$ (0.75) at 90% (95%) CL is obtained. The result is based on 109 pb$^{-1}$ of data at $\sqrt{s} = 1.8$ TeV.

| | | | |
|---|---|---|---|
| [3] ABULENCIA | 06R | CDF | $\ell\tau$ + jets |
| [4] ABE | 97V | CDF | $\ell\tau$ + jets |

[1] AAD 15CC based on 4.6 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. The original value is given by $7.0 \pm 0.3 \pm 0.5\%$, which includes only the hadronic decay of $\tau$ leptons. It is assumed that the top branching ratios to leptons and jets add up to one and that only SM processes contribute to the background. The event selection criteria are optimized for the $\ell\tau_h$ + jets channel. We have converted the original value to include leptonic decays of $\tau$'s, by using the AAD 15CC measurements of the branching ratios to $e$ and $\mu$ channels, as well as the PDG values of $\tau$ branching ratios into $e$ and $\mu$ channels.

[2] Based on 9 fb$^{-1}$ of data. The measurement is in the channel $t\bar{t} \to (b\ell\nu)(b\tau\nu)$, where $\tau$ decays into hadrons ($\tau_h$), and $\ell$ ($e$ or $\mu$) include $\ell$ from $\tau$ decays ($\tau_\ell$). The result is consistent with lepton universality.

[3] ABULENCIA 06R looked for $t\bar{t} \to (\ell\nu_\ell)(\tau\nu_\tau)b\bar{b}$ events in 194 pb$^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. 2 events are found where $1.00 \pm 0.17$ signal and $1.29 \pm 0.25$ background events are expected, giving a 95% CL upper bound for the partial width ratio $\Gamma(t \to \tau\nu q) / \Gamma_{SM}(t \to \tau\nu q) < 5.2$.

[4] ABE 97V searched for $t\bar{t} \to (\ell\nu_\ell)(\tau\nu_\tau)b\bar{b}$ events in 109 pb$^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV. They observed 4 candidate events where one expects $\sim 1$ signal and $\sim 2$ background events. Three of the four observed events have jets identified as $b$ candidates.

[1] AAD 20B based on 81 fb$^{-1}$ of data in $pp$ collisions at $\sqrt{s} = 13$ TeV. FCNC through single top production in association with a photon is searched for in the mode $\ell\gamma + \not{E}_T$ + 1$j$ ($b$-tag). Anomalous FCNC left-handed and right-handed couplings are searched for, which result in different kinematical properties of top decay such as the lepton distribution. Limits are set on the $tq\gamma$ couplings in an effective field theory.

[2] KHACHATRYAN 16AS based on 19.8 fb$^{-1}$ of data in $pp$ collisions at $\sqrt{s} = 8$ TeV. FCNC through single top production in association with a photon is searched for in the mode $\mu + \gamma + \not{E}_T + \geq 1j$ (0,1$b$). Bounds on the anomalous FCNC couplings are given by $\kappa_{tu\gamma} < 0.025$ and $\kappa_{tc\gamma} < 0.091$.

[3] CHEKANOV 03 looked for single top production via FCNC in the reaction $e^{\pm}p \to e^{\pm}$ ($t$ or $\bar{t}$) X in 130.1 pb$^{-1}$ of data at $\sqrt{s}$=300–318 GeV. No evidence for top production and its decay into $bW$ was found. The result is obtained for $m_t$=175 GeV when B($\gamma c$)=B($Zq$)=0, where $q$ is a $u$ or $c$ quark. Bounds on the effective $t$-$u$-$\gamma$ and $t$-$u$-$Z$ couplings are found in their Fig. 4. The conversion to the constraint listed is from private communication, E. Gallo, January 2004.

[4] AARON 09A looked for single top production via FCNC in $e^{\pm}p$ collisions at HERA with 474 pb$^{-1}$. The upper bound of the cross section gives the bound on the FCNC coupling $\kappa_{tu\gamma}/\Lambda < 1.03$ TeV$^{-1}$, which corresponds to the result for $m_t = 175$ GeV.

[5] ABDALLAH 04C looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 541 pb$^{-1}$ of data at $\sqrt{s}$=189–208 GeV. No deviation from the SM is found, which leads to the bound on B($t \to \gamma q$), where $q$ is a $u$ or a $c$ quark, for $m_t$ = 175 GeV when B($t \to Zq$)=0 is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective $t$-$q$-$\gamma$ and $t$-$q$-$Z$ couplings are given in their Fig. 7 and Table 4, for $m_t$ = 170–180 GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual $\gamma$ and $Z$ exchange amplitudes.

[6] AKTAS 04 looked for single top production via FCNC in $e^{\pm}$ collisions at HERA with 118.3 pb$^{-1}$, and found 5 events in the $e$ or $\mu$ channels. By assuming that they are due to statistical fluctuation, the upper bound on the $tu\gamma$ coupling $\kappa_{tu\gamma} < 0.27$ (95% CL) is obtained. The conversion to the partial width limit, when B($\gamma c$) = B($Zu$) = B($Zc$) = 0, is from private communication, E. Perez, May 2005.

[7] ACHARD 02J looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 634 pb$^{-1}$ of data at $\sqrt{s}$= 189–209 GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction B($\gamma q$), where $q$ is a $u$ or $c$ quark. The bound assumes B($Zq$)=0 and is for $m_t$= 175 GeV; bounds for $m_t$=170 GeV and 180 GeV and B($Zq$) ≠ 0 are given in Fig. 5 and Table 7.

[8] ABE 98G looked for $t\bar{t}$ events where one $t$ decays into $q\gamma$ while the other decays into $bW$. The quoted bound is for $\Gamma(\gamma q)/\Gamma(Wb)$.

[1] Based on 36.1 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. The final states $t\bar{t} \to \ell^+\ell^-\ell'^{\pm}\nu$ + jets ($\ell, \ell' = e, \mu$) are investigated and no significant excess over the SM background contributions is observed.

[2] SIRUNYAN 17E based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. The final states $t\bar{t} \to \ell^+\ell^-\ell'^{\pm}\nu$ + jets ($\ell, \ell' = e, \mu$) are investigated and the cross section $\sigma(pp \to tZq \to \ell\nu b\ell^+\ell^- q) = 10^{+8}_{-7}$ fb is measured, giving no sign of FCNC decays of the top quark.

[3] AAD 16D based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. The FCNC decay is searched for in $t\bar{t}$ events in the final state $(bW)(qZ)$ when both $W$ and $Z$ decay leptonically, giving 3 charged leptons.

[4] CHATRCHYAN 14S combined search limit from this and CHATRCHYAN 13F data.

[5] Based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. The flavor changing decay is searched for in $t\bar{t}$ events in the final state $(bW)(qZ)$ when both $W$ and $Z$ decay leptoically, giving 3 charged leptons.

[6] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. Search for FCNC decays of the top quark in $t\bar{t} \to \ell^+\ell^-\ell'^{\pm}\nu$ + jets ($\ell, \ell' = e, \mu$) final states found no excess of signal events.

[7] Based on 2.1 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV.

[8] Based on 4.1 fb$^{-1}$ of data. ABAZOV 11M searched for FCNC decays of the top quark in $t\bar{t} \to \ell^+\ell^-\ell'^{\pm}\nu$ + jets ($\ell, \ell' = e, \mu$) final states, and absence of the signal gives the bound.

[9] Based on $p\bar{p}$ data of 1.52 fb$^{-1}$. AALTONEN 09AL compared $t\bar{t} \to WbWb \to \ell\nu bjjb$ and $t\bar{t} \to ZcWb \to \ell\ell cjjb$ decay chains, and absence of the latter signal gives the bound. The result is for 100% longitudinally polarized Z boson and the theoretical $t\bar{t}$ production cross section The results for different $Z$ polarizations and those without the cross section assumption are given in their Table XII.

[10] Result is based on 1.9 fb$^{-1}$ of data at $\sqrt{s}$ = 1.96 TeV. $t\bar{t} \to WbZq$ or $ZqZq$ processes have been looked for in $Z \geq 4$ jet events with and without $b$-tag. No signal leads to the bound $B(t \to Zq) < 0.037$ (0.041) for $m_t$ = 175 (170) GeV.

[11] ABDALLAH 04C looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 541 pb$^{-1}$ of data at $\sqrt{s}$=189–208 GeV. No deviation from the SM is found, which leads to the bound on $B(t \to Zq)$, where $q$ is a $u$ or a $c$ quark, for $m_t$ = 175 GeV when $B(t \to \gamma q)$=0 is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective $t$-$q$-$\gamma$ and $t$-$q$-$Z$ couplings are given in their Fig. 7 and Table 4, for $m_t$ = 170–180 GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual $\gamma$ and $Z$ exchange amplitudes.

[12] ACHARD 02J looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 634 pb$^{-1}$ of data at $\sqrt{s}$= 189–209 GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction $B(Zq)$, where $q$ is a $u$ or $c$ quark. The bound assumes $B(\gamma q)$=0 and is for $m_t$= 175 GeV; bounds for $m_t$=170 GeV and 180 GeV and $B(\gamma q) \neq 0$ are given in Fig. 5 and Table 7. Table 6 gives constraints on $t$-$c$-$e$-$e$ four-fermi contact interactions.

[13] HEISTER 02Q looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 214 pb$^{-1}$ of data at $\sqrt{s}$= 204–209 GeV. No deviation from the SM is found, which leads to a bound on the branching fraction $B(Zq)$, where $q$ is a $u$ or $c$ quark. The bound assumes $B(\gamma q)$=0 and is for $m_t$= 174 GeV. Bounds on the effective $t$- ($c$ or $u$)-$\gamma$ and $t$- ($c$ or $u$)- $Z$ couplings are given in their Fig. 2.

[14] ABBIENDI 01T looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 600 pb$^{-1}$ of data at $\sqrt{s}$= 189–209 GeV. No deviation from the SM is found, which leads to bounds on the branching fractions $B(Zq)$ and $B(\gamma q)$, where $q$ is a $u$ or $c$ quark. The result is obtained for $m_t$= 174 GeV. The upper bound becomes 9.7% (20.6%) for $m_t$= 169 (179) GeV. Bounds on the effective $t$- ($c$ or $u$)-$\gamma$ and $t$- ($c$ or $u$)-$Z$ couplings are given in their Fig. 4.

[15] BARATE 00S looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 411 pb$^{-1}$ of data at c.m. energies between 189 and 202 GeV. No deviation from the SM is found, which leads to a bound on the branching fraction. The bound assumes $B(\gamma q)$=0. Bounds on the effective $t$- ($c$ or $u$)-$\gamma$ and $t$- ($c$ or $u$)-$Z$ couplings are given in their Fig. 4.

[16] ABE 98G looked for $t\bar{t}$ events where one $t$ decays into three jets and the other decays into $qZ$ with $Z \to \ell\ell$. The quoted bound is for $\Gamma(Zq)/\Gamma(Wb)$.

[1] AABOUD 19S based on 36.1 fb$^{-1}$ at $\sqrt{s}$ = 13 TeV of $pp$ data. The searches using $H \to bb$ and $H \to \tau_h\tau_h$ are combined with searches in diphoton and multilepton final states. The upper limit on the Yukawa coupling $|Y_{tuH}| < 0.066$ (95% CL) is obtained.

[2] AABOUD 19S based on 36.1 fb$^{-1}$ at $\sqrt{s}$ = 13 TeV of $pp$ data. Uses events with one isolated lepton and multiple jets (several of them $b$-tagged with high purity). A multivariate analysis is performed to distinguish the signal from backgrounds.

[3] AABOUD 19S based on 36.1 fb$^{-1}$ at $\sqrt{s}$ = 13 TeV of $pp$ data. Uses events with one or two hadronically decaying $\tau$ and multiple jets. A multivariate analysis is performed to distinguish the signal from backgrounds.

[4] AABOUD 18X based on 36.1 fb$^{-1}$ at $\sqrt{s}$ = 13 TeV of $pp$ data. $\ell\ell$(same sign) + $\geq$4j mode and $\ell\ell\ell$ + $\geq$2j mode are targeted and specialized boosted decision trees are used to distinguish signals from backgrounds.

[5] SIRUNYAN 18BC based on 35.9 fb$^{-1}$ at $\sqrt{s}$ = 13 TeV of $pp$ data. Two channels $pp \to tH$ and $pp \to t\bar{t}$ in final states with one isolated lepton and >=3 jets with >=2 b jets are considered assuming a single $tHu$ FCNC coupling. Reconstructed kinematical variables are fed into a multivariate analysis and no significant deviation is observed from the predicted background.

[6] AABOUD 17AV based on 36.1 fb$^{-1}$ at $\sqrt{s}$ = 13 TeV of $pp$ data. Search for $t\bar{t}$ events, where the other top quark decays hadronically or semi-leptonically.

[7] KHACHATRYAN 17I based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV, using the topologies $t\bar{t} \to Hq$+$Wb$, where $q$=$u$, $c$.

[8] AAD 15CO based on 20.3 fb$^{-1}$ at $\sqrt{s}$ = 8 TeV of $pp$ data. Searches for $t\bar{t}$ events, where the other top quark decays semi-leptonically. Exploits high multiplicity of $b$-jets and uses a likelihood discriminant. Combining with other ATLAS searches for different Higgs decay modes, $B(t \to Hc) < 0.46\%$ and $B(t \to Hu) < 0.45\%$ are obtained.

[9] AAD 14AA based on 4.7 fb$^{-1}$ at $\sqrt{s}$ = 7 TeV and 20.3 fb$^{-1}$ at $\sqrt{s}$ = 8 TeV of $pp$ data. The upper-bound is for the sum of $Br(t \to Hc)$ and $Br(t \to Hu)$. Search for $t\bar{t}$ events, where the other top quark decays hadronically or semi-leptonically. The upper bound constrains the $H$-$t$-$c$ Yukawa couplings $\sqrt{|Y^H_{tc_L}|^2 + |Y^H_{tc_R}|^2} < 0.17$ (95% CL).

[1] Based on 19.5 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Baryon number violating decays of the top quark are searched for in $t\bar{t}$ production events where one of the pair decays into hadronic three jets.

## $t$-quark EW Couplings

$W$ helicity fractions in top decays. $F_0$ is the fraction of longitudinal and $F_+$ the fraction of right-handed $W$ bosons. $F_{V+A}$ is the fraction of $V+A$ current in top decays. The effective Lagrangian (cited by ABAZOV 08AI) has terms $f_1^L$ and $f_1^R$ for $V-A$ and $V+A$ couplings, $f_2^L$ and $f_2^R$ for tensor couplings with $b_R$ and $b_L$ respectively.

[1] AABOUD 17BB based on 20.2 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Triple-differential decay rate of top quark in the $t$-channel single-top production is used to simultaneously determine five generalized $Wtb$ couplings as well as the top polarization. No assumption is made for the other couplings. See this paper for constraints on other couplings not included here. The paper reported $f_1$, and we converted it to $F_0$.

[2] KHACHATRYAN 16BU based on 19.8 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV using $t\bar{t}$ events with $\ell + \not{E}_T + \geq 4$ jets($\geq 2$ $b$). The errors of $F_0$ and $F_-$ are correlated with a correlation coefficient $\rho(F_0, F_-) = -0.87$. The result is consistent with the NNLO SM prediction of $0.687 \pm 0.005$ for $m_t = 172.8 \pm 1.3$ GeV.

[3] Based on 8.7 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV using $t\bar{t}$ events with $\ell + \not{E}_T + \geq 4$ jets($\geq 1$ $b$), and under the constraint $F_0 + F_+ + F_- = 1$. The statstical errors of $F_0$ and $F_+$ are correlated with correlation coefficient $\rho(F_0,F_+) = -0.69$.

[4] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 13BH studied $tt$ events with large $\not{E}_T$ and $\ell + \geq 4$ jets using a constrained kinematic fit.

[5] Based on 1.04 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. AAD 12BG studied $tt$ events with large $\not{E}_T$ and either $\ell + \geq 4$j or $\ell\ell + \geq 2$j. The uncertainties are not independent, $\rho(F_0,F_-) = -0.96$.

[6] Based on 2.7 and 5.1 fb$^{-1}$ of CDF data in $\ell +$ jets and dilepton channels, and 5.4 fb$^{-1}$ of D0 data in $\ell +$ jets and dilepton channels. $F_0 = 0.682 \pm 0.035 \pm 0.046$ if $F_+ = 0.0017(1)$, while $F_+ = -0.015 \pm 0.018 \pm 0.030$ if $F_0 = 0.688(4)$, where the assumed fixed values are the SM prediction for $m_t = 173.3 \pm 1.1$ GeV and $m_W = 80.399 \pm 0.023$ GeV.

[7] Results are based on 5.4 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV, including those of ABAZOV 08B. Under the SM constraint of $f_0 = 0.698$ (for $m_t = 173.3$ GeV, $m_W = 80.399$ GeV), $f_+ = 0.010 \pm 0.022 \pm 0.030$ is obtained.

[8] AFFOLDER 00B studied the angular distribution of leptonic decays of $W$ bosons in $t \to Wb$ events. The ratio $F_0$ is the fraction of the helicity zero (longitudinal) $W$ bosons in the decaying top quark rest frame. $B(t \to W_+ b)$ is the fraction of positive helicity (right-handed) positive charge $W$ bosons in the top quark decays. It is obtained by assuming the Standard Model value of $F_0$.

[9] Results are based on 2.7 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. $F_0$ result is obtained by assuming $F_+ = 0$, while $F_+$ result is obtained for $F_0 = 0.70$, the SM value. Model independent fits for the two fractions give $F_0 = 0.88 \pm 0.11 \pm 0.06$ and $F_+ = -0.15 \pm 0.07 \pm 0.06$ with correlation coefficient of $-0.59$. The results are for $m_t = 175$ GeV.

[10] Results are based on 1.9 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. $F_0$ result is obtained assuming $F_+ = 0$, while $F_+$ result is obtained for $F_0 = 0.70$, the SM values. Model independent fits for the two fractions give $F_0 = 0.66 \pm 0.16 \pm 0.05$ and $F_+ = -0.03 \pm 0.06 \pm 0.03$.

[11] Based on 1 fb$^{-1}$ at $\sqrt{s} = 1.96$ TeV.

[12] Based on 318 pb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV.

[13] Based on 200 pb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV. $t \to Wb \to \ell\nu b$ ($\ell = e$ or $\mu$). The errors are stat + syst.

[14] ABAZOV 05G studied the angular distribution of leptonic decays of $W$ bosons in $t\bar{t}$ candidate events with lepton + jets final states, and obtained the fraction of longitudinally polarized $W$ under the constraint of no right-handed current, $F_+ = 0$. Based on 125 pb$^{-1}$ of data at $\sqrt{s} = 1.8$ TeV.

### $F_-$

[1] AABOUD 17BB based on 20.2 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Triple-differential decay rate of top quark in the $t$-channel single-top production is used to simultaneously determine five generalized $Wtb$ couplings as well as the top polarization. No assumption is made for the other couplings. The authors reported $f_1 = 0.30 \pm 0.05$ and $f_1^+ < 0.120$ which we converted to $F_- = f_1(1 - f_1^+)$. See this paper for constraints on other couplings not included here.

[2] KHACHATRYAN 16BU based on 19.8 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV using $t\bar{t}$ events with $\ell + \not{E}_T + \geq 4$ jets($\geq 2$ $b$). The errors of $F_0$ and $F_-$ are correlated with a correlation coefficient $\rho(F_0, F_-) = -0.87$. The result is consistent with the NNLO SM prediction of $0.311 \pm 0.005$ for $m_t = 172.8 \pm 1.3$ GeV.

[3] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 13BH studied $tt$ events with large $\not{E}_T$ and $\ell + \geq 4$ jets using a constrained kinematic fit.

[4] Based on 1.04 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. AAD 12BG studied $tt$ events with large $\not{E}_T$ and either $\ell + \geq 4$j or $\ell\ell + \geq 2$j. The uncertainties are not independent, $\rho(F_0,F_-) = -0.96$.

See this paper for constraints on other couplings not included here.

[2] KHACHATRYAN 16BU based on 19.8 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV using $t\bar{t}$ events with $\ell + \not{E}_T + \geq 4$ jets($\geq 2$ $b$). The result is consistent with the NNLO SM prediction of $0.0017 \pm 0.0001$ for $m_t = 172.8 \pm 1.3$ GeV.

[3] Based on 8.7 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV using $t\bar{t}$ events with $\ell + \not{E}_T + \geq 4$ jets($\geq 1$ $b$), and under the constraint $F_0 + F_+ + F_- = 1$. The statstical errors of $F_0$ and $F_+$ are correlated with correlation coefficient $\rho(F_0,F_+) = -0.69$.

[4] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 13BH studied $tt$ events with large $\not{E}_T$ and $\ell + \geq 4$ jets using a constrained kinematic fit.

[5] Based on 1.04 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. AAD 12BG studied $tt$ events with large $\not{E}_T$ and either $\ell + \geq 4$j or $\ell\ell + \geq 2$j.

[6] Results are based on 5.4 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV, including those of ABAZOV 08B. Under the SM constraint of $f_0 = 0.698$ (for $m_t = 173.3$ GeV, $m_W = 80.399$ GeV), $f_+ = 0.010 \pm 0.022 \pm 0.030$ is obtained.

[7] AFFOLDER 00B studied the angular distribution of leptonic decays of $W$ bosons in $t \to Wb$ events. The ratio $F_0$ is the fraction of the helicity zero (longitudinal) $W$ bosons in the decaying top quark rest frame. $B(t \to W_+ b)$ is the fraction of positive helicity (right-handed) positive charge $W$ bosons in the top quark decays. It is obtained by assuming the Standard Model value of $F_0$.

[8] Based on 2.7 and 5.1 fb$^{-1}$ of CDF data in $\ell +$ jets and dilepton channels, and 5.4 fb$^{-1}$ of D0 data in $\ell +$ jets and dilepton channels. $F_0 = 0.682 \pm 0.035 \pm 0.046$ if $F_+ = 0.0017(1)$, while $F_+ = -0.015 \pm 0.018 \pm 0.030$ if $F_0 = 0.688(4)$, where the assumed

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

fixed values are the SM prediction for $m_t = 173.3 \pm 1.1$ GeV and $m_W = 80.399 \pm 0.023$ GeV.

[9] Results are based on 2.7 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. $F_0$ result is obtained by assuming $F_+ = 0$, while $F_+$ result is obtained for $F_0 = 0.70$, the SM value. Model independent fits for the two fractions give $F_0 = 0.88 \pm 0.11 \pm 0.06$ and $F_+ = -0.15 \pm 0.07 \pm 0.06$ with correlation coefficient of $-0.59$. The results are for $m_t = 175$ GeV.

[10] Results are based on 1.9 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. $F_0$ result is obtained assuming $F_+ = 0$, while $F_+$ result is obtained for $F_0 = 0.70$, the SM values. Model independent fits for the two fractions give $F_0 = 0.66 \pm 0.16 \pm 0.05$ and $F_+ = -0.03 \pm 0.06 \pm 0.03$.

[11] Based on 1 fb$^{-1}$ at $\sqrt{s} = 1.96$ TeV.

[12] Based on 370 pb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV, using the $\ell$ + jets and dilepton decay channels. The result assumes $F_0 = 0.70$, and it gives $F_+ < 0.23$ at 95% CL.

[13] Based on 318 pb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV.

[14] Based on 200 pb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV. $t \to Wb \to \ell\nu b$ ($\ell = e$ or $\mu$). The errors are stat + syst.

[15] ABAZOV 05L studied the angular distribution of leptonic decays of $W$ bosons in $t\overline{t}$ events, where one of the $W$'s from $t$ or $\overline{t}$ decays into $e$ or $\mu$ and the other decays hadronically. The fraction of the "+" helicity $W$ boson is obtained by assuming $F_0 = 0.7$, which is the generic prediction for any linear combination of V and A currents. Based on $230 \pm 15$ pb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV.

[16] ACOSTA 05D measures the $m^2_{\ell b}$ distribution in $t\overline{t}$ production events where one or both $W$'s decay leptonically to $\ell = e$ or $\mu$, and finds a bound on the V+A coupling of the $tbW$ vertex. By assuming the SM value of the longitudinal $W$ fraction $F_0 = B(t \to W_0 b) = 0.70$, the bound on $F_+$ is obtained. If the results are combined with those of AFFOLDER 00B, the bounds become $F_{V+A} < 0.61$ (95% CL) and $F_+ < 0.18$ (95 %CL), respectively. Based on $109 \pm 7$ pb$^{-1}$ of data at $\sqrt{s} = 1.8$ TeV (run I).

[1] AABOUD 17BB based on 20.2 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Triple-differential decay rate of top quark is used to simultaneously determine five generalized $Wtb$ couplings as well as the top polarization. No assumption is made for the other couplings. See this paper for constraints on other couplings not included here.

[2] AABOUD 17I based on 20.2 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. A cut-based analysis is used to discriminate between signal and backgrounds. All anomalous couplings other than $\mathrm{Im}(f)_2^R$ are assumed to be zero. See this paper for a number of other asymmetries and measurements that are not included here.

[3] KHACHATRYAN 17G based on 5.0 and 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ and 8 TeV, respectively. A Bayesian neural network technique is used to discriminate between signal and backgrounds. This is a 95% CL exclusion limit obtained by a three-dimensional fit with simultaneous variation of ($f_1^L$, $f_2^L$, $f_2^R$).

[4] AAD 16AK based on 4.6 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. The results are obtained from an analysis of angular distributions of the decay products of single top quarks, assuming $f_1^R = f_2^L = 0$. The fraction of decays containing transversely polarized $W$ is measured to be $F_+ + F_- = 0.37 \pm 0.07$.

[5] Based on 1.04 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. AAD 12BG studied $tt$ events with large $\not{E}_T$ and either $\ell + \geq 4$j or $\ell\ell + \geq 2$j.

[6] Based on 5.4 fb$^{-1}$ of data. For each value of the form factor quoted the other two are assumed to have their SM value. Their Fig. 4 shows two-dimensional posterior probability density distributions for the anomalous couplings.

[7] Based on 5.4 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV. Results are obtained by combining the limits from the $W$ helicity measurements and those from the single top quark production.

[8] Based on 1 fb$^{-1}$ of data at $p\overline{p}$ collisions $\sqrt{s} = 1.96$ TeV. Combined result of the $W$ helicity measurement in $t\overline{t}$ events (ABAZOV 08B) and the search for anomalous $tbW$ couplings in the single top production (ABAZOV 08AI). Constraints when $f_1^L$ and one of the anomalous couplings are simultaneously allowed to vary are given in their Fig. 1 and Table 1.

[9] Result is based on 0.9 fb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV. Single top quark production events are used to measure the Lorentz structure of the $tbW$ coupling. The upper bounds on the non-standard couplings are obtained when only one non-standard coupling is allowed to be present together with the SM one, $f_1^L = V^*_{tb}$.

## $|f_{LV} V_{tb}|$

Assumed that the top-quark-related CKM matrix elements obey the relation $|V_{td}|$, $|V_{ts}| \ll |V_{tb}|$ and a form factor $f_{LV}$ is determined for each production mode and centre-of-mass energy.

### Spin Correlation in $t\bar{t}$ Production in $p\bar{p}$ Collisions

C is the correlation strength parameter, f is the ratio of events with correlated $t$ and $\bar{t}$ spins (SM prediction: f = 1), and $\kappa$ is the spin correlation coefficient. See "The Top Quark" review for more information.

[1] ABAZOV 16A based on 9.7 fb$^{-1}$ of data. A matrix element method is used. It corresponds to evidence of spin correlation at $4.2\sigma$ and is in agreement with the NLO SM prediction $0.80^{+0.01}_{-0.02}$.
[2] This is a combination of the lepton + jets analysis presented in ABAZOV 12B and the dilepton measurement of ABAZOV 11AE. It provides a 3.1 $\sigma$ evidence for the $t\bar{t}$ spin correlation.
[3] Based on 5.3 fb$^{-1}$ of data. The error is statistical and systematic combined. A matrix element method is used.
[4] Based on 4.3 fb$^{-1}$ of data. The measurement is based on the angular study of the top quark decay products in the helicity basis.The theory prediction is $\kappa \approx 0.40$.
[5] Based on 5.4 fb$^{-1}$ of data using a matrix element method. The error is statistical and systematic combined. The no-correlation hypothesis is excluded at the 97.7% CL.
[6] Based on 5.4 fb$^{-1}$ of data. The error is statistical and systematic combined. The NLO QCD prediction is C = 0.78 ± 0.03. The neutrino weighting method is used for reconstruction of kinematics.

### Spin Correlation in $t\bar{t}$ Production in $pp$ Collisions

Spin correlation, $f_{SM}$, measures the strength of the correlation between the spins of the pair produced $t\bar{t}$. $f_{SM}$ =1 for the SM, while $f_{SM}$ =0 for no spin correlation.

[1] KHACHATRYAN 17G based on 5.0 and 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 and 8 TeV, respectively. $t$-channel single top production is used. The result corresponds to $B(t \to ug) < 2.0 \times 10^{-5}$ or $B(t \to cg) < 4.1 \times 10^{-4}$.
[2] AAD 16AS based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. The results are obtained from the 95% CL upper limit on the single top-quark production $\sigma(qg \to t)\cdot B(t \to bW) < 3.4$ pb, $B(t \to ug) < 4.0 \times 10^{-5}$ and $B(t \to cg) < 20 \times 10^{-5}$.
[3] Based on 2.05 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. The results are obtained from the 95% CL upper limit on the single top-quark production $\sigma(qg \to t)\cdot B(t \to bW) < 3.9$ pb, for $q$=$u$ or $q$=$c$, $B(t \to ug) < 5.7 \times 10^{-5}$ and $B(t \to ug) < 2.7 \times 10^{-4}$.
[4] Based on 2.3 fb$^{-1}$ of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. Upper limit of single top quark production cross section 0.20 pb and 0.27 pb via FCNC $t$-$u$-$g$ and $t$-$c$-$g$ couplings, respectively, lead to the bounds without assuming the absence of the other coupling. $B(t \to u + g) < 2.0 \times 10^{-4}$ and $B(t \to c + g) < 3.9 \times 10^{-3}$ follow.
[5] Based on 2.2 fb$^{-1}$ of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. Upper limit of single top quark production cross section $\sigma(u(c) + g \to t) < 1.8$ pb (95% CL) via FCNC $t$-$u$-$g$ and $t$-$c$-$g$ couplings lead to the bounds. $B(t \to u + g) < 3.9 \times 10^{-4}$ and $B(t \to c + g) < 5.7 \times 10^{-3}$ follow.
[6] Result is based on 230 pb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV. Absence of single top quark production events via FCNC $t$-$u$-$g$ and $t$-$c$-$g$ couplings lead to the upper bounds on the dimensioned couplings, $\kappa^{utg}/\Lambda$ and $\kappa^{ctg}/\Lambda$, respectively.

### $t$-Quark Yukawa Coupling from $t\bar{t}$ Kinematic Distributions in $pp$ Collisions

The ratio of $t$-quark Yukawa coupling to its standard model predicted value.

[1] SIRUNYAN 19R based on 35.9 fb$^{-1}$ of $pp$ data at 13 TeV. Multivariate techniques are employed to separate the signal from the dominant $t\bar{t}$+jets background. The result is for $m_H$ = 125 GeV. The measured ratio corresponds to a signal significance of $1.6\sigma$ above the background-only hypothesis.
[2] SIRUNYAN 18BD based on 35.9 fb$^{-1}$ of $pp$ data at 13 TeV. A combined fit of signal and background templates to data is performed in six event categories separated by jet and $b$-jet multiplicities. An upper limit of 3.8 is obtained for the cross section ratio.
[3] SIRUNYAN 18L based on up to 5.1, 19.7, and 35.9 fb$^{-1}$ of $pp$ data at 7, 8, and 13 TeV, respectively. An excess of events is observed, with a significance of 5.2 standard deviations, over the expectation from the background-only hypothesis. The result is for the Higgs boson mass of 125.09 GeV.
[4] Based on 4.5 fb$^{-1}$ of data at 7 TeV and 20.3 fb$^{-1}$ at 8 TeV. The result is for $m_H$ = 125.4 GeV. The measurement constrains the top quark Yukawa coupling strength parameter $\kappa_t = Y_t/Y_t^{SM}$ to be $-1.3 < \kappa_t < 8.0$ (95% CL).

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[5] Based on 5.1 fb$^{-1}$ of $pp$ data at 7 TeV and 19.7 fb$^{-1}$ at 8 TeV. The results are obtained by assuming the SM decay branching fractions for the Higgs boson of mass 125.6 GeV. The signal strength for individual Higgs decay channels are given in Fig. 13, and the preferred region in the $(\kappa_V, \kappa_f)$ space is given in Fig. 14.

## Single *t*-Quark Production Cross Section in $p\overline{p}$ Collisions at $\sqrt{s} = 1.8$ TeV

Direct probe of the $tbW$ coupling and possible new physics at $\sqrt{s} = 1.8$ TeV.

[1] AALTONEN 16 based on 9.5 fb$^{-1}$ of data. This includes, as a part, the result of AALTONEN 14K. Combination of this result with that of AALTONEN 14O gives a $s+t$ cross section of $3.02^{+0.49}_{-0.48}$ pb and $|V_{tb}| > 0.84$ (95% CL).

[2] AALTONEN 15H based on 9.7 fb$^{-1}$ of data per experiment. The result is for $m_t = 172.5$ GeV, and is a combination of the CDF measurements (AALTONEN 16) and the D0 measurements (ABAZOV 13O) on the $t$-channel single $t$-quark production cross section. The result is consistent with the NLO+NNLL SM prediction and gives $|V_{tb}| = 1.02^{+0.06}_{-0.05}$ and $|V_{tb}| > 0.92$ (95% CL).

[3] AALTONEN 15H is a combined measurement of $s$-channel single top cross section by CDF + D0. AALTONEN 14M is not included.

[4] Based on 9.45 fb$^{-1}$ of data, using neural networks to separate signal from backgrounds. The result is for $m_t = 172.5$ GeV. Combination of this result with the CDF measurement in the 1 lepton channel AALTONEN 14L gives $1.36^{+0.37}_{-0.32}$ pb, consistent with the SM prediction, and is 4.2 sigma away from the background only hypothesis.

[5] Based on 9.4 fb$^{-1}$ of data, using neural networks to separate signal from backgrounds. The result is for $m_t = 172.5$ GeV. The result is 3.8 sigma away from the background only hypothesis.

[6] Based on 9.7 fb$^{-1}$ of data per experiment. The result is for $m_t = 172.5$ GeV, and is a combination of the CDF measurements AALTONEN 14L, AALTONEN 14K and the D0 measurement ABAZOV 13O on the $s$-channel single $t$-quark production cross section. The result is consistent with the SM prediction of $1.05 \pm 0.06$ pb and the significance of the observation is of 6.3 standard deviations.

[7] Based on 7.5 fb$^{-1}$ of data. Neural network is used to discriminate signals ($s$-, $t$- and $Wt$-channel single top production) from backgrounds. The result is consistent with the SM prediction, and gives $|V_{tb}| = 0.95 \pm 0.09(\text{stat + syst}) \pm 0.05(\text{theory})$ and $|V_{tb}| > 0.78$ (95% CL). The result is for $m_t = 172.5$ GeV.

[8] Based on 9.7 fb$^{-1}$ of data. Events with $\ell + \not\!\!E_T$ + 2 or 3 jets (1 or 2 $b$-tag) are analysed, assuming $m_t = 172.5$ GeV. The combined s- + t-channel cross section gives $|V_{tb}\ f_1^L| = 1.12^{+0.09}_{-0.08}$, or $|V_{tb}| > 0.92$ at 95% CL for $f_1^L = 1$ and a flat prior within $0 \leq |V_{tb}|^2 \leq 1$.

[9] Based on 5.4 fb$^{-1}$ of data. The error is statistical + systematic combined. The results are for $m_t = 172.5$ GeV. Results for other $m_t$ values are given in Table 2 of ABAZOV 11AA.

[10] Based on 5.4 fb$^{-1}$ of data and for $m_t = 172.5$ GeV. The error is statistical + systematic combined. Results for other $m_t$ values are given in Table III of ABAZOV 11AD. The result is obtained by assuming the SM ratio between $tb$ ($s$-channel) and $tqb$ ($t$-channel) productions, and gives $|V_{tb}\ f_1^L| = 1.02^{+0.10}_{-0.11}$, or $|V_{tb}| > 0.79$ at 95% CL for a flat prior within $0 < |V_{tb}|^2 < 1$.

[11] Based on 3.2 fb$^{-1}$ of data. For combined $s-$ + $t$-channel result see AALTONEN 09AT.

[12] Result is based on 2.1 fb$^{-1}$ of data. Events with large missing $E_T$ and jets with at least one $b$-jet without identified electron or muon are selected. Result is obtained when observed 2.1 $\sigma$ excess over the background originates from the signal for $m_t = 175$ GeV, giving $|V_{tb}| = 1.24^{+0.34}_{-0.29} \pm 0.07$(theory).

[13] Result is based on 2.3 fb$^{-1}$ of data. Events with isolated $\ell + \not\!\!E_T$ + 2 ,3, 4 jets with one or two $b$-tags are selected. The analysis assumes $m_t = 170$ GeV.

[14] Result is based on 4.8 fb$^{-1}$ of data. Events with an isolated reconstructed tau lepton, missing $E_T$ + 2, 3 jets with one or two $b$-tags are selected. When combined with ABAZOV 09Z result for $e + \mu$ channels, the $s$- and $t$-channels combined cross section is $3.84^{+0.89}_{-0.83}$ pb.

[15] Based on 3.2 fb$^{-1}$ of data. Events with isolated $\ell + \not\!\!E_T$ + jets with at least one $b$-tag are analyzed and $s$- and $t$-channel single top events are selected by using the likelihood function, matrix element, neural-network, boosted decision tree, likelihood function optimized for $s$-channel process, and neural-networked based analysis of events with $\not\!\!E_T$ that has sensitivity for $W \to \tau\nu$ decays. The result is for $m_t = 175$ GeV, and the mean value decreases by 0.02 pb/GeV for smaller $m_t$. The signal has 5.0 sigma significance. The result gives $|V_{tb}| = 0.91 \pm 0.11$ (stat+syst) $\pm 0.07$ (theory), or $|V_{tb}| > 0.71$ at 95% CL.

[16] Based on 2.3 fb$^{-1}$ of data. Events with isolated $\ell + \not\!\!E_T + \geq 2$ jets with 1 or 2 $b$-tags are analyzed and $s$- and $t$-channel single top events are selected by using boosted decision tree, Bayesian neural networks and the matrix element method. The signal has 5.0 sigma significance. The result gives $|V_{tb}| = 1.07 \pm 0.12$ , or $|V_{tb}| > 0.78$ at 95% CL. The analysis assumes $m_t = 170$ GeV.

[17] Result is based on 2.2 fb$^{-1}$ of data. Events with isolated $\ell + \not\!\!E_T$ + 2, 3 jets with at least one $b$-tag are selected, and $s$- and $t$-channel single top events are selected by using likelihood, matrix element, and neural network discriminants. The result can be interpreted as $|V_{tb}| = 0.88^{+0.13}_{-0.12}(\text{stat + syst}) \pm 0.07(\text{theory})$, and $|V_{tb}| > 0.66$ (95% CL) under the $|V_{tb}| < 1$ constraint.

[18] Result is based on 0.9 fb$^{-1}$ of data. Events with isolated $\ell + \not\!\!E_T$ + 2, 3, 4 jets with one or two $b$-vertex-tag are selected, and contributions from $W$ + jets, $t\overline{t}$, $s$- and $t$-channel single top events are identified by using boosted decision trees, Bayesian neural networks, and matrix element analysis. The result can be interpreted as the measurement of the CKM matrix element $|V_{tb}| = 1.31^{+0.25}_{-0.21}$, or $|V_{tb}| > 0.68$ (95% CL) under the $|V_{tb}| < 1$ constraint.

[19] Result is based on 0.9 fb$^{-1}$ of data. This result constrains $V_{tb}$ to $0.68 < |V_{tb}| \leq 1$ at 95% CL.

[20] ABAZOV 05P bounds single top-quark production from either the $s$-channel $W$-exchange process, $q'\overline{q} \to t\overline{b}$, or the $t$-channel $W$-exchange process, $q'g \to qt\overline{b}$, based on $\sim 230$ pb$^{-1}$ of data.

[21] ACOSTA 05N bounds single top-quark production from the $t$-channel $W$-exchange process ($q'g \to qt\overline{b}$), the $s$-channel $W$-exchange process ($q'\overline{q} \to t\overline{b}$), and from the combined cross section of $t$- and $s$-channel. Based on $\sim$ 162 pb$^{-1}$ of data.

## t-channel Single *t* Production Cross Section in $pp$ Collisions at $\sqrt{s} = 7$ TeV

Direct probe of the $tbW$ coupling and possible new physics at $\sqrt{s} = 7$ TeV.

| $83.6 \pm 29.8 \pm 3.3$ | [5] CHATRCHYAN | 11R | CMS | $t$-channel |

[1] AABOUD 19R based on 1.17 to 5.1 fb$^{-1}$ of data from ATLAS and CMS at 7 TeV.

[2] Based on 4.59 fb$^{-1}$ of data, using neural networks for signal and background separation. $\sigma(tq) = 46 \pm 1 \pm 6$ pb and $\sigma(\overline{t}q) = 23 \pm 1 \pm 3$ pb are separately measured, as well as their ratio $R = \sigma(tq)/\sigma(\overline{t}q) = 2.04 \pm 0.13 \pm 0.12$. The results are for $m_t = 172.5$ GeV, and those for other $m_t$ values are given by eq.(4) and Table IV. The measurements give $|V_{tb}| = 1.02 \pm 0.07$ or $|V_{tb}| > 0.88$ (95% CL).

[3] Based on 1.04 fb$^{-1}$ of data. The result gives $|V_{tb}| = 1.13^{+0.14}_{-0.13}$ from the ratio $\sigma(\text{exp})/\sigma(\text{th})$, where $\sigma(\text{th})$ is the SM prediction for $|V_{tb}| = 1$. The 95% CL lower bound of $|V_{tb}| > 0.75$ is found if $|V_{tb}| < 1$ is assumed. $\sigma(t) = 59^{+18}_{-16}$ pb and $\sigma(\overline{t}) = 33^{+13}_{-12}$ pb are found for the separate single $t$ and $\overline{t}$ production cross sections, respectively. The results assume $m_t = 172.5$ GeV for the acceptance.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[4] Based on 1.17 fb$^{-1}$ of data for $\ell = \mu$, 1.56 fb$^{-1}$ of data for $\ell = e$ at 7 TeV collected during 2011. The result gives $|V_{tb}| = 1.020 \pm 0.046(\text{meas}) \pm 0.017(\text{th})$. The 95% CL lower bound of $|V_{tb}| > 0.92$ is found if $|V_{tb}| < 1$ is assumed. The results assume $m_t = 172.5$ GeV for the acceptance.

[5] Based on 36 pb$^{-1}$ of data. The first error is statistical + systematic combined, the second is luminosity. The result gives $|V_{tb}| = 1.114 \pm 0.22(\text{exp}) \pm 0.02(\text{th})$ from the ratio $\sigma(\text{exp})/\sigma(\text{th})$, where $\sigma(\text{th})$ is the SM prediction for $|V_{tb}| = 1$. The 95% CL lower bound of $|V_{tb}| > 0.62$ (0.68) is found from the 2D (BDT) analysis under the constraint $0 < |V_{tb}|^2 < 1$.

### t-channel Single $t$ Production Cross Section in $pp$ Collisions at $\sqrt{s} = 8$ TeV

| VALUE (pb) | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| $87.7 \pm 5.8$ | [1] AABOUD | 19R | LHC | combination of ATLAS+CMS |
| $89.6^{+7.1}_{-6.3}$ | [2] AABOUD | 17T | ATLS | $\ell + \not{E}_T + 2$ j ($1b$ j) |
| $83.6 \pm 2.3 \pm 7.4$ | [3] KHACHATRY...14F | | CMS | $\ell + \not{E}_T + \geq 2$ j (1,2 $b$, 1 forward j) |

[1] AABOUD 19R based on 12.2 to 20.3 fb$^{-1}$ of data from ATLAS and CMS at 8 TeV.

[2] AABOUD 17T based on 20.2 fb$^{-1}$ of data. A maximum-likelihood fit to neural-network discriminant distributions is used to separate signal and background events. Individual cross sections are measured as $\sigma(tq) = 56.7^{+4.3}_{-3.8}$ pb and $\sigma(\bar{t}q) = 32.9^{+3.0}_{-2.7}$ pb, while their ratio is given by $\sigma(tq)/\sigma(\bar{t}q) = 1.72 \pm 0.09$. A lower limit $|V_{tb}| > 0.92$ (95% CL) is obtained. Measured total and differential cross sections are described well by the SM.

[3] Based on 19.7 fb$^{-1}$ of data. The $t$ and $\bar{t}$ production cross sections are measured separately as $\sigma_{t-ch.}(t) = 53.8 \pm 1.5 \pm 4.4$ pb and $\sigma_{t-ch.}(\bar{t}) = 27.6 \pm 1.3 \pm 3.7$ pb, respectively, as well as their ratio $R_{t-ch} = \sigma_{t-ch.}(t)/\sigma_{t-ch.}(\bar{t}) = 1.95 \pm 0.10 \pm 0.19$, in agreement with the SM predictions. Combination with a previous CMS result at $\sqrt{s} = 7$ TeV [CHATRCHYAN 12BQ] gives $|V_{tb}| = 0.998 \pm 0.038 \pm 0.016$. Also obtained is the ratio $R_{8/7} = \sigma_{t-ch.}(8\text{TeV})/\sigma_{t-ch.}(7\text{TeV}) = 1.24 \pm 0.08 \pm 0.12$.

### s-channel Single $t$ Production Cross Section in $pp$ Collisions at $\sqrt{s} = 8$ TeV

| VALUE (pb) | DOCUMENT ID | | TECN | COMMENT |

| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| $4.9 \pm 1.4$ | [1] AABOUD | 19R | LHC | ATLAS + CMS |
| $4.8 \pm 0.8^{+1.6}_{-1.3}$ | [2] AAD | 16U | ATLS | $\ell + \not{E}_T + 2b$ |
| $13.4 \pm 7.3$ | [3] KHACHATRY...16AZ | | CMS | $\ell + \not{E}_T + 2b$ |
| $5.0 \pm 4.3$ | [4] AAD | 15A | ATLS | $\ell + \not{E}_T + 2b$ |

[1] AABOUD 19R based on 12.2 to 20.3 fb$^{-1}$ of data from ATLAS and CMS at 8 TeV.

[2] AAD 16U based on 20.3 fb$^{-1}$ of data, using a maximum-likelihood fit of a matrix element method discriminant. The same data set as in AAD 15A is used. The result corresponds to an observed significance of $3.2\sigma$.

[3] KHACHATRYAN 16AZ based on 19.7 fb$^{-1}$ of data, using a multivariate analysis to separate signal and backgrounds. The same method is applied to 5.1 fb$^{-1}$ of data at $\sqrt{s} = 7$ TeV, giving $7.1 \pm 8.1$ pb. Combining both measurements, the observed significance is $2.5\sigma$. A best fit value of $2.0 \pm 0.9$ is obtained for the combined ratio of the measured values and SM expectations.

[4] AAD 15A based on 20.3 fb$^{-1}$ of data, using a multivariate analysis to separate signal and backgrounds. The 95% CL upper bound of the cross section is 14.6 pb. The results are consistent with the SM prediction of $5.61 \pm 0.22$ pb at approximate NNLO.

### t-channel Single $t$ Production Cross Section in $pp$ Collisions at $\sqrt{s} = 13$ TeV

[1] SIRUNYAN 20D based on 35.9 fb$^{-1}$ of data. Different categories of jet and b jet multiplicity and multivariate discriminators are used to separate signal and background events. The cross section ratio is measured to be $\sigma(tq)/\sigma(\bar{t}q) = 1.68 \pm 0.02 \pm 0.05$. CKM matrix element is obtained as $|f_{LV} V_{tb}| = 0.98 \pm 0.07(\text{exp}) \pm 0.02(\text{theo})$ where $f_{LV}$ is an anomalous form factor. All results are in agreement with the SM.

[2] AABOUD 17H based on 3.2 fb$^{-1}$ of data. A maximum-likelihood fit to neural-network discriminant distributions is used to separate signal and background events. The third error is for luminosity. The cross section ratio is measured to be $\sigma(tq)/\sigma(\bar{t}q) = 1.72 \pm 0.09 \pm 0.18$. A lower limit $|V_{tb}| > 0.84$ (95% CL) is obtained. All results are in agreement with the SM.

[3] SIRUNYAN 17AA based on 2.2 fb$^{-1}$ of data. A multivariate discriminator is used to separate signal and background events. The four errors are from statitics, experimental systematics, theory, and luminosity. The cross section ratio is measured to be $\sigma(tq)/\sigma(\bar{t}q) = 1.81 \pm 0.18 \pm 0.15$. CKM matrix element is obtained as $|V_{tb}| = 1.05 \pm 0.07(\text{exp}) \pm 0.02(\text{theo})$. All results are in agreement with the SM.

|---|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| $<0.25$ | 95 | [1] AARON | 09A | H1 | $e^\pm p \to e^\pm tX$ |
| $<0.55$ | 95 | [2] AKTAS | 04 | H1 | $e^\pm p \to e^\pm tX$ |
| $<0.225$ | 95 | [3] CHEKANOV | 03 | ZEUS | $e^\pm p \to e^\pm tX$ |

[1] AARON 09A looked for single top production via FCNC in $e^\pm p$ collisions at HERA with 474 pb$^{-1}$ of data at $\sqrt{s} = 301$–$319$ GeV. The result supersedes that of AKTAS 04.

[2] AKTAS 04 looked for single top production via FCNC in $e^\pm$ collisions at HERA with 118.3 pb$^{-1}$, and found 5 events in the $e$ or $\mu$ channels while $1.31 \pm 0.22$ events are expected from the Standard Model background. No excess was found for the hadronic channel. The observed cross section of $\sigma(ep \to etX) = 0.29^{+0.15}_{-0.14}$ pb at $\sqrt{s} = 319$ GeV gives the quoted upper bound if the observed events are due to statistical fluctuation.

[3] CHEKANOV 03 looked in 130.1 pb$^{-1}$ of data at $\sqrt{s} = 301$ and 318 GeV. The limit is for $\sqrt{s} = 318$ GeV and assumes $m_t = 175$ GeV.

### $t\bar{t}$ Production Cross Section in $p\bar{p}$ Collisions at $\sqrt{s} = 1.8$ TeV

Only the final combined $t\bar{t}$ production cross sections obtained from Tevatron Run I by the CDF and D0 experiments are quoted below.

[1] ABAZOV 16F based on 9.7 fb$^{-1}$ of data. The result is for $m_t = 172.5$ GeV, and the $m_t$ dependence is shown in Table V and Fig. 9. The result agrees with the NNLO+NNLL SM prediction of $7.35 ^{+0.23}_{-0.27}$ pb.

[2] Based on 9 fb$^{-1}$ of data. The measurement is in the channel $t\bar{t} \rightarrow (b\ell\nu)(b\tau\nu)$, where $\tau$ decays into hadrons ($\tau_h$), and $\ell$ ($e$ or $\mu$) include $\ell$ from $\tau$ decays ($\tau_\ell$). The result is for $m_t = 173$ GeV.

[3] Based on 8.8 fb$^{-1}$ of data. Combination of CDF and D0 measurements given, respectively, by $\sigma(t\bar{t}$; CDF) $= 7.63 \pm 0.31 \pm 0.36 \pm 0.16$ pb, $\sigma(t\bar{t}$; D0) $= 7.56 \pm 0.20 \pm 0.32 \pm 0.46$ pb. All the results are for $m_t = 172.5$ GeV. The $m_t$ dependence of the mean value is parametrized in eq. (1) and shown in Fig. 2.

[4] Based on 9.7 fb$^{-1}$ of data. Differential cross sections with respect to $m_{tt}$, $|y(\text{top})|$, $E_T(\text{top})$ are shown in Figs. 9, 10, 11, respectively, and are compared to the predictions of MC models.

[5] Based on 8.8 fb$^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[6] Based on 8.7 fb$^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. Measure the $t\bar{t}$ cross section simultaneously with the fraction of $t \rightarrow Wb$ decays. The correlation coefficient between those two measurements is $-0.434$. Assume unitarity of the 3×3 CKM matrix and set $|V_{tb}| > 0.89$ at 95% CL.

[7] Based on 2.2 fb$^{-1}$ of data in $p\bar{p}$ collisions at 1.96 TeV. The result assumes the acceptance for $m_t = 172.5$ GeV.

[8] Based on 1.12 fb$^{-1}$ and assumes $m_t = 175$ GeV, where the cross section changes by $\pm 0.1$ pb for every $\mp 1$ GeV shift in $m_t$. AALTONEN 11D fits simultaneously the $t\bar{t}$ production cross section and the $b$-tagging efficiency and find improvements in both measurements.

[9] Based on 2.7 fb$^{-1}$. The first error is from statistics and systematics, the second is from luminosity. The result is for $m_t = 175$ GeV. AALTONEN 11W fits simultaneously a jet flavor discriminator between $b$-, $c$-, and light-quarks, and find significant reduction in the systematic error.

[10] Based on 2.2 fb$^{-1}$. The result is for $m_t = 172.5$ GeV. AALTONEN 11Y selects multi-jet events with large $\not{E}_T$, and vetoes identified electrons and muons.

[11] Based on 5.3 fb$^{-1}$. The error is statistical + systematic + luminosity combined. The result is for $m_t = 172.5$ GeV. The results for other $m_t$ values are given in Table XII and eq.(10) of ABAZOV 11E.

[12] Combination of a dilepton measurement presented in ABAZOV 11Z (based on 5.4 fb$^{-1}$), which yields $7.36 ^{+0.90}_{-0.79}$ (stat+syst) pb, and the lepton + jets measurement of ABAZOV 11E. The result is for $m_t = 172.5$ GeV. The results for other $m_t$ values is given by eq.(5) of ABAZOV 11A.

[13] Based on 2.8 fb$^{-1}$. The result is for $m_t = 175$ GeV.

[14] Based on 2.9 fb$^{-1}$. Result is obtained from the fraction of signal events in the top quark mass measurement in the all hadronic decay channel.

[15] Based on 1.7 fb$^{-1}$. The result is for $m_t = 175$ GeV. AALTONEN 10V uses soft electrons from $b$-hadron decays to suppress $W$+jets background events.

[16] Based on 4.6 fb$^{-1}$. The result is for $m_t = 172.5$ GeV. The ratio $\sigma(t\bar{t} \rightarrow \ell$+jets) / $\sigma(Z/\gamma^* \rightarrow \ell\ell)$ is measured and then multiplied by the theoretical $Z/\gamma^* \rightarrow \ell\ell$ cross section of $\sigma(Z/\gamma^* \rightarrow \ell\ell) = 251.3 \pm 5.0$ pb, which is free from the luminosity error.

[17] Based on 1 fb$^{-1}$. The result is for $m_t = 175$ GeV. $7.9 \pm 2.3$ pb is found for $m_t = 170$ GeV. ABAZOV 10I uses a likelihood discriminant to separate signal from background, where the background model was created from lower jet-multiplicity data.

[18] Based on 1 fb$^{-1}$. The result is for $m_t = 170$ GeV. For $m_t = 175$ GeV, the result is $6.3 ^{+1.2}_{-1.1}$(stat) $\pm 0.7$(syst) $\pm 0.4$(lumi) pb. Cross section of $t\bar{t}$ production has been measured in the $t\bar{t} \rightarrow \tau_h +$ jets topology, where $\tau_h$ denotes hadronically decaying $\tau$ leptons. The result for the cross section times the branching ratio is $\sigma(t\bar{t}) \cdot$ B($t\bar{t} \rightarrow \tau_h +$ jets) $= 0.60 ^{+0.23}_{-0.22} ^{+0.15}_{-0.14} \pm 0.04$ pb for $m_t = 170$ GeV.

[19] Based on 1.1 fb$^{-1}$. The result is for B($W \rightarrow \ell\nu$) = 10.8% and $m_t = 175$ GeV; the mean value is 9.8 for $m_t = 172.5$ GeV and 10.1 for $m_t = 170$ GeV. AALTONEN 09AD used high $p_T$ $e$ or $\mu$ with an isolated track to select $t\bar{t}$ decays into dileptons including $\ell = \tau$. The result is based on the candidate event samples with and without vertex $b$-tag.

[20] Based on 2 fb$^{-1}$. The result is for $m_t = 175$ GeV; the mean value is 3% higher for $m_t = 170$ GeV and 4% lower for $m_t = 180$ GeV.

[21] Result is based on 1 fb$^{-1}$ of data. The result is for $m_t = 170$ GeV, and the mean value decreases with increasing $m_t$; see their Fig. 2. The result is obtained after combining $\ell$ + jets, $\ell\ell$, and $\ell\tau$ final states, and the ratios of the extracted cross sections are $R^{\ell\ell\ell/\ell j} = 0.86 ^{+0.19}_{-0.17}$ and $R^{\ell\tau/\ell\ell-\ell j} = 0.97 ^{+0.32}_{-0.29}$, consistent with the SM expectation of R = 1. This leads to the upper bound of B($t \rightarrow bH^+$) as a function of $m_{H^+}$. Results are shown in their Fig. 1 for B($H^+ \rightarrow \tau\nu$) = 1 and B($H^+ \rightarrow c\bar{s}$) = 1 cases. Comparison of the $m_t$ dependence of the extracted cross section and a partial NNLO prediction gives $m_t = 169.1 ^{+5.9}_{-5.2}$ GeV.

[22] Result is based on 1 fb$^{-1}$ of data. The result is for $m_t = 170$ GeV, and the mean value changes by $-0.07$ [$m_t$(GeV)$-170$] pb near the reference $m_t$ value. Comparison of the $m_t$ dependence of the extracted cross section and a partial NNLO QCD prediction gives $m_t = 171.5 ^{+9.9}_{-8.8}$ GeV. The $\ell\tau$ channel alone gives $7.6 ^{+4.9}_{-4.3} ^{+3.5}_{-3.4} ^{+1.4}_{-0.9}$ pb and the $\ell\ell$ channel gives $7.5 ^{+1.2}_{-1.1} ^{+0.7}_{-0.6} ^{+0.7}_{-0.5}$ pb.

[23] Result is based on 0.9 fb$^{-1}$ of data. The first error is from stat + syst, while the latter error is from luminosity. The result is for $m_t$=175 GeV, and the mean value changes by $-0.09$ pb·[$m_t$(GeV)$-175$].

[24] Result is based on 0.9 fb$^{-1}$ of data. The cross section is obtained from the $\ell + \geq 3$jet event rates with 1 or 2 $b$-tag, and also from the kinematical likelihood analysis of the $\ell +$ 3, 4 jet events. The result is for $m_t$= 172.6 GeV, and its $m_t$ dependence shown in Fig. 3 leads to the constraint $m_t = 170 \pm 7$ GeV when compared to the SM prediction.

[25] Result is based on 360 pb$^{-1}$ of data. Events with high $p_T$ oppositely charged dileptons $\ell^+\ell^-$ ($\ell = e, \mu$) are used to obtain cross sections for $t\bar{t}$, $W^+W^-$, and $Z \rightarrow \tau^+\tau^-$ production processes simultaneously. The other cross sections are given in Table IV.

[26] Based on 1.02 fb$^{-1}$ of data. Result is for $m_t = 175$ GeV. Secondary vertex $b$-tag and neural network selections are used to achieve a signal-to-background ratio of about 1/2.

[27] Based on 425 pb$^{-1}$ of data. Result is for $m_t = 175$ GeV. For $m_t = 170.9$ GeV, $7.8 \pm 1.8$(stat + syst) pb is obtained.

[28] Based on 405 ± 25 pb$^{-1}$ of data. Result is for $m_t = 175$ GeV. The last error is for luminosity. Secondary vertex $b$-tag and neural network are used to separate the signal events from the background.

[29] Based on 425 pb$^{-1}$ of data. Assumes $m_t = 175$ GeV.

[30] Based on $\sim$ 425 pb$^{-1}$. Assuming $m_t = 175$ GeV. The first error is combined statistical and systematic, the second one is luminosity.

[31] Based on $\sim$ 318 pb$^{-1}$. Assuming $m_t = 178$ GeV. The cross section changes by $\pm 0.08$ pb for each $\mp$ GeV change in the assumed $m_t$. Result is for at least one $b$-tag. For at least two $b$-tagged jets, $t\bar{t}$ signal of significance greater than $5\sigma$ is found, and the cross section is $10.1 ^{+1.6}_{-1.4} ^{+2.0}_{-1.3}$ pb for $m_t = 178$ GeV.

[32] Based on $\sim$ 311 pb$^{-1}$. Assuming $m_t = 178$ GeV. For $m_t = 175$ GeV, the result is $6.0 \pm 1.2 ^{+0.9}_{-0.7}$. This is the first CDF measurement without lepton identification, and hence it has sensitivity to the $W \rightarrow \tau\nu$ mode.

[33] ABULENCIA,A 06E measures the $t\bar{t}$ production cross section in the all hadronic decay mode by selecting events with 6 to 8 jets and at least one b-jet. S/B = 1/5 has been achieved. Based on 311 pb$^{-1}$. Assuming $m_t = 178$ GeV.

[34] Based on $\sim$ 318 pb$^{-1}$. Assuming $m_t = 178$ GeV. Result is for at least one $b$-tag. For at least two $b$-tagged jets, the cross section is $11.1 ^{+2.3}_{-1.9} ^{+2.5}_{-1.9}$ pb.

[35] ABAZOV 05Q measures the top-quark pair production cross section with $\sim$ 230 pb$^{-1}$ of data, based on the analysis of $W$ plus n-jet events where W decays into $e$ or $\mu$ plus neutrino, and at least one of the jets is $b$-jet like. The first error is statistical and systematic, and the second accounts for the luminosity uncertainty. The result assumes

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

$m_t$ = 175 GeV; the mean value changes by $(175-m_t(\text{GeV})) \times 0.06$ pb in the mass range 160 to 190 GeV.

[36] ABAZOV 05R measures the top-quark pair production cross section with 224–243 pb$^{-1}$ of data, based on the analysis of events with two charged leptons in the final state. The result assumes $m_t$ = 175 GeV; the mean value changes by $(175-m_t(\text{GeV})) \times 0.08$ pb in the mass range 160 to 190 GeV.

[37] Based on 230 pb$^{-1}$. Assuming $m_t$ = 175 GeV.

[38] Based on 194 pb$^{-1}$. Assuming $m_t$ = 175 GeV.

[39] Based on 194 ± 11 pb$^{-1}$. Assuming $m_t$ = 175 GeV.

[40] Based on 162 ± 10 pb$^{-1}$. Assuming $m_t$ = 175 GeV.

[41] ACOSTA 05V measures the top-quark pair production cross section with ∼ 162 pb$^{-1}$ data, based on the analysis of $W$ plus n-jet events where $W$ decays into $e$ or $\mu$ plus neutrino, and at least one of the jets is $b$-jet like. Assumes $m_t$ = 175 GeV.

[42] ACOSTA 04I measures the top-quark pair production cross section with 197 ± 12 pb$^{-1}$ data, based on the analysis of events with two charged leptons in the final state. Assumes $m_t$ = 175 GeV.

### Ratio of the Production Cross Sections of $t\bar{t}\gamma$ to $t\bar{t}$ at $\sqrt{s}$ = 1.96 TeV

| VALUE | DOCUMENT ID | TECN | COMMENT |
|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | |
| 0.024±0.009 | [1] AALTONEN 11Z | CDF | $E_T(\gamma) > 10$ GeV, $\lvert\eta(\gamma)\rvert < 1.0$ |

[1] Based on 6.0 fb$^{-1}$ of data. The error is statistical and systematic combined. Events with lepton + $\not{E}_T$ + ≥ 3 jets( ≥ 1$b$) with and without central, high $E_T$ photon are measured. The result is consistent with the SM prediction of 0.024 ± 0.005. The absolute production cross section is measured to be 0.18 ± 0.08 fb. The statistical significance is 3.0 standard deviations.

[1] KHACHATRYAN 17B based on 5.0 fb$^{-1}$ of data, using a binned likelihood fit of templates to the data. Also the ratio $\sigma(t\bar{t};\ 8\ \text{TeV})/\sigma(t\bar{t};\ 7\ \text{TeV}) = 1.43\pm0.04\pm0.07\pm0.05$ is reported. The results are in agreement with NNLO SM predictions.

[2] KHACHATRYAN 16AW based on 5.0 fb$^{-1}$ of data, using a binned likelihood fit to differential distributions of $b$-tagged and non-$b$-tagged jets. The result is in good agreement with NNLO SM predictions.

[3] Based on 4.6 fb$^{-1}$ of data. Uses a template fit to distributions of $\not{E}_T$ and jet multiplicities to measure simultaneously $t\bar{t}$, $WW$, and $Z/\gamma^* \to \tau\tau$ cross sections, assuming $m_t$ = 172.5 GeV.

[4] AAD 15CC based on 4.6 fb$^{-1}$ of data. The event selection criteria are optimized for the $\ell\tau_h$ + jets channel. Using only this channel 183 ± 9 ± 23 ± 3 pb is derived for the cross section.

[5] AAIJ 15R, based on 1.0 fb$^{-1}$ of data, reports 0.239 ± 0.053 ± 0.033 ± 0.024 pb cross section for the forward fiducial region $p_T(\mu) > 25$ GeV, $2.0 < \eta(\mu) < 4.5$, 50 GeV < $p_T(b) < 100$ GeV, $2.2 < \eta(b) < 4.2$, $\Delta R(\mu,b) > 0.5$, and $p_T(\mu+b) > 20$ GeV. The three errors are from statistics, systematics, and theory. The result agrees with the SM NLO prediction.

[6] AAD 14AY reports 182.9 ± 3.1 ± 4.2 ± 3.6 ± 3.3 pb value based on 4.6 fb$^{-1}$ of data. The four errors are from statistics, systematic, luminosity, and the 0.66% beam energy uncertainty. We have combined the systematic uncertainties in quadrature. The result is for $m_t$ = 172.5GeV; for other $m_t$, $\sigma(m_t) = \sigma(172.5\text{GeV})\times[1-0.0028\times(m_t - 172.5\text{GeV})]$. The result is consistent with the SM prediction at NNLO.

[7] Based on 1.67 fb$^{-1}$ of data. The result uses the acceptance for $m_t$ = 172.5 GeV.

[8] Based on 3.54 fb$^{-1}$ of data.

[9] Based on 2.3 fb$^{-1}$ of data.

[10] Based on 3.9 fb$^{-1}$ of data.

[11] Based on 35 pb$^{-1}$ of data for an assumed top quark mass of $m_t$ = 172.5 GeV.

[12] Based on 0.70 fb$^{-1}$ of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for $m_t$ = 172.5 GeV.

[13] Based on 35 pb$^{-1}$ of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for $m_t$ = 172.5 GeV and 173 ± 17$^{+18}_{-16}$ ± 6 pb is found without the $b$-tag.

[14] Based on 2.05 fb$^{-1}$ of data. The hadronic $\tau$ candidates are selected using a BDT technique. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for $m_t$ = 172.5 GeV.

[15] Based on 2.0 fb$^{-1}$ and 2.2 fb$^{-1}$ of data for $\ell = e$ and $\ell = \mu$, respectively. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for $m_t$ = 172.5 GeV.

[16] Based on 2.3 fb$^{-1}$ of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the profile likelihood-ratio (PLB) method and an assumed $m_t$ of 172.5 GeV.

[17] Based on 2.9 pb$^{-1}$ of data. The result for single lepton channels is 142 ± 34$^{+50}_{-31}$ pb, while for the dilepton channels is 151$^{+\ 78+37}_{-\ 62-24}$ pb.

[18] Result is based on 36 pb$^{-1}$ of data. The first uncertainty corresponds to the statistical and systematic uncertainties, and the second corresponds to the luminosity.

[19] Based on 36 pb$^{-1}$ of data. The ratio of $t\bar{t}$ and $Z/\gamma^*$ cross sections is measured as $\sigma(pp \to t\bar{t})/\sigma(pp \to Z/\gamma^* \to e^+e^-/\mu^+\mu^-) = 0.175 \pm 0.018(\text{stat}) \pm 0.015(\text{syst})$ for $60 < m_{\ell\ell} < 120$ GeV, for which they use an NNLO prediction for the denominator cross section of 972 ± 42 pb.

[20] Result is based on 36 pb$^{-1}$ of data. The first error is from statistical and systematic uncertainties, and the second from luminosity. This is a combination of a measurement in the dilepton channel (CHATRCHYAN 11F) and the measurement in the $\ell$ + jets channel (CHATRCHYAN 11Z) which yields 150 ± 9 ± 17 ± 6 pb.

[21] Result is based on 3.1 ± 0.3 pb$^{-1}$ of data.

### $t\bar{t}$ Production Cross Section in $pp$ Collisions at $\sqrt{s}$ = 8 TeV

Unless otherwise noted the first quoted error is from statistics, the second from systematic uncertainties, and the third from luminosity. If only two errors are quoted the luminosity is included in the systematic uncertainties.

[1] AABOUD 18BH based on 20.2 fb$^{-1}$ of data. The result is for $m_t$ = 172.5 GeV. To reduce effects of uncertainties in the jet energy scale and $b$-tagging efficiency, they are included as nuisance parameters in the fit of discriminant distributions, after separating selected events into three regions. Furthermore the $W$+jets background distribution is modelled using $Z$+jets event data.

[2] AABOUD 17Z based on 20.2 fb$^{-1}$ of data, using the mode $t\bar{t} \to \tau\nu q'\bar{q}b\bar{b}$ with $\tau$ decaying hadronically. Single prong and 3 prong decays of $\tau$ are separately analyzed. The result is consistent with the SM. The third quoted uncertainty is due to luminosity.

[3] KHACHATRYAN 17B based on 19.6 fb$^{-1}$ of data, using a binned likelihood fit of templates to the data. Also the ratio $\sigma(t\bar{t};\ 8\ \text{TeV})/\sigma(t\bar{t};\ 7\ \text{TeV}) = 1.43\pm0.04\pm0.07\pm0.05$ is reported. The results are in agreement with NNLO SM predictions.

[4] AAD 16BK is an update of the value from AAD 14AY using the improved luminosity calibration. The value 242.9 ± 1.7 ± 5.5 ± 5.1 ± 4.2 pb is reported, where we have combined the systematic uncertainties in quadrature. Also the ratio $\sigma(t\bar{t};\ 8\text{TeV})/\sigma(t\bar{t};\ 7\text{TeV}) = 1.328 \pm 0.024 \pm 0.015 \pm 0.038 \pm 0.001$ has been updated. The former result is consistent with the SM predictions at NNLO, while the latter result is 2.1 $\sigma$ below the expectation.

[5] KHACHATRYAN 16AW based on 19.7 fb$^{-1}$ of data, using a binned likelihood fit to differential distributions of $b$-tagged and non-$b$-tagged jets. The result is in good agreement with NNLO SM predictions.

[6] KHACHATRYAN 16BC based on 18.4 fb$^{-1}$ of data. The last uncertainty is due to luminosity. Cuts on kinematical fit probability and $\Delta R(b,b)$ are imposed. The major QCD background is determined from the data. The result is for $m_t$ = 172.5 GeV and in agreement with the SM prediction. The top quark $p_T$ spectra, also measured, are significantly softer than theoretical predictions.

[7] AAD 15BP based on 20.3 fb$^{-1}$ of data. The result is for $m_t$ = 172.5 GeV and in agreement with the SM prediction 253$^{+13}_{-15}$ pb at NNLO+NNLL. Superseded by AABOUD 18BH.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[8] AAIJ 15R, based on 2.0 fb$^{-1}$ of data, reports 0.289 ± 0.043 ± 0.040 ± 0.029 pb cross section for the forward fiducial region $p_T(\mu) > 25$ GeV, $2.0 < \eta(\mu) < 4.5$, 50 GeV < $p_T(b) < 100$ GeV, $2.2 < \eta(b) < 4.2$, $\Delta R(\mu,b) > 0.5$, and $p_T(\mu+b) > 20$ GeV. The three errors are from statistics, systematics, and theory. The result agrees with the SM NLO prediction.

[9] AAD 14AY reports 242.4 ± 1.7 ± 5.5 ± 7.5 ± 4.2 pb value based on 20.3 fb$^{-1}$ of data. The four errors are from statistics, systematic, luminosity, and the 0.66% beam energy uncertainty. We have combined the systematic uncertainties in quadrature. The result is for $m_t = 172.5$GeV; for other $m_t$, $\sigma(m_t) = \sigma(172.5\text{GeV})\times[1-0.0028\times(m_t - 172.5\text{GeV})]$. Also measured is the ratio $\sigma(t\bar{t}; 8\text{TeV})/\sigma(t\bar{t}; 7\text{TeV}) = 1.326 \pm 0.024 \pm 0.015 \pm 0.049 \pm 0.001$. The results are consistent with the SM predictions at NNLO.

[10] Based on 5.3 fb$^{-1}$ of data. The result is for $m_t = 172.5$ GeV, and a parametrization is given in eq.(6.1) for the mean value at other $m_t$ values. The result is in agreement with the SM prediction $252.9^{+6.4}_{-8.6}$ pb at NNLO.

[11] Based on 19.6 fb$^{-1}$ of data. The measurement is in the channel $t\bar{t} \to (b\ell\nu)(b\tau\nu)$, where $\tau$ decays into hadrons ($\tau_h$). The result is for $m_t = 172.5$ GeV. For $m_t = 173.3$ GeV, the cross section is lower by 3.1 pb.

[1] AABOUD 19AP based on 36.1 fb$^{-1}$ of data. The upper limit corresponds to 5.1 times the NLO SM cross section.

[2] AABOUD 19AP limit from data combined with AABOUD 18CE. The upper limit corresponds to 5.3 times the NLO SM cross section. Also a limit on the four-top-quark contact interaction of $|C_{4t}|/\Lambda^2 < 1.9$ TeV$^{-2}$ (95% CL) is obtained in an EFT model.

[3] SIRUNYAN 19CN based on 35.8 fb$^{-1}$ of data, combined with SIRUNYAN 18BU. The results are also interpreted in the effective field theory framework.

[4] SIRUNYAN 19CN based on 35.8 fb$^{-1}$ of data. A multivariate analysis using global event and jet propoerties is performed to discriminate from $t\bar{t}$ background.

[5] AABOUD 18CE based on 36.1 fb$^{-1}$ of proton-proton data taken at $\sqrt{s} = 13$ TeV. Events including a same-sign lepton pair are used. The result is consistent with the NLO SM cross section of 9.2 fb.

[6] SIRUNYAN 18BU based on 35.9 fb$^{-1}$ of proton-proton data taken at $\sqrt{s} = 13$ TeV. Yields from signal regions and control regions defined based on $N_{jets}$, $N_b$ and $N_l$ are combined in a maximum-likelihood fit. The result is in agreement with the NLO SM prediction $9.2^{+2.9}_{-2.4}$ fb. The measurement constrains the top quark Yukawa coupling strength parameter to be $|Y_t/Y_t^{SM}| < 2.1$ (95% CL).

[7] SIRUNYAN 17AB based on 2.6 fb$^{-1}$ of data. A multivariate analysis is used to discriminate between $t\bar{t}\,t\bar{t}$ signal and $t\bar{t}$ background. A combination with a previous search (CMS, KHACHATRYAN 16BJ) in the same-sign dilepton channel gives an upper limit of 69 fb (95% CL), corresponding to 7.4·(SM prediction).

[8] SIRUNYAN 17S based on 35.9 fb$^{-1}$. The limit is in agreement with the NLO SM prediction $9.2^{+2.9}_{-2.4}$ fb. Superseded by SIRUNYAN 18BU. The signal events are also used to constrain various new physics models.

[1] AABOUD 19AR based on 35.9 fb$^{-1}$ of data. $t\bar{t}W$ and $t\bar{t}Z$ cross sections are simultaneously measured using a combined fit to the events divided into multiple regions. The result is consistent with the SM prediction at NLO $0.88^{+0.09}_{-0.11}$ pb. It is also used to constrain the Wilson coefficients for dimension-six operators which modify the $t\bar{t}Z$ vertex.

[2] Based on 35.9 fb$^{-1}$ of proton-proton data taken at $\sqrt{s} = 13$ TeV. The result is consistent with the SM prediction and is used to constrain the Wilson coefficients for dimension-six operators describing new interactions. The result is consistent with the SM prediction at NLO 0.839 ± 0.101 pb.

### $t\bar{t}\gamma$ Production Cross Section in pp Collisions at $\sqrt{s} = 13$ TeV

### Fraction of $t\bar{t}$ + multi-jet Events in $pp$ Collisions at $\sqrt{s} = 7$ TeV

| VALUE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| | [1] AAD | 15D | ATLS | $\ell$+$\not{E}_T$ + nj (n=3 to 8) |
| 0.332±0.090 | [2] CHATRCHYAN | 14AE | CMS | $t\bar{t}(\ell\ell)$ + 0 jet ($E_T$ > 30GeV) |
| 0.436±0.098 | [2] CHATRCHYAN | 14AE | CMS | $t\bar{t}(\ell\ell)$ + 1 jet ($E_T$ > 30GeV) |
| 0.232±0.125 | [2] CHATRCHYAN | 14AE | CMS | $t\bar{t}(\ell\ell)$ + ≥ 2 jet ($E_T$ > 30GeV) |

[1] Based on 4.6 fb$^{-1}$ of data. Fiducial $t\bar{t}$ production cross section is presented as a function of the jet multiplicity for up to eight jets with the jet $p_T$ threshold of 25, 40, 60, and 80 GeV, and as a function of jet $p_T$ up to the 5th jet. MC models can be discriminated by using data for high jet multiplicity and by $p_T$ distributions of the leading and 5th jet.

[2] Based on 5.0 fb$^{-1}$ of data. Events with two oppositely charged leptons, large $\not{E}_T$ and jets with at least 1 *b*-tag are used to measure the fraction of $t\bar{t}$ plus additional jets. The gap fraction (n=0 jet rate) as a function of the jet $p_T$ and that of $H_T$, the scalar sum of the $p_T$'s of additional jets, is shown in Fig. 8.

### $t\bar{t}$ Charge Asymmetry ($A_C$) in $pp$ Collisions at $\sqrt{s} = 7$ TeV

$A_C$ = (N($\Delta|y| > 0$) − N($\Delta|y| < 0$) ) / (N($\Delta|y| > 0$) + N($\Delta|y| < 0$) ) where $\Delta|y| = |y_t| - |y_{\bar{t}}|$ is the difference between the absolute values of the top and antitop rapidities and N is the number of events with $\Delta|y|$ positive or negative.

| $-1.3\pm2.8^{+2.9}_{-3.1}$ | [7] CHATRCHYAN | 12BS | CMS | $\ell$ +$\not{E}_T$ + ≥ 4j ( ≥ 1b) |

[1] ATLAS and CMS combination based on the data of AAD 14I and CHATRCHYAN 12BB. It takes into account the correlations of the measurements and systematic errors. The result is in agreement with the SM prediction (NLO QCD + NLO EW).

[2] AAD 15AJ based on 4.6 fb$^{-1}$ of data. After kinematic reconstruction the top quark momenta are corrected for detector resolution and acceptance effects by unfolding, using parton level information of the MC generators. The lepton charge asymmetry is measured as $A_C^{\ell} = 0.024 \pm 0.015 \pm 0.009$. All the measurements are consistent with the SM predictions.

[3] Based on 4.7 fb$^{-1}$ of data. The result is consistent with the SM prediction of $A_C = 0.0123 \pm 0.0005$. The asymmetry is 0.011 ± 0.018 if restricted to those events where $\beta_Z(t\bar{t}) > 0.6$, which is also consistent with the SM prediction of $0.020^{+0.006}_{-0.007}$.

[4] Based on 5.0 fb$^{-1}$ of data. The lepton charge asymmetry is measured as $A_C^{\ell} = 0.009 \pm 0.0010 \pm 0.006$. $A_C^{\ell}$ dependences on $m_{t\bar{t}}$, $|y(t\bar{t})|$, and $p_T(t\bar{t})$ are given in Fig. 5. All measurements are consistent with the SM predictions.

[5] Based on 1.04 fb$^{-1}$ of data. The result is consistent with $A_C = 0.006 \pm 0.002$ (MC at NLO). No significant dependence of $A_C$ on $m_{t\bar{t}}$ is observed.

[6] Based on 5.0 fb$^{-1}$ of data at 7 TeV.

[7] Based on 1.09 fb$^{-1}$ of data. The result is consistent with the SM predictions.

| 0.10±0.68±0.37 | [7] KHACHATRY...16T | | CMS | $\ell$ +$\not{E}_T$ + ≥ 4j ( ≥ 1b) |

[1] ATLAS and CMS combination based on the data of AAD 16AZ and KHACHATRYAN 16AH. It takes into account the correlations of the measurements and systematic errors. A combination of the differential measurements of the charge asymmetry is also presented. The results are in agreement with the SM prediction (NNLO QCD + NLO EW).

[2] AAD 16AE is based on 20.3 fb$^{-1}$ of data. After kinematic reconstruction, the top quark momenta are corrected for detector resolution and acceptance effects by unfolding, using parton level information of the MC generators. The lepton charge asymmetry is measured as $A_C^{\ell\ell} = 0.008 \pm 0.006$. All the measurements are consistent with the SM predictions.

[3] AAD 16AZ based on 20.3 fb$^{-1}$ of data. All the differential and inclusive measurements are statistically limited and consistent with the SM predictions.

[4] AAD 16T based on 20.3 fb$^{-1}$ of data. Uses reconstruction techniques for the decay topology of highly boosted top quarks. The observed asymmetry is transformed by unfolding to a parton-level result in the shown fiducial region. The result is consistent with the NLO SM prediction.

[5] KHACHATRYAN 16AD based on 19.5 fb$^{-1}$ of data. The lepton charge asymmetry is measured as $A_C^{\ell\ell} = 0.003 \pm 0.006 \pm 0.003$. All the measurements are consistent with the SM predictions.

[6] KHACHATRYAN 16AH based on 19.6 fb$^{-1}$ of data. The same data set as in KHACHATRYAN 16T is used. A template technique is used, which is sensitive to the charge anti-symmetric component of the $t\bar{t}$ rapidity distributions and statistically advantageous. The result is consistent with the SM predictions.

[7] KHACHATRYAN 16T based on 19.7 fb$^{-1}$ of data. The same data set as in KHACHATRYAN 16AH is used. After kinematic reconstruction the top quark momenta are corrected for detector resolution and acceptance effects by unfolding, using parton level information of the MC generators. All the measurements are consistent with the SM predictions.

### *t*-quark Polarization in $t\bar{t}$ Events in $p\bar{p}$ Collisions at $\sqrt{s} = 1.96$ TeV

[1] ABAZOV 17 based on 9.7 fb$^{-1}$ of data. The value is top quark polarization times spin analyzing power in the beam basis. Combination with the result of ABAZOV 15K yields 0.081 ± 0.048. This result together with the helicity polarization is shown in a 2-dimensional plot in Fig.4. These results are consistent with the SM prediction.

[2] ABAZOV 17 based on 9.7 fb$^{-1}$ of data. The value is top quark polarization times spin analyzing power in the helicity basis. The result is consistent with the SM prediction. This result together with the beam polarization is shown in a 2-dimensional plot in Fig.4.

[3] ABAZOV 17 based on 9.7 fb$^{-1}$ of data. The value is top quark polarization times spin analyzing power in the transverse basis. The result is consistent with the SM prediction.

[4] ABAZOV 15K based on 9.7 fb$^{-1}$ of data. The value is top quark polarization times spin analyzing power in the beam basis. The result is consistent with the SM prediction of −0.0019 ± 0.0005.

### *t*-quark Polarization in $t\bar{t}$ Events in $pp$ Collisions at $\sqrt{s} = 7$ TeV

The double differential distribution in polar angles, $\theta_1$ ($\theta_2$) of the decay particle of the top (anti-top) decay products, is parametrized as $(1/\sigma)d\sigma/(d\cos\theta_1\, d\cos\theta_2) = (1/4)\,(\,1 + A_t \cos\theta_1 + A_{\bar{t}} \cos\theta_2 - C \cos\theta_1 \cos\theta_2\,)$. The charged lepton is used to tag *t* or $\bar{t}$. The coefficient $A_t$ and $A_{\bar{t}}$ measure the average helicity of *t* and $\bar{t}$, respectively. $A_{CPC} = A_t = A_{\bar{t}}$ assumes *CP* conservation, whereas $A_{CPV} = A_t = -A_{\bar{t}}$ corresponds to maximal *CP* violation.

| 0.26±0.03±0.10 | | [4] KHACHATRY...16BO | | CMS | $(\alpha_\mu P)/2$; t-channel |

[1] AABOUD 17BB based on 20.2 fb$^{-1}$ of $pp$ data. Triple-differential decay rate of top quark is used to simultaneously determine five generalized $W\,t\,b$ couplings as well as the top polarization. $\alpha_\ell$ denotes the spin analyzing power of charged lepton, and the spin axis of the top polarization *P* is taken along the spectator-quark momentum in the top rest frame. The value is compatible with the SM prediction of about 0.9.

[2] AABOUD 17I based on 20.2 fb$^{-1}$ of $pp$ data. A cut-based analysis is used to discriminate between signal and backgrounds. $\alpha_\ell$ denotes the spin analyzing power of charged lepton, and the spin axis of the top polarization *P* is taken along the spectator-quark momentum in the top rest frame. See this paper for a number of other asymmetries and measurements that are not included here.

[3] AABOUD 17I based on 20.2 fb$^{-1}$ of $pp$ data. A cut-based analysis is used to discriminate between signal and backgrounds. $F_+$ denotes *W* helicity fraction, and the spin axis of the top polarization *P* is taken along the spectator-quark momentum in the top rest frame. See this paper for a number of other asymmetries and measurements that are not included here.

[4] KHACHATRYAN 16BO based on 19.7 fb$^{-1}$ of data. A high-purity sample with a muon is selected by a multivariate analysis. The value is the top spin asymmetry, given by one half of the spin analyzing power $\alpha_\mu$ (=1 at LO of SM) times the top polarization, *P*, where the spin axis is defined as the direction of the untagged jet in the top rest frame. The value is compatible with the SM prediction of 0.44 with a 2.0$\sigma$ deviation.

### $gg \to t\bar{t}$ Fraction in $p\bar{p}$ Collisions at $\sqrt{s} = 1.96$ TeV

| VALUE | CL% | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| <0.33 | 68 | [1] AALTONEN | 09F | CDF | $t\bar{t}$ correlations |
| 0.07±0.14±0.07 | | [2] AALTONEN | 08AG | CDF | low $p_T$ number of tracks |

[1] Based on 955 pb$^{-1}$. AALTONEN 09F used differences in the $t\bar{t}$ production angular distribution and polarization correlation to descriminate between $gg \to t\bar{t}$ and $q\bar{q} \to t\bar{t}$ subprocesses. The combination with the result of AALTONEN 08AG gives $0.07^{+0.15}_{-0.07}$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[2] Result is based on 0.96 fb$^{-1}$ of data. The contribution of the subprocesses $gg \to t\bar{t}$ and $q\bar{q} \to t\bar{t}$ is distinguished by using the difference between quark and gluon initiated jets in the number of small $p_T$ (0.3 GeV $< p_T <$ 3 GeV) charged particles in the central region ($|\eta| < 1.1$).

### $A_{FB}$ of $t\bar{t}$ in $p\bar{p}$ Collisions at $\sqrt{s} = 1.96$ TeV

$A_{FB}$ = Forward-backward asymmetry.

| 12 ± 8 ±1 | [13] ABAZOV | 08L | D0 | $\ell$ + $\not\!\!E_T$ + $\geq$ 4 jets |

[1] AALTONEN 18 based on 9–10 fb$^{-1}$ of $p\bar{p}$ data at $\sqrt{s} = 1.96$ TeV. The value is the asymmetry in the number of reconstructed $t\bar{t}$ events with rapidity $y_t > y_{\bar{t}}$ and those with $y_t < y_{\bar{t}}$. The combined fits to CDF and D0 single lepton and $\ell\ell$ asymmetries give $A^{\ell}_{FB} = 0.073 \pm 0.016 \pm 0.012$ and $A^{\ell\ell}_{FB} = 0.108 \pm 0.043 \pm 0.016$, respectively. The results are consistent with the SM predictions.

[2] ABAZOV 15K based on 9.7 fb$^{-1}$ of data. The result is consistent with the SM predictions. By combining with the previous D0 measurement in the $\ell$ + jet channel ABAZOV 14H, $A^{\ell}_{FB} = 0.118 \pm 0.025 \pm 0.013$ is obtained.

[3] AALTONEN 14F based on 9.1 fb$^{-1}$ of data. $A^{\ell}_{FB}$ and $A^{\ell\ell}_{FB}$ denote, respectively, the asymmetries $(N(x>0) - N(x<0))/N_{tot}$ for $x = q_\ell \eta_\ell$ ($q_\ell$ is the charge of $\ell$) and $x = \eta_{\ell^+} - \eta_{\ell^-}$. Both results are consistent with the SM predictions. By combining with the previous CDF measurement in the $\ell$+jet channel AALTONEN 13X, $A^{\ell}_{FB} = 0.098^{+0.028}_{-0.026}$ is obtained. The combined result is about two sigma larger than the SM prediction of $A^{\ell}_{FB} = 0.038 \pm 0.003$.

[4] Based on 9.7 fb$^{-1}$ of $p\bar{p}$ data at $\sqrt{s} = 1.96$ TeV. The asymmetry is corrected for the production level for events with $|y_l| < 1.5$. Asymmetry as functions of $E_T(\ell)$ and $|y_l|$ are given in Figs. 7 and 8, respectively. Combination with the asymmetry measured in the dilepton channel [ABAZOV 13P] gives $A^{\ell}_{FB} = 4.2 \pm 2.0 \pm 1.4$ %, in agreement with the SM prediction of 2.0%.

[5] Based on 9.7 fb$^{-1}$ of data of $p\bar{p}$ data at $\sqrt{s}$=1.96 TeV. The measured asymmetry is in agreement with the SM predictions of 8.8 ± 0.9 % [BERNREUTHER 12], which includes the EW effects. The dependences of the asymmetry on $|y(t) - y(\bar{t})|$ and $m_{t\bar{t}}$ are shown in Figs. 9 and 10, respectively.

[6] Based on 9.4 fb$^{-1}$ of data. Reported $A_{FB}$ values come from the determination of $a_i$ coefficients of $d\sigma/d(\cos\theta_t) = \Sigma_i\ a_i P_i(\cos(\theta_t))$ measurement. The result of $a_1/a_0 = (40 \pm 12)$% seems higher than the NLO SM prediction of $(15^{+7}_{-3})$%.

[7] Based on 9.4 fb$^{-1}$ of data. The quoted result is the asymmetry at the parton level.

[8] Based on 9.4 fb$^{-1}$ of data. The observed asymmetry is to be compared with the SM prediction of $A^{\ell}_{FB} = 0.038 \pm 0.003$.

[9] Based on 5.4 fb$^{-1}$ of data. ABAZOV 13A studied the dilepton channel of the $t\bar{t}$ events and measured the leptonic forward-backward asymmetry to be $A^{\ell}_{FB} = 5.8 \pm 5.1 \pm 1.3$%, which is consistent with the SM (QCD+EW) prediction of 4.7 ± 0.1%. The result is obtained after combining the measurement (15.2 ± 4.0%) in the $\ell$ + jets channel ABAZOV 11AH. The top quark helicity is measured by using the neutrino weighting method to be consistent with zero in both dilepton and $\ell$ + jets channels.

[10] Based on 5.3 fb$^{-1}$ of data. The error is statistical and systematic combined. Events with lepton + $\not\!\!E_T$ + $\geq$ 4jets( $\geq$ 1$b$) are used. AALTONEN 11F also measures the asymmetry as a function of the rapidity difference $|y_t - y_{\bar{t}}|$. The NLO QCD predictions [MCFM] are (4.0 ± 0.6)% and (8.8 ± 1.3)% for $m_{t\bar{t}} <$ 450 and > 450 GeV, respectively.

[11] Based on 5.4 fb$^{-1}$ of data. The error is statistical and systematic combined. The quoted asymmetry is obtained after unfolding to be compared with the MC@NLO prediction of (5.0 ± 0.1)%. No significant difference between the $m_{t\bar{t}} <$ 450 and > 450 GeV data samples is found. A corrected asymmetry based on the lepton from a top quark decay of (15.2 ± 4.0)% is measured to be compared to the MC@NLO prediction of (2.1 ± 0.1)%.

[12] Result is based on 1.9 fb$^{-1}$ of data. The $FB$ asymmetry in the $t\bar{t}$ events has been measured in the $\ell$ + jets mode, where the lepton charge is used as the flavor tag. The asymmetry in the $p\bar{p}$ frame is defined in terms of cos($\theta$) of hadronically decaying $t$-quark momentum, whereas that in the $t\bar{t}$ frame is defined in terms of the $t$ and $\bar{t}$ rapidity difference. The results are consistent ( $\leq$ 2 $\sigma$) with the SM predictions.

[13] Result is based on 0.9 fb$^{-1}$ of data. The asymmetry in the number of $t\bar{t}$ events with $y_t > y_{\bar{t}}$ and those with $y_t < y_{\bar{t}}$ has been measured in the lepton + jets final state. The observed value is consistent with the SM prediction of 0.8% by MC@NLO, and an upper bound on the $Z' \to t\bar{t}$ contribution for the SM $Z$-like couplings is given in in Fig. 2 for 350 GeV $< m_{Z'} <$ 1 TeV.

### $t$-Quark Electric Charge

| VALUE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|

| | [2] ABAZOV | 14D | D0 | $\ell$+$\not\!\!E_T$+ $\geq$ 4 jets ( $\geq$ 2 $b$) |
| | [3] AALTONEN | 13J | CDF | $p\bar{p}$ at 1.96 TeV |
| | [4] AALTONEN | 10S | CDF | Repl. by AALTONEN 13J |
| | [5] ABAZOV | 07C | D0 | fraction of $\|q\|$=4e/3 pair |

[1] AAD 13AY result is based on 2.05 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV, the result is obtained by reconstructing $t\bar{t}$ events in the lepton + jets final state, where $b$-jet charges are tagged by the jet-charge algorithm. This measurement excludes the charge $-4/3$ assignment to the top quark at more than 8 standard deviations.

[2] ABAZOV 14D result is based on 5.3 fb$^{-1}$ of $p\bar{p}$ data at $\sqrt{s}$=1.96 TeV. The electric charge of $b + W$ system in $t\bar{t}$ candidate events is measured from the charges of the leptons from $W$ decay and in $b$ jets. Under the assumption that the $b + W$ system consists of the sum of the top quark and the charge $-4/3$ quark $b'$(-4/3) of the same mass, the top quark fraction is found to be $f = 0.88 \pm 0.13$ (stat) $\pm 0.11$ (syst), or the upper bound for the $b'$(-4/3) contamination of $1 - f < 0.46$ (95% CL).

[3] AALTONEN 13J excludes the charge $-4/3$ assignment to the top quark at 99% CL, using 5.6 fb$^{-1}$ of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. Result is obtained by reconstructing $t\bar{t}$ events in the lepton + jets final state, where $b$-jet charges are tagged by the jet-charge algorithm.

[4] AALTONEN 10S excludes the charge $-4/3$ assignment for the top quark [CHANG 99] at 95%CL, using 2.7 fb$^{-1}$ of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. Result is obtained by reconstructing $t\bar{t}$ events in the lepton + jets final state, where $b$-jet charges are tagged by the SLT (soft lepton tag) algorithm.

[5] ABAZOV 07C reports an upper limit $\rho < 0.80$ (90% CL) on the fraction $\rho$ of exotic quark pairs $Q\overline{Q}$ with electric charge $|q| = 4e/3$ in $t\bar{t}$ candidate events with high $p_T$ lepton, missing $E_T$ and $\geq$ 4 jets. The result is obtained by measuring the fraction of events in which the quark pair decays into $W^- + b$ and $W^+ + \bar{b}$, where $b$ and $\bar{b}$ jets are discriminated by using the charge and momenta of tracks within the jet cones. The maximum CL at which the model of CHANG 99 can be excluded is 92%. Based on 370 pb$^{-1}$ of data at $\sqrt{s} = 1.96$ TeV.

[1] SIRUNYAN 19AQ based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. Pair production of vector-like $b'$ is seached for with one $b'$ decaying into $Zb$ and the other $b'$ decaying into $Wt$, $Zb$, $hb$. Events with an opposite-sign lepton pair consistent with coming from $Z$ and jets are used. Mass limits are obtained for a variety of branching ratios of $b'$.

[2] SIRUNYAN 19BW based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. The limit is for the pair-produced vector-like $b'$ using all-hadronic final state. The analysis is made for the $Zb$, $Wt$, $hb$ modes and mass limits are obtained for a variety of branching ratios.

[3] AABOUD 18AW based on 36.1 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. The limit is for the pair-produced vector-like $b'$ using lepton-plus-jets final state. The search is also sensitive to the decays into $Zb$ and $Hb$ final states.

[4] AABOUD 18CE based on 36.1 fb$^{-1}$ of proton-proton data taken at $\sqrt{s}$ = 13 TeV. Events including a same-sign lepton pair are used. The limit is for a singlet model, assuming the branching ratios of $b'$ into $Zb$, $Wt$ and $Hb$ as predicted by the model.

[5] AABOUD 18CL, AABOUD 18CP based on 36.1 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. The limit is for the pair-produced vector-like $b'$ using all-hadronic final state. The analysis is particularly powerful for the $b' \to hb$ mode. Assuming the pure decay only in this mode sets a limit $m_{b'} > 1010$ GeV.

[6] AABOUD 18CP based on 36.1 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. Pair and single production of vector-like $b'$ are seached for with at least one $b'$ decaying into $Zb$. In the case of $B(b' \to Zb) = 1$, the limit is $m_{b'} > 1220$ GeV.

[7] The limit is for the singlet model, assuming that the branching ratios into $Wt$, $Zb$, $hb$ add up to one.

[8] The limit is for the doublet model, assuming that the branching ratios into $Wt$, $Zb$, $hb$ add up to one.

[9] AABOUD 18CR based on 36.1 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. A combination of searches for the pair-produced vector-like $b'$ in various decay channels ($b' \to Wt$, $Zb$, $hb$). Also a model-independent limit is obtained as $m_{b'} > 1.03$ TeV, assuming that the branching ratios into $Zb$, $Wt$, and $hb$ add up to one.

[10] The limit is for the singlet $b'$.

[11] The limit is for $b'$ in a weak isospin doublet $(t',b')$ and $|V_{t'b}| \ll |V_{tb'}|$. For a $b'$ in a doublet with a charge $-4/3$ vector-like quark, the limit $m_{b'} > 1.14$ TeV is obtained.

[12] SIRUNYAN 18BM based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. The limit is for the pair-produced vector-like $b'$. Three channels (single lepton, same-charge 2 leptons, or at least 3 leptons) are considered for various branching fraction combinations. Assuming $B(tW) = 1$, the limit is 1240 GeV and for $B(bZ) = 1$ it is 960 GeV.

[13] SIRUNYAN 18Q based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. The limit is for the pair-produced vector-like $b'$ that couple only to light quarks. Upper cross section limits on the single production of a $b'$ and constraints for other decay channels ($Zq$ and $Hq$) are also given in the paper.

[14] SIRUNYAN 17AU based on 2.3–2.6 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. Limit on pair-produced singlet vector-like $b'$ using one lepton and several jets. The mass bound is given for a $b'$ transforming as a singlet under the electroweak symmetry group, assumed to decay through $W$, $Z$ or Higgs boson (which decays to jets) and to a third generation quark.

[15] KHACHATRYAN 16AN based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. Limit on pair-produced vector-like $b'$ using 1, 2, and >2 leptons as well as fully hadronic final states. Other limits depending on the branching fractions to $tW$, $bZ$, and $bH$ are given in Table IX.

[16] AAD 15BY based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. Limit on pair-produced vector-like $b'$ assuming the branching fractions to $W$, $Z$, and $h$ modes of the singlet model. Used events containing $\geq 2\ell + \not{E}_T + \geq 2$j ($\geq 1$ $b$) and including a same-sign lepton pair.

[17] AAD 15BY based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. Limit on pair-produced chiral $b'$-quark. Used events containing $\geq 2\ell + \not{E}_T + \geq 2$j ($\geq 1$ $b$) and including a same-sign lepton pair.

[18] AAD 15Z based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. Used events with $\ell + \not{E}_T + \geq 6$j ($\geq 1$ $b$) and at least one pair of jets from weak boson decay, primarily designed to select the signature $b'\overline{b}' \to WWt\overline{t} \to WWWWb\overline{b}$. This is a limit on pair-produced vector-like $b'$. The lower mass limit is 640 GeV for a vector-like singlet $b'$.

[19] Based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. No significant excess over SM expectation is found in the search for pair production or single production of $b'$ in the events with dilepton from a high $p_T$ $Z$ and additional jets ($\geq 1$ $b$-tag). If instead of $B(b' \to Wt) = 1$ an electroweak singlet with $B(b' \to Wt) \sim 0.45$ is assumed, the limit reduces to 685 GeV.

[20] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 13I looked for events with one isolated electron or muon, large $\not{E}_T$, and at least four jets with large transverse momenta, where one jet is likely to originate from the decay of a bottom quark.

[21] Result is based on 1.1 fb$^{-1}$ of data. No signal is found for the search of long-lived particles which decay into final states with two electrons or photons, and upper bound on the cross section times branching fraction is obtained for $2 < c\tau < 7000$ mm; see Fig. 3. 95% CL excluded region of $b'$ lifetime and mass is shown in Fig. 4.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[22] ACOSTA 03 looked for long-lived fourth generation quarks in the data sample of 90 pb$^{-1}$ of $\sqrt{s}$=1.8 TeV $p\overline{p}$ collisions by using the muon-like penetration and anomalously high ionization energy loss signature. The corresponding lower mass bound for the charge (2/3)e quark ($t'$) is 220 GeV. The $t'$ bound is higher than the $b'$ bound because $t'$ is more likely to produce charged hadrons than $b'$. The 95% CL upper bounds for the production cross sections are given in their Fig. 3.

[23] AAD 15AR based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. Used lepton-plus-jets final state. See Fig. 24 for mass limits in the plane of B($b' \rightarrow Wt$) vs. B($b' \rightarrow Hb$) from $b'\overline{b}' \rightarrow Hb + X$ searches.

[24] AAD 15CN based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 8 TeV. Limit on pair-production of chiral $b'$-quark. Used events with $\ell + \not{E}_T + \geq$4j (non-$b$-tagged). Limits on a heavy vector-like quark, which decays into $Wq$, $Zq$, $hq$, are presented in the plane B($Q \rightarrow Wq$) vs. B($Q \rightarrow hq$) in Fig. 12.

[25] Based on 1.04 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. No signal is found for the search of heavy quark pair production that decay into $W$ and a $t$ quark in the events with a high $p_T$ isolated lepton, large $\not{E}_T$, and at least 6 jets in which one, two or more dijets are from $W$.

[26] Based on 2.0 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. No $b' \rightarrow Zb$ invariant mass peak is found in the search of heavy quark pair production that decay into $Z$ and a $b$ quark in events with $Z \rightarrow e^+e^-$ and at least one $b$-jet. The lower mass limit is 358 GeV for a vector-like singlet $b'$ mixing solely with the third SM generation.

[27] Based on 1.04 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. No signal is found for the search of heavy quark pair production that decay into $W$ and a quark in the events with dileptons, large $\not{E}_T$, and $\geq$ 2 jets.

[28] Based on 1.04 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. AAD 12BE looked for events with two isolated like-sign leptons and at least 2 jets, large $\not{E}_T$ and $H_T$ > 350 GeV.

[29] Based on 5 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 12BH searched for QCD and EW production of single and pair of degenerate 4'th generation quarks that decay to $bW$ or $tW$. Absence of signal in events with one lepton, same-sign dileptons or tri-leptons gives the bound. With a mass difference of 25 GeV/c$^2$ between $m_{t'}$ and $m_{b'}$, the corresponding limit shifts by about $\pm$20 GeV/c$^2$.

[30] Based on 4.9 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 12X looked for events with trileptons or same-sign dileptons and at least one $b$ jet.

[31] Based on 4.8 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV. AALTONEN 11J looked for events with $\ell + \not{E}_T + \geq$5j ( $\geq 1\,b$ or $c$). No signal is observed and the bound $\sigma(b'\overline{b}')$ < 30 fb for $m_{b'} > 375$ GeV is found for B($b' \rightarrow Wt$) = 1.

[32] Based on 34 pb$^{-1}$ of data in $pp$ collisions at 7 TeV. CHATRCHYAN 11L looked for multi-jet events with trileptons or same-sign dileptons. No excess above the SM background excludes $m_{b'}$ between 255 and 361 GeV at 95% CL for B($b' \rightarrow Wt$) = 1.

[33] Based on 2.7 fb$^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. AALTONEN 10H looked for pair production of heavy quarks which decay into $tW^-$ or $tW^+$, in events with same sign dileptons ($e$ or $\mu$), several jets and large missing $E_T$. The result is obtained for $b'$ which decays into $tW^-$. For the charge 5/3 quark ( $T_{5/3}$) which decays into $tW^+$, $m_{T_{5/3}} > 365$ GeV (95% CL) is found when it has the charge $-1/3$ partner B of the same mass.

[34] FLACCO 10 result is obtained from AALTONEN 10H result of $m_{b'} > 338$ GeV, by relaxing the condition B($b' \rightarrow Wt$) = 100% when $m_{b'} > m_{t'}$.

[35] Result is based on 1.06 fb$^{-1}$ of data. No excess from the SM $Z$+jet events is found when $Z$ decays into $ee$ or $\mu\mu$. The $m_{b'}$ bound is found by comparing the resulting upper bound on $\sigma(b'\overline{b}')$ [1-(1-B($b' \rightarrow Zb$))$^2$] and the LO estimate of the $b'$ pair production cross section shown in Fig. 38 of the article.

[36] HUANG 08 reexamined the $b'$ mass lower bound of 268 GeV obtained in AALTONEN 07C that assumes B($b' \rightarrow Zb$) = 1, which does not hold for $m_{b'} > 255$ GeV. The lower mass bound is given in the plane of $\sin^2(\theta_{tb'})$ and $m_{b'}$.

[37] AFFOLDER 00 looked for $b'$ that decays in to $b$+$Z$. The signal searched for is $bbZZ$ events where one $Z$ decays into $e^+e^-$ or $\mu^+\mu^-$ and the other $Z$ decays hadronically. The bound assumes B($b' \rightarrow Zb$)= 100%. Between 100 GeV and 199 GeV, the 95%CL upper bound on $\sigma(b' \rightarrow \overline{b}') \times$B$^2(b' \rightarrow Zb)$ is also given (see their Fig. 2).

[38] ABE 98N looked for $Z \rightarrow e^+e^-$ decays with displaced vertices. Quoted limit assumes B($b' \rightarrow Zb$)=1 and $c\tau_{b'}$=1 cm. The limit is lower than $m_Z + m_b$ ($\sim$ 96 GeV) if $c\tau >$ 22 cm or $c\tau <$ 0.009 cm. See their Fig. 4.

[39] ABACHI 97D searched for $b'$ that decays mainly via FCNC. They obtained 95%CL upper bounds on B($b'\overline{b}' \rightarrow \gamma$+ 3 jets) and B($b'\overline{b}' \rightarrow 2\gamma$+ 2 jets), which can be interpreted as the lower mass bound $m_{b'} > m_Z + m_b$.

[40] ABACHI 95F bound on the top-quark also applies to $b'$ and $t'$ quarks that decay predominantly into $W$. See FROGGATT 97.

[41] MUKHOPADHYAYA 93 analyze CDF dilepton data of ABE 92G in terms of a new quark decaying via flavor-changing neutral current. The above limit assumes B($b' \rightarrow b\ell^+\ell^-$)=1%. For an exotic quark decaying only via virtual $Z$ [B($b\ell^+\ell^-$) = 3%], the limit is 85 GeV.

[42] ABE 92 dilepton analysis limit of >85 GeV at CL=95% also applies to $b'$ quarks, as discussed in ABE 90B.

[43] ABE 90B exclude the region 28–72 GeV.

[44] AKESSON 90 searched for events having an electron with $p_T$ > 12 GeV, missing momentum > 15 GeV, and a jet with $E_T$ > 10 GeV, $|\eta|$ < 2.2, and excluded $m_{b'}$ between 30 and 69 GeV.

[45] For the reduction of the limit due to non-charged-current decay modes, see Fig. 19 of ALBAJAR 90B.

[46] ALBAJAR 88 study events at $E_{cm}$ = 546 and 630 GeV with a muon or isolated electron, accompanied by one or more jets and find agreement with Monte Carlo predictions for the production of charm and bottom, without the need for a new quark. The lower mass limit is obtained by using a conservative estimate for the $b'\overline{b}'$ production cross section and by assuming that it cannot be produced in $W$ decays. The value quoted here is revised using the full $O(\alpha_s^3)$ cross section of ALTARELLI 88.

## $b'(-1/3)$ mass limits from single production in $p\overline{p}$ and $pp$ collisions

| | | | | | |
|---|---|---|---|---|---|
| | [6] SIRUNYAN | 19AI | CMS | | $bZ/tW \rightarrow b' \rightarrow tW$ |

[1] AAD 16AH based on 20.3 fb$^{-1}$ of data in $pp$ collisions at 8 TeV. No significant excess over SM expectation is found in the search for a vector-like $b'$ in the single-lepton and dilepton channels ($\ell$ or $\ell\ell$) + 1,2,3 $j$ ( $\geq 1b$). The model assumes that the $b'$ has the excited quark couplings.

[2] Based on 19.7 fb$^{-1}$ of data in $pp$ collisions at 8 TeV. Limit on left-handed $b'$ assuming 100% decay to $tW$ and using all-hadronic, lepton + jets, and dilepton final states.

[3] Based on 19.7 fb$^{-1}$ of data in $pp$ collisions at 8 TeV. Limit on right-handed $b'$ assuming 100% decay to $tW$ and using all-hadronic, lepton + jets, and dilepton final states.

[4] Based on 19.7 fb$^{-1}$ of data in $pp$ collisions at 8 TeV. Limit on vector-like $b'$ assuming 100% decay to $tW$ and using all-hadronic, lepton+jets, and dilepton final states.

[5] Based on 5.4 fb$^{-1}$ of data in ppbar collisions at 1.96 TeV. ABAZOV 11F looked for single production of $b'$ via the $W$ or $Z$ coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes $p\overline{p} \rightarrow b'q \rightarrow Wuq$, and $p\overline{p} \rightarrow b'q \rightarrow Zdq$ are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

[6] SIRUNYAN 19AI based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s}$ = 13 TeV. Exclusion limits are set on the product of the production cross section and branching fraction for the $b'(-1/3) + b$ and $b'(-1/3) + t$ modes as a function of the vector-like quark mass in Figs. 7 and 8 and in Tab. 2 for relative vector-like quark widths between 1 and 30% for left- and right-handed vector-like quark couplings. No significant deviation from the SM prediction is observed.

## MASS LIMITS for $b'$ (4$^{th}$ Generation) Quark or Hadron in $e^+e^-$ Collisions

Search for hadrons containing a fourth-generation $-1/3$ quark denoted $b'$.

The last column specifies the assumption for the decay mode ($CC$ denotes the conventional charged-current decay) and the event signature which is looked for.

[1] DECAMP 90F looked for isolated charged particles, for isolated photons, and for four-jet final states. The modes $b' \rightarrow bg$ for B($b' \rightarrow bg$) > 65% $b' \rightarrow b\gamma$ for B($b' \rightarrow b\gamma$) > 5% are excluded. Charged Higgs decay were not discussed.

[2] ABDALLAH 07 searched for $b'$ pair production at $E_{cm}$=196–209 GeV, with 420 pb$^{-1}$. No signal leads to the 95% CL upper limits on B($b' \rightarrow bZ$) and B($b' \rightarrow cW$) for $m_{b'}$ = 96 to 103 GeV.

[3] ADRIANI 93G search for vector quarkonium states near $Z$ and give limit on quarkonium-$Z$ mixing parameter $\delta m^2$ <(10–30) GeV$^2$ (95%CL) for the mass 88–94.5 GeV. Using

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

Richardson potential, a 1S ($b'\overline{b}'$) state is excluded for the mass range 87.7–94.7 GeV. This range depends on the potential choice.

[4] ABREU 90D assumed $m_{H^-} < m_{b'} - 3$ GeV.

[5] Superseded by ABREU 91F.

[6] AKRAWY 90B search was restricted to data near the $Z$ peak at $E_{cm} = 91.26$ GeV at LEP. The excluded region is between 23.6 and 41.4 GeV if no $H^+$ decays exist. For charged Higgs decays the excluded regions are between ($m_{H^+} + 1.5$ GeV) and 45.5 GeV.

[7] AKRAWY 90J search for isolated photons in hadronic $Z$ decay and derive $B(Z \to b'\overline{b}')\cdot B(b' \to \gamma X)/B(Z \to \text{hadrons}) < 2.2 \times 10^{-3}$. Mass limit assumes $B(b' \to \gamma X) > 10\%$.

[8] ABE 89E search at $E_{cm} = 56$–57 GeV at TRISTAN for multihadron events with a spherical shape (using thrust and acoplanarity) or containing isolated leptons.

[9] ABE 89G search was at $E_{cm} = 55$–60.8 GeV at TRISTAN.

[10] If the photonic decay mode is large ($B(b' \to b\gamma) > 25\%$), the ABRAMS 89C limit is 45.4 GeV. The limit for for Higgs decay ($b' \to cH^-$, $H^- \to \overline{c}s$) is 45.2 GeV.

[11] ADACHI 89C search was at $E_{cm} = 56.5$–60.8 GeV at TRISTAN using multi-hadron events accompanying muons.

[12] ADACHI 89C also gives limits for any mixture of $CC$ and $bg$ decays.

[13] ENO 89 search at $E_{cm} = 50$–60.8 at TRISTAN.

[14] ENO 89 considers arbitrary mixture of the charged current, $bg$, and $b\gamma$ decays.

[15] IGARASHI 88 searches for leptons in low-thrust events and gives $\Delta R(b') < 0.26$ (95% CL) assuming charged current decay, which translates to $m_{b'} > 24.4$ GeV.

[16] SAGAWA 88 set limit $\sigma(\text{top}) < 6.1$ pb at CL=95% for top-flavored hadron production from event shape analyses at $E_{cm} = 52$ GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of 23.8 GeV for charge $-1/3$ quarks.

[17] ADEVA 86 give 95%CL upper bound on an excess of the normalized cross section, $\Delta R$, as a function of the minimum c.m. energy (see their figure 3). Production of a pair of 1/3 charge quarks is excluded up to $E_{cm} = 45.4$ GeV.

[18] ALTHOFF 84C narrow state search sets limit $\Gamma(e^+e^-)B(\text{hadrons}) < 2.4$ keV CL = 95% and heavy charge 1/3 quark pair production $m > 21$ GeV, CL = 95%.

[19] ALTHOFF 84I exclude heavy quark pair production for $7 < m < 19$ GeV (1/3 charge) using aplanarity distributions (CL = 95%).

[1] SIRUNYAN 19AQ based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. Pair production of vector-like $t'$ is seached for with one $t'$ decaying into $Zt$ and the other $t'$ decaying into $Wb$, $Zt$, $ht$. Events with an opposite-sign lepton pair consistent with coming from $Z$ and jets are used. Mass limits are obtained for a variety of branching ratios of $t'$.

[2] SIRUNYAN 19BW based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. The limit is for the pair-produced vector-like $t'$ using all-hadronic final state. The analysis is made for the $Wb$, $Zt$, $ht$ modes and mass limits are obtained for a variety of branching ratios.

[3] AABOUD 18CE based on 36.1 fb$^{-1}$ of proton-proton data taken at $\sqrt{s} = 13$ TeV. Events including a same-sign lepton pair are used. The limit is for a singlet model, assuming the branching ratios of $t'$ into $Zt$, $Wb$ and $Ht$ as predicted by the model.

[4] AABOUD 18CL based on 36.1 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. The limit is for the pair-produced vector-like $t'$ using all-hadronic final state. The analysis is also made for the $Wb$, $Zt$, $ht$ modes and mass limits are obtained for a variety of branching ratios.

[5] AABOUD 18CP based on 36.1 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. Pair and single production of vector-like $t'$ are seached for with at least one $t'$ decaying into $Zt$. In the case of $B(t' \to Zt) = 1$, the limit is $m_{t'} > 1340$ GeV.

[6] The limit is for the singlet model, assuming that the branching ratios into $Zt$, $Wb$, and $Ht$ add up to one.

[7] The limit is for the doublet model, assuming that the branching ratios into $Zt$, $Wb$, and $Ht$ add up to one.

[8] AABOUD 18CR based on 36.1 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. A combination of searches for the pair-produced vector-like $t'$ in various decay channels ($t' \to Wb$, $Zt$, $ht$). Also a model-independent limit is obtained as $m_{t'} > 1.31$ TeV, assuming that the branching ratios into $Zt$, $Wb$ and $ht$ add up to one.

[9] The limit is for the singlet $t'$.

[10] The limit is for $t'$ in a weak isospin doublet ($t'$,$b'$) and $|V_{t'b}| \ll |V_{tb'}|$.

[11] SIRUNYAN 18BM based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. The limit is for the pair-produced vector-like $t'$. Three channels (single lepton, same-charge 2 leptons, or at least 3 leptons) are considered for various branching fraction combinations. Assuming $B(tH) = 1$, the limit is 1270 GeV and for $B(tZ) = 1$ it is 1300 GeV.

[12] SIRUNYAN 18Q based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. The limit is for the pair-produced vector-like $t'$ that couple only to light quarks. Constraints for other decay channels ($Zq$ and $Hq$) are also given in the paper.

[13] SIRUNYAN 18W based on 35.8 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. The limit is for the vector-like $t'$ pair-produced by strong interaction using lepton-plus-jets mode and assuming that $B(t' \to Wb)$ is 100product of the production cross section and branching faction to $Wb$ for any new pair-produced heavy quark decaying to this channel as a narrow resonance.

[14] AABOUD 17L based on 36.1 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. No signal is found in the search for heavy quark pair production that decay into $Zt$ followed by $Z \to \nu\nu$ in

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

the events with one lepton, large $\not{E}_T$, and $\geq 4$ jets. The lower mass limit 0.87 (1.05) TeV is obtained for the singlet (doublet) model with other possible decay modes.

[15] SIRUNYAN 17AU based on 2.3-2.6 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. Limit on pair-produced singlet vector-like $t'$ using one lepton and several jets. The mass bound is given for a $t'$ transforming as a singlet under the electroweak symmetry group, assumed to decay through $W$, $Z$ or Higgs boson (which decays to jets) and to a third generation quark. For a doublet, the limit is >830 GeV. Other limits are also given in the paper.

[16] AAD 15AR based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Used lepton-plus-jets final state. See Fig. 20 for mass limits in the plane of B($t' \to Ht$) vs. B($t' \to Wb$) from a combination of $t'\overline{t}' \to Wb + X$ and $t'\overline{t}' \to Ht + X$ searches. Any branching ratio scenario is excluded for mass below 715 GeV.

[17] AAD 15BY based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Limit on pair-produced vector-like $t'$ assuming the branching fractions to $W$, $Z$, and $h$ modes of the singlet model. Used events containing $\geq 2\ell + \not{E}_T + \geq 2$j ( $\geq 1$ $b$) and including a same-sign lepton pair.

[18] KHACHATRYAN 15AI based on 19.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. The search exploits all-hadronic final states by tagging boosted Higgs boson using jet substructure and $b$-tagging.

[19] Based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. No significant excess over SM expectation is found in the search for pair production or single production of $t'$ in the events with dilepton from a high $p_T$ $Z$ and additional jets ( $\geq$ 1 $b$-tag). If instead of B($b' \to Wt$) = 1 an electroweak singlet with B($b' \to Wt$) $\sim$ 0.45 is assumed, the limit reduces to 685 GeV.

[20] Based on 19.5 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$TeV. The $t'$ quark is pair produced and is assumed to decay into three different final states of $bW$, $tZ$, and $th$. The search is carried out using events with at least one isolated lepton.

[21] Based on 1.04 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. No signal is found for the search of heavy quark pair production that decay into $W$ and a quark in the events with dileptons, large $\not{E}_T$, and $\geq 2$ jets.

[22] Based on 1.04 fb$^{-1}$ of data in $pp$ collisions at 7 TeV. AAD 12C looked for $t'\overline{t}'$ production followed by $t'$ decaying into a top quark and $X$, an invisible particle, in a final state with an isolated high-$P_T$ lepton, four or more jets, and a large missing transverse energy. No excess over the SM $t\overline{t}$ production gives the upper limit on $t'\overline{t}'$ production cross section as a function of $m_{t'}$ and $m_X$. The result is obtained for B($t' \to Wt$) = 1.

[23] Based on 5 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 12BH searched for QCD and EW production of single and pair of degenerate 4'th generation quarks that decay to $Wb$ or $Wt$. Absence of signal in events with one lepton, same-sign dileptons or tri-leptons gives the bound. With a mass difference of 25 GeV/c$^2$ between $m_{t'}$ and $m_{b'}$, the corresponding limit shifts by about $\pm$20 GeV/c$^2$.

[24] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 12P looked for $t'\overline{t}'$ production events with two isolated high $p_T$ leptons, large $\not{E}_T$, and 2 high $p_T$ jets with $b$-tag. The absence of signal above the SM background gives the limit for B($t' \to Wb$) = 1.

[25] Based on 4.7 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. No signal is found for the search of heavy quark pair production that decay into $W$ and a $b$ quark in the events with a high $p_T$ isolated lepton, large $\not{E}_T$ and at least 3 jets ( $\geq$ 1 $b$-tag). Vector-like quark of charge 2/3 with $400 < m_{t'} < 550$ GeV and B($t' \to Wb$) $> 0.63$ is excluded at 95% CL.

[26] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 13I looked for events with one isolated electron or muon, large $\not{E}_T$, and at least four jets with large transverse momenta, where one jet is likely to originate from the decay of a bottom quark.

[27] Based on 1.04 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. No signal is found in the search for pair produced heavy quarks that decay into $W$ boson and a $b$ quark in the events with a high $p_T$ isolated lepton, large $\not{E}_T$ and at least 3 jets ( $\geq 1$ $b$-tag).

[28] Based on 5.0 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 12BC looked for $t'\overline{t}'$ production events with a single isolated high $p_T$ lepton, large $\not{E}_T$ and at least 4 high $p_T$ jets with a $b$-tag. The absence of signal above the SM background gives the limit for B($t' \to Wb$) = 1.

[29] Based on 5.7 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV. AALTONEN 11AH looked for $t'\overline{t}'$ production followed by $t'$ decaying into a top quark and $X$, an invisible particle, in the all hadronic decay mode of $t\overline{t}$. No excess over the SM $t\overline{t}$ production gives the upper limit on $t'\overline{t}'$ production cross section as a function of $m_{t'}$ and $m_X$. The result is obtained for B($t' \to Xt$) = 1.

[30] Based on 5.6 fb$^{-1}$ of data in ppbar collisions at 1.96 TeV. AALTONEN 11AL looked for $\ell + \geq 4$j events and set upper limits on $\sigma(t'\overline{t}')$ as functions of $m_{t'}$.

[31] Based on 4.8 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV. AALTONEN 11O looked for $t'\overline{t}'$ production signal when $t'$ decays into a top quark and $X$, an invisible particle, in $\ell + \not{E}_T$ + jets channel. No excess over the SM $t\overline{t}$ production gives the upper limit on $t'\overline{t}'$ production cross section as a function of $m_{t'}$ and $m_X$. The result is obtained for B($t' \to Xt$) = 1.

[32] Based on 5.3 fb$^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV. ABAZOV 11Q looked for $\ell + \not{E}_T + \geq 4$j events and set upper limits on $\sigma(t'\overline{t}')$ as functions of $m_{t'}$.

[33] Searches for pair production of a new heavy top-like quark $t'$ decaying to a $W$ boson and another quark by fitting the observed spectrum of total transverse energy and reconstructed $t'$ mass in the lepton + jets events.

[34] HUANG 08 reexamined the $t'$ mass lower bound of 256 GeV obtained in AALTONEN 08H that assumes B($b' \to qZ$) = 1 for $q = u, c$ which does not hold when $m_{b'} < m_{t'} - m_W$ or the mixing $\sin^2(\theta_{bt'})$ is so tiny that the decay occurs outside of the vertex detector. Fig. 1 gives that lower bound on $m_{t'}$ in the plane of $\sin^2(\theta_{bt'})$ and $m_{b'}$.

[1] SIRUNYAN 19T based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. Signals are searched in the final states of $t'$ pair production, with same-sign leptons (which come from a $t'$ decay) or a single lepton (which comes from a $W$ out of 4$W$s), along with jets, and no excess over the SM expectation is found.

[2] AABOUD 18AW based on 36.1 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. Limit on $t'(5/3)$ in pair production assuming its coupling to $Wt$ is equal to one. Lepton-plus-jets final state is used, characterized by $\ell + \not{E}_T$ + jets ( $\geq 1$ $b$-tagged).

[3] AABOUD 18CE based on 36.1 fb$^{-1}$ of proton-proton data taken at $\sqrt{s} = 13$ TeV. Events including a same-sign lepton pair are used. The limit is for the pair-produced vector-like $t'$. With single $t'$ production included, assuming $t'tW$ coupling of one, the limit is $m_{t'} > 1.6$ TeV.

[4] SIRUNYAN 17J based on 2.3 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. Signals are searched in the final states of $t'$ pair production, with same-sign leptons (which come from a $t'$ decay) or a single lepton (which comes from a $W$ out of 4$W$s), along with jets, and no excess over the SM expectation is found.

[5] AAD 15BY based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Limit on $t'(5/3)$ in pair and single production assuming its coupling to $Wt$ is equal to one. Used events containing $\geq 2\ell + \not{E}_T + \geq 2$j ( $\geq 1$ $b$) and including a same-sign lepton pair.

[6] AAD 15Z based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Used events with $\ell + \not{E}_T + \geq 6$j ( $\geq 1$ $b$) and at least one pair of jets from weak boson decay, sensitive to the final state $b\overline{b}W^+W^-W^+W^-$.

[7] CHATRCHYAN 14T based on 19.5 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. Non-observation of anomaly in $H_T$ distribution in the same-sign dilepton events leads to the limit when pair produced $t'(5/3)$ quark decays exclusively into $t$ and $W^+$, resulting in the final state with $b\overline{b}W^+W^-W^+W^-$.

### $t'(2/3)$ mass limits from single production in $p\overline{p}$ and $pp$ collisions

| VALUE (GeV) | CL% | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| >950 | 95 | [1] AAD | 16AV | ATLS | $qg \to q't'b$, B($t' \to Wb$)=0.5 |
| **>403** | 95 | [2] ABAZOV | 11F | D0 | $qd \to q't' \to q'(Wd)$ $\tilde{\kappa}_{dt'}$=1, B($t' \to Wd$)=1 |
| **>551** | 95 | [2] ABAZOV | 11F | D0 | $qu \to qt' \to q(Zu)$ $\tilde{\kappa}_{ut'}$=$\sqrt{2}$, B($t' \to Zu$)=1 |

[1] AAD 16AV based on 20.3 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 8$ TeV. No significant excess over SM expectation is found in the search for a fully reconstructed vector-like $t'$ in the mode $\ell + \not{E}_T + \geq 2j$ ( $\geq 1b$). A veto on massive large-radius jets is used to reject the $t\overline{t}$ background.

[2] Based on 5.4 fb$^{-1}$ of data in ppbar collisions at 1.96 TeV. ABAZOV 11F looked for single production of $t'$ via the $Z$ or $E$ coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes $p\overline{p} \to t'q \to (Wd)q$, and $p\overline{p} \to t'q \to (Zd)q$ are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

### $t'(5/3)$ mass limits from single production in $p\overline{p}$ and $pp$ collisions

| VALUE (GeV) | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| | [1] SIRUNYAN | 19AI | CMS | $tW \to t'(5/3) \to tW$ |

[1] SIRUNYAN 19AI based on 35.9 fb$^{-1}$ of $pp$ data at $\sqrt{s} = 13$ TeV. Exclusion limits are set on the product of the production cross section and branching fraction for the $b'(-1/3) + t$ and $t'(5/3) + t$ modes as a function of the vector-like quark mass in Fig. 8 and Tab. 2 for relative vector-like quark widths between 1 and 30% for left- and right-handed vector-like quark couplings. No significant deviation from the SM prediction is observed.

# Free Quark Searches

## FREE QUARK SEARCHES

The basis for much of the theory of particle scattering and hadron spectroscopy is the construction of the hadrons from a set of fractionally charged constituents (quarks). A central element of Quantum Chromodynamics is that quarks cannot be observed as free particles but are confined to mesons and baryons. Experiments have produced no evidence for free quarks.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative. Reviews can be found in Refs. 1–4.

### Quark Flux — Accelerator Searches

The definition of FLUX depends on the experiment

(a) is the ratio of measured free quarks to predicted free quarks if there is no "confinement."
(b) is the probability of fractional charge on nuclear fragments. Energy is in GeV/nucleon.
(c) is the 90%CL upper limit on fractionally-charged particles produced per interaction.
(d) is quarks per collision.
(e) is inclusive quark-production cross-section ratio to $\sigma(e^+e^-\to\mu^+\mu^-)$.
(f) is quark flux per charged particle.
(g) is the flux per $\nu$-event.
(h) is quark yield per $\pi^-$ yield.
(i) is 2-body exclusive quark-production cross-section ratio to $\sigma(e^+e^-\to\mu^+\mu^-)$.

[1] HUENTRUP 96 quote 95% CL limits for production of fragments with charge differing by as much as ±1/3 (in units of e) for charge $6 \le Z \le 10$.
[2] BUSKULIC 93C limits for inclusive quark production are more conservative if the ALEPH hadronic fragmentation function is assumed.
[3] CECCHINI 93 limit at 90%CL for $23/3 \le Z \le 40/3$, for 16*A* GeV O, 14.5*A* Si, and 200*A* S incident on Cu target. Other limits are $2.3 \times 10^{-4}$ for $17/3 \le Z \le 20/3$ and $1.2 \times 10^{-4}$ for $20/3 \le Z \le 23/3$.
[4] GHOSH 92 reports measurement of spallation fragment charge based on ionization in emulsion. Out of 650 measured tracks, 2 were consistent with charge 5*e*/3, and 4 with 7*e*/3.
[5] Hadronic quark.
[6] Leptonic quark.
[7] HE 91 limits are for charges of the form $N \pm 1/3$ from 23/3 to 38/3, and correspond to cross-section limits of 380$\mu$b (Pb) and 320$\mu$b (Cu).
[8] The limits apply to projectile fragment charges of 17, 19, 20, 22, 23 in units of *e*/3.
[9] The limits apply to projectile fragment charges of 16, 17, 19, 20, 22, 23 in units of *e*/3.
[10] Flux limits and mass range depend on charge.
[11] Bound to nuclei.
[12] Quark lifetimes $> 1 \times 10^{-8}$ s.
[13] One candidate $m$ <0.17 GeV.

## Quark Flux — Cosmic Ray Searches

Shielding values followed with an asterisk indicate altitude in km. Shielding values not followed with an asterisk indicate sea level in kg/cm$^2$.

[1] See AGNESE 15 Fig.6 for limits on vertical density as function of charge extending to $|q|/e < 1/10$.
[2] AMBROSIO 00C limit is below $11 \times 10^{-15}$ for $0.25 < q/e < 0.5$, and is changing rapidly near $q/e$=2/3, where it is $2 \times 10^{-14}$.
[3] Distribution in celestial sphere was described as anisotropic.
[4] With telescope axis at zenith angle 40° to the south.
[5] Leptonic quarks.
[6] Lifetime $> 10^{-8}$ s; charge ±0.70, 0.68, 0.42; and mass >4.4, 4.8, and 20 GeV, respectively.
[7] Time delayed air shower search.
[8] Prompt air shower search.
[9] Also *e*/4 and *e*/6 charges.
[10] No events in subsequent experiments.

[1] 95% CL limit for fractional charge particles with $0.18e \le |Q_{residual}| \le 0.82e$ in total of 70.1 mg of silicone oil.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[2] 95% CL limit for particles with fractional charge $|Q_{residual}| > 0.16e$ in total of 17.4 mg of silicone oil.
[3] Also set limits for $Q = \pm e/6$.
[4] Note that in PHILLIPS 88 these authors report a subtle magnetic effect which could account for the apparent fractional charges.
[5] Limit inferred by JONES 77B.

# LIGHT UNFLAVORED MESONS ($S = C = B = 0$)

For $I = 1$ ($\pi$, $b$, $\rho$, $a$): $u\overline{d}$, $(u\overline{u}-d\overline{d})/\sqrt{2}$, $d\overline{u}$;
for $I = 0$ ($\eta$, $\eta'$, $h$, $h'$, $\omega$, $\phi$, $f$, $f'$): $c_1(u\overline{u} + d\overline{d}) + c_2(s\overline{s})$

## $\pi^{\pm}$

$I^G(J^P) = 1^-(0^-)$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** 1 (1988).

## $\pi^{\pm}$ MASS

The most accurate charged pion mass measurements are based upon x-ray wavelength measurements for transitions in $\pi^-$-mesonic atoms. The observed line is the blend of three components, corresponding to different K-shell occupancies. JECKELMANN 94 revisits the occupancy question, with the conclusion that two sets of occupancy ratios, resulting in two different pion masses (Solutions A and B), are equally probable. We choose the higher Solution B since only this solution is consistent with a positive mass-squared for the muon neutrino, given the precise muon momentum measurements now available (DAUM 91, ASSAMAGAN 94, and ASSAMAGAN 96) for the decay of pions at rest. Earlier mass determinations with pi-mesonic atoms may have used incorrect K-shell screening corrections.

Measurements with an error of $> 0.005$ MeV have been omitted from this Listing.

[1] DAUM 19 value is based on their previous (1991+1996) measurements of the $\mu^+$ momentum of 29.79200 ± 0.00011 MeV for $\pi^+$ decay at rest. It also uses $m_{\mu}$ = 105.658 3745 ± 0.0000024 MeV, and assumes conservatively $m_{\nu_\mu} = 2.0 \pm 2.0$ MeV. It is the most precise charged pion mass determination.

[2] TRASSINELLI 16 use the muonic oxygen line for online energy calibration of the pionic line.

[3] LENZ 98 result does not suffer K-electron configuration uncertainties as does JECKELMANN 94.

[4] JECKELMANN 94 Solution B (dominant 2-electron K-shell occupancy), chosen for consistency with positive $m^2_{\nu_\mu}$.

[5] ASSAMAGAN 96 measures the $\mu^+$ momentum $p_\mu$ in $\pi^+ \to \mu^+\nu_\mu$ decay at rest to be 29.79200 ± 0.00011 MeV/$c$. Combined with the $\mu^+$ mass and the assumption $m_{\nu_\mu}$ = 0, this gives the $\pi^+$ mass above; if $m_{\nu_\mu} > 0$, $m_{\pi^+}$ given above is a lower limit. Combined instead with $m_\mu$ and (assuming $CPT$) the $\pi^-$ mass of JECKELMANN 94, $p_\mu$ gives an upper limit on $m_{\nu_\mu}$ (see the $\nu_\mu$).

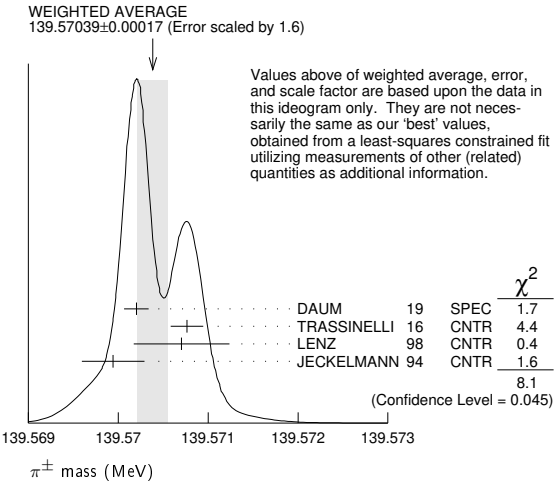
[6] JECKELMANN 94 Solution A (small 2-electron K-shell occupancy) in combination with either the DAUM 91 or ASSAMAGAN 94 pion decay muon momentum measurement yields a significantly negative $m^2_{\nu_\mu}$. It is accordingly not used in our fits.

[7] The DAUM 91 value includes the ABELA 84 result. The value is based on a measurement of the $\mu^+$ momentum for $\pi^+$ decay at rest, $p_\mu$ = 29.79179 ± 0.00053 MeV, uses $m_\mu$ = 105.658 8389 ± 0.000034 MeV, and assumes that $m_{\nu_\mu} = 0$. The last assumption means that in fact the value is a lower limit.

[8] JECKELMANN 86B gives $m_\pi/m_e$ = 273.12677(71). We use $m_e$ = 0.51099906(15) MeV from COHEN 87. The authors note that two solutions for the probability distribution of K-shell occupancy fit equally well, and use other data to choose the lower of the two possible $\pi^{\pm}$ masses.

[9] These values are scaled with a new wavelength-energy conversion factor $V\lambda$ = 1.23984244(37) × $10^{-6}$ eV m from COHEN 87. The LU 80 screening correction relies upon a theoretical calculation of inner-shell refilling rates.

[10] This MARUSHENKO 76 value used at the authors' request to use the accepted set of calibration $\gamma$ energies. Error increased from 0.0017 MeV to include QED calculation error of 0.0017 MeV (12 ppm).



## $m_{\pi^+} - m_{\mu^+}$

Measurements with an error $> 0.05$ MeV have been omitted from this Listing.

# Meson Particle Listings

## $\pi^{\pm}$

### $\pi^+$ DECAY MODES

$\pi^-$ modes are charge conjugates of the modes below.

For decay limits to particles which are not established, see the section on Searches for Axions and Other Very Light Bosons.

| | Mode | | Fraction ($\Gamma_i/\Gamma$) | Confidence level |
|---|---|---|---|---|
| $\Gamma_1$ | $\mu^+\nu_\mu$ | [a] | (99.98770 ± 0.00004) % | |
| $\Gamma_2$ | $\mu^+\nu_\mu\gamma$ | [b] | ( 2.00 ± 0.25 ) × $10^{-4}$ | |
| $\Gamma_3$ | $e^+\nu_e$ | [a] | ( 1.230 ± 0.004 ) × $10^{-4}$ | |
| $\Gamma_4$ | $e^+\nu_e\gamma$ | [b] | ( 7.39 ± 0.05 ) × $10^{-7}$ | |
| $\Gamma_5$ | $e^+\nu_e\pi^0$ | | ( 1.036 ± 0.006 ) × $10^{-8}$ | |
| $\Gamma_6$ | $e^+\nu_e e^+e^-$ | | ( 3.2 ± 0.5 ) × $10^{-9}$ | |
| $\Gamma_7$ | $e^+\nu_e\nu\overline{\nu}$ | | < 5 × $10^{-6}$ | 90% |

**Lepton Family number ($LF$) or Lepton number ($L$) violating modes**

| | | | | | | |
|---|---|---|---|---|---|---|
| $\Gamma_8$ | $\mu^+\overline{\nu}_e$ | $L$ | [c] | < 1.5 × $10^{-3}$ | 90% |
| $\Gamma_9$ | $\mu^+\nu_e$ | $LF$ | [c] | < 8.0 × $10^{-3}$ | 90% |
| $\Gamma_{10}$ | $\mu^-e^+e^+\nu$ | $LF$ | | < 1.6 × $10^{-6}$ | 90% |

[a] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with $\gamma$'s, and measurements of $\Gamma(e^+\nu_e\gamma)$ and $\Gamma(\mu^+\nu_\mu\gamma)$ never include low-energy $\gamma$'s. Therefore, since no clean separation is possible, we consider the modes with $\gamma$'s to be subreactions of the modes without them, and let $[\Gamma(e^+\nu_e) + \Gamma(\mu^+\nu_\mu)]/\Gamma_{\rm total} = 100\%$.

[b] See the Particle Listings below for the energy limits used in this measurement; low-energy $\gamma$'s are not included.

[c] Derived from an analysis of neutrino-oscillation experiments.

[1] POCANIC 04 normalizes to $e^+\nu_e$ decays, using the PDG 2004 value $B(\pi^+ \to e^+\nu_e) = (1.230 \pm 0.004) \times 10^{-4}$. We add their statistical ($0.004 \times 10^{-8}$), systematic ($0.004 \times 10^{-8}$) and systematic error due to the uncertainty of $B(\pi^+ \to e^+\nu_e)$ ($0.003 \times 10^{-8}$) in quadrature.

[2] This result can be used to calculate $V_{ud}$ from pion beta decay: $V_{ud}^{PIBETA} = 0.9728 \pm 0.0030$.

[3] MCFARLANE 85 combines a measured rate (0.394 ± 0.015)/s with 1982 PDG mean life.

[4] DEPOMMIER 68 says the result of DEPOMMIER 63 is at least 10% too large because of a systematic error in the $\pi^0$ detection efficiency, and that this may be true of all the previous measurements (also V. Soergel, private communication, 1972).

| 0.011 ±0.003 | | [1,4,5] STETZ | 78 | SPEC | $\pi^+ \to e^+\nu\gamma$ |

[1] These values come from fixing the vector form factor at the CVC prediction, $F_V = 0.0259 \pm 0.0005$.

[2] When $F_V$ is released, the BYCHKOV 09 $F_A$ is $0.0117 \pm 0.0017$, and $F_A$ and $F_V$ results are highly (anti-)correlated: $F_A + 1.0286\, F_V = 0.03853 \pm 0.00014$.

[3] The sign of $\gamma = F_A/F_V$ is determined to be positive.

[4] Only the absolute value of $F_A$ is determined.

[5] The result of STETZ 78 has a two-fold ambiguity. We take the solution compatible with later determinations.

## $\pi^{\pm}$ CHARGE RADIUS

The charge radius of the pion $\sqrt{\langle r_\pi^2\rangle}$ is defined in relation to the form factor of the pion electromagnetic vertex, called vector form factor VFF, $F_\pi^V$. The VFF is a function of the squared four-momentum transfer $t$, or of the squared c.m. energy $s$, depending on the channel in which the photon exchange takes place. In both cases, it is related to the slope of the VFF at zero, namely

$$\langle r_\pi^2\rangle = 6\,\frac{dF_\pi^V(q)}{dq}(q{=}0) \text{ where } q = t,\, s.$$

The quantity cannot be measured directly. It can be extracted from the cross sections of three processes: pion electroproduction, $eN \to eN\pi$, and pion electron scattering $e\pi \to e\pi$, for the $t$ channel, and positron electron annihilation into two charged pions, $e^+e^- \to \pi^+\pi^-$, for the $s$ channel. We encode all measurements, but we do not use electroproduction data in averaging because the extraction of the pion radius involves, in this case, theoretical uncertainties that cannot be controlled at the needed level of accuracy. In case of analyses based on the same data set, as ANANTHANARAYAN 17 and COLANGELO 19, which cannot be averaged, we combine the results into a common value, with the uncertainty range chosen to cover both analyses. Note that for consistency the form factor needs to be defined in both channels with the vacuum polarisation removed. For details see COLANGELO 19 or Appendix B of ANANTHANARAYAN 16A.

[1] This value combines the measurements of ANANTHANARAYAN 17 and COLANGELO 19 which are based on the same data set. The uncertainty range is chosen to cover both results.

[2] COLANGELO 19 fit existing $F_V$ data, using an extended Omnes dispersive representation. This analysis is based on the same data set of ANANTHANARAYAN 17. Accordingly, they cannot be averaged. We combine the results into a common value, with the uncertainty range chosen to cover the uncertainty ranges of both analyses.

[3] ANANTHANARAYAN 17 fit existing $F_V$ data, using a mixed phase-modulus dispersive representation. This analysis is based on the same data set of COLANGELO 19. Accordingly, they cannot be averaged. We combine the results into a common value, with the uncertainty range chosen to cover the uncertainty ranges of both analyses.

[4] According to the authors the uncertainty could be underestimated. The value quoted omits the BaBar data AUBERT 09.

[5] The extractions could contain an additional theoretical uncertainty which cannot be sufficiently quantified.

[6] BIJNENS 98 fits existing data.

[7] The extraction is based on a parametrization that does not have correct analytic properties.

## $\pi^{\pm}$ REFERENCES

We have omitted some papers that have been superseded by later experiments. The omitted papers may be found in our 1988 edition Physics Letters **B204** 1 (1988).

# Meson Particle Listings

## $\pi^0$

$\pi^0$ $I^G(J^{PC}) = 1^-(0^{-+})$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** 1 (1988).

### $\pi^0$ MASS

The value is calculated from $m_{\pi^\pm}$ and $(m_{\pi^\pm} - m_{\pi^0})$. See also the notes under the $\pi^\pm$ Mass Listings.

| VALUE (MeV) | DOCUMENT ID |
|---|---|
| **134.9768±0.0005 OUR FIT** | Error includes scale factor of 1.1. |

### $m_{\pi^\pm} - m_{\pi^0}$

Measurements with an error > 0.01 MeV have been omitted.

| VALUE (MeV) | DOCUMENT ID | | TECN | COMMENT |

### $\pi^0$ MEAN LIFE

Most experiments measure the $\pi^0$ width which we convert to a lifetime. ATHERTON 85 is the only direct measurement of the $\pi^0$ lifetime. Our average based only on indirect measurement yields $(8.30 \pm 0.19) \times 10^{-17}$ s. The two Primakoff measurements from 1970 have been excluded from our average because they suffered model-related systematics unknown at the time. More information on the $\pi^0$ lifetime can be found in BERNSTEIN 13.

[1] LARIN 11 reported $\Gamma(\pi^0 \to \gamma\gamma) = 7.82 \pm 0.14 \pm 0.17$ eV which we converted to mean life $\tau = \hbar/\Gamma$(total).
[2] BYCHKOV 09 obtains this using the conserved-vector-current relation between the vector form factor $F_V$ and the $\pi^0$ lifetime.
[3] WILLIAMS 88 gives $\Gamma(\gamma\gamma) = 7.7 \pm 0.5 \pm 0.5$ eV. We give here $\tau = \hbar/\Gamma$(total).
[4] BROWMAN 74 gives a $\pi^0$ width $\Gamma = 8.02 \pm 0.42$ eV. The mean life is $\hbar/\Gamma$.

### $\pi^0$ DECAY MODES

For decay limits to particles which are not established, see the appropriate Search sections ($A^0$ (axion) and Other Light Boson ($X^0$) Searches, etc.).

| | Mode | Fraction ($\Gamma_i/\Gamma$) | | Scale factor/ Confidence level |
|---|---|---|---|---|
| $\Gamma_1$ | $2\gamma$ | (98.823±0.034) % | | S=1.5 |

| $\Gamma_9$ | $\nu_\mu\overline{\nu}_\mu$ | < 1.6 | $\times 10^{-6}$ | CL=90% |
| $\Gamma_{10}$ | $\nu_\tau\overline{\nu}_\tau$ | < 2.1 | $\times 10^{-6}$ | CL=90% |
| $\Gamma_{11}$ | $\gamma\nu\overline{\nu}$ | < 1.9 | $\times 10^{-7}$ | CL=90% |
| | **Charge conjugation ($C$) or Lepton Family number ($LF$) violating modes** | | | |
| $\Gamma_{12}$ | $3\gamma$ | $C$ < 3.1 | $\times 10^{-8}$ | CL=90% |
| $\Gamma_{13}$ | $\mu^+ e^-$ | $LF$ < 3.8 | $\times 10^{-10}$ | CL=90% |
| $\Gamma_{14}$ | $\mu^- e^+$ | $LF$ < 3.4 | $\times 10^{-9}$ | CL=90% |
| $\Gamma_{15}$ | $\mu^+ e^- + \mu^- e^+$ | $LF$ < 3.6 | $\times 10^{-10}$ | CL=90% |

[a] Astrophysical and cosmological arguments give limits of order $10^{-13}$.

### CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 4.6$ for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

| 3.18±0.30 | 146 | [2] SAMIOS | 62B | HBC | |

[1] This ABOUZAID 08D value includes all radiative final states. The error includes both statistical and systematic errors. The correlation between the Dalitz-pair planes gives a direct measurement of the $\pi^0$ parity. The $\pi^0 2\gamma^*$ form factor is measured and limits are placed on a scalar contribution to the decay.
[2] SAMIOS 62B value uses a Panofsky ratio = 1.62.

#### $\Gamma(e^+ e^-)/\Gamma_{\rm total}$ $\Gamma_5/\Gamma$

Experimental results are listed; branching ratios corrected for radiative effects are given in the footnotes. BERMAN 60 found $B(\pi^0 \to e^+ e^-) \geq 4.69 \times 10^{-8}$ via an exact QED calculation.

6.09±0.40±0.24 275 [4] ALAVI-HARATI 99C SPEC 0 Repl. by ABOUZAID 07

[1] ABOUZAID 07 result is for $m_{e^+e^-}/m_{\pi^0} > 0.95$. With radiative corrections the result becomes $(7.48 \pm 0.29 \pm 0.25) \times 10^{-8}$.

[2] The DESHPANDE 93 result with bremsstrahlung radiative corrections is $(8.0 \pm 2.6 \pm 0.6) \times 10^{-8}$.

[3] The MCFARLAND 93 result is for $B[\pi^0 \to e^+e^-, (m_{e^+e^-}/m_{\pi^0})^2 > 0.95]$. With radiative corrections it becomes $(8.8^{+4.5}_{-3.2} \pm 0.6) \times 10^{-8}$.

[4] ALAVI-HARATI 99C quote result for $B[\pi^0 \to e^+e^-, (m_{e^+e^-}/m_{\pi^0})^2 > 0.95]$ to minimize radiative contributions from $\pi^0 \to e^+e^-\gamma$. After radiative corrections they obtain $(7.04 \pm 0.46 \pm 0.28) \times 10^{-8}$.

## $\pi^0$ ELECTROMAGNETIC FORM FACTOR

The amplitude for the process $\pi^0 \to e^+e^-\gamma$ contains a form factor $F(x)$ at the $\pi^0\gamma\gamma$ vertex, where $x = [m_{e^+e^-}/m_{\pi^0}]^2$. The parameter $a$ in the linear expansion $F(x) = 1 + ax$ is listed below.

All the measurements except that of BEHREND 91 are in the time-like region of momentum transfer.

[1] BEHREND 91 estimates that their systematic error is of the same order of magnitude as their statistical error, and so we have included a systematic error of this magnitude. The value of $a$ is obtained by extrapolation from the region of large space-like momentum transfer assuming vector dominance.

[2] TUPPER 83 is a theoretical analysis of FISCHER 78 including 2-photon exchange in the corrections.

[3] The FISCHER 78 error is statistical only. The result without radiation corrections is $+0.05 \pm 0.03$.

## $\pi^0$ REFERENCES

We have omitted some papers that have been superseded by later experiments. The omitted papers may be found in our 1988 edition Physics Letters **B204** 1 (1988).

# $\eta$

$I^G(J^{PC}) = 0^+(0^{-+})$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** (1988).

## $\eta$ MASS

Recent measurements resolve the obvious inconsistency in previous $\eta$ mass measurements in favor of the higher value first reported by NA48 (LAI 02). We use only precise measurements consistent with this higher mass value for our $\eta$ mass average.

[1] ABDEL-BARY 05 disagrees significantly with recent measurements of similar or better precision. See comment in the header.

## $\eta$ WIDTH

This is the partial decay rate $\Gamma(\eta \to \gamma\gamma)$ divided by the fitted branching fraction for that mode. See the note at the start of the $\Gamma(2\gamma)$ data block, next below.

| $\Gamma_{33}$ | $\mu^+e^- + \mu^-e^+$ $LF$ | < 6 $\times 10^{-6}$ | CL=90% |

[a] Forbidden by angular momentum conservation.

[b] $C$ parity forbids this to occur as a single-photon process.

## CONSTRAINED FIT INFORMATION

An overall fit to 2 decay rate and 19 branching ratios uses 50 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 43.8$ for 42 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\mathrm{total}}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

## $\eta$ DECAY RATES

### $\Gamma(2\gamma)$ $\Gamma_2$

See the table immediately above giving the fitted decay rates. Following the advice of NEFKENS 02, we have removed the Primakoff-effect measurement from the average. See also the "Note on the Decay Width $\Gamma(\eta \to \gamma\gamma)$," in our 1994 edition, Phys. Rev. **D50**, 1 August 1994, Part I, p. 1451, for a discussion of the various measurements.

| 1.00 ±0.22 | | [2] BEMPORAD | 67 | CNTR | Primakoff effect |

[1] RODRIGUES 08 uses a more sophisticated calculation for the inelastic background due to incoherent photoproduction to reanalyze the $\eta$ photoproduction data on Be and Cu at 9 GeV from BROWMAN 74B. This brings the value of $\Gamma(\eta \to 2\gamma)$ in line with direct measurements of the width. The error here is only statistical.

[2] BEMPORAD 67 gives $\Gamma(2\gamma) = 1.21 \pm 0.26$ keV assuming $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.314$. Bemporad private communication gives $\Gamma(2\gamma)^2/\Gamma(\text{total}) = 0.380 \pm 0.083$. We evaluate this using $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.38 \pm 0.01$. Not included in average because the uncertainty resulting from the separation of the coulomb and nuclear amplitudes has apparently been underestimated.

| <30 | 90 | 0 | DAVYDOV | 81 | GAM2 | $\pi^-p \to \eta n$ |

[1] PRAKHOV 08 is a reanalysis of the data of PRAKHOV 05, using for the first time the invariant-mass spectrum of the two photons.

[2] Normalized using $\Gamma(\eta \to 2\gamma)/\Gamma = 0.3943 \pm 0.0026$.

[3] This measurement and the independent analysis of the same data by KNECHT 04 both imply a lower value of $\Gamma(\pi^0 2\gamma)$ than the one obtained by ALDE 84 from $\Gamma(\pi^0 2\gamma)/\Gamma(2\gamma)$.

| $0.10\pm0.22$ | 220k | LAYTER | 72 | ASPK |
| $0.5\ \pm0.5$ | 37k | GORMLEY | 68C | WIRE |

### $\pi^+\pi^-\pi^0$ QUADRANT ASYMMETRY PARAMETER

| VALUE (units $10^{-2}$) | EVTS | DOCUMENT ID | | TECN |
|---|---|---|---|---|
| **$-0.09\pm0.09$ OUR AVERAGE** | | | | |
| $-0.05\pm0.10^{+0.03}_{-0.05}$ | 1.34M | AMBROSINO | 08D | KLOE |
| $-0.30\pm0.25$ | 165k | JANE | 74 | OSPK |
| $-0.07\pm0.22$ | 220k | LAYTER | 72 | ASPK |

### $\pi^+\pi^-\gamma$ LEFT-RIGHT ASYMMETRY PARAMETER

Measurements with an error $> 2.0\times10^{-2}$ have been omitted.

| VALUE (units $10^{-2}$) | EVTS | DOCUMENT ID | | TECN |
|---|---|---|---|---|
| **0.9 ±0.4 OUR AVERAGE** | | | | |
| $1.2\ \pm0.6$ | 35k | JANE | 74B | OSPK |
| $0.5\ \pm0.6$ | 36k | THALER | 72 | ASPK |
| $1.22\pm1.56$ | 7257 | GORMLEY | 70 | ASPK |

### $\pi^+\pi^-\gamma$ PARAMETER $\beta$ ($D$-wave)

Sensitive to a $D$-wave contribution: $dN/d\cos\theta = \sin^2\theta\ (1+\beta\ \cos^2\theta)$.

| VALUE | EVTS | DOCUMENT ID | | TECN |
|---|---|---|---|---|
| **$-0.02\ \pm0.07$ OUR AVERAGE** | Error includes scale factor of 1.3. | | | |
| $0.11\ \pm0.11$ | 35k | JANE | 74B | OSPK |
| $-0.060\pm0.065$ | 7250 | GORMLEY | 70 | WIRE |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| $0.12\ \pm0.06$ | | [1] THALER | 72 | ASPK |

[1] The authors don't believe this indicates $D$-wave because the dependence of $\beta$ on the $\gamma$ energy is inconsistent with the theoretical prediction. A $\cos^2\theta$ dependence can also come from $P$- and $F$-wave interference.

## $\eta$ $CP$-NONCONSERVING DECAY PARAMETER

### $\pi^+\pi^-e^+e^-$ DECAY-PLANE ASYMMETRY PARAMETER $A_\phi$

In the $\eta$ rest frame, the total momentum of the $e^+e^-$ pair is equal and opposite to that of the $\pi^+\pi^-$ pair. Let $\hat{z}$ be the unit vector along the momentum of the $e^+e^-$ pair; let $\hat{n}_{ee}$ and $\hat{n}_{\pi\pi}$ be the unit vectors normal to the $e^+e^-$ and $\pi^+\pi^-$ planes; and let $\phi$ be the angle between the two normals. Then

$$\sin\phi\cos\phi = [(\hat{n}_{ee}\times\hat{n}_{\pi\pi})\cdot\hat{z}]\,(\hat{n}_{ee}\cdot\hat{n}_{\pi\pi})\ ,$$

and

$$A_\phi \equiv \frac{N_{\sin\phi\cos\phi>0} - N_{\sin\phi\cos\phi<0}}{N_{\sin\phi\cos\phi>0} + N_{\sin\phi\cos\phi<0}}\ .$$

| VALUE (units $10^{-2}$) | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **$-0.6\pm2.5\pm1.8$** | $1555\pm52$ | AMBROSINO | 09B | KLOE | $e^+e^-\to\phi\to\eta\gamma$ |

## ENERGY DEPENDENCE OF $\eta\to3\pi$ DALITZ PLOTS

### PARAMETERS FOR $\eta\to\pi^+\pi^-\pi^0$

See the "Note on $\eta$ Decay Parameters," page 1454, in our 1994 edition (Physical Review **D50** 1173 (1994)). The following experiments fit to one or more of the coefficients $a$, $b$, $c$, $d$, $e$, $f$ or $g$ for $|\text{matrix element}|^2 = 1 + ay + by^2 + cx + dx^2 + exy + fy^3 + gx^2y$.

| VALUE | EVTS | DOCUMENT ID | | TECN | COMMENT |

[1] ANASTASI 16A measure the Dalitz parameters $a$, $b$, $d$, $f$, and $g$. This is the first measurement of $g$.
[2] ABELE 98D obtains $a=-1.22\pm0.07$ and $b=0.22\pm0.11$ when $c$ (or $d$) is fixed at 0.06.
[3] AMSLER 95 fits to $(1+ay+by^2)$ and obtains $a=-0.94\pm0.15$ and $b=0.11\pm0.27$.

### $\alpha$ PARAMETER FOR $\eta\to3\pi^0$

See the "Note on $\eta$ Decay Parameters" in our 1994 edition, Phys. Rev. **D50**, 1 August 1994, Part I, p. 1454. The value here is of $\alpha$ in $|\text{matrix element}|^2 = 1 + 2\alpha z$.

| $-0.32\ \pm0.37$ | 192 | BAGLIN | 70 | HLBC | |

[1] This ADOLPH 09 result is independent of the BASHKANOV 07 result.
[2] The PRAKHOV 09 and UNVERZAGT 09 results are independent.
[3] This AMBROSINO 08D value is an indirect result using $\eta\to\pi^+\pi^0\pi^-$ events and a rescattering matrix that mixes isospin decay amplitudes.

### PARAMETER $\Lambda$ IN $\eta\to\ell^+\ell^-\gamma$ DECAY

In the pole approximation the electromagnetic transition form factor for a resonance of mass $M$ is given by the expression:

$$|F|^2 = (1 - M^2_{\ell\ell}/\Lambda^2)^{-2},$$

where for the parameter $\Lambda$ vector dominance predicts $\Lambda\ \approx\ 0.770$ GeV.

| VALUE (GeV/$c^2$) | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **0.716 ±0.011 OUR AVERAGE** | | | | | |

[1] S-matrix pole; 8595 events.
[2] Applying the chiral unitary approach at NLO to the $K_{e4}$ data of BATLEY 10 and $\pi N \to \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[3] Uses the $K_{e4}$ data of BATLEY 10C and the $\pi N \to \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73.
[4] Analytic continuation using Roy equations.
[5] Analytic continuation using GKPY equations.
[6] Using Roy equations.
[7] Average of three variants of the analytic K-matrix model. Uses the $K_{e4}$ data of BATLEY 08A and the $\pi N \to \pi\pi N$ data of HYAMS 73 and GRAYER 74.
[8] Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B.
[9] From the $K_{e4}$ data of BATLEY 08A and $\pi N \to \pi\pi N$ data of HYAMS 73.
[10] From the $K_{e4}$ data of BATLEY 08A and $\pi N \to \pi\pi N$ data of PROTOPOPESCU 73, GRAYER 74, and ESTABROOKS 74.
[11] From a mean of three different $f_0(500)$ parametrizations. Uses 40k events.
[12] From an isobar model using 2.6k events.
[13] Reanalysis of ABLIKIM 04A, PISLAK 01, and HYAMS 73 data.
[14] Using the N/D method.
[15] From the solution of the Roy equation (ROY 71) for the isoscalar S-wave and using a phase-shift analysis of HYAMS 73 and PROTOPOPESCU 73 data.
[16] Reanalysis of the data from PROTOPOPESCU 73, ESTABROOKS 74, GRAYER 74, ROSSELET 77, PISLAK 03, and AKHMETSHIN 04.
[17] From a mean of six different analyses and $f_0(500)$ parameterizations.
[18] Using data on $\psi(2S) \to J/\psi\pi\pi$ from BAI 00E and on $\Upsilon(nS) \to \Upsilon(mS)\pi\pi$ from BUTLER 94B and ALEXANDER 98.
[19] Reanalysis of data from PROTOPOPESCU 73, ESTABROOKS 74, GRAYER 74, and COHEN 80 in the unitarized ChPT model.
[20] From a combined analysis of HYAMS 73, AUGUSTIN 89, AITALA 01B, and PISLAK 01.
[21] A similar analysis (KOMADA 01) finds $(580^{+79}_{-30}) - i(190^{+107}_{-49})$ MeV.
[22] Coupled channel reanalysis of BATON 70, BENSINGER 71, BAILLON 72, HYAMS 73, HYAMS 75, ROSSELET 77, COHEN 80, and ETKIN 82B using the uniformizing variable.
[23] Using the inverse amplitude method and data of ESTABROOKS 73, GRAYER 74, and PROTOPOPESCU 73.
[24] Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
[25] Average and spread of 4 variants ("up" and "down") of KAMINSKI 97B 3-channel model.
[26] Uses data from BEIER 72B, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91B. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
[27] Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two different poles.
[28] Analysis of data from FALVARD 88.
[29] Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.
[30] Analysis of data from OCHS 73, GRAYER 74, and ROSSELET 77.
[31] Coupled-channel analysis using data from PROTOPOPESCU 73, HYAMS 73, HYAMS 75, GRAYER 74, ESTABROOKS 74, ESTABROOKS 75, FROGGATT 77, CORDEN 79, BISWAS 81.
[32] Analysis of data from APEL 72C, GRAYER 74, CASON 76, PAWLICKI 77. Includes spread and errors of 4 solutions.
[33] Analysis of data from BATON 70, BENSINGER 71, COLTON 71, BAILLON 72,PROTOPOPESCU 73, and WALKER 67.

## $f_0(500)$ BREIT-WIGNER MASS OR K-MATRIX POLE PARAMETERS

| VALUE (MeV) | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| **(400–550) OUR ESTIMATE** | | | | |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| $513 \pm 32$ | [34] MURAMATSU | 02 | CLEO | $e^+e^- \approx$ 10 GeV |
| $478^{+24}_{-23} \pm 17$ | AITALA | 01B | E791 | $D^+ \to \pi^-\pi^+\pi^+$ |
| $563^{+58}_{-29}$ | [35] ISHIDA | 01 | | $\Upsilon(3S) \to \Upsilon\pi\pi$ |
| 555 | [36] ASNER | 00 | CLE2 | $\tau^- \to \pi^-\pi^0\pi^0\nu_\tau$ |
| $540 \pm 36$ | ISHIDA | 00B | | $p\overline{p} \to \pi^0\pi^0\pi^0$ |
| $750 \pm 4$ | ALEKSEEV | 99 | SPEC | 1.78 $\pi^-$ $p_{\rm polar} \to \pi^-\pi^+ n$ |
| $744 \pm 5$ | ALEKSEEV | 98 | SPEC | 1.78 $\pi^-$ $p_{\rm polar} \to \pi^-\pi^+ n$ |
| $759 \pm 5$ | [37] TROYAN | 98 | | 5.2 $np \to np\pi^+\pi^-$ |
| $780 \pm 30$ | ALDE | 97 | GAM2 | 450 $pp \to pp\pi^0\pi^0$ |
| $585 \pm 20$ | [38] ISHIDA | 97 | | $\pi\pi \to \pi\pi$ |
| $761 \pm 12$ | [39] SVEC | 96 | RVUE | 6–17 $\pi N_{\rm polar} \to \pi^+\pi^- N$ |
| $\sim 860$ | [40,41] TORNQVIST | 96 | RVUE | $\pi\pi \to \pi\pi$, $K\overline{K}$, $K\pi$, $\eta\pi$ |
| $1165 \pm 50$ | [42,43] ANISOVICH | 95 | RVUE | $\pi^-p \to \pi^0\pi^0 n$, $\overline{p}p \to \pi^0\pi^0\pi^0$, $\pi^0\pi^0\eta$, $\pi^0\eta\eta$ |
| $\sim 1000$ | [44] ACHASOV | 94 | RVUE | $\pi\pi \to \pi\pi$ |
| $414 \pm 20$ | [39] AUGUSTIN | 89 | DM2 | |

[34] Statistical uncertainty only.
[35] A similar analysis (KOMADA 01) finds $526^{+48}_{-37}$ MeV.
[36] From the best fit of the Dalitz plot.
[37] $6\sigma$ effect, no PWA.
[38] Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
[39] Breit-Wigner fit to S-wave intensity measured in $\pi N \to \pi^-\pi^+ N$ on polarized targets. The fit does not include $f_0(980)$.
[40] Uses data from ASTON 88, OCHS 73, HYAMS 73, ARMSTRONG 91B, GRAYER 74, CASON 83, ROSSELET 77, and BEIER 72B. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
[41] Also observed by ASNER 00 in $\tau^- \to \pi^-\pi^0\pi^0\nu_\tau$ decays.
[42] Uses $\pi^0\pi^0$ data from ANISOVICH 94, AMSLER 94D, and ALDE 95B, $\pi^+\pi^-$ data from OCHS 73, GRAYER 74 and ROSSELET 77, and $\eta\eta$ data from ANISOVICH 94.
[43] The pole is on Sheet III. Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two different poles.
[44] Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.

[56] Using dispersive analysis with phases from GARCIA-MARTIN 11A and BUETTIKER 04 as input.
[57] Using Roy-Steiner equations with $\pi\pi$ phase shifts from an update of COLANGELO 01 and from GARCIA-MARTIN 11A.
[58] Using an analytic K-matrix model.
[59] Using dispersion integral with phase input from Roy equations and data from MARSISKE 90, BOYER 90, BEHREND 92, UEHARA 08A, and MORI 07.
[60] Used dispersion theory. The value quoted used the $f_0(500)$ pole position of $457 - i276$ MeV.
[61] Using $p$, $n$ polarizabilities from PDG 06 and fitting to $\pi\pi$ phase motion from GARCIA-MARTIN 07 and $\sigma$-poles from GARCIA-MARTIN 07 and CAPRINI 06.
[62] Using twice-subtracted dispersion integrals.
[63] Supersedes OLLER 08.
[64] Solution A (preferred solution based on $\chi^2$-analysis).

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[65] Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.

[66] Solution B (worse than solution A; still acceptable when systematic uncertainties are included).

[67] Using unitarity and the $\sigma$ pole position from CAPRINI 06.

[68] This width could equally well be assigned to the $f_0(1370)$. The authors analyse data from BOYER 90 and MARSISKE 90 and report strong correlation with $\gamma\gamma$ width of $f_2(1270)$.

[69] Supersedes MORGAN 90.

## $\rho(770)$

$I^G(J^{PC}) = 1^+(1^{--})$

### THE $\rho(770)$

Updated September 2019 by S. Eidelman (Novosibirsk) and G. Venanzoni (Pisa).

The determination of the parameters of the $\rho(770)$ is beset with many difficulties because of its large width. In physical region fits, the line shape does not correspond to a relativistic Breit-Wigner function with a $P$-wave width, but requires some additional shape parameter. This dependence on parameterization was demonstrated long ago [1]. Bose-Einstein correlations are another source of shifts in the $\rho(770)$ line shape, particularly in multiparticle final-state systems [2].

The same model dependence afflicts any other source of resonance parameters, such as the energy dependence of the phase shift $\delta_1^1$, or the pole position. It is, therefore, not surprising that a study of $\rho(770)$ dominance in the decays of the $\eta$ and $\eta'$ reveals the need for specific dynamical effects, in addition to the $\rho(770)$ pole [3,4].

The cleanest determination of the $\rho(770)$ mass and width comes from $e^+e^-$ annihilation and $\tau$-lepton decays. Analysis of ALEPH [5] showed that the charged $\rho(770)$ parameters measured from $\tau$-lepton decays are consistent with those of the neutral one determined from $e^+e^-$ data [6]. This conclusion is qualitatively supported by the later studies of CLEO [7] and Belle [8]. However, comparison of the two-pion mass spectrum in $\tau$ decays from OPAL [9], CLEO [7], and ALEPH [10,11], and the $e^+e^- \to \pi^+\pi^-$ cross section from CMD-2 [12,13], showed significant discrepancies between the two shapes which can be as high as 10%above the $\rho$ meson [14,15]. This discrepancy remains after measurements of the two-pion cross section in $e^+e^-$ annihilation at KLOE [16,17,18,19], SND [20,21], BaBar [22] and, more recently BESIII [23] The effect is not accounted for by isospin breaking [24,25,26,27], but the accuracy of its calculation may be overestimated [28,29].

This problem seems to be solved after a recent analysis in [30] which showed that after correcting the $\tau$ data for the missing $\rho$ - $\gamma$ mixing contribution, besides the other known isospin symmetry violating corrections, the $\pi\pi$ I=1 part of the hadronic vacuum polarization contribution to the muon g - 2 is fully compatible between $\tau$ based and $e^+e^-$ based evaluations. The global fit of the whole set of the $\rho$, $\omega$, and $\phi$ decays, taking into account mixing effects in the hidden local symmetry model, also showed consistency of the data on $\tau$ decays to two pions and $e^+e^-$ annihilation [31,32]. However, because

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

of the progress in $e^+e^-$ data, the $\tau$ input is now less precise and less reliable due to additional theoretical uncertainties [33] decreasing importance of $\tau$ versus $e^+e^-$ comparison for the determination of $\rho(770)$ parameters and other applications, like, e.g., calculations of hadronic vacuum polarization.

[1] Without limitations on masses and widths.

### $\rho(770)$ RANGE PARAMETER

The range parameter $R$ enters an energy-dependent correction to the width, of the form $(1 + q_r^2 R^2) / (1 + q^2 R^2)$, where $q$ is the momentum of one of the pions in the $\pi\pi$ rest system. At resonance, $q = q_r$.

| 4.66 ± 0.85 | | [3] BARTOS | 17A | RVUE | $e^+e^- \to \pi^+\pi^-, \tau^- \to \pi^-\pi^0\nu_\tau$ |

[1] From the combined fit of the $\tau^-$ data from ANDERSON 00A and SCHAEL 05C and $e^+e^-$ data from the compilation of BARKOV 85, AKHMETSHIN 04, and ALOISIO 05. Supersedes BARATE 97M.
[2] Assuming $m_{\rho^+} = m_{\rho^-}$, $\Gamma_{\rho^+} = \Gamma_{\rho^-}$.
[3] Applies the Unitary & Analytic Model of the pion electromagnetic form factor of DUBNICKA 10 to analyze the data of ACHASOV 06, AKHMETSHIN 07, AUBERT 09AS, AMBROSINO 11A, and FUJIKAWA 08.

### $\Gamma_{\rho(770)^+} - \Gamma_{\rho(770)^-}$

| VALUE | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **1.8 ± 2.0 ± 0.5** | 1.98M | [1] ALOISIO | 03 | KLOE | $1.02\ e^+e^- \to \pi^+\pi^-\pi^0$ |

[1] Without limitations on masses and widths.

## $\rho(770)$ DECAY MODES

| | Mode | Fraction ($\Gamma_i/\Gamma$) | | Scale factor / Confidence level |
|---|---|---|---|---|
| $\Gamma_1$ | $\pi\pi$ | ~ 100 | % | |
| | **$\rho(770)^\pm$ decays** | | | |
| $\Gamma_2$ | $\pi^\pm\pi^0$ | ~ 100 | % | |
| $\Gamma_3$ | $\pi^\pm\gamma$ | ( 4.5 ±0.5 ) | $\times 10^{-4}$ | S=2.2 |
| $\Gamma_4$ | $\pi^\pm\eta$ | < 6 | $\times 10^{-3}$ | CL=84% |
| $\Gamma_5$ | $\pi^\pm\pi^+\pi^-\pi^0$ | < 2.0 | $\times 10^{-3}$ | CL=84% |
| | **$\rho(770)^0$ decays** | | | |
| $\Gamma_6$ | $\pi^+\pi^-$ | ~ 100 | % | |
| $\Gamma_7$ | $\pi^+\pi^-\gamma$ | ( 9.9 ±1.6 ) | $\times 10^{-3}$ | |
| $\Gamma_8$ | $\pi^0\gamma$ | ( 4.7 ±0.6 ) | $\times 10^{-4}$ | S=1.4 |
| $\Gamma_9$ | $\eta\gamma$ | ( 3.00 ± 0.21 ) | $\times 10^{-4}$ | |
| $\Gamma_{10}$ | $\pi^0\pi^0\gamma$ | ( 4.5 ±0.8 ) | $\times 10^{-5}$ | |
| $\Gamma_{11}$ | $\mu^+\mu^-$ | [a] ( 4.55 ± 0.28 ) | $\times 10^{-5}$ | |
| $\Gamma_{12}$ | $e^+e^-$ | [a] ( 4.72 ± 0.05 ) | $\times 10^{-5}$ | |
| $\Gamma_{13}$ | $\pi^+\pi^-\pi^0$ | $(\ 1.01\ ^{+\ 0.54}_{-\ 0.36} \pm 0.34\ )$ | $\times 10^{-4}$ | |
| $\Gamma_{14}$ | $\pi^+\pi^-\pi^+\pi^-$ | ( 1.8 ±0.9 ) | $\times 10^{-5}$ | |
| $\Gamma_{15}$ | $\pi^+\pi^-\pi^0\pi^0$ | ( 1.6 ±0.8 ) | $\times 10^{-5}$ | |
| $\Gamma_{16}$ | $\pi^0 e^+ e^-$ | < 1.2 | $\times 10^{-5}$ | CL=90% |
| $\Gamma_{17}$ | $\eta e^+ e^-$ | | | |

[a] The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \to \mu^+\mu^-) = \Gamma(\rho^0 \to e^+e^-) \times 0.99785$.

### CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 10 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 10.7$ for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters $p_i$, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

| | | | |
|---|---|---|---|
| $x_3$ | −100 | | |
| $\Gamma$ | 15 | −15 | |

| 4.1 $^{+1.0}_{-0.9}$ ±0.3 | 295 | [2] ACHASOV | 02F | SND | 0.36–0.97 $e^+e^- \to \pi^0\pi^0\gamma$ |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| 4.8 $^{+3.4}_{-1.8}$ ±0.5 | 63 | [3] ACHASOV | 00G | SND | $e^+e^- \to \pi^0\pi^0\gamma$ |

[1] This branching ratio includes the conventional VMD mechanism $\rho \to \omega\pi^0$, $\omega \to \pi^0\gamma$, and the new decay mode $\rho \to f_0(500)\gamma$, $f_0(500) \to \pi^0\pi^0$ with a branching ratio $(2.0^{+1.1}_{-0.9} \pm 0.3) \times 10^{-5}$ differing from zero by 2.0 standard deviations.

[2] This branching ratio includes the conventional VMD mechanism $\rho \to \omega\pi^0$, $\omega \to \pi^0\gamma$ and the new decay mode $\rho \to f_0(500)\gamma$, $f_0(500) \to \pi^0\pi^0$ with a branching ratio $(1.9^{+0.9}_{-0.8} \pm 0.4) \times 10^{-5}$ differing from zero by 2.4 standard deviations. Supersedes ACHASOV 00G.

[3] Superseded by ACHASOV 02F.

## $\Gamma(\mu^+\mu^-)/\Gamma(\pi^+\pi^-)$ $\Gamma_{11}/\Gamma_6$

| VALUE (units $10^{-5}$) | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| **4.60±0.28 OUR FIT** | | | | |
| **4.6 ±0.2 ±0.2** | ANTIPOV | 89 | SIGM | $\pi^-$Cu $\to \mu^+\mu^-\pi^-$Cu |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| 8.2 $^{+1.6}_{-3.6}$ | [1] ROTHWELL | 69 | CNTR | Photoproduction |
| 5.6 ±1.5 | [2] WEHMANN | 69 | OSPK | 12 $\pi^-$C, Fe |
| 9.7 $^{+3.1}_{-3.3}$ | [3,4] HYAMS | 67 | OSPK | 11 $\pi^-$Li, H |

[1] Possibly large $\rho$-$\omega$ interference leads us to increase the minus error.

[2] Result contains 11 ± 11% correction using SU(3) for central value. The error on the correction takes account of possible $\rho$-$\omega$ interference and the upper limit agrees with the upper limit of $\omega \to \mu^+\mu^-$ from this experiment.

[3] But he even enlarges his error to take residual $\omega$ contamination into account. Since his value is high, seems the other experiments also can't have too many $\omega$'s. But maybe Hyams has additional $\mu$'s from $\rho \to \pi\pi$, decaying $\pi$'s.

[4] HYAMS 67's mass resolution is 20 MeV. The $\omega$ region was excluded.

## $\Gamma(e^+e^-)/\Gamma(\pi\pi)$ $\Gamma_{12}/\Gamma_1$

## CONSTRAINED FIT INFORMATION

An overall fit to 15 branching ratios uses 55 measurements and one constraint to determine 10 parameters. The overall fit has a $\chi^2 = 57.0$ for 46 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

| **<8.1 × $10^{-5}$** | 90 | ABLIKIM | 18S | BES3 | $J/\psi \to\ \omega\eta \to\ \omega\pi^+\pi^-\pi^0$ |

## PARAMETER Λ IN $\omega \to\ \pi^0\ell^+\ell^-$ DECAY

In the pole approximation the electromagnetic transition form factor for a resonance of mass $M$ is given by the expression:

$$|F|^2 = (1 - M^2/\Lambda^2)^{-2},$$

where for the parameter Λ vector dominance predicts $\Lambda = M_\rho \approx 0.770$ GeV. The ARNALDI 09 measurement is in obvious conflict with this expectation. Note that for $\eta \to\ \gamma\mu^+\mu^-$ decay ARNALDI 09 and DZHELYADIN 80 obtain the value of Λ consistent with vector dominance.

## PARAMETER Λ IN $\omega \to\ \pi^0\mu^+\mu^-$ DECAY

| VALUE (GeV) | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **0.670 ±0.006 OUR AVERAGE** | | | | | |
| $0.6707\pm0.0039\pm0.0056$ | | [1] ARNALDI | 16 | NA60 | 400 GeV ($p$-$A$) collisions |
| $0.668\ \pm0.009\ \pm0.003$ | 3k | [2] ARNALDI | 09 | NA60 | 158$A$ In−In collisions |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| $0.65\ \pm0.03$ | | DZHELYADIN | 81B | CNTR | $25$–$33\ \pi^- p \to\ \omega n$ |

[1] ARNALDI 16 reports $\Lambda^{-2}(\omega) = 2.223 \pm 0.026 \pm 0.037$ GeV$^{-2}$ which we converted to the quoted Λ value.

[2] ARNALDI 09 reports $\Lambda^{-2}(\omega) = 2.24 \pm 0.06 \pm 0.02$ GeV$^{-2}$ which we converted to the quoted Λ value.

## PARAMETER Λ IN $\omega \to \pi^0 e^+e^-$ DECAY

| VALUE (GeV) | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **0.709±0.037** | 1.1k | [1] ADLARSON | 17B | A2MM | $\gamma p \to\ \omega p$ |

[1] ADLARSON 17B reports $\Lambda^{-2}(\omega\pi^0) = 1.99 \pm 0.21$ GeV$^{-2}$ that we converted to the quoted Λ value.

## ENERGY DEPENDENCE OF $\omega \to\ \pi^+\pi^-\pi^0$ DALITZ PLOT

The following experiments fit to one or more of the coefficients $\alpha$, $\beta$, $\gamma$ for $|\text{matrix element}|^2 \propto P\,(1 + 2\alpha\,Z + 2\beta\,Z^{3/2}\sin(3\phi) + 2\gamma Z^2 + O(Z^{5/2}))$ where $P$ is the $P$-wave phase-space factor and Z, $\phi$ are kinematical variables as defined in ADLARSON 17.

| VALUE | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **0.133 ±0.008 OUR AVERAGE** | | | | | |
| $0.1321\pm0.0067\pm0.0046$ | 260k | [1] ABLIKIM | 18AD | BES3 | $J/\psi \to\ \omega\eta$ |
| $0.147\ \pm0.036$ | 44k | ADLARSON | 17 | WASA | $\alpha$ in $pd \to\ ^3\text{He}\,\omega$, $pp \to\ pp\omega$ |

[1] Keeping a term linear in Z only. A fit with the terms proportional to Z and $Z^{3/2}$ gives $\alpha = 0.133 \pm 0.041$ and $\beta = 0.037 \pm 0.054$.

## $\eta'(958)$

### Charge conjugation ($C$), Parity ($P$), Lepton family number ($LF$) violating modes

| | | | | | | |
|---|---|---|---|---|---|---|
| $\Gamma_{31}$ | $\pi^+\pi^-$ | $P,CP$ | < | 1.8 | $\times 10^{-5}$ | 90% |
| $\Gamma_{32}$ | $\pi^0\pi^0$ | $P,CP$ | < | 4 | $\times 10^{-4}$ | 90% |
| $\Gamma_{33}$ | $\pi^0 e^+ e^-$ | $C$ | [a] < | 1.4 | $\times 10^{-3}$ | 90% |
| $\Gamma_{34}$ | $\eta e^+ e^-$ | $C$ | [a] < | 2.4 | $\times 10^{-3}$ | 90% |
| $\Gamma_{35}$ | $3\gamma$ | $C$ | < | 1.0 | $\times 10^{-4}$ | 90% |
| $\Gamma_{36}$ | $\mu^+\mu^-\pi^0$ | $C$ | [a] < | 6.0 | $\times 10^{-5}$ | 90% |
| $\Gamma_{37}$ | $\mu^+\mu^-\eta$ | $C$ | [a] < | 1.5 | $\times 10^{-5}$ | 90% |
| $\Gamma_{38}$ | $e\mu$ | $LF$ | < | 4.7 | $\times 10^{-4}$ | 90% |

[a] $C$ parity forbids this to occur as a single-photon process.

### CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, 2 combinations of partial widths obtained from integrated cross section, and 19 branching ratios uses 51 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 69.4$ for 43 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters $p_i$, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

## $\eta'(958)\to\eta\pi\pi$ DECAY PARAMETERS

$$|\text{MATRIX ELEMENT}|^2 = |1+\alpha Y|^2 + CX + DX^2$$

$X$ and $Y$ are Dalitz variables; $\alpha$ is complex and $C$, and $D$ are real-valued. Parameters $C$ and $D$ are not necessarily equal to $c$ and $d$, respectively, in the generalized parameterization following this one. May be different for $\eta'(958)\to\eta\pi^+\pi^-$ and $\eta'(958)\to\eta\pi^0\pi^0$ decays. Because of different initial assumptions and strong correlations of the parameters we do not average the parameters in the section below.

## $\eta'(958) \to \eta\pi\pi$ DECAY PARAMETERS

$$|\text{MATRIX ELEMENT}|^2 \propto 1 + a\,Y + b\,Y^2 + c\,X + d\,X^2$$

$X$ and $Y$ are Dalitz variables and $a$, $b$, $c$, and $d$ are real-valued parameters. May be different for $\eta'(958) \to \eta\pi^+\pi^-$ and $\eta'(958) \to \eta\pi^0\pi^0$ decays. We do not average measurements in the section below because parameter values from each experiment are strongly correlated.

[1] From the $D^\pm \to K^\pm K^+ K^-$ Dalitz plot fit with the Triple-M amplitude in the multi-meson model of AOUDE 18.
[2] Quoted number refers to real part of pole position.
[3] Analytic continuation using Roy equations. Uses the $K_{e4}$ data of BATLEY 10C and the $\pi N \to \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73.
[4] Analytic continuation using GKPY equations. Uses the $K_{e4}$ data of BATLEY 10C and the $\pi N \to \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73.
[5] Pole position. Used Roy equations.
[6] Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B.
[7] On sheet II in a 2-pole solution. The other pole is found on sheet III at (850−100$i$) MeV
[8] Using a relativistic Breit-Wigner function and taking into account the finite $D_s$ mass.
[9] Breit-Wigner mass. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0 K K}/g_{f_0 \pi\pi} = 0$.
[10] In the kaon-loop fit.
[11] In the no-structure fit.
[12] Systematic errors not estimated.
[13] FLATTE 76 parameterization. $g_{f_0\pi\pi} = 329 \pm 96$ MeV/c$^2$ assuming $g_{f_0 K\overline{K}}/g_{f_0\pi\pi}$=2.
[14] Breit-Wigner mass. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0 K K}/g_{f_0\pi\pi} = 4.21 \pm 0.25 \pm 0.21$ from ABLIKIM 05.
[15] In the kaon-loop fit following formalism of ACHASOV 89.
[16] In the no-structure fit assuming a direct coupling of $\phi$ to $f_0\gamma$.
[17] FLATTE 76 parameterization. Supersedes GARMASH 05.
[18] FLATTE 76 parameterization, $g_{f_0 K\overline{K}}/g_{f_0\pi\pi} = 4.21 \pm 0.25 \pm 0.21$.
[19] K-matrix pole from combined analysis of $\pi^- p \to \pi^0\pi^0 n$, $\pi^- p \to K\overline{K} n$, $\pi^+\pi^- \to \pi^+\pi^-$, $\overline{p}p \to \pi^0\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, $K^0_S K^0_S \pi^0$, $K^+K^0_S\pi^-$ at rest, $\overline{p}n \to \pi^-\pi^-\pi^+$, $K^0_S K^-\pi^0$, $K^0_S K^0_S\pi^-$ at rest.
[20] From the negative interference with the $f_0(500)$ meson of AITALA 01B using the ACHASOV 89 parameterization for the $f_0(980)$, a Breit-Wigner for the $f_0(500)$, and ACHASOV 01F for the $\rho\pi$ contribution.
[21] Coupled-channel Breit-Wigner, couplings $g_\pi$=0.09±0.01±0.01, $g_K$=0.02±0.04±0.03.
[22] Supersedes ACHASOV 98I. Using the model of ACHASOV 89.
[23] Supersedes ACHASOV 98I.
[24] In the "narrow resonance" approximation.
[25] Assuming $\Gamma(f_0)$= 40 MeV.
[26] From a narrow pole fit taking into account $f_0(980)$ and $f_0(1200)$ intermediate mechanisms.
[27] From the combined fit of the photon spectra in the reactions $e^+e^- \to \pi^+\pi^-\gamma$, $\pi^0\pi^0\gamma$.
[28] Supersedes BARBERIS 99 and BARBERIS 99B
[29] T-matrix pole.
[30] From invariant mass fit.
[31] On sheet II in a 2 pole solution. The other pole is found on sheet III at (1039−93$i$) MeV.
[32] On sheet II in a 2 pole solution. The other pole is found on sheet III at (963-29i) MeV.
[33] Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
[34] At high $|t|$.
[35] At low $|t|$.
[36] On sheet II in a 4-pole solution, the other poles are found on sheet III at (953−55$i$) MeV and on sheet IV at (938−35$i$) MeV.
[37] Combined fit of ALDE 95B, ANISOVICH 94, AMSLER 94D.
[38] On sheet II in a 2 pole solution. The other pole is found on sheet III at (996−103$i$) MeV.
[39] From sheet II pole position.
[40] On sheet II in a 2 pole solution. The other pole is found on sheet III at (797−185$i$) MeV and can be interpreted as a shadow pole.
[41] On sheet II in a 2 pole solution. The other pole is found on sheet III at (978−28$i$) MeV.
[42] From coupled channel analysis.
[43] Coupled channel analysis with finite width corrections.
[44] Included in AGUILAR-BENITEZ 78 fit.

### $f_0(980)$ WIDTH

Width determination very model dependent. Peak width in $\pi\pi$ is about 50 MeV, but decay width can be much larger.

[1] Analytic continuation using Roy equations. Uses the $K_{e4}$ data of BATLEY 10C and the $\pi N \to \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73.
[2] Quoted number refers to twice imaginary part of pole position.
[3] Analytic continuation using GKPY equations. Uses the $K_{e4}$ data of BATLEY 10C and the $\pi N \to \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73.
[4] Pole position. Used Roy equations.
[5] Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B.
[6] On sheet II in a 2-pole solution. The other pole is found on sheet III at (850−100$i$) MeV
[7] Using a relativistic Breit-Wigner function and taking into account the finite $D_s$ mass.
[8] Breit-Wigner $\pi\pi$ width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0 K K}/g_{f_0\pi\pi} = 0$.
[9] Systematic errors not estimated.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[10] Breit-Wigner $\pi\pi$ width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0 K K}/g_{f_0 \pi\pi} = 4.21 \pm 0.25 \pm 0.21$ from ABLIKIM 05.

[11] Breit-Wigner, solution 1, PWA ambiguous.

[12] K-matrix pole from combined analysis of $\pi^- p \to \pi^0\pi^0 n$, $\pi^- p \to K\overline{K} n$, $\pi^+\pi^- \to \pi^+\pi^-$, $\overline{p}p \to \pi^0\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, $K^0_S K^0_S \pi^0$, $K^+K^0_S\pi^-$ at rest, $\overline{p}n \to \pi^-\pi^-\pi^+$, $K^0_S K^-\pi^0$, $K^0_S K^0_S \pi^-$ at rest.

[13] Using the data of AKHMETSHIN 99C, ACHASOV 00H, and ALOISIO 02D.

[14] Breit-Wigner width.

[15] Supersedes ACHASOV 98I. Using the model of ACHASOV 89.

[16] Supersedes ACHASOV 98I.

[17] In the "narrow resonance" approximation.

[18] From the combined fit of the photon spectra in the reactions $e^+e^- \to \pi^+\pi^-\gamma$, $\pi^0\pi^0\gamma$.

[19] Supersedes BARBERIS 99 and BARBERIS 99B

[20] T-matrix pole.

[21] On sheet II in a 2 pole solution. The other pole is found on sheet III at $(1039-93i)$ MeV.

[22] From invariant mass fit.

[23] On sheet II in a 2 pole solution. The other pole is found on sheet III at $(963-29i)$ MeV.

[24] Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.

[25] At high $|t|$.

[26] At low $|t|$.

[27] On sheet II in a 4-pole solution, the other poles are found on sheet III at $(953-55i)$ MeV and on sheet IV at $(938-35i)$ MeV.

[28] Combined fit of ALDE 95B, ANISOVICH 94,

[29] On sheet II in a 2 pole solution. The other pole is found on sheet III at $(996-103i)$ MeV.

[30] From sheet II pole position.

[31] On sheet II in a 2 pole solution. The other pole is found on sheet III at $(797-185i)$ MeV and can be interpreted as a shadow pole.

[32] On sheet II in a 2 pole solution. The other pole is found on sheet III at $(978-28i)$ MeV.

[33] From coupled channel analysis.

[34] Coupled channel analysis with finite width corrections.

[35] From coupled channel fit to the HYAMS 73 and PROTOPOPESCU 73 data. With a simultaneous fit to the $\pi\pi$ phase-shifts, inelasticity and to the $K^0_S K^0_S$ invariant mass.

[36] Included in AGUILAR-BENITEZ 78 fit.

## $f_0(980)$ DECAY MODES

| 0.63 | $\pm 0.14$ | [13] MORGAN | 90 | RVUE | $\gamma\gamma \to \pi^+\pi^-, \pi^0\pi^0$ |

[1] Using dispersive analysis with phases from GARCIA-MARTIN 11A and BUETTIKER 04 as input.

[2] Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0 K K}/g_{f_0 \pi\pi} = 0$.

[3] Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0 K K}/g_{f_0 \pi\pi} = 4.21 \pm 0.25 \pm 0.21$ from ABLIKIM 05.

[4] OEST 90 quote systematic errors $^{+0.08}_{-0.18}$. We use $\pm 0.18$. Observed 60 events.

[5] Uses an analytic K-matrix model. Compilation.

[6] Using dispersion integral with phase input from Roy equations and data from MARSISKE 90, BOYER 90, BEHREND 92, UEHARA 08A, and MORI 07.

[7] Solution A (preferred solution based on $\chi^2$-analysis).

[8] Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.

[9] Solution B (worse than solution A; still acceptable when systematic uncertainties are included).

[10] Supersedes MORGAN 90.

[11] From analysis allowing arbitrary background unconstrained by unitarity.

[12] Data included in MORGAN 90, BOGLIONE 99 analyses.

[13] From amplitude analysis of BOYER 90 and MARSISKE 90, data corresponds to resonance parameters $m = 989$ MeV, $\Gamma = 61$ MeV.

[1] Using the model of ACHASOV 89 and ACHASOV 03B.
[2] From a fit with the S-wave amplitude including two interfering Breit-Wigners plus a background term.
[3] Parameterizes couplings to $\overline{K}K$, $\pi\eta$, and $\pi\eta'$.
[4] Using AMSLER 94D and ABELE 98.
[5] From the T-matrix pole on sheet II.
[6] Using the model of ACHASOV 89. Supersedes ACHASOV 98B.
[7] Using the model of JAFFE 77. Supersedes ACHASOV 98B.
[8] T-matrix pole.
[9] Breit-Wigner fit, average between $a_0^\pm$ and $a_0^0$. The fit favors a slightly heavier $a_0^\pm$.
[10] From a single Breit-Wigner fit.
[11] From $f_1(1285)$ decay.

[1] Average of KOZYREV 16 and KOZYREV 18 values taking into account the correlated uncertainties. Supersedes individual KOZYREV 16 and KOZYREV 18 results.
[2] Using a vector meson dominance model with contribution from $\phi(1020)$ and higher mass excitations of $\rho(770)$, $\omega(782)$, and $\phi(1020)$.
[3] Using a phenomenological model based on KUHN 90 with a sum of Breit-Wigner resonances for $\rho(770)$, $\omega(782)$, $\phi(1020)$ and their higher mass excitations.
[4] Update of AKHMETSHIN 99D
[5] From the combined fit assuming that the total $\phi(1020)$ production cross section is saturated by those of $K^+K^-$, $K_S K_L$, $\pi^+\pi^-\pi^0$, and $\eta\gamma$ decays modes and using ACHASOV 00B for the $\eta\gamma$ decay mode.
[6] Using a total width of 4.43 ± 0.05 MeV. Systematic uncertainty included.
[7] Using a total width of 4.43 ± 0.05 MeV.
[8] PELLINEN 82 review includes AKERLOF 77, DAUM 81, BALDI 77, AYRES 74, DEGROOT 74.
[9] From the $D^\pm \to K^\pm K^+ K^-$ Dalitz plot fit with the Triple-M amplitude in the multimeson model of AOUDE 18.
[10] Strongly correlated with AKHMETSHIN 04.
[11] Systematic errors not evaluated.
[12] Weighted and scaled average of 12 measurements of DIJKSTRA 86.
[13] Mass errors enlarged by us to $\Gamma/\sqrt{N}$; see the note with the $K^*(892)$ mass.

### CONSTRAINED FIT INFORMATION

An overall fit to 30 branching ratios uses 82 measurements and one constraint to determine 14 parameters. The overall fit has a $\chi^2 = 63.7$ for 69 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

[1] Using a phenomenological model based on KUHN 90 with a sum of Breit-Wigner resonances for $\rho(770)$, $\omega(782)$, $\phi(1020)$ and their higher mass excitations. The first error combines statistical and systematic uncertainties. The second one is due to the parametrization of the charged kaon form factor and mass calibration.

[1] Obtained by the authors taking into account the $\pi^+\pi^-$ decay mode. Includes a component due to $\pi\pi$ production via the $f_0(500)$ meson. Supersedes ALOISIO 02D.
[2] From the combined fit of the photon spectra in the reactions $e^+e^- \to \pi^+\pi^-\gamma$, $\pi^0\pi^0\gamma$.
[3] From the negative interference with the $f_0(500)$ meson of AITALA 01B using the ACHASOV 89 parameterization for the $f_0(980)$, a Breit-Wigner for the $f_0(500)$, and ACHASOV 01F for the $\rho\pi$ contribution. Superseded by AMBROSINO 07.
[4] Assuming that the $\pi^0\pi^0\gamma$ final state is completely determined by the $f_0\gamma$ mechanism, neglecting the decay $B(\phi \to K\overline{K}\gamma)$ and using $B(f_0 \to \pi^+\pi^-) = 2B(f_0 \to \pi^0\pi^0)$.
[5] Using the value $B(\phi \to \eta\gamma) = (1.338 \pm 0.053) \times 10^{-2}$.
[6] For $E_\gamma > 20$ MeV. Supersedes AKHMETSHIN 97C.
[7] Neglecting other intermediate mechanisms ($\rho\pi$, $\sigma\gamma$).
[8] A narrow pole fit taking into account $f_0(980)$ and $f_0(1200)$ intermediate mechanisms.
[9] For destructive interference with the Bremsstrahlung process
[10] For constructive interference with the Bremsstrahlung process

[1] Dalitz plot analysis taking into account interference between the contact and $\rho\pi$ amplitudes.
[2] From a fit without limitations on charged and neutral $\rho$ masses and widths.
[3] Recalculated by us to match the notations of AKHMETSHIN 98.
[4] Assuming zero phase for the contact term.

## PARAMETER $\beta$ IN $\phi \to P e^+ e^-$ DECAYS

In the one-pole approximation the electromagnetic transition form factor for $\phi \to P e^+ e^-$ ($P = \pi,\eta$) is given as a function of the $e^+e^-$ invariant mass squared, $q^2$, by the expression:

$$|F(q^2)|^2 = (1 - q^2/\Lambda^2)^{-2},$$

where vector meson dominance predicts parameter $\Lambda \approx 0.770$ GeV ($\Lambda^{-2} \approx 1.687$ GeV$^{-2}$). The slope of this form factor, $\beta = dF/dq^2(q^2{=}0)$, equals $\Lambda^{-2}$ in this approximation.

The measurements below obtain $\beta$ in the one-pole approximation.

## PARAMETER $\beta$ IN $\phi \to \pi^0 e^+ e^-$ DECAY

| VALUE (GeV$^{-2}$) | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **2.02±0.11** | 9.5k | [1] ANASTASI | 16B | KLOE | 1.02 $e^+e^- \to \pi^0 e^+ e^-$ |

[1] The error combines statistical and systematic uncertainties.

## PARAMETER $\beta$ IN $\phi \to \eta e^+ e^-$ DECAY

| VALUE (GeV$^{-2}$) | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **1.29±0.13 OUR AVERAGE** | | | | | |
| $1.28 \pm 0.10^{+0.09}_{-0.08}$ | 30k | BABUSCI | 15 | KLOE | 1.02 $e^+e^- \to \eta e^+ e^-$ |
| 3.8 ±1.8 | 213 | [1] ACHASOV | 01B | SND | 1.02 $e^+e^- \to \eta e^+ e^-$ |

[1] The uncertainty is statistical only. The systematic one is negligible, in comparison.

[1] Statistical error negligible.
[2] From the pole position. Using an amplitude analysis based on approximate three-body unitary of $\tau$ data from SCHAEL 05C.
[3] Reanalysis of CLEO data using Breit-Wigner parameterization.
[4] Superseded by AGHASYAN 2018B.
[5] The $\rho^\pm\pi^\mp$ state can be also due to the $\pi(1300)$.
[6] Using the Breit-Wigner parameterization; strong correlation between mass and width.
[7] Using the data of BARATE 98R.
[8] From a fit to the $3\pi$ mass spectrum including the $K\overline{K}^*(892)$ threshold.
[9] Uses the model of KUHN 90.
[10] Uses the model of ISGUR 89.
[11] Includes the effect of a possible $a_1'$ state.
[12] Uses the model of FEINDT 90.
[13] Supersedes AKERS 95P.
[14] Average and spread of values using 2 variants of the model of BOWLER 75.
[15] Reanalysis of RUCKSTUHL 86.
[16] Reanalysis of SCHMIDKE 86.
[17] Reanalysis of ALBRECHT 86B.
[18] From a combined reanalysis of ALBRECHT 86B, SCHMIDKE 86, and RUCKSTUHL 86.
[19] From a combined reanalysis of ALBRECHT 86B and DAUM 81B.
[20] Uses the model of BOWLER 75.
[21] Produced in $K^-$ backward scattering.

[1] Statistical error negligible.
[2] From the pole position. Using an amplitude analysis based on approximate three-body unitary of $\tau$ data from SCHAEL 05C.
[3] Superseded by AGHASYAN 2018B.
[4] The $\rho^\pm\pi^\mp$ state can be also due to the $\pi(1300)$.
[5] Using the Breit-Wigner parameterization; strong correlation between mass and width.
[6] Using the data of BARATE 98R.
[7] From a fit of the $K^- K^{*0}$ distribution assuming $m_{a_1} = 1230$ MeV and purely resonant production of the $K^- K^{*0}$ system.
[8] From a fit to the $3\pi$ mass spectrum including the $K\overline{K}^*(892)$ threshold.
[9] Using the $a_1(1260)$ mass of 1230 MeV.
[10] From AKHMETSHIN 99E and ASNER 00 data using the $a_1(1260)$ mass of 1230 MeV.
[11] Uses the model of KUHN 90.
[12] Uses the model of ISGUR 89.
[13] Includes the effect of a possible $a_1'$ state.
[14] Uses the model of FEINDT 90.
[15] Supersedes AKERS 95P.
[16] Average and spread of values using 2 variants of the model of BOWLER 75.
[17] Reanalysis of RUCKSTUHL 86.
[18] Reanalysis of SCHMIDKE 86.
[19] Reanalysis of ALBRECHT 86B.
[20] From a combined reanalysis of ALBRECHT 86B, SCHMIDKE 86, and RUCKSTUHL 86.
[21] From a combined reanalysis of ALBRECHT 86B and DAUM 81B.
[22] Uses the model of BOWLER 75.
[23] Produced in $K^-$ backward scattering.

[1] From a fit to the Dalitz plot.
[2] Assuming for $\rho(1450)$ mass and width of 1370 and 386 MeV respectively.
[3] Assuming for $f_0(500)$ ($\sigma$) mass and width of 860 and 880 MeV respectively.
[4] Uses multichannel Aitchison-Bowler model (BOWLER 75). Uses data from GAVILLET 77, DAUM 80, and DANKOWYCH 81.
[5] Assuming for $f_0(1370)$ mass and width of 1186 and 350 MeV respectively.
[6] Assuming for $f_2(1270)$ mass and width of 1275 and 185 MeV respectively.
[7] Inconsistent with observations of $\sigma\pi$, $f_0(1370)\pi$, and $f_2(1270)\pi$ decay modes.
[8] Using structure functions from KUHN 92 and DECKER 93A and $B(\tau^- \to K^-\pi^-K^+\nu_\tau) = (0.155 \pm 0.006 \pm 0.009)\%$ from BRIERE 03.
[9] From a comparison to ALAM 94 assuming purely resonant production of the $K^-K^{*0}$ system.
[10] From a fit to the $3\pi$ mass spectrum including the $K\overline{K}^*(892)$ threshold.
[11] Assuming $a_1(1260)$ dominance and taking $B(\tau \to a_1(1260)\nu_\tau)$ from BUSKULIC 96.

### CONSTRAINED FIT INFORMATION

An overall fit to the total width, 4 partial widths, a combination of partial widths obtained from integrated cross sections, and 6 branching ratios uses 45 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 83.0$ for 38 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters $p_i$, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

### $\Gamma(\gamma\gamma)$ $\Gamma_7$

The value of this width depends on the theoretical model used. Unitary approaches with scalars typically (with exception of PENNINGTON 08) give values clustering around 2.6 keV; without an $S$-wave contribution, values are systematically higher (typically around 3 keV).

[1] From a partial-wave analysis of data using a K-matrix formalism with 5 poles.
[2] From analysis of L3 data at 91 and 183–209 GeV and using SU(3) relations.
[3] Based on a *K*-matrix analysis of BELLE data from MORI 07, UEHARA 08A, UEHARA 09 and UEHARA 13. The width is derived for the pole on the third sheet which is closest to the physical axis. Supersedes PENNINGTON 08.
[4] Solution A (preferred solution based on $\chi^2$-analysis).
[5] Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.
[6] Solution B (worse than solution A; still acceptable when systematic uncertainties are included).
[7] With a narrow scalar state around 1220 MeV.
[8] Using a unitarized model with a 300 - 500 keV wide scalar at 1100 MeV.
[9] Using the unitarized model of LYTH 85.
[10] Error includes spread of different solutions. Data of MARK2 and CRYSTAL BALL used in the analysis. Authors report strong correlations with $\gamma\gamma$ width of $f_0(1370)$ : $\Gamma(f_2) + 1/4\ \Gamma(f^0) = 3.6 \pm 0.3$ KeV.
[11] Radiative corrections modify the partial widths; for instance the COURAU 84 value becomes $2.66 \pm 0.21$ in the calculation of LANDRO 86.
[12] Using the MENNESSIER 83 model.
[13] Superseded by BOYER 90.
[14] If helicity = 2 assumption is not made.
[15] Using mass, width and $B(f_2(1270) \to 2\pi)$ from PDG 78.

### $\Gamma(K\overline{K})/\Gamma(\pi\pi)$ $\Gamma_3/\Gamma_1$

We average only experiments which either take into account $f_2(1270)$-$a_2(1320)$ interference explicitly or demonstrate that $a_2(1320)$ production is negligible.

[1] Coupled channel analysis of $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, and $K^\pm K^0_S \pi^\mp$.

[2] Re-evaluated by CHABAUD 83.

[3] Includes PAWLICKI 77 data.

[4] Takes into account the $f_2(1270)$-$f_2'(1525)$ interference.

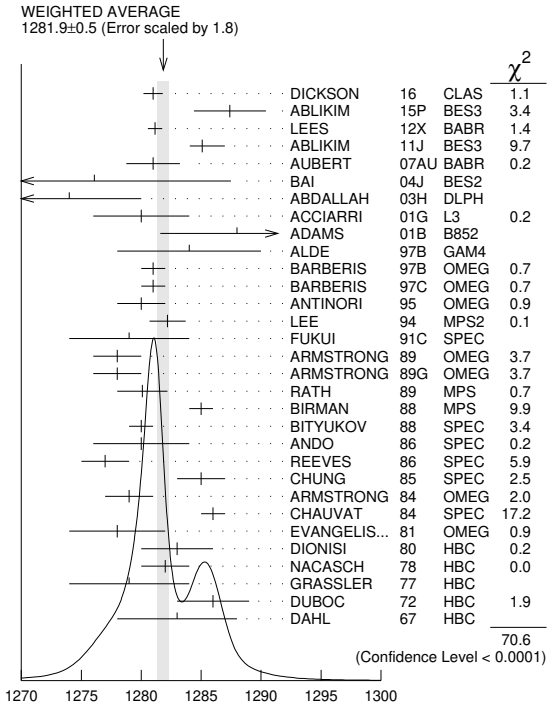
# Meson Particle Listings

## $f_1(1285)$

[2] The selected process is $J/\psi \to \omega a_0(980)\pi$.
[3] Supersedes ABATZIS 94, ARMSTRONG 89E.
[4] From partial wave analysis of $K^+\overline{K}^0\pi^-$ system.
[5] No systematic error given.
[6] From a unitarized quark-model calculation.
[7] From phase shift analysis of $\eta\pi^+\pi^-$ system.
[8] Seen in the missing mass spectrum.



$f_1(1285)$ mass (MeV)

### $f_1(1285)$ WIDTH

Only experiments giving width error less than 20 MeV are kept for averaging.

### CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 18 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 24.0$ for 14 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

[1] The coupled-channel analysis of both the $\eta\pi$ and $\eta'\pi$ systems using ADOLPH 15data. The width is extracted from the T-matrix pole.
[2] The systematic error of 2 MeV corresponds to the spread of solutions.
[3] Superseded by RODAS 19.
[4] ADOLPH 15 value is derived from a Breit-Wigner fit with mass-dependent width taking the $\eta\pi$ and $\rho\pi$ channels into account.
[5] Resolution is not unfolded.
[6] Missing mass with enriched MMS = $\eta\pi^-$, $\eta = 2\gamma$.

## $a_2(1320)$

### CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 18 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 9.3$ for 15 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

[1] KARSHON 74 suggest an additional $I = 0$ state strongly coupled to $\omega\pi\pi$ which could explain discrepancies in branching ratios and masses. We use a central value and a systematic spread.
[2] Decays to $b_1(1040)\pi$, $b_1 \to \omega\pi$. Error increased to account for possible systematic errors of complicated analysis.

[1] From a fit of the interfering $\omega(1420)$ and $\omega(1650)$ with a relative phase of $\pi$ and other parameters floating.
[2] From a fit with contributions from $\omega(782)$, $\phi(1020)$, $\omega(1420)$, and $\omega(1650)$.
[3] From a fit of a VMD model with two effective resonances with masses of 1450 MeV and 1700 MeV to describe the excited vector states $\omega(1420)$, $\rho(1450)$, $\omega(1650)$, and $\rho(1700)$. Systematic errors not evaluated.
[4] From the combined fit of ANTONELLI 92, ACHASOV 01E, ACHASOV 02E, and ACHASOV 03D data on the $\pi^+\pi^-\pi^0$ and ANTONELLI 92 on the $\omega\pi^+\pi^-$ final states. Supersedes ACHASOV 99E and ACHASOV 02E.
[5] Using results of CORDIER 81 and preliminary data of DOLINSKY 91 and ANTONELLI 92.
[6] Using the data of AKHMETSHIN 00D and ANTONELLI 92. The $\rho\pi$ dominance for the energy dependence of the $\omega(1420)$ and $\omega(1650)$ width assumed.
[7] From a fit to two Breit-Wigner functions and using the data of DOLINSKY 91 and ANTONELLI 92.
[8] From a fit to two Breit-Wigner functions interfering between them and with the $\omega,\phi$ tails with fixed $(+,-,+)$ phases.

## $\rho(1450)$ $I^G(J^{PC}) = 1^+(1^{--})$

### THE $\rho(1450)$ AND THE $\rho(1700)$

Updated September 2019 by S. Eidelman (Novosibirsk), C. Hanhart (Juelich) and G. Venanzoni (Pisa).

In our 1988 edition, we replaced the $\rho(1600)$ entry with two new ones, the $\rho(1450)$ and the $\rho(1700)$, because there was emerging evidence that the 1600-MeV region actually contains two $\rho$-like resonances. Erkal [1] had pointed out this possibility with a theoretical analysis on the consistency of $2\pi$ and $4\pi$ electromagnetic form factors and the $\pi\pi$ scattering length. Donnachie [2], with a full analysis of data on the $2\pi$ and $4\pi$ final states in $e^+e^-$ annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture, two resonances were necessary. The existence of $\rho(1450)$ was supported by the analysis of $\eta\rho^0$ mass spectra obtained in photoproduction and $e^+e^-$ annihilation [3], as well as that of $e^+e^- \to \omega\pi$ [4].

The analysis of [2] was further extended by [5,6] to include new data on $4\pi$-systems produced in $e^+e^-$ annihilation, and in $\tau$-decays ($\tau$ decays to $4\pi$, and $e^+e^-$ annihilation to $4\pi$ can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two $\rho$-like states, and from the tail of the $\rho(770)$ decaying into two-body states. While specific conclusions on $\rho(1450) \to 4\pi$ were obtained, little could be said about the $\rho(1700)$.

Independent evidence for two $1^-$ states is provided by [7] in $4\pi$ electroproduction at $\langle Q^2\rangle = 1$ (GeV/$c$)$^2$, and by [8] in a high-statistics sample of the $\eta\pi\pi$ system in $\pi^-p$ charge exchange.

This scenario with two overlapping resonances is supported by other data. Bisello [9] measured the pion form factor in the interval 1.35–2.4 GeV, and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of $\rho$-like resonances at 1420 and 1770 MeV, with widths of about 250 MeV. Antonelli [10] found that the $e^+e^- \to \eta\pi^+\pi^-$ cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of [2] and [9]. These results can be considered as a confirmation of the $\rho(1450)$.

Decisive evidence for the $\pi\pi$ decay mode of both $\rho(1450)$ and $\rho(1700)$ comes from $\overline{p}p$ annihilation at rest [11]. It has been shown that these resonances also possess a $K\overline{K}$ decay mode [12–14]. . High-statistics studies of the decays $\tau \to \pi\pi\nu_\tau$ [15,16], and $\tau \to 4\pi\nu_\tau$ [17] also require the $\rho(1450)$, but are not sensitive to the $\rho(1700)$, because it is too close to the $\tau$ mass. A recent very-high-statistics study of the $\tau \to \pi\pi\nu_\tau$ decay performed at Belle [18] reports the first observation of both $\rho(1450)$ and $\rho(1700)$ in $\tau$ decays. A clear picture of the two $\pi^+\pi^-$ resonances interfering with the $\rho(770)$ in $e^+e^-$ annihilation was also reported by BaBar using the ISR method [19].

The structure of these $\rho$ states is not yet completely clear. Barnes [20] and Close [21] claim that $\rho(1450)$ has a mass

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

consistent with radial $2S$, but its decays show characteristics of hybrids, and suggest that this state may be a $2S$-hybrid mixture. Donnachie [22] argues that hybrid states could have a $4\pi$ decay mode dominated by the $a_1\pi$. Such behavior has been observed by [23] in $e^+e^- \to 4\pi$ in the energy range 1.05–1.38 GeV, and by [17] in $\tau \to 4\pi$ decays. CLEO [24] and Belle [25] observe the $\rho(1450) \to \omega\pi$ decay mode in $B$-meson decays, however, do not find $\rho(1700) \to \omega\pi^0$. A similar conclusion is made by [26,27], who studied the process $e^+e^- \to \omega\pi^0$ and do not observe a statistically significant signal of the $\rho(1700)$. Various decay modes of the $\rho(1450)$ and $\rho(1700)$ are observed in $\overline{p}n$ and $\overline{p}p$ annihilation [28,29], but no definite conclusions can be drawn. More data should be collected to clarify the nature of the $\rho$ states, particularly in the energy range above 1.6 GeV.

We now list under a separate entry the $\rho(1570)$, the $\phi\pi$ state with $J^{PC} = 1^{--}$ earlier observed by [30] (referred to as $C(1480)$) and recently confirmed by [31]. While [32] shows that it may be a threshold effect, [5] and [33] suggest two independent vector states with this decay mode. The $C(1480)$ has not been seen in the $\overline{p}p$ [34] and $e^+e^-$ [35,36] experiments. However, the sensitivity of the two latter is an order of magnitude lower than that of [31]. Note that [31] can not exclude that their observation is due to an OZI-suppressed decay mode of the $\rho(1700)$.

Several observations on the $\omega\pi$ system in the 1200-MeV region [37–43] mmay be interpreted in terms of either $J^P = 1^-$ $\rho(770) \to \omega\pi$ production [44], or $J^P = 1^+$ $b_1(1235)$ production [42,43]. We argue that no special entry for a $\rho(1250)$ is needed. The LASS amplitude analysis [45] showing evidence for $\rho(1270)$ is preliminary and needs confirmation. For completeness, the relevant observations are listed under the $\rho(1450)$.

Recently [46] reported a very broad $1^{--}$ resonance-like $K^+K^-$ state in $J/\psi \to K^+K^-\pi^0$ decays. Its pole position corresponds to mass of 1576 MeV and width of 818 MeV. [47–49] ssuggest its exotic structure (molecular or multiquark), while [50] and [51] explain it by the interference between the $\rho(1450)$ and $\rho(1700)$. The latter statement is qualitatively supported by BaBar [52] and SND [53]. We quote [46] as $X(1575)$ in the section "Further States."

Evidence for $\rho$-like mesons decaying into $6\pi$ states was first noted by [54] in the analysis of $6\pi$ mass spectra from $e^+e^-$ annihilation [55,56] and diffractive photoproduction [57]. Clegg [54] argued that two states at about 2.1 and 1.8 GeV exist: while the former is a candidate for the $\rho(2150)$, the latter could be a manifestation of the $\rho(1700)$ distorted by threshold effects. BaBar reported observations of the new decay modes of the $\rho(2150)$ in the channels $\eta'(958)\pi^+\pi^-$ and $f_1(1285)\pi^+\pi^-$ [58]. The relativistic quark model [59] predicts the $2^3D_1$ state with $J^{PC} = 1^{--}$ at 2.15 GeV which can be identified with the $\rho(2150)$.

We no longer list under a separate particle $\rho(1900)$ various observations of irregular behavior of the cross sections near the $N\bar{N}$ threshold. Dips of various width around 1.9 GeV were reported by the E687 Collaboration (a narrow one in the $3\pi^+3\pi^-$ diffractive photoproduction [60,61]) , by the FENICE experiment (a narrow structure in the $R$ value [62]) , by BaBar in ISR (a narrow structure in $e^+e^- \to \phi\pi$ final state [63], but much broader in $e^+e^- \to 3\pi^+3\pi^-$ and $e^+e^- \to 2(\pi^+\pi^-\pi^0)$ [64]) , by CMD-3 (also a rather broad dip in $e^+e^- \to 3\pi^+3\pi^-$ [65]) . A dedicated scan of the $N\bar{N}$-threshold region by CMD-3 confirms this effect in the $e^+e^- \to 3\pi^+3\pi^-$ and $e^+e^- \to K^+K^-\pi^+\pi^-$ final states, but does not see it in the cross section of $e^+e^- \to 2\pi^+2\pi^-$ [66]. Most probably, these structures emerge as a threshold effect due to the opening of the $N\bar{N}$ channel [67,68,69].

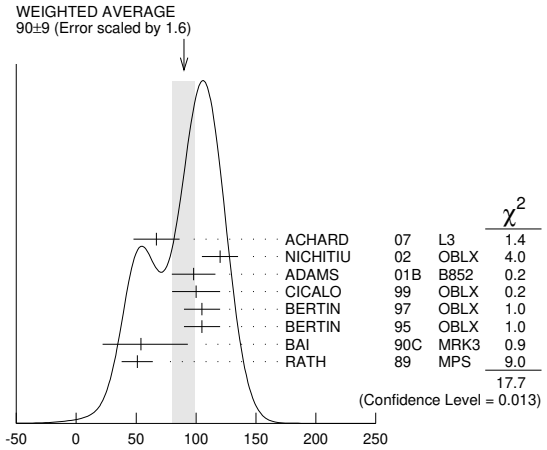
# Meson Particle Listings

## $\eta(1475)$, $f_0(1500)$

• • • We do not use the following data for averages, fits, limits, etc. • • •

| | | | | | |
|---|---|---|---|---|---|
| $118\pm22\pm17$ | [1] ABLIKIM | 18I | BES3 | $J/\psi \to \gamma\gamma\phi(1020)$ | |
| $45^{+14+21}_{-13-28}$ | [2] ABLIKIM | 15T | BES3 | $J/\psi \to \gamma K^0_S K^0_S \eta$ | |
| $63\pm18$ | AUGUSTIN | 92 | DM2 | $J/\psi \to \gamma K\overline{K}\pi$ | |

[1] From a fit to $\gamma\phi$ invariant mass. Angular analysis consistent with $J^{PC} = 0^{-+}$. Other $J^{PC}$ not excluded.
[2] Could also be the $\eta(1405)$.



### $\eta(1475)$ DECAY MODES

| | Mode | Fraction ($\Gamma_i/\Gamma$) |
|---|---|---|
| $\Gamma_1$ | $K\overline{K}\pi$ | seen |
| $\Gamma_2$ | $K\overline{K}^*(892)+$ c.c. | seen |
| $\Gamma_3$ | $a_0(980)\pi$ | seen |
| $\Gamma_4$ | $\gamma\gamma$ | seen |
| $\Gamma_5$ | $K^0_S K^0_S \eta$ | possibly seen |
| $\Gamma_6$ | $\gamma\phi(1020)$ | possibly seen |

### $\eta(1475)$ $\Gamma(i)\Gamma(\gamma\gamma)/\Gamma(\text{total})$

**$\Gamma(K\overline{K}\pi) \times \Gamma(\gamma\gamma)/\Gamma_{\text{total}}$** $\Gamma_1\Gamma_4/\Gamma$

| VALUE (keV) | CL% | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|---|
| **$0.23\pm0.05\pm0.05$** | | 74 | [1] ACHARD | 07 | L3 | 183–209 $e^+e^- \to e^+e^- K^0_S K^\pm\pi^\mp$ |

• • • We do not use the following data for averages, fits, limits, etc. • • •

| | | | | | | |
|---|---|---|---|---|---|---|
| $< 0.089$ | 90 | [2,3] AHOHE | 05 | CLE2 | 10.6 $e^+e^- \to e^+e^- K^0_S K^\pm\pi^\mp$ | |

[1] Supersedes ACCIARRI 01G. Using $B(K^0_S \to \pi^+\pi^-) = 0.6895$.
[2] Using $\eta(1475)$ mass of 1481 MeV and width of 48 MeV. The upper limit increases to 0.140 keV if the world average value, 87 MeV, of the width is used.
[3] Assuming three-body phase-space decay to $K^0_S K^\pm\pi^\mp$.

### $\eta(1475)$ BRANCHING RATIOS

**$\Gamma(K\overline{K}^*(892)+\text{c.c.})/\Gamma(K\overline{K}\pi)$** $\Gamma_2/\Gamma_1$

| VALUE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| $0.50\pm0.10$ | [1] BAILLON | 67 | HBC | 0.0 $\overline{p}p \to K\overline{K}\pi\pi\pi$ |

[1] Data could also refer to $\eta(1405)$.

**$\Gamma(K\overline{K}^*(892)+\text{c.c.})/[\Gamma(K\overline{K}^*(892)+\text{c.c.}) + \Gamma(a_0(980)\pi)]$** $\Gamma_2/(\Gamma_2+\Gamma_3)$

| VALUE | CL% | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| $<0.25$ | 90 | EDWARDS | 82E | CBAL | $J/\psi \to K^+K^-\pi^0\gamma$ |

**$\Gamma(\gamma\gamma)/\Gamma(K\overline{K}\pi)$** $\Gamma_4/\Gamma_1$

| VALUE | CL% | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **$<1.27\times10^{-3}$** | 90 | [1] ABLIKIM | 18O | BES3 | $\psi(2S) \to \pi^+\pi^-\gamma\gamma\gamma$ |

[1] Using results from BAI 00D.

**$\Gamma(\gamma\phi(1020))/\Gamma_{\text{total}}$** $\Gamma_6/\Gamma$

| VALUE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| **possibly seen** | [1] ABLIKIM | 18I | BES3 | $J/\psi \to \gamma\gamma\phi(1020)$ |

[1] Seen as a peak in $\gamma\phi$ invariant mass. Angular analysis consistent with $J^{PC} = 0^{-+}$. Other $J^{PC}$ not excluded. Also see $\eta(1405)$.

[1] T-matrix pole.
[2] Average between $\pi^+\pi^- 2\pi^0$ and $2(\pi^+\pi^-)$.
[3] T-matrix pole. Coupled-channel analysis of AMSLER 95B, AMSLER 95C, and AMSLER 94D.
[4] T-matrix pole of 3 channel unitary model fit to data from AAIJ 14BR and AAIJ 17V extracted using Pade approximants.
[5] Using CLEO-c data but not authored by the CLEO Collaboration.
[6] From a fit to a Breit-Wigner line shape with fixed $\Gamma = 109$ MeV.
[7] Solution I, statistical error only.
[8] From partial wave analysis including all possible combinations of $0^{++}$, $2^{++}$, and $4^{++}$ resonances.
[9] Reanalysis of AITALA 01A data. This state could also be $f_0(1370)$.
[10] Breit-Wigner mass. May also be the $f_0(1370)$.
[11] Breit-Wigner mass.
[12] Statistical error only.
[13] Breit-Wigner, solution 1, PWA ambiguous.
[14] K-matrix pole from combined analysis of $\pi^- p \to \pi^0\pi^0 n$, $\pi^- p \to K\overline{K} n$, $\pi^+\pi^- \to \pi^+\pi^-$, $\overline{p}p \to \pi^0\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, $K^0_S K^0_S \pi^0$, $K^+K^0_S\pi^-$ at rest, $\overline{p}n \to \pi^-\pi^-\pi^+$, $K^0_S K^-\pi^0$, $K^0_S K^0_S \pi^-$ at rest.
[15] Supersedes BARBERIS 99 and BARBERIS 99B.
[16] T-matrix pole on sheet $--+$.
[17] T-matrix pole, supersedes ANISOVICH 94.
[18] T-matrix pole, supersedes ANISOVICH 94 and AMSLER 92.
[19] Supersedes ABATZIS 94, ARMSTRONG 89E. Breit-Wigner mass.
[20] From a simultaneous analysis of the annihilations $\overline{p}p \to 3\pi^0, \pi^0\eta\eta$.
[21] Reanalysis of ANISOVICH 94 data.
[22] From central value and spread of two solutions. Breit-Wigner mass.

## $f_0(1500)$

### CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 10 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 5.6$ for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

| | | | | |
|---|---|---|---|---|

[1] From a partial-wave analysis of data using a K-matrix formalism with 5 poles.
[2] CHABAUD 81 is a reanalysis of PAWLICKI 77 data.
[3] From an amplitude analysis where the $f_2'(1525)$ width and elasticity are in complete disagreement with the values obtained from $K\overline{K}$ channel, making the solution dubious.
[4] Systematic errors not estimated.
[5] From partial wave analysis including all possible combinations of $0^{++}$, $2^{++}$, and $4^{++}$ resonances.
[6] Supersedes ACCIARRI 95J.
[7] From an analysis including interference with $f_0(1710)$.
[8] Using CLEO-c data but not authored by the CLEO Collaboration.
[9] From a fit to a Breit-Wigner line shape with fixed $\Gamma = 73$ MeV.
[10] From a fit to a Breit-Wigner line shape plus a second-order polynomial function. Systematic errors not evaluated.
[11] From analysis of L3 data at 91 and 183–209 GeV.
[12] From an analysis ignoring interference with $f_0(1710)$.
[13] T-matrix pole.
[14] 4-poles, 5-channel K matrix fit.
[15] In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^0(1320)$, and $f_2'(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.
[16] Systematic errors not estimated.

[17] From a partial-wave analysis of data using a K-matrix formalism with 5 poles.
[18] CHABAUD 81 is a reanalysis of PAWLICKI 77 data.
[19] From an amplitude analysis where the $f_2'(1525)$ width and elasticity are in complete disagreement with the values obtained from $K\overline{K}$ channel, making the solution dubious.
[20] From a fit to the $D$ with $f_2(1270)$-$f_2'(1525)$ interference. Mass fixed at 1516 MeV.
[21] Systematic errors not estimated.
[22] From partial wave analysis including all possible combinations of $0^{++}$, $2^{++}$, and $4^{++}$ resonances.
[23] Supersedes ACCIARRI 95J.
[24] From an analysis including interference with $f_0(1710)$.
[25] From a fit to a Breit-Wigner line shape plus a second-order polynomial function. Systematic errors not evaluated.
[26] From analysis of L3 data at 91 and 183–209 GeV.
[27] From an analysis ignoring interference with $f_0(1710)$.
[28] T-matrix pole.
[29] 4-poles, 5-channel K matrix fit.
[30] In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^0(1320)$, and $f_2'(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.
[31] Systematic errors not estimated.

### $f_2'(1525)$ DECAY MODES

| | Mode | Fraction ($\Gamma_i/\Gamma$) | Scale factor |
|---|---|---|---|
| $\Gamma_1$ | $K\overline{K}$ | (87.6±2.2) % | 1.1 |
| $\Gamma_2$ | $\eta\eta$ | (11.6±2.2) % | 1.1 |
| $\Gamma_3$ | $\pi\pi$ | ( 8.3±1.6) × $10^{-3}$ | |
| $\Gamma_4$ | $K\overline{K}^*(892)$ + c.c. | | |
| $\Gamma_5$ | $\pi K\overline{K}$ | | |
| $\Gamma_6$ | $\pi\pi\eta$ | | |
| $\Gamma_7$ | $\pi^+\pi^+\pi^-\pi^-$ | | |
| $\Gamma_8$ | $\gamma\gamma$ | ( 9.5±1.1) × $10^{-7}$ | 1.1 |

### CONSTRAINED FIT INFORMATION

An overall fit to the total width, 2 partial widths, a combination of partial widths obtained from integrated cross sections, and 3 branching ratios uses 17 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 18.2$ for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters $p_i$, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

| | $x_1$ | $x_2$ | $x_3$ | $x_8$ |
|---|---|---|---|---|
| $x_2$ | −100 | | | |
| $x_3$ | −6 | −1 | | |
| $x_8$ | −19 | 19 | 1 | |
| $\Gamma$ | −4 | 4 | 0 | −44 |

| | Mode | Rate (MeV) | Scale factor |
|---|---|---|---|
| $\Gamma_1$ | $K\overline{K}$ | 75 ±4 | 1.8 |
| $\Gamma_2$ | $\eta\eta$ | 9.9 ±1.9 | 1.1 |
| $\Gamma_3$ | $\pi\pi$ | 0.71±0.14 | 1.1 |
| $\Gamma_8$ | $\gamma\gamma$ | ( 8.2 ±0.9 ) × $10^{-5}$ | |

[1] T-matrix pole.

[2] On sheet II in a two-pole solution.

[3] Supersedes the $\omega\omega$ state of BELADIDZE 92B earlier assigned to the $f_2(1640)$.

[4] Breit-Wigner width.

[5] T-matrix pole, large coupling to $\rho\rho$ and $\omega\omega$, could be $f_2(1640)$.

[6] Coupled-channel analysis of AMSLER 95B, AMSLER 95C, and AMSLER 94D.

[7] From a simultaneous analysis of the annihilations $\overline{p}p \to 3\pi^0, \pi^0\eta\eta$ including AKER 91 data.

[8] $J^P$ not determined, could be partly $f_0(1500)$.

[9] $J^P$ not determined.

[10] Superseded by AMSLER 95B.

## CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 1.9$ for 3 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

| | $x_4$ | $x_5$ | $x_7$ |
|---|---|---|---|
| $x_5$ | −53 | | |
| $x_7$ | −29 | −59 | |
| $x_9$ | −8 | −21 | −9 |

[1] From a fit with coherent interference of the $\phi(1680)$ with a non-resonant contribution.
[2] Assuming the $K\overline{K}^*(892)+$ c.c. dynamics. Systematic uncertainties not estimated.
[3] Using a vector meson dominance model with contribution from $\phi(1020)$, $\phi(1680)$, and higher mass excitations of $\rho(770)$ and $\omega(782)$.
[4] Using events with $\pi\pi$ invariant mass less than 0.85 GeV.
[5] From a fit with two incoherent Breit-Wigners.
[6] From the simultaneous fit to the $K\overline{K}^*(892)+$ c.c. and $\phi\eta$ data from AUBERT 08S using the results of AUBERT 07AK.
[7] From the combined fit of AKHMETSHIN 03 and MANE 81 also including $\rho$, $\omega$, and $\phi$. Neither isospin nor flavor structure known.
[8] Using data from IVANOV 81, BARKOV 87, BISELLO 88B, DOLINSKY 91, and ANTONELLI 92.
[9] Using the data from BISELLO 91C.
[10] Using BISELLO 88B and MANE 82 data.
[11] From global fit including $\rho$, $\omega$, $\phi$ and $\rho(1700)$ assume mass 1570 MeV and width 510 MeV for $\rho$ radial excitation.
[12] From global fit of $\rho$, $\omega$, $\phi$ and their radial excitations to channels $\omega\pi^+\pi^-$, $K^+K^-$, $K^0_SK^0_L$, $K^0_SK^\pm\pi^\mp$. Assume mass 1570 MeV and width 510 MeV for $\rho$ radial excitations, mass 1570 and width 500 MeV for $\omega$ radial excitation.
[13] Fit to one channel only, neglecting interference with $\omega$, $\rho(1700)$.

## $\phi(1680)$ $\Gamma(i)\Gamma(e^+e^-)/\Gamma(\text{total})$

This combination of a partial width with the partial width into $e^+e^-$ and with the total width is obtained from the integrated cross section into channel (i) in $e^+e^-$ annihilation. We list only data that have not been used to determine the partial width $\Gamma(i)$ or the branching ratio $\Gamma(i)/\text{total}$.

### $\Gamma(K^0_L K^0_S) \times \Gamma(e^+e^-)/\Gamma_{\text{total}}$ $\quad \Gamma_4\Gamma_5/\Gamma$

| 94±13±15 | 3k | [1] IVANOV | 19A | CMD3 | 1.59–2.007 $e^+e^- \to K^+K^-\eta$ |

[1] From a fit with coherent interference of the $\phi(1680)$ with a non-resonant contribution.

## $\phi(1680)$ $\Gamma(i)\Gamma(e^+e^-)/\Gamma^2(\text{total})$

This combination of a branching ratio into channel ($i$) and branching ratio into $e^+e^-$ is directly measured and obtained from the cross section at the peak. We list only data that have not been used to determine the branching ratio into ($i$) or $e^+e^-$.

### $\Gamma(K^0_L K^0_S)/\Gamma_{\text{total}} \times \Gamma(e^+e^-)/\Gamma_{\text{total}}$ $\quad \Gamma_4/\Gamma \times \Gamma_5/\Gamma$

### CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 14.7$ for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the $x_i$ whose labels appear in this array to sum to one.

## $\rho(1700)$

$I^G(J^{PC}) = 1^+(1^{--})$

### THE $\rho(1450)$ AND THE $\rho(1700)$

Updated September 2019 by S. Eidelman (Novosibirsk), C. Hanhart (Juelich) and G. Venanzoni (Pisa).

In our 1988 edition, we replaced the $\rho(1600)$ entry with two new ones, the $\rho(1450)$ and the $\rho(1700)$, because there was emerging evidence that the 1600-MeV region actually contains two $\rho$-like resonances. Erkal [1] had pointed out this possibility with a theoretical analysis on the consistency of $2\pi$ and $4\pi$ electromagnetic form factors and the $\pi\pi$ scattering length. Donnachie [2], with a full analysis of data on the $2\pi$ and $4\pi$ final states in $e^+e^-$ annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture, two resonances were necessary. The existence of $\rho(1450)$ was supported by the analysis of $\eta\rho^0$ mass spectra obtained in photoproduction and $e^+e^-$ annihilation [3], as well as that of $e^+e^- \to \omega\pi$ [4].

The analysis of [2] was further extended by [5,6] to include new data on $4\pi$-systems produced in $e^+e^-$ annihilation, and in $\tau$-decays ($\tau$ decays to $4\pi$, and $e^+e^-$ annihilation to $4\pi$ can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two $\rho$-like states, and from the tail of the $\rho(770)$ decaying into two-body states. While specific conclusions on $\rho(1450) \to 4\pi$ were obtained, little could be said about the $\rho(1700)$.

Independent evidence for two $1^-$ states is provided by [7] in $4\pi$ electroproduction at $\langle Q^2\rangle = 1$ (GeV/$c$)$^2$, and by [8] in a high-statistics sample of the $\eta\pi\pi$ system in $\pi^- p$ charge exchange.

This scenario with two overlapping resonances is supported by other data. Bisello [9] measured the pion form factor in the interval 1.35–2.4 GeV, and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of $\rho$-like resonances at 1420 and 1770 MeV, with widths of about 250 MeV. Antonelli [10] found that the $e^+e^- \to \eta\pi^+\pi^-$ cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of [2] and [9]. These results can be considered as a confirmation of the $\rho(1450)$.

Decisive evidence for the $\pi\pi$ decay mode of both $\rho(1450)$ and $\rho(1700)$ comes from $\overline{p}p$ annihilation at rest [11]. It has been shown that these resonances also possess a $K\overline{K}$ decay mode [12–14]. . High-statistics studies of the decays $\tau \to \pi\pi\nu_\tau$ [15,16], and $\tau \to 4\pi\nu_\tau$ [17] also require the $\rho(1450)$, but are not sensitive to the $\rho(1700)$, because it is too close to the $\tau$ mass. A recent very-high-statistics study of the $\tau \to \pi\pi\nu_\tau$ decay performed at Belle [18] reports the first observation of both $\rho(1450)$ and $\rho(1700)$ in $\tau$ decays. A clear picture of the two $\pi^+\pi^-$ resonances interfering with the $\rho(770)$ in $e^+e^-$ annihilation was also reported by BaBar using the ISR method [19].

The structure of these $\rho$ states is not yet completely clear. Barnes [20] and Close [21] claim that $\rho(1450)$ has a mass consistent with radial $2S$, but its decays show characteristics of hybrids, and suggest that this state may be a $2S$-hybrid mixture. Donnachie [22] argues that hybrid states could have a $4\pi$ decay mode dominated by the $a_1\pi$. Such behavior has been observed by [23] in $e^+e^- \to 4\pi$ in the energy range 1.05–1.38 GeV, and by [17] in $\tau \to 4\pi$ decays. CLEO [24] and Belle [25] observe the $\rho(1450) \to \omega\pi$ decay mode in $B$-meson decays, however, do not find $\rho(1700) \to \omega\pi^0$. A similar conclusion is made by [26,27], who studied the process $e^+e^- \to \omega\pi^0$ and do not observe a statistically significant signal of the $\rho(1700)$. Various decay modes of the $\rho(1450)$ and $\rho(1700)$ are observed in $\overline{p}n$ and $\overline{p}p$ annihilation [28,29], but no definite conclusions can be drawn. More data should be collected to clarify the nature of the $\rho$ states, particularly in the energy range above 1.6 GeV.

We now list under a separate entry the $\rho(1570)$, the $\phi\pi$ state with $J^{PC} = 1^{--}$ earlier observed by [30] (referred to as $C(1480)$) and recently confirmed by [31]. While [32] shows that it may be a threshold effect, [5] and [33] suggest two independent vector states with this decay mode. The $C(1480)$ has not been seen in the $\overline{p}p$ [34] and $e^+e^-$ [35,36] experiments. However, the sensitivity of the two latter is an order of magnitude lower than that of [31]. Note that [31] can not exclude that their observation is due to an OZI-suppressed decay mode of the $\rho(1700)$.

Several observations on the $\omega\pi$ system in the 1200-MeV region [37–43] mmay be interpreted in terms of either $J^P = 1^-$ $\rho(770) \to \omega\pi$ production [44], or $J^P = 1^+$ $b_1(1235)$ production [42,43]. We argue that no special entry for a $\rho(1250)$ is needed. The LASS amplitude analysis [45] showing evidence for $\rho(1270)$ is preliminary and needs confirmation.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

For completeness, the relevant observations are listed under the $\rho(1450)$.

Recently [46] reported a very broad $1^{--}$ resonance-like $K^+K^-$ state in $J/\psi \to K^+K^-\pi^0$ decays. Its pole position corresponds to mass of 1576 MeV and width of 818 MeV. [47–49] ssuggest its exotic structure (molecular or multiquark), while [50] and [51] explain it by the interference between the $\rho(1450)$ and $\rho(1700)$. The latter statement is qualitatively supported by BaBar [52] and SND [53]. We quote [46] as $X(1575)$ in the section "Further States."

Evidence for $\rho$-like mesons decaying into $6\pi$ states was first noted by [54] in the analysis of $6\pi$ mass spectra from $e^+e^-$ annihilation [55,56] and diffractive photoproduction [57]. Clegg [54] argued that two states at about 2.1 and 1.8 GeV exist: while the former is a candidate for the $\rho(2150)$, the latter could be a manifestation of the $\rho(1700)$ distorted by threshold effects. BaBar reported observations of the new decay modes of the $\rho(2150)$ in the channels $\eta'(958)\pi^+\pi^-$ and $f_1(1285)\pi^+\pi^-$ [58]. The relativistic quark model [59] predicts the $2^3D_1$ state with $J^{PC} = 1^{--}$ at 2.15 GeV which can be identified with the $\rho(2150)$.

We no longer list under a separate particle $\rho(1900)$ various observations of irregular behavior of the cross sections near the $N\bar{N}$ threshold. Dips of various width around 1.9 GeV were reported by the E687 Collaboration (a narrow one in the $3\pi^+3\pi^-$ diffractive photoproduction [60,61]) , by the FENICE experiment (a narrow structure in the $R$ value [62]) , by BaBar in ISR (a narrow structure in $e^+e^- \to \phi\pi$ final state [63], but much broader in $e^+e^- \to 3\pi^+3\pi^-$ and $e^+e^- \to 2(\pi^+\pi^-\pi^0)$ [64]) , by CMD-3 (also a rather broad dip in $e^+e^- \to 3\pi^+3\pi^-$ [65]) . A dedicated scan of the $N\bar{N}$-threshold region by CMD-3 confirms this effect in the $e^+e^- \to 3\pi^+3\pi^-$ and $e^+e^- \to K^+K^-\pi^+\pi^-$ final states, but does not see it in the cross section of $e^+e^- \to 2\pi^+2\pi^-$ [66]. Most probably, these structures emerge as a threshold effect due to the opening of the $N\bar{N}$ channel [67,68,69].

[1] From partial wave analysis including all possible combinations of $0^{++}$, $2^{++}$, and $4^{++}$ resonances.
[2] Spin 0 favored over spin 2.
[3] In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^0(1320)$, and $f_2'(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.
[4] Breit-Wigner mass.
[5] $J^P = 0^+$, supersedes by ARMSTRONG 89D.
[6] Using CLEO-c data but not authored by the CLEO Collaboration.
[7] From a fit to a Breit-Wigner line shape with fixed $\Gamma$ = 135 MeV.
[8] Systematic errors not estimated.
[9] This state may be different from $f_0(1710)$, see CLOSE 05.
[10] K-matrix pole, assuming $J^P = 0^+$, from combined analysis of $\pi^-p \to \pi^0\pi^0 n$, $\pi^-p \to K\overline{K}n$, $\pi^+\pi^- \to \pi^+\pi^-$, $\overline{p}p \to \pi^0\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, $K^0_S K^0_S\pi^0$, $K^+K^0_S\pi^-$ at rest, $\overline{p}n \to \pi^-\pi^-\pi^+$, $K^0_S K^-\pi^0$, $K^0_S K^0_S\pi^-$ at rest.
[11] Decaying to $f_0(1370)\pi\pi$.
[12] T-matrix pole.
[13] Not seen by AMSLER 02.
[14] Supersedes BARBERIS 99 and BARBERIS 99B.
[15] T-matrix pole, assuming $J^P = 0^+$
[16] No $J^{PC}$ determination.
[17] No $J^{PC}$ determination, width not determined.
[18] $J^P = 2^+$.
[19] From a fit to the $0^+$ partial wave.
[20] No $J^{PC}$ determination.
[21] ALDE 92D combines all the GAMS-2000 data.
[22] $J^P = 2^+$, superseded by FRENCH 99.
[23] From an analysis ignoring interference with $f_2'(1525)$.
[24] From an analysis including interference with $f_2'(1525)$.
[25] Superseded by ALDE 92D.
[26] Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.
[27] $J^P = 2^+$ preferred.
[28] From fit neglecting nearby $f_2'(1525)$. Replaced by BLOOM 83.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[29] Superseded by LONGACRE 86.

[1] From partial wave analysis including all possible combinations of $0^{++}$, $2^{++}$, and $4^{++}$ resonances.
[2] Spin 0 favored over spin 2.
[3] In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^0(1320)$, and $f_2'(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.
[4] Breit-Wigner width.
[5] $J^P = 0^+$, supersedes by ARMSTRONG 89D.
[6] Systematic errors not estimated.
[7] This state may be different from $f_0(1710)$, see CLOSE 05.
[8] (Solution I)
[9] K-matrix pole, assuming $J^P = 0^+$, from combined analysis of $\pi^-p \to \pi^0\pi^0 n$, $\pi^-p \to K\overline{K}n$, $\pi^+\pi^- \to \pi^+\pi^-$, $\overline{p}p \to \pi^0\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, $K^0_S K^0_S\pi^0$, $K^+K^0_S\pi^-$ at rest, $\overline{p}n \to \pi^-\pi^-\pi^+$, $K^0_S K^-\pi^0$, $K^0_S K^0_S\pi^-$ at rest.
[10] (Solution I)
[11] Decaying to $f_0(1370)\pi\pi$.
[12] T-matrix pole.
[13] $J^P = 0^+$.
[14] Not seen by AMSLER 02.
[15] Supersedes BARBERIS 99 and BARBERIS 99B.
[16] T-matrix pole, assuming $J^P = 0^+$
[17] No $J^{PC}$ determination.
[18] $J^P = 2^+$.
[19] From a fit to the $0^+$ partial wave.
[20] No $J^{PC}$ determination.
[21] ALDE 92D combines all the GAMS-2000 data.
[22] $J^P = 2^+$, ($0^+$ excluded).
[23] From an analysis ignoring interference with $f_2'(1525)$.
[24] From an analysis including interference with $f_2'(1525)$.
[25] Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.
[26] No $J^{PC}$ determination.
[27] $J^P = 2^+$ preferred.
[28] From fit neglecting nearby $f_2'(1525)$. Replaced by BLOOM 83.
[29] From an amplitude analysis of the $K^0_S K^0_S$ system, superseded by LONGACRE 86.

## $\eta(1760)$

$I^G(J^{PC}) = 0^+(0^{-+})$

OMITTED FROM SUMMARY TABLE

Seen by DM2 in the $\rho\rho$ system (BISELLO 89B). Structure in this region has been reported before in the same system (BALTRUSAITIS 86B) and in the $\omega\omega$ system (BALTRUSAITIS 85C, BISELLO 87).

### $\eta(1760)$ MASS

| VALUE (MeV) | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **1751±15 OUR AVERAGE** | | | | | |
| $1768^{+24}_{-25}\pm10$ | 465 | [1] ZHANG | 12A | BELL | $e^+e^- \to e^+e^-\eta'\pi^+\pi^-$ |
| $1744\pm10\pm15$ | 1045 | [2] ABLIKIM | 06H | BES | $J/\psi \to \gamma\omega\omega$ |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| $1703^{+12}_{-11}\pm\ 2$ | | [3] ZHANG | 12A | BELL | $e^+e^- \to e^+e^-\eta'\pi^+\pi^-$ |
| $1760\pm11$ | 320 | [4] BISELLO | 89B | DM2 | $J/\psi \to 4\pi\gamma$ |

[1] From a single-resonance fit.
[2] From a partial wave analysis including $\eta(1760)$, $f_0(1710)$, $f_2(1640)$, and $f_2(1910)$.
[3] From a two-resonance fit.
[4] Estimated by us from various fits. Systematic uncertainties not estimated.

### $\eta(1760)$ WIDTH

| VALUE (MeV) | EVTS | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **240±30 OUR AVERAGE** | | | | | |

# $X(1835)$ $I^G(J^{PC}) = ?^?(0^{-+})$

OMITTED FROM SUMMARY TABLE

Could be a superposition of two states, one with small width appearing as threshold enhancement in $p\bar{p}$, the other one with a larger width. For the former ABLIKIM 12D determine $J^{PC} = 0^{-+}$.

## $X(1835)$ MASS

| $1833.7\pm 6.1\pm 2.7$ | 264 | ABLIKIM | 05R | BES2 | $J/\psi \to \gamma\pi^+\pi^-\eta'$ |
| $1831 \pm 7$ | | [8,9] ABLIKIM | 05R | BES2 | $J/\psi \to \gamma p\bar{p}$ |
| $1859 {}^{+3}_{-10} {}^{+5}_{-25}$ | | [8] BAI | 03F | BES2 | $J/\psi \to \gamma p\bar{p}$ |

[1] From a fit of the measured $\pi^+\pi^-\eta'$ lineshape that accounts for the abrupt distortion observed at the $p\bar{p}$ threshold through interference with a second previously unseen narrow resonance near 1870 MeV. The fit uses Breit-Wigner functions for the signal shapes and includes known backgrounds and contributors.
[2] From a fit to $\gamma\phi$ invariant mass. Angular analysis consistent with $J^{PC} = 0^{-+}$. Other $J^{PC}$ not excluded.
[3] Pole mass from a fit of the measured $\pi^+\pi^-\eta'$ lineshape to a Flatte formula that accounts for the abrupt distortion observed at the $p\bar{p}$ threshold; the fit also includes known backgrounds and contributors, as well as an *ad hoc* Breit-Wigner function ($M \approx 1919$ MeV; $\Gamma \approx 51$ MeV) that is required for a good fit.
[4] From the fit including final state interaction effects in isospin 0 $S$-wave according to SIBIRTSEV 05A. Supersedes ABLIKIM 10G.
[5] From a fit of the $\pi^+\pi^-\eta'$ mass distribution to a combination of $\gamma f_1(1510)$, $\gamma X(1835)$, and two unconfirmed states $\gamma X(2120)$, and $\gamma X(2370)$, for $M(p\bar{p}) < 2.8$ GeV, and accounting for backgrounds from non-$\eta'$ events and $J/\psi \to \pi^0\pi^+\pi^-\eta'$.
[6] The selected process is $J/\psi \to \omega a_0(980)\pi$. This state may be due also to $\eta_2(1870)$ or to a combination of $X(1835)$ and $\eta_2(1870)$.
[7] From a fit of the $p\bar{p}$ mass distribution to a combination of $\gamma X(1835)$, $\gamma R$ with $M(R) = 2100$ MeV and $\Gamma(R) = 160$ MeV, and $\gamma p\bar{p}$ phase space, for $M(p\bar{p}) < 2.85$ GeV.
[8] Evidence for a threshold enhancement in the $p\bar{p}$ mass spectrum was also reported by ABE 02K, AUBERT,B 05L, and WANG 05A in $B^+ \to p\bar{p}K^+$, WANG 05A in $B^0 \to p\bar{p}K^0_S$, ABE 02W in $\overline{B}{}^0 \to p\bar{p}D^0$, DEL-AMO-SANCHEZ 12 in $B \to D(D^*)p\bar{p}(\pi)$, and WEI 08 in $B^+ \to p\bar{p}\pi^+$ decays. Not seen by ATHAR 06 in $\Upsilon(1S) \to p\bar{p}\gamma$.
[9] From the fit including final state interaction effects in isospin 0 $S$-wave according to SIBIRTSEV 05A. Systematic errors not estimated.
