Following the above AdS/CFT dictionary one can understand the RS solution to the hierarchy problem from a 4D viewpoint. The equivalent 4D model is a CFT with a TeV mass gap and a Higgs boson emerging as a composite state. In the particular case where the Higgs is the fifth-component of the gauge-boson, $A_5$ [108], this corresponds to models, similar to those proposed in Ref. [109,110], where the Higgs is a composite pseudo-Goldstone boson arising from the spontaneous breaking $\mathcal{G}_5 \to \mathcal{H}_{IR}$ in the CFT. The AdS/CFT dictionary tells us that KK states must behave as composite resonances. For example, if the SM gauge bosons propagate in the 5D bulk, the lowest KK $SU(2)_L$-gauge boson must have properties similar to those of the Techni-rho $\rho_T$ [98] with a coupling to longitudinal $W/Z$ bosons given by $g_5\sqrt{k} \approx g_{\rho_T}$, while the coupling to elementary fermions is $g^2/\sqrt{g_5^2 k} \approx g^2 F_{\rho_T}/M_{\rho_T}$.

Fermions in compactified AdS$_5$ also have a simple 4D holographic interpretation. The 4D massless mode described in Sec. 86.3.1 corresponds to an external fermion $\psi_i$ linearly coupled to a fermionic CFT operator $\mathcal{O}_i$: $\mathcal{L}_{\rm int} = \lambda_i \bar{\psi}_i \mathcal{O}_i + h.c.$. The dimension of the operator $\mathcal{O}_i$ is related to the 5D fermion mass according to $\mathrm{Dim}[\mathcal{O}_i] = |c_f + 1/2| - 1$. Therefore, by varying $c_f$ one varies $\mathrm{Dim}[\mathcal{O}_i]$, making the coupling $\lambda_i$ irrelevant ($c_f > 1/2$), marginal ($c_f = 1/2$) or relevant ($c_f < 1/2$). When irrelevant, the coupling is exponentially suppressed at low energies, and then the coupling of $\psi_i$ to the CFT (and eventually to the composite Higgs) is very small. When relevant, the coupling grows in the IR and become as large as $g_5$ (in units of $k$), meaning that the fermion is as strongly coupled as the CFT states [76]. In this latter case $\psi_i$ behaves as a composite fermion.

### 86.3.3 *Flat Extra Dimensions*

Models with quantum gravity at the TeV scale, as in the ADD scenario, can have extra (flat) dimensions of 1/TeV size, as happens in string scenarios (see, for example, [111]). All SM fields may propagate in these extra dimensions, leading to the possibility of observing their corresponding KK states.

A simple example is to assume that the SM gauge bosons propagate in a flat five-dimensional orbifold $S^1/Z_2$ of radius $R$, with the fermions localized on a 4D boundary. The KK gauge bosons behave as sequential SM gauge bosons with a coupling to fermions enhanced by a factor $\sqrt{2}$ [111]. The experimental limits on such sequential gauge bosons could therefore be recast as limits on KK gauge bosons. Such an interpretation of the ATLAS 7 TeV dilepton analysis [112] yielded the bound $1/R > 4.16$ TeV, while a CMS 8 TeV search with a lepton and missing transverse energy in the final state [113] give $1/R > 3.4$ TeV. Indirect bounds from LEP2 require however $1/R \gtrsim 6$ TeV [81, 114], a bound that can considerable improve in the future by high-energy measurements of the dilepton invariant mass spectrum from Drell-Yan processes at the LHC [115]. More recent LHC limits on leptonically decaying gauge bosons [42, 82, 116, 117] are not interpreted as bounds on $1/R$ by the collaborations, but the published results allow for independent derivation of such bound.

An alternative scenario, known as Universal Extra Dimensions

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

(UED) [118] (for a review see, for example, [119]), assumes that all SM fields propagate universally in a flat orbifold $S^1/Z_2$ with an extra $Z_2$ parity, called KK-parity, that interchanges the two boundaries. In this case, the lowest KK state is stable and is a Dark Matter candidate. At colliders, the KK particles would have to be created in pairs, and would then cascade decay to the lightest KK particle, which would be stable and escape detection. The UED mass-spectrum depends not only on the extra-dimensional radius $R$, but also on the cut-off of the 5D theory $\Lambda$, since quantum corrections sensitive to $\Lambda R$ induce mass-splittings between the KK states. Experimental signatures, such as jets or leptons and $\not{E}_T$, would be similar to those of typical $R$-parity conserving SUSY searches. An interpretation of the recent LHC experimental SUSY searches for UED models has been presented in Refs. [120,121]. A lower bound $1/R > 1.4-1.5$ TeV was derived for $\Lambda R \sim 5-35$ [120].

Finally, realistic models of electroweak symmetry breaking can also be constructed with flat extra spatial dimensions, similarly to those in the warped case, requiring, however, the presence of sizeable boundary kinetic terms [122]. There is also the possibility of breaking supersymmetry by boundary conditions [123]. Models of this type could explain naturally the presence of a Higgs boson lighter than $M_D \sim$ TeV (see, for example, [124–126]).

# 87. $W'$-Boson Searches

Revised November, 2019 by B.A. Dobrescu (Fermilab) and S. Willocq (U. Massachusetts).

The $W'$ boson is a massive hypothetical particle of spin 1 and electric charge $\pm 1$, which is a color singlet and is predicted in various extensions of the Standard Model (SM).

## 87.1 $W'$ couplings to quarks and leptons

The Lagrangian terms describing the couplings of a $W'^{+}$ boson to fermions are given by

$$\frac{W'^{+}_{\mu}}{\sqrt{2}}\left[\overline{u}_i\left(C^R_{q_{ij}}P_R+C^L_{q_{ij}}P_L\right)\gamma^\mu d_j+\overline{\nu}_i\left(C^R_{\ell_{ij}}P_R+C^L_{\ell_{ij}}P_L\right)\gamma^\mu e_j\right]. \tag{87.1}$$

Here, $u, d, \nu$, and $e$ are the SM fermions in the mass eigenstate basis, $i, j = 1, 2, 3$ label the fermion generation, and $P_{R,L} = (1 \pm \gamma_5)/2$. The coefficients $C^L_{q_{ij}}$, $C^R_{q_{ij}}$, $C^L_{\ell_{ij}}$, and $C^R_{\ell_{ij}}$ are complex dimensionless parameters. If $C^R_{\ell_{ij}} \neq 0$, then the $i$th generation includes a right-handed neutrino. Using this notation, the SM $W$ couplings are $C^L_q = gV_{\rm CKM}$, $C^L_\ell = g \approx 0.63$ and $C^R_q = C^R_\ell = 0$.

Unitarity considerations imply that the $W'$ boson is associated with a spontaneously-broken gauge symmetry. This is true even when it is a composite particle (*e.g.* $\rho^{\pm}$-like bound states [1]) if its mass is much smaller than the compositeness scale, or a Kaluza-Klein mode in theories where the $W$ boson propagates in extra dimensions [2]. The simplest extension of the electroweak gauge group that includes a $W'$ boson is $SU(2)_1 \times SU(2)_2 \times U(1)$, but larger groups are encountered in some theories. A generic property of these gauge theories is that they also include a $Z'$ boson [3]; the $W'$-to-$Z'$ mass ratio is often a free parameter.

A tree-level mass mixing may be induced between the electrically-charged gauge bosons. Upon diagonalization of their mass matrix, the $W$-to-$Z$ mass ratio and the couplings of the observed $W$ boson are shifted from the SM values. Their measurements imply that the mixing angle, $\theta_+$, between the gauge eigenstates must be smaller than about $10^{-2}$. In certain theories the mixing is negligible (*e.g.*, due to a new parity [4]), even when the $W'$ mass is near the electroweak scale. Note that $SU(2)$ gauge invariance suppresses the kinetic mixing between the $W$ and $W'$ bosons (in contrast to the case of a $Z'$ boson [3]).

The $W'$ coupling to $WZ$ is fixed by Lorentz and gauge invariances, and to leading order in $\theta_+$ is given by [5]

$$\frac{g\,\theta_+\,i}{\cos\theta_W}\left[W'^{+}_{\mu}\left(W^-_\nu Z^{\nu\mu}+Z_\nu W^{-\mu\nu}\right)+Z^\nu W^{-\mu}W'^{+}_{\nu\mu}\right]+\text{H.c.}, \tag{87.2}$$

where $W^{\mu\nu} \equiv \partial^\mu W^\nu - \partial^\nu W^\mu$, etc. The $\theta_W$ dependence shown here corrects the one given in Ref. [6], which has been referred to as the Extended Gauge Model by the experimental collaborations. The $W'$ coupling to $Wh^0$, where $h^0$ is the SM Higgs boson, is

$$-\,\xi_h\, g_{W'}\, M_W\; W'^{+}_{\mu}\, W^{\mu-} h^0 + \text{H.c.}, \tag{87.3}$$

where $g_{W'}$ is the gauge coupling of the $W'$ boson, and the coefficient $\xi_h$ satisfies $\xi_h \leq 1$ in simple Higgs sectors [5].

In models based on the "left-right symmetric" gauge group [7], $SU(2)_L \times SU(2)_R \times U(1)_{B-L}$, the SM fermions that couple to the $W$ boson transform as doublets under $SU(2)_L$ while the other fermions transform as doublets under $SU(2)_R$. Consequently, the $W'$ boson couples primarily to right-handed fermions; its coupling to left-handed fermions arises due to the $\theta_+$ mixing, so that $C^L_q$ is proportional to the CKM matrix and its elements are much smaller than the diagonal elements of $C^R_q$. Generically, $C^R_q$ does not need to be proportional to $V_{\rm CKM}$.

There are many other models based on the $SU(2)_1 \times SU(2)_2 \times U(1)$ gauge symmetry. In the "alternate left-right" model [8], all the couplings shown in Eq. (87.1) vanish, but there are some new fermions such that the $W'$ boson couples to pairs involving a SM fermion and a new fermion. In the "ununified SM" [9], the left-handed quarks are doublets under one $SU(2)$, and the left-handed leptons are doublets under a different $SU(2)$, leading to a mostly leptophobic $W'$ boson: $C^L_{\ell_{ij}} \ll C^L_{q_{ij}}$ and $C^R_{\ell_{ij}} = C^R_{q_{ij}} = 0$. Fermions of different generations may also transform as doublets under different $SU(2)$ gauge groups [10]. In particular, the couplings to third generation quarks may be enhanced [11].

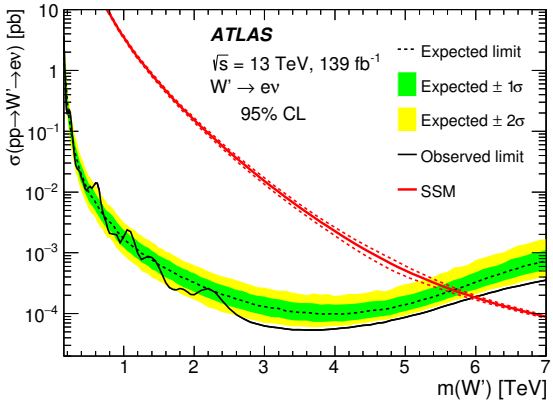

Figure 87.1: Upper limit on $\sigma(pp \to W'X)\, B(W' \to e\nu)$ from ATLAS [12]. The red line shows the theoretical prediction in the Sequential SM.

It is also possible that the $W'$ couplings to SM fermions are highly suppressed. For example, if the quarks and leptons are singlets under one $SU(2)$ [13], then the couplings are proportional to the tiny mixing angle $\theta_+$. Similar suppressions may arise if some vectorlike fermions mix with the SM fermions [14].

Gauge groups that embed the electroweak symmetry, such as $SU(3)_W \times U(1)$ or $SU(4)_W \times U(1)$, also include one or more $W'$ bosons [15].

## 87.2 Collider searches

At LEP-II, $W'$ bosons could have been produced in pairs via their photon and $Z$ couplings. The production cross section is large enough to rule out $M_{W'} < \sqrt{s}/2 \approx 105$ GeV for most patterns of decay modes.

At hadron colliders, $W'$ bosons can be detected through resonant pair production of fermions ($f$ and $f'$) or electroweak bosons with a net electric charge equal to $\pm 1$. When $W'$ has a width much smaller than its mass ($M_{W'}/\Gamma_{W'} \lesssim 7\%$), the contribution of the $s$-channel $W'$ exchange to the total rate for $pp \to f\bar{f}'X$, where $X$ is any final state, may be approximated by the branching fraction $B(W' \to f\bar{f}')$ times the production cross section

$$\sigma\left(pp \to W'X\right) \simeq \frac{\pi}{6s}\sum_{i,j}\left[(C^L_{q_{ij}})^2+(C^R_{q_{ij}})^2\right] w_{ij}\left(M^2_{W'}/s, M_{W'}\right). \tag{87.4}$$

The functions $w_{ij}$ include the information about proton structure, and are given to leading order in $\alpha_s$ by

$$w_{ij}(z,\mu) = \int_z^1 \frac{dx}{x}\left[u_i(x,\mu)\,\overline{d}_j\left(\frac{z}{x},\mu\right)+\overline{u}_i(x,\mu)\,d_j\left(\frac{z}{x},\mu\right)\right], \tag{87.5}$$

where $u_i(x,\mu)$ and $d_i(x,\mu)$ are the parton distributions inside the proton at the factorization scale $\mu$ and parton momentum fraction $x$ for the up- and down-type quarks of the $i$th generation, respectively. QCD corrections to $W'$ production are sizable (they also include quark-gluon initial states), but preserve the above factorization of couplings at next-to-leading order [16].

The most commonly studied $W'$ signal consists of a high-momentum electron or muon and large missing transverse momentum. The signal transverse mass distribution forms a Jacobian peak with its endpoint at $M_{W'}$ (see Fig. 1 (top) of Ref. [12]). Given that the branching fractions for $W' \to e\nu$ and $W' \to \mu\nu$ could be very different, the results in these channels should be presented separately. Searches in these channels often implicitly assume that the left-handed couplings vanish (no interference between $W$ and $W'$), and that the right-handed neutrino is light compared to the $W'$ boson and escapes the detector. An example of parameter values that satisfy these assumptions is $C^R_q = gV_{\rm CKM}$, $C^R_\ell = g$, $C^L_q = C^L_\ell = 0$, which define a model that

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

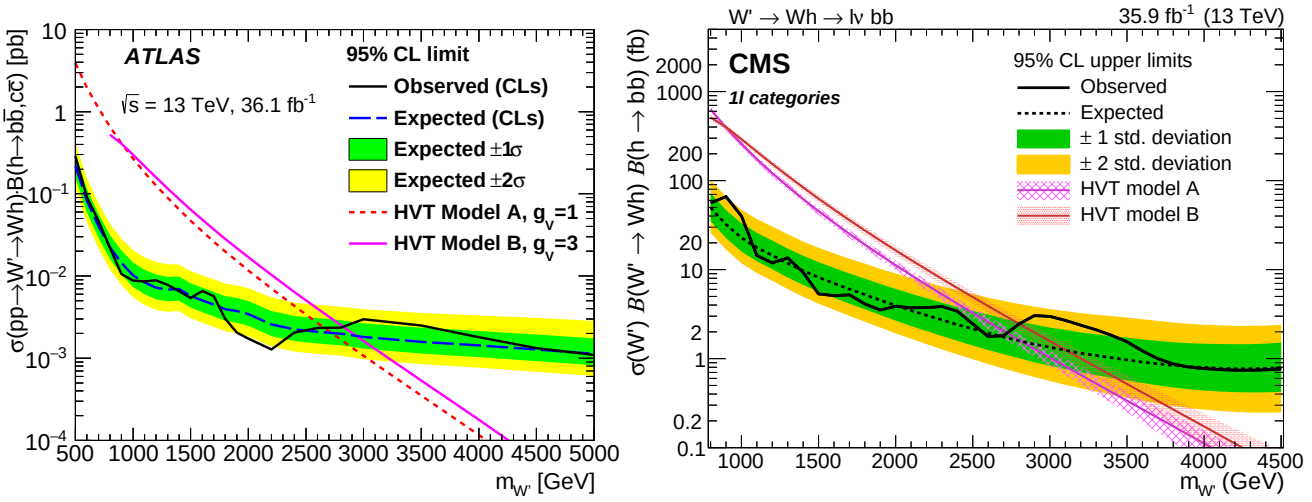

Figure 87.2: Upper limits on $W'$ production cross section times branching fraction into a $W$ and a SM Higgs boson decaying into heavy-flavor quarks, from ATLAS [17] (left) and CMS [18] (right).

preserves lepton universality and predicts the same total cross section as the Sequential SM used in many $W'$ searches. However, if a $W'$ boson were discovered and the final state fermions have left-handed helicity, then the effects of $W - W'$ interference could be observed [19], providing information about the $W'$ couplings. The effects of the $W'$ width on interference are discussed in [20].

In the $e\nu$ channel, the ATLAS and CMS collaborations set limits on the $W'$ production cross section times branching fraction (and thus indirectly on the $W'$ couplings). These limits are set for $M_{W'}$ in the $0.15 - 7$ TeV range and are based on 36–139 fb$^{-1}$ at $\sqrt{s} = 13$ TeV [12,21], as shown in Fig. 87.1 for the most stringent limits. ATLAS sets the strongest mass limit $M_{W'} > 6.0$ TeV in the Sequential SM (all limits in this mini-review are at the 95% CL). The coupling limits are much weaker for $M_{W'} < 150$ GeV, a range last explored with the Tevatron at $\sqrt{s} = 1.8$ TeV [22].

In the $\mu\nu$ channel, ATLAS and CMS set rate limits for $M_{W'}$ in the $0.15-7$ TeV range from the same analyses as mentioned above, with the strongest mass lower limit of 5.1 TeV in the Sequential SM set by ATLAS [12] using 139 fb$^{-1}$ of $\sqrt{s} = 13$ TeV data. When combined with the $e\nu$ channel assuming lepton universality, the upper limit on the $\sqrt{s} = 13$ TeV cross section times branching fraction to $\ell\nu$ varies between 0.05 and 2.1 fb for $M_{W'}$ values in the range between 1 and 6 TeV [12]. Only weak limits on $W' \to \mu\nu$ exist for $M_{W'} < 150$ GeV [23]. Note that masses of the order of the electroweak scale are interesting from a theory point of view, while lepton universality does not necessarily apply to a $W'$ boson.

Dedicated searches for $W' \to \tau\nu$ have been performed by CMS at 8 TeV [24] and both ATLAS and CMS with 36 fb$^{-1}$ at 13 TeV [25,26]. Limits are set on $\sigma \cdot B$ for $M_{W'}$ between 0.4 and 4 TeV for the former and between 0.4 and 5.6 TeV for the latter. A mass lower limit of 4.0 TeV is set in the Sequential SM and the upper limit on the cross section times branching fraction to $\tau\nu$ at 13 TeV varies between 1.7 and 12 fb for $M_{W'}$ values in the range between 1 and 5 TeV [26].

The $W'$ decay into a charged lepton and a right-handed neutrino, $\nu_R$, may also be followed by the $\nu_R$ decay through a virtual $W'$ boson into a charged lepton and two quark jets. The CMS [27] and ATLAS [28] searches in the $eejj$ and $\mu\mu jj$ channels have set limits on the cross section times branching fraction as a function of the $\nu_R$ mass or of $M_{W'}$. No requirement is placed on the charge of the lepton pair. A related $W'$ search in the $\tau\tau jj$ channel with hadronic $\tau$ decays was also performed by CMS [29].

The $t\bar{b}$ channel is particularly important because a $W'$ boson that couples only to right-handed fermions cannot decay to leptons when the right-handed neutrinos are heavier than $M_{W'}$. Additional motivations are provided by a $W'$ boson with enhanced couplings to the third generation [11], and by a leptophobic $W'$ boson. The usual signature consists of a leptonically-decaying $W$ boson and two $b$-jets. Recent studies have also incorporated the fully hadronic decay channel for $M_{W'} \gg m_t$ with the use of jet substructure techniques to tag highly boosted top-jets. For a detailed discussion of this channel, see Ref. [30].

Searches for dijet resonances may be used to set limits on $W' \to q\bar{q}'$. ATLAS [31] and CMS [32] provide similar coverage in the $\sim 1.5 - 8.0$ TeV mass range with 139 and 137 fb$^{-1}$ of data, respectively, collected at $\sqrt{s} = 13$ TeV. Interpretation in terms of $W'$ decays with 139 fb$^{-1}$ of 13 TeV data yields a $W'$ mass lower limit of 4.0 TeV in the Sequential SM [31]. For masses in the range $\sim 0.5 - 1.5$ TeV, analyses based on jets reconstructed online provide the best sensitivity because they circumvent trigger bandwidth limitations [33,34]. For $W'$ masses below $\sim 0.5$ TeV, the best limits are set in novel analyses exploiting boosted technologies and initial state radiation [35–38]. Cross-section limits for $W'$ masses below $\sim 1.5$ TeV can be derived from the dijet limits on $Z'$ bosons summarized in Ref. [3].

In some theories [4] the $W'$ couplings to SM fermions are suppressed by discrete symmetries. $W'$ production then occurs in pairs, through a photon or $Z$ boson. The decay modes are model-dependent and often involve other new particles. The ensuing collider signals arise from cascade decays and typically include missing transverse momentum.

Searches for $WZ$ resonances at the LHC have focused on the process $pp \to W' \to WZ$ with the production mainly from $u\bar{d} \to W'$ assuming SM-like couplings to quarks. ATLAS and CMS have set the upper limits on the $W'WZ$ coupling for $M_{W'}$ in the $0.2 - 5.0$ TeV range with a combination of fully leptonic, semi-leptonic and fully hadronic channels with $\sim 36$ fb$^{-1}$ at 13 TeV [39,40] (see also Ref. [30]). The strongest lower limits on the $W'$ mass are set by ATLAS [41] and CMS [42] at 13 TeV with 139 fb$^{-1}$ and 77 fb$^{-1}$, respectively, in the $WZ \to (jj)(jj)$ final state, where the parentheses represent a resonance. The lower limit on $M_{W'}$ is 3.4 TeV in the context of the Heavy Vector Triplet (HVT) weakly-coupled scenario A [43]. A fermiophobic $W'$ boson that couples to $WZ$ may be produced at hadron colliders in association with a $Z$ boson, or via $WZ$ fusion. This would give rise to $(WZ)Z$ and $(WZ)jj$ final states [44].

$W'$ bosons have also been searched for in final states with a $W$ boson and a SM Higgs boson in the channels $W \to \ell\nu$ or $W \to q\bar{q}'$ and $h^0 \to b\bar{b}$ by ATLAS [17,45] and CMS [18,46] with 36 fb$^{-1}$ at $\sqrt{s} = 13$ TeV. Cross-section limits are set for $W'$ masses in the range between 0.5 and 5.0 TeV. The ATLAS and CMS 13 TeV analyses both set the most stringent lower limit on the mass: $M_{W'} > 2.7$ TeV for the HVT weakly-coupled scenario A, as shown in Fig. 87.2.

## 87.3 Low-energy constraints

The properties of $W'$ bosons are also constrained by measurements of processes at energies much below $M_{W'}$. The bounds on

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

$W-W'$ mixing [47] are mostly due to the change in $W$ properties compared to the SM. Limits on deviations in the $ZWW$ couplings provide a leading constraint for fermiophobic $W'$ bosons [14].

Constraints arising from low-energy effects of $W'$ exchange are strongly model-dependent. If the $W'$ couplings to quarks are not suppressed, then box diagrams involving a $W$ and a $W'$ boson contribute to neutral meson-mixing. In the case of $W'$ couplings to right-handed quarks as in the left-right symmetric model, the limit from $K_L - K_S$ mixing is severe: $M_{W'} > 2.9$ TeV for $C_q^R = gV_{\rm CKM}$ [48]. However, if no correlation between the $W'$ and $W$ couplings is assumed, then the limit on $M_{W'}$ may be significantly relaxed [49].

$W'$ exchange also contributes at tree level to various low-energy processes. In particular, it would impact the measurement of the Fermi constant $G_F$ in muon decay, which in turn would change the predictions of many other electroweak processes. A recent test of parity violation in polarized muon decay [50] has set limits of about 600 GeV on $M_{W'}$, assuming $W'$ couplings to right-handed leptons as in left-right symmetric models and a light $\nu_R$. There are also $W'$ contributions to the neutron electric dipole moment, $\beta$ decays, and other processes [47].

If right-handed neutrinos have Majorana masses, then there are tree-level contributions to neutrinoless double-beta decay, and a limit on $M_{W'}$ versus the $\nu_R$ mass may be derived [51]. For $\nu_R$ masses below a few GeV, the $W'$ boson contributes to leptonic and semileptonic $B$ meson decays, so that limits may be placed on various combinations of $W'$ parameters [49]. For $\nu_R$ masses below $\sim$30 MeV, the most stringent constraints on $M_{W'}$ are due to the limits on $\nu_R$ emission from supernovae.

# 88. $Z'$-Boson Searches

Revised October, 2019 by B.A. Dobrescu (Fermilab) and S. Willocq (U. Massachusetts).

The $Z'$ boson is a massive, electrically-neutral and color-singlet hypothetical particle of spin 1. This particle is predicted in many extensions of the Standard Model (SM) and has been the object of extensive phenomenological studies [1].

## 88.1 $Z'$ boson couplings

The couplings of a $Z'$ boson to the first-generation fermions are given by

$$Z'_\mu \left( g_u^L\, \overline{u}_L \gamma^\mu u_L + g_d^L\, \overline{d}_L \gamma^\mu d_L + g_u^R\, \overline{u}_R \gamma^\mu u_R + g_d^R\, \overline{d}_R \gamma^\mu d_R + g_\nu^L\, \overline{\nu}_L \gamma^\mu \nu_L + g_e^L\, \overline{e}_L \gamma^\mu e_L + g_e^R\, \overline{e}_R \gamma^\mu e_R \right), \tag{88.1}$$

where $u, d, \nu, e$ are the quark and lepton fields in the mass eigenstate basis, and the coefficients $g_u^L$, $g_d^L$, $g_u^R$, $g_d^R$, $g_\nu^L$, $g_e^L$, $g_e^R$ are real dimensionless parameters. If the $Z'$ couplings to quarks and leptons are generation-independent, then these seven parameters describe the couplings of the $Z'$ boson to all SM fermions. More generally, however, the $Z'$ couplings to fermions are generation-dependent, in which case Eq. (88.1) may be written with generation indices $i$, $j = 1$, 2, 3 labeling the quark and lepton fields, and with the seven coefficients promoted to $3 \times 3$ Hermitian matrices (*e.g.*, $g_{e\,ij}^L\, \overline{e}_L^i \gamma^\mu e_L^j$, where $e_L^2$ is the left-handed muon, etc.).

The parameters describing the $Z'$ boson interactions with quarks and leptons are subject to some theoretical constraints. Quantum field theories that include a heavy spin-1 particle are well behaved at high energies only if that particle is a gauge boson associated with a spontaneously broken gauge symmetry. Quantum effects preserve the gauge symmetry only if the couplings of the gauge boson to fermions satisfy the anomaly equations [2]. Furthermore, the fermion charges under the new gauge symmetry are constrained by the requirement that the quarks and leptons get masses from gauge-invariant interactions with the Higgs fields.

The relation between the couplings displayed in Eq. (88.1) and the gauge charges $z_{fi}^L$ and $z_{fi}^R$ of the fermions $f = u, d, \nu, e$ involves the unitary $3 \times 3$ matrices $V_f^L$ and $V_f^R$ that transform the gauge eigenstate fermions $f_L^i$ and $f_R^i$, respectively, into the mass eigenstates. The $Z'$ couplings also depend on the mixings of the new gauge boson in the gauge eigenstate basis ($\tilde{Z}'_\mu$). The main ones are a kinetic mixing $(-\chi/2) B^{\mu\nu} \tilde{Z}'_{\mu\nu}$ with the hypercharge gauge boson $B^\mu$ ($\chi$ is a dimensionless parameter), and a mass mixing $\delta M^2\, \tilde{Z}^\mu \tilde{Z}'_\mu$ with the linear combination ($\tilde{Z}_\mu$) of neutral bosons that couples as the SM $Z$ boson [3]. Since both the kinetic and mass mixings shift the mass and couplings of the $Z$ boson, electroweak measurements impose upper limits on $\chi$ and $\delta M^2/(M_{Z'}^2 - M_Z^2)$ of the order of $10^{-3}$ [4]. Keeping only linear terms in these two small quantities, the couplings of the mass-eigenstate $Z'$ boson are given by

$$g_{f\,ij}^L = g_z V_{fii'}^L\, z_{f\,i'}^L \left(V_f^L\right)_{i'j}^\dagger + \frac{e}{c_W} \left( \frac{s_W \chi M_{Z'}^2 + \delta M^2}{2 s_W \left(M_{Z'}^2 - M_Z^2\right)} \sigma_f^3 - \epsilon\, Q_f \right), \tag{88.2}$$

$$g_{f\,ij}^R = g_z V_{fii'}^R\, z_{fi'}^R \left(V_f^R\right)_{i'j}^\dagger - \frac{e}{c_W}\, \epsilon\, Q_f, \tag{88.3}$$

where $g_z$ is the new gauge coupling, $Q_f$ is the electric charge of $f$, $e$ is the electromagnetic gauge coupling, $s_W$ and $c_W$ are the sine and cosine of the weak mixing angle, $\sigma_f^3 = +1$ for $f = u, \nu$ and $\sigma_f^3 = -1$ for $f = d, e$, and

$$\epsilon = \frac{\chi \left(M_{Z'}^2 - c_W^2 M_Z^2\right) + s_W \delta M^2}{M_{Z'}^2 - M_Z^2}. \tag{88.4}$$

The interaction of the $Z'$ boson with a pair of $W$ bosons has the form

$$\left[ i \left( W_\mu^- Z'_\nu - W_\nu^- Z'_\mu \right) \partial^\mu W^{+\nu} + \text{H.c.} \right] + i \left( W_\mu^+ W_\nu^- - W_\nu^+ W_\mu^- \right) \partial^\mu Z'^\nu \tag{88.5}$$

with a coefficient of order $M_W^2/M_{Z'}^2$ [5]. The $Z'$ also couples to one SM Higgs boson and one $Z$ boson, $Z'_\mu Z^\mu\, h^0$, with a coefficient of order $M_Z$.

## 88.2 $Z'$ models

A simple origin of a $Z'$ boson is a new $U(1)'$ gauge symmetry. In that case, the matricial equalities $z_u^L = z_d^L$ and $z_\nu^L = z_e^L$ are required by the SM $SU(2)_W$ gauge symmetry. Given that the $U(1)'$ interaction is not asymptotically free, the theory may be well-behaved at high energies (*e.g.*, by embedding $U(1)'$ in a non-Abelian gauge group) only if the charges are commensurate numbers, *i.e.* any ratio of charges is a rational number. Satisfying the anomaly equations with rational numbers is highly nontrivial, and typically new fermions charged under $U(1)'$ are necessary.

If the couplings are generation-independent ($V_f^{L,R}$ are then unit matrices in Eq. (88.2)) and the mixings of $\tilde{Z}'$ are negligible, then there are five commensurate couplings: $g_u^R$, $g_d^R$, $g_e^R$, $g_q^L$ ($q = u$ or $d$), $g_l^L$ ($l = \nu$ or $e$). Four sets of charges are displayed in Table 88.1, each of them spanned by a free parameter $x$ [6]. The first set, labelled $B - xL$, has charges proportional to the baryon number minus $x$ times the lepton number. These charges allow all SM Yukawa couplings to a Higgs doublet which is neutral under $U(1)_{B-xL}$, so that there is no tree-level $\tilde{Z} - \tilde{Z}'$ mixing. For $x = 1$ one recovers the $U(1)_{B-L}$ group, which is non-anomalous in the presence of one "right-handed neutrino" (a chiral fermion that is a singlet under the SM gauge group) per generation. For $x \neq 1$, it is necessary to include some fermions that are vectorlike (*i.e.* their mass terms are gauge invariant) with respect to the electroweak gauge group and chiral with respect to $U(1)_{B-xL}$. In the particular cases $x = 0$ or $x \gg 1$, the $Z'$ is leptophobic or quark-phobic, respectively.

The second set, $U(1)_{10+x\bar{5}}$, has charges that commute with the representations of the $SU(5)$ grand unified group. Here $x$ is related to the mixing angle between the two $U(1)$ bosons encountered in the $E_6 \to SU(5) \times U(1) \times U(1)$ symmetry breaking patterns of grand unified theories [1, 9]. With these charges, two Higgs doublets are typically required to generate masses for both up- and down- type fermions. This set leads to $\tilde{Z} - \tilde{Z}'$ mass mixing at tree level, such that for a $Z'$ mass close to the electroweak scale, the measurements at the $Z$-pole require some fine tuning between the charges and VEVs of the two Higgs doublets. Vectorlike fermions charged under the electroweak gauge group and also carrying color are required (except for $x = -3$) to make this set anomaly free. The particular cases $x = -3, 1, -1/2$ are usually labelled $U(1)_\chi$, $U(1)_\psi$, and $U(1)_\eta$, respectively. Under the third set, $U(1)_{d-xu}$, the weak-doublet quarks are neutral, and the ratio of $u_R$ and $d_R$ charges is $-x$. For $x = 1$, this is the "right-handed" group $U(1)_R$. For $x = 0$, the charges are those of the $E_6$-inspired $U(1)_I$ group, which requires new quarks and leptons. Other generation-independent sets of $U(1)'$ charges are given in [10].

In the absence of new fermions charged under the SM group, the most general generation-independent charge assignment is $U(1)_{q+xu}$, which is a linear combination of hypercharge and $B-L$. Many other anomaly-free solutions exist if generation-dependent charges are allowed. An example is $B - xL_e - yL_\mu + (y-3)L_\tau$, with $x, y$ free parameters. This allows all fermion masses to be generated by Yukawa couplings to a single Higgs doublet, without inducing tree-level flavor-changing neutral current (FCNC) processes. There are also lepton-flavor dependent charges that allow neutrino masses to arise only from operators of high dimensionality [11].

If the $SU(2)_W$-doublet quarks have generation-dependent $U(1)'$ charges, then the mass eigenstate quarks have flavor off-diagonal couplings to the $Z'$ boson (see Eq. (88.1), and note that $V_u^L \left(V_d^L\right)^\dagger$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

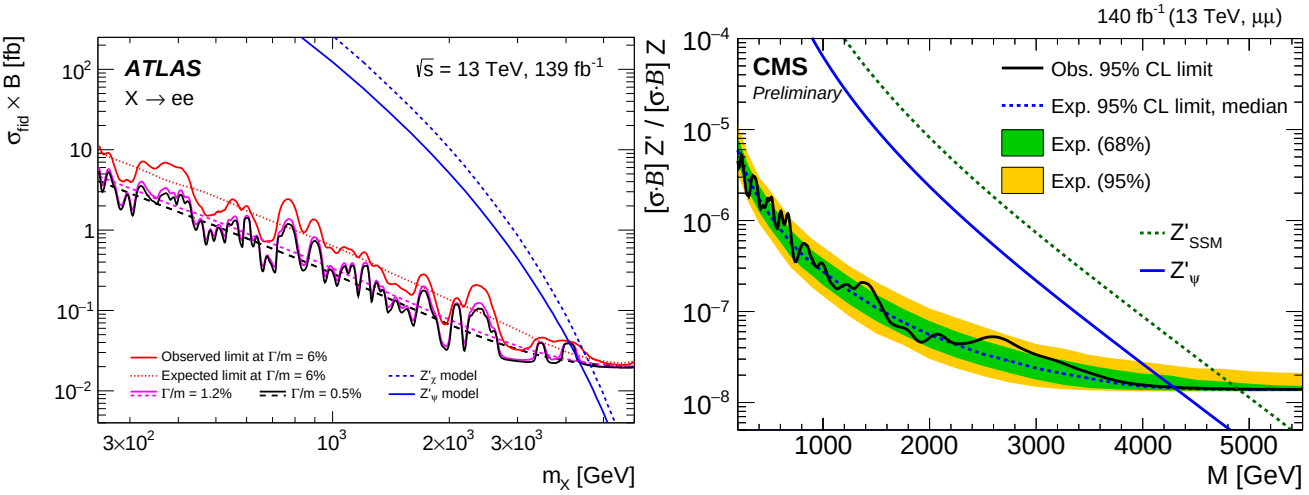

Figure 88.1: Upper limits on the cross section for $Z'$ production times the branching fraction for $Z' \to e^+e^-$ (left panel, set by ATLAS [7]) or $Z' \to \mu^+\mu^-$ (right panel, set by CMS [8]) as a function of $M_{Z'}$. The lines labelled by $Z'_\psi$ and $Z'_\chi$ are theoretical predictions for the $U(1)_{10+x\bar{5}}$ models in Table 88.1 with $x = -3$ and $x = +1$, respectivxoely, for $g_z$ fixed by an $E_6$ unification condition. The $Z'_{\rm SSM}$ line corresponds to $Z'$ couplings equal to those of the $Z$ boson.

**Table 88.1:** Examples of generation-independent $U(1)'$ charges for quarks and leptons. The parameter $x$ is an arbitrary rational number. Gauge anomaly cancellation requires certain new fermions [6].

| fermion | $U(1)_{B-xL}$ | $U(1)_{10+x\bar{5}}$ | $U(1)_{d-xu}$ | $U(1)_{q+xu}$ |
|---|---|---|---|---|
| $(u_L, d_L)$ | $1/3$ | $1/3$ | $0$ | $1/3$ |
| $u_R$ | $1/3$ | $-1/3$ | $-x/3$ | $x/3$ |
| $d_R$ | $1/3$ | $-x/3$ | $1/3$ | $(2-x)/3$ |
| $(\nu_L, e_L)$ | $-x$ | $x/3$ | $(-1+x)/3$ | $-1$ |
| $e_R$ | $-x$ | $-1/3$ | $x/3$ | $-(2+x)/3$ |

is the CKM matrix). These are severely constrained by measurements of FCNC processes, which in this case are mediated at tree-level by $Z'$ boson exchange [12]. The constraints are relaxed if the first and second generation charges are the same, although they are increasingly tightened by the measurements of $B$ meson properties [13]. If only the $SU(2)_W$-singlet quarks have generation-dependent $U(1)'$ charges, there is more freedom in adjusting the flavor off-diagonal couplings because the $V^R_{u,d}$ matrices are not observable in the SM.

The anomaly equations for $U(1)'$ could be circumvented only if there is an axion with certain dimension-5 couplings to the gauge bosons. However, such a scenario violates unitarity unless the quantum field theory description breaks down at a scale near $M_{Z'}$ [14].

$Z'$ bosons may also arise from larger gauge groups. These may extend the electroweak group, as in $SU(2)\times SU(2)\times U(1)$, or may embed the electroweak group, as in $SU(3)_W \times U(1)$ [15]. If the larger group is spontaneously broken down to $SU(2)_W \times U(1)_Y \times U(1)'$ at a scale $v_\star \gg M_{Z'}/g_z$, then the above discussion applies up to corrections of order $M^2_{Z'}/(g_z v_\star)^2$. For $v_\star \sim M_{Z'}/g_z$, additional gauge bosons have masses comparable to $M_{Z'}$, including at least a $W'$ boson [15]. If the larger gauge group breaks together with the electroweak symmetry directly to the electromagnetic $U(1)_{\rm em}$, then the left-handed fermion charges are no longer correlated ($z^L_u \neq z^L_d$, $z^L_\nu \neq z^L_e$) and a $Z'W^+W^-$ coupling is induced.

If the electroweak gauge bosons propagate in extra dimensions, then their Kaluza-Klein (KK) excitations include a series of $Z'$ boson pairs. Each of these pairs can be associated with a different $SU(2)\times U(1)$ gauge group in four dimensions. The properties of the KK particles depend strongly on the extra-dimensional theory [16]. For example, in universal extra dimensions there is a parity that forces all couplings of Eq. (88.1) to vanish in the case of the lightest KK bosons, while allowing couplings to pairs of fermions involving a SM and a heavy vectorlike fermion. There are also 4-dimensional gauge theories (*e.g.* little Higgs with $T$ parity) with $Z'$ bosons exhibiting similar properties. By contrast, in a warped extra dimension, the couplings of Eq. (88.1) may be sizable even when SM fields propagate along the extra dimension.

$Z'$ bosons may also be composite particles. For example, in confining gauge theories [17], the $\rho$-like bound state is a spin-1 boson that may be interpreted as arising from a spontaneously broken gauge symmetry [18].

## 88.3 Non-resonant $Z'$ signatures at colliders

In the presence of the couplings shown in Eq. (88.1), the $Z'$ boson may be produced in the $s$-channel at colliders, and would decay to pairs of fermions. The decay width into a pair of electrons is given by

$$\Gamma\left(Z' \to e^+e^-\right) \simeq \left[\left(g^L_e\right)^2 + \left(g^R_e\right)^2\right] \frac{M_{Z'}}{24\pi}, \qquad (88.6)$$

where small corrections from electroweak loops are not included. The decay width into $q\bar{q}$ is similar, except for an additional color factor of 3, QCD radiative corrections, and fermion mass corrections. Thus, one may compute the $Z'$ branching fractions in terms of the couplings of Eq. (88.1). However, other decay channels, such as $WW$ or a pair of new particles, could have large widths and need to be added to the total decay width.

As mentioned above, there are theories in which the $Z'$ couplings are controlled by a discrete symmetry that forbids decays into a pair of SM particles. Typically, such theories involve several new particles, which may be produced only in pairs and undergo cascade decays through $Z'$ bosons, leading to signals involving missing (transverse) momentum. Given that the cascade decays depend on the properties of new particles other than the $Z'$ boson, this case is not discussed further here.

The $Z'$ contribution to the cross sections for $e^+e^- \to f\bar{f}$ proceeds through an $s$-channel $Z'$ exchange (when $f = e$, there are also $t$- and $u$-channel exchanges). For $M_{Z'} < \sqrt{s}$, the $Z'$ appears as an $f\bar{f}$ resonance in the radiative return process where photon emission tunes the effective center-of-mass energy to $M_{Z'}$. The agreement between the LEP-II measurements and the SM predictions implies that either the $Z'$ couplings are smaller than or of order $10^{-2}$, or else $M_{Z'}$ is above 209 GeV, the maximum energy of LEP-II. In the latter case, the $Z'$ exchange may be approximated

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

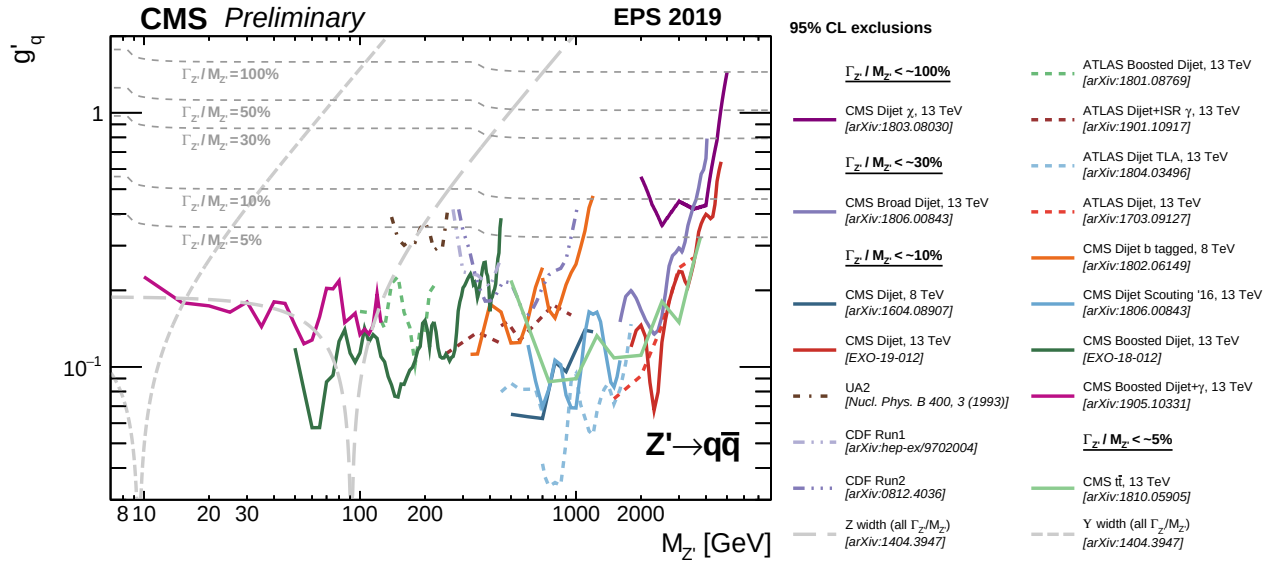

Figure 88.2: Upper limits on the $Z'$ coupling to quarks as a function of $M_{Z'}$ based on various searches performed by the ATLAS, CMS, CDF, and UA2 experiments [19].

up to corrections of order $s/M_{Z'}^2$, by the contact interactions

$$\frac{g_z^2}{M_{Z'}^2 - s}\left[\bar{e}\gamma_\mu\left(z_e^L P_L + z_e^R P_R\right)e\right]\left[\bar{f}\gamma^\mu\left(z_f^L P_L + z_f^R P_R\right)f\right], \tag{88.7}$$

where $P_{L,R}$ are chirality projection operators, and the relation between $Z'$ couplings and charges (see Eq. (88.2) in the limit where the mass and kinetic mixings are neglected) is used, assuming generation-independent charges. The four LEP collaborations have set limits on the coefficients of such operators for all possible chiral structures and for various combinations of fermions [20]. Thus, one may derive bounds on $(M_{Z'}/g_z)|z_e^L z_f^L|^{-1/2}$ and the analogous combinations of $LR$, $RL$ and $RR$ charges, which are typically on the order of a few TeV. LEP-II limits were derived [6] on the four sets of charges shown in Table 88.1.

Somewhat stronger bounds can be set on $M_{Z'}/g_z$ for specific sets of $Z'$ couplings if the effects of several operators (88.7) are combined. Dedicated analyses by the LEP collaborations have set limits on $Z'$ bosons for particular values of the gauge coupling (see section 3.5 of Ref. [20]). For example, $M_{Z_{\rm SSM}} > 1.76$ TeV for a "sequential" $Z'$ of same couplings as the SM $Z$ boson, while $M_{Z_\chi} > 0.785$ TeV for the $Z'$ associated with $U(1)_\chi$ assuming a unification condition for the gauge coupling.

## 88.4 Searches at hadron colliders

$Z'$ bosons with couplings to quarks (see Eq. (88.1)) may be produced at hadron colliders in the $s$-channel and would show up as resonances in the invariant mass distribution of the decay products. The cross section for producing a $Z'$ boson at the LHC, which then decays to some $f\bar{f}$ final state, takes the form [21]

$$\sigma\left(pp \to Z'X \to f\bar{f}X\right) \simeq \frac{\pi}{6\,s}\sum_q c_q^f\, w_q\left(s, M_{Z'}^2\right) \tag{88.8}$$

for flavor-diagonal couplings to quarks. Here, we have neglected the interference with the SM contribution to $f\bar{f}$ production, which is a good approximation for a narrow $Z'$ resonance (deviations from the narrow width approximation are discussed in Ref. [22]). The coefficients

$$c_q^f = \left[\left(g_q^L\right)^2 + \left(g_q^R\right)^2\right] B(Z' \to f\bar{f}) \tag{88.9}$$

contain all the dependence on the $Z'$ couplings, while the functions $w_q$ include all the information about parton distributions and QCD corrections [6, 10]. This factorization holds exactly to NLO and the deviations from it induced at NNLO are very small. Note that the $w_u$ and $w_d$ functions are substantially larger than the $w_q$ functions for the other quarks. Eq. (88.8) also applies to the Tevatron, except for changing the $pp$ initial state to $p\bar{p}$, which implies that the $w_q(s, M_{Z'}^2)$ functions are replaced by some other functions $\bar{w}_q((1.96\,\text{TeV})^2, M_{Z'}^2)$.

It is common to present results of $Z'$ searches as limits on the cross section versus $M_{Z'}$ (see for example Fig. 88.1).

An alternative is to plot exclusion curves for fixed $M_{Z'}$ values in the $c_u^f - c_d^f$ planes, allowing a simple derivation of the mass limit within any $Z'$ model. CMS upper limits in the $c_u^\ell - c_d^\ell$ plane ($\ell = e$ or $\mu$) for different $M_{Z'}$ are shown in Ref. [23] (for Tevatron limits, see Refs. [10, 24]).

The discovery of a dilepton resonance at the LHC would determine the $Z'$ mass and width. A measurement of the total cross section would define a band in the $c_u^\ell - c_d^\ell$ plane. Angular distributions can be used to measure several combinations of $Z'$ parameters (angular distributions were used in Ref. [25] to improve the Tevatron sensitivity). Even though the original quark direction in a $pp$ collider is unknown, the leptonic forward-backward asymmetry $A_{\rm FB}^\ell$ can be extracted from the kinematics of the dilepton system, and is sensitive to parity-violating couplings. A fit to the $Z'$ rapidity distribution can distinguish between the couplings to up and down quarks. These measurements, combined with off-peak observables, have the potential to differentiate among various $Z'$ models [26]. In some cases, $A_{\rm FB}^\ell$ may provide discovery sensitivity that is competitive with the mass distribution [27]. The spin of the $Z'$ boson may be determined from angular distributions [28].

Searches for $Z'$ decays into $e^+e^-$ and $\mu^+\mu^-$ by the ATLAS and CMS collaborations [7, 8] have set 95% C.L. upper cross-section limits as low as 0.02 fb (see Fig. 88.1), with the mass lower limits in specific models as high as 4.9 TeV in a single channel. Cross section limits in the dimuon channel for low mass regions, below 200 GeV but not near the $Z$ mass, have been set at the LHC by CMS [29] and LHCb [30] (and also in $e^+e^-$ collisions by BaBar [31], assuming a dark photon, *i.e.*, a $Z'$ boson whose couplings arise only from the kinetic mixing with the hypercharge gauge boson).

In the case of final states with tau-leptons, the mass lower limits obtained at 13 TeV are as high as $\sim 2.4$ TeV for the $\tau^+\tau^-$ [32] decay in the case of a sequential $Z'$. Limits in the flavor-violating leptonic final states have also been reported by ATLAS [33] and CMS [34] at 13 TeV, for resonances in the $e^\pm\mu^\mp$, $e^\pm\tau^\mp$ and $\mu^\pm\tau^\mp$ channels.

Final states with higher background, $t\bar{t}$, $b\bar{b}$ and $jj$, are also important as they probe various combinations of $Z'$ couplings to

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

quarks, see Ref. [35] for further discussion. Besides the improved sensitivity at masses of several TeV, the LHC searches in the dijet channel have been also extended to masses as low as 10 GeV, through the use of new techniques involving boosted topologies and initial state radiation [36]. Limits from such $Z'$ searches in hadronic final states are summarized in Fig. 88.2.

$Z'$ decays to $Zh^0$ with $Z \to \ell^+\ell^-$, $\nu\bar{\nu}$ or $q\bar{q}$ and $h^0 \to b\bar{b}$ have been studied by ATLAS [37, 38] and CMS [39, 40] using 13 TeV data. The most stringent constraint is set in the fully hadronic channel, with a mass lower limit of 2.65 TeV in the context of the Heavy Vector Triplet (HVT) model weakly-coupled scenario A [41].

Searches for a $Z'$ boson lighter than the SM $Z$ and which couples to leptons have been performed in the 4-lepton final state. CMS [42] focused on the $Z$ decays into a muon pair followed by the radiation of a $Z'$ boson which decays itself into a muon pair. ATLAS [43] considered the $h^0 \to ZZ'$ and $h^0 \to Z'Z'$ processes followed by the leptonic decays of both $Z$ and $Z'$.

The $pp \to Z'X \to W^+W^-X$ process has also been searched for at the LHC. The channel where the $Z'$ boson is produced through its couplings to quarks, and the $W$ bosons decay hadronically, has been explored using boosted techniques to analyze the 13 TeV data [44,45] with a mass lower limit of 2.9 TeV in the HVT model A. The $Z'$ boson may also be produced through its couplings to $W$ bosons [46], which has been explored by ATLAS with the use of forward jets consistent with a vector boson fusion event topology.

At the Tevatron, the CDF and DØ collaborations have searched for $Z'$ bosons in the $e^+e^-$ [47], $\mu^+\mu^-$ [48], $e^\pm\mu^\mp$ [49], $\tau^+\tau^-$ [50], $t\bar{t}$ [51], $jj$ [52] and $W^+W^-$ [53] final states. These limits have been mostly superseded by the LHC results.

## 88.5 Low-energy constraints

$Z'$ boson properties are also constrained by a variety of low-energy experiments [54]. Polarized electron-nucleon scattering and atomic parity violation are sensitive to electron-quark contact interactions, which get contributions from $Z'$ exchange that can be expressed in terms of the couplings introduced in Eq. (88.1) and $M'_Z$. Further corrections to the electron-quark contact interactions are induced in the presence of $\tilde{Z}-\tilde{Z}'$ mixing because of the shifts in the $Z$ couplings to quarks and leptons [3]. Deep-inelastic neutrino-nucleon scattering is similarly affected by $Z'$ bosons. Other low-energy observables are discussed in [4]. Viable models with $Z'$ bosons much lighter than the $Z$ boson have been constructed, despite many additional experimental constraints [55].

In some models, the lower limits on $M_{Z'}$ set by low-energy data are above 1 TeV. For example, $M_{Z_\chi} > 1.1$ TeV and $M_{Z_\eta} > 0.43$ TeV assuming that the Higgs sectors consist of electroweak doublets and singlets only [4], while the gauge coupling is fixed by an $SO(10)$ unification condition for $U(1)_\chi$ and $U(1)_\eta$. For more general models, see [1, 6, 56]. The mass bounds from direct searches at the LHC [7, 8] exceed the electroweak constraints by a factor of three or more for the models mentioned here. This conclusion could change if the collider bounds are weakened by exotic decay channels [57].

Although the LHC data are most constraining for many $Z'$ models, one should be careful in assessing the relative reach of various experiments given the freedom in $Z'$ couplings. For example, a $Z'$ coupled to $B-yL_\mu+(y-3)L_\tau$ has implications for the muon $g-2$, neutrino oscillations or $\tau$ decays, and would be hard to see in processes involving first-generation fermions. Moreover, the combination of LHC searches and low-energy measurements could allow a precise determination of the $Z'$ parameters [58].

## 89.1 Introduction

Supersymmetry (SUSY) is a generalization of the space-time symmetries of quantum field theory that transforms fermions into bosons and vice versa [1]. The existence of such a non-trivial extension of the Poincaré symmetry of ordinary quantum field theory was initially surprising, and its form is highly constrained by theoretical principles [2]. SUSY also provides a framework for the unification of particle physics and gravity [3–6] at the Planck energy scale, $M_{\rm P} \sim 10^{19}$ GeV, where the gravitational interactions become comparable in strength to the gauge interactions. Moreover, supersymmetry can stabilize the hierarchy between the energy scale that characterizes electroweak symmetry breaking, $M_{\rm EW} \sim 100$ GeV, and the Planck scale [7–10] against large radiative corrections. The stability of this large gauge hierarchy with respect to radiative quantum corrections is not possible to maintain in the Standard Model (SM) without an unnatural fine-tuning of the parameters of the fundamental theory at the Planck scale. In contrast, in a supersymmetric extension of the SM, it is possible to maintain the gauge hierarchy while providing a natural framework for elementary scalar fields.

If supersymmetry were an exact symmetry of nature, then particles and their superpartners, which differ in spin by half a unit, would be degenerate in mass. Since superpartners have not (yet) been observed, supersymmetry must be a broken symmetry. Nevertheless, the stability of the gauge hierarchy can still be maintained if the SUSY breaking is soft [11, 12], and the corresponding SUSY-breaking mass parameters are no larger than a few TeV. Whether this is still plausible in light of recent SUSY searches at the LHC (see Sec. 90) will be discussed in Sec. 89.7.

In particular, soft-SUSY-breaking terms of the Lagrangian involve combinations of fields with total mass dimension of three or less, with some restrictions on the dimension-three terms as elucidated in Ref. [11]. The impact of the soft terms becomes negligible at energy scales much larger than the size of the SUSY-breaking masses. Thus, a theory of weak-scale supersymmetry, where the effective scale of supersymmetry breaking is tied to the scale of electroweak symmetry breaking, provides a natural framework for the origin and the stability of the gauge hierarchy [7–10].

At present, there is no unambiguous experimental evidence for the breakdown of the SM at or below the TeV scale. The expectations for new TeV-scale physics beyond the SM are based primarily on three theoretical arguments. First, in a theory with an elementary scalar field of mass $m$ and interaction strength $\lambda$ (e.g., a quartic scalar self-coupling, the square of a gauge coupling or the square of a Yukawa coupling), the stability with respect to quantum corrections requires the existence of an energy cutoff roughly of order $(16\pi^2/\lambda)^{1/2}m$, beyond which new physics must enter [13]. A significantly larger energy cutoff would require an unnatural fine-tuning of parameters that govern the effective low-energy theory. Applying this argument to the SM leads to an expectation of new physics at the TeV scale [10].

Second, the unification of the three SM gauge couplings at a very high energy close to the Planck scale is possible if new physics beyond the SM (which modifies the running of the gauge couplings above the electroweak scale) is present. The minimal supersymmetric extension of the SM, where superpartner masses lie below a few TeV, provides an example of successful gauge coupling unification [14].

Third, the existence of dark matter that makes up approximately one quarter of the energy density of the universe, cannot be explained within the SM of particle physics [15]. Remarkably, a stable weakly-interacting massive particle (WIMP) whose mass and interaction rate are governed by new physics associated with the TeV-scale can be consistent with the observed density of dark matter (this is the so-called WIMP miracle, which is reviewed in Ref. [16]). The lightest supersymmetric particle, if stable, is a promising (although not the unique) candidate for the dark matter [17–21]. Further aspects of dark matter can be found in Sec. 27.

## 89.2 Structure of the MSSM

The minimal supersymmetric extension of the SM (MSSM) consists of the fields of the two-Higgs-doublet extension of the SM and the corresponding superpartners [22, 23]. A particle and its superpartner together form a supermultiplet. The corresponding field content of the supermultiplets of the MSSM and their gauge quantum numbers are shown in Table 89.1. The electric charge $Q = T_3 + \frac{1}{2}Y$ is determined in terms of the third component of the weak isospin ($T_3$) and the U(1) weak hypercharge ($Y$).

The gauge supermultiplets consist of the gluons and their gluino fermionic superpartners and the SU(2)×U(1) gauge bosons and their gaugino fermionic superpartners. The matter supermultiplets consist of three generations of left-handed quarks and leptons and their scalar superpartners (squarks and sleptons, collectively referred to as sfermions), and the corresponding antiparticles. The Higgs supermultiplets consist of two complex Higgs doublets, their higgsino fermionic superpartners, and the corresponding antiparticles. The enlarged Higgs sector of the MSSM constitutes the minimal structure needed to guarantee the cancellation of gauge anomalies [25] generated by the higgsino superpartners that can appear as internal lines in triangle diagrams with three external electroweak gauge bosons. Moreover, without a second Higgs doublet, one cannot generate mass for both "up"-type and "down"-type quarks (and charged leptons) in a way consistent with the underlying SUSY [26–28].

In the most elegant treatment of SUSY, spacetime is extended to superspace which consists of the spacetime coordinates and new anticommuting fermionic coordinates $\theta$ and $\theta^\dagger$ [29, 30]. Each supermultiplet is represented by a superfield that is a function of the superspace coordinates. The fields of a given supermultiplet (which are functions of the spacetime coordinates) are coefficients of the $\theta$ and $\theta^\dagger$ expansion of the corresponding superfield.

Vector superfields contain the gauge boson fields and their gaugino partners. Chiral superfields contain the spin-0 and spin-1/2

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

**Table 89.1:** The fields of the MSSM and their SU(3)×SU(2)×U(1) quantum numbers are listed. For simplicity, only one generation of quarks and leptons is exhibited. For each lepton, quark, and Higgs supermultiplet (each denoted by a hatted upper-case letter), there is a corresponding antiparticle multiplet of charge-conjugated fermions and their associated scalar partners [24].

| Field Content of the MSSM | | | | | | |
|---|---|---|---|---|---|---|
| Super-multiplets | Super-field | Bosonic fields | Fermionic partners | SU(3) | SU(2) | U(1) |
| gluon/gluino | $\hat{V}_8$ | $g$ | $\widetilde{g}$ | 8 | 1 | 0 |
| gauge boson/ | $\hat{V}$ | $W^{\pm}$, $W^0$ | $\widetilde{W}^{\pm}$, $\widetilde{W}^0$ | 1 | 3 | 0 |
| gaugino | $\hat{V}'$ | $B$ | $\widetilde{B}$ | 1 | 1 | 0 |
| slepton/ | $\hat{L}$ | $(\widetilde{\nu}_L, \widetilde{e}^-_L)$ | $(\nu, e^-)_L$ | 1 | 2 | $-1$ |
| lepton | $\hat{E}^c$ | $\widetilde{e}^+_R$ | $e^c_L$ | 1 | 1 | 2 |
| squark/ | $\hat{Q}$ | $(\widetilde{u}_L, \widetilde{d}_L)$ | $(u, d)_L$ | 3 | 2 | 1/3 |
| quark | $\hat{U}^c$ | $\widetilde{u}^*_R$ | $u^c_L$ | $\bar{3}$ | 1 | $-4/3$ |
| | $\hat{D}^c$ | $\widetilde{d}^*_R$ | $d^c_L$ | $\bar{3}$ | 1 | 2/3 |
| Higgs/ | $\hat{H}_d$ | $(H^0_d, H^-_d)$ | $(\widetilde{H}^0_d, \widetilde{H}^-_d)$ | 1 | 2 | $-1$ |
| higgsino | $\hat{H}_u$ | $(H^+_u, H^0_u)$ | $(\widetilde{H}^+_u, \widetilde{H}^0_u)$ | 1 | 2 | 1 |

fields of the matter or Higgs supermultiplets. A general supersymmetric Lagrangian is determined by three functions of the chiral superfields [4]: the superpotential, the Kähler potential, and the gauge kinetic function (which can be appropriately generalized to accommodate higher derivative terms [31]). Minimal forms for the Kähler potential and gauge kinetic function, which generate canonical kinetic energy terms for all the fields, are required for renormalizable globally supersymmetric theories. A renormalizable superpotential, which is at most cubic in the chiral superfields, yields supersymmetric Yukawa couplings and mass terms. A combination of gauge invariance and SUSY produces couplings of gaugino fields to matter (or Higgs) fields and their corresponding superpartners. The (renormalizable) MSSM Lagrangian is then constructed by including all possible supersymmetric interaction terms (of dimension four or less) that satisfy SU(3)×SU(2)×U(1) gauge invariance and $B$–$L$ conservation (where $B$ = baryon number and $L$ = lepton number). Finally, the most general soft-supersymmetry-breaking terms consistent with these symmetries are added [11, 12, 32].

Although the MSSM is the focus of much of this review, there is some motivation for considering non-minimal supersymmetric extensions of the SM. For example, extra structure is needed to generate non-zero neutrino masses as discussed in Sec. 89.8. In addition, in order to address some theoretical issues and tensions associated with the MSSM, it has been fruitful to introduce one additional singlet Higgs superfield. The resulting next-to-minimal supersymmetric extension of the Standard Model (NMSSM) [33] is considered further in Sec. 89.4–89.7 and 89.9. Finally, one is always free to add additional fields to the SM along with the corresponding superpartners. However, only certain choices for the new fields (*e.g.*, the addition of complete SU(5) multiplets) will preserve the successful gauge coupling unification of the MSSM. Some examples will be briefly mentioned in Sec. 89.9.

### 89.2.1 *R-parity and the lightest supersymmetric particle*

The (renormalizable) SM Lagrangian possesses an accidental global $B$–$L$ symmetry due to the fact that $B$ and $L$-violating operators composed of SM fields must have dimension $d = 5$ or larger [34]. Consequently, $B$ and $L$-violating effects are suppressed by $(M_{\rm EW}/M)^{d-4}$, where $M$ is the characteristic mass scale of the physics that generates the corresponding higher dimensional operators. Indeed, values of $M$ of order the grand unification scale or larger yield the observed (approximate) stability of the proton and suppression of neutrino masses. Unfortunately, these results are not guaranteed in a generic supersymmetric extension of the SM. For example, it is possible to construct gauge invariant supersymmetric dimension-four $B$ and $L$-violating operators made up of fields of SM particles and their superpartners. Such operators, if present in the theory, could yield a proton decay rate many orders of magnitude larger than the current experimental bound. It is for this reason that $B$–$L$ conservation is *imposed* on the supersymmetric Lagrangian when defining the MSSM, which is sufficient for eliminating all $B$ and $L$-violating operators of dimension $d \leq 4$.

As a consequence of the $B$–$L$ symmetry, the MSSM possesses a multiplicative R-parity invariance, where $R = (-1)^{3(B-L)+2S}$ for a particle of spin $S$ [35]. This implies that all the particles of the SM have even R-parity, whereas the corresponding superpartners have odd R-parity. The conservation of R-parity in scattering and decay processes has a critical impact on supersymmetric phenomenology. For example, any initial state in a scattering experiment will involve ordinary (R-even) particles. Consequently, it follows that supersymmetric particles must be produced in pairs. In general, these particles are highly unstable and decay into lighter states. Moreover, R-parity invariance also implies that the lightest supersymmetric particle (LSP) is absolutely stable, and must eventually be produced at the end of a decay chain initiated by the decay of a heavy unstable supersymmetric particle.

In order to be consistent with cosmological constraints, a stable LSP is almost certainly electrically and color neutral [19]. Consequently, the LSP in an R-parity-conserving theory is weakly interacting with ordinary matter, *i.e.*, it behaves like a stable heavy neutrino and will escape collider detectors without being directly observed. Thus, the canonical signature for conventional R-parity-conserving supersymmetric theories is missing (transverse) momentum, due to the escape of the LSP. Moreover, as noted in Sec. 89.1 and reviewed in Refs. [20] and [21], the stability of the LSP in R-parity-conserving SUSY makes it a promising candidate for dark matter.

The possibility of relaxing the R-parity invariance of the MSSM (which would generate new $B$ and/or $L$-violating interactions) will be addressed in Sec. 89.8.2.

### 89.2.2 *The goldstino and gravitino*

In the MSSM, SUSY breaking is accomplished by including the most general renormalizable soft-SUSY-breaking terms consistent with the SU(3)×SU(2)×U(1) gauge symmetry and R-parity invariance. These terms parameterize our ignorance of the fundamental mechanism of supersymmetry breaking. If supersymmetry breaking occurs spontaneously, then a massless Goldstone fermion called the goldstino ($\widetilde{G}_{1/2}$) must exist. The goldstino would then be the LSP, and could play an important role in supersymmetric phenomenology [36].

However, the goldstino degrees of freedom are physical only in models of spontaneously-broken global SUSY. If SUSY is a local symmetry, then the theory must incorporate gravity; the resulting theory is called supergravity [5, 37]. In models of spontaneously-broken supergravity, the goldstino is "absorbed" by the gravitino ($\widetilde{G}$), the spin-3/2 superpartner of the graviton, via the super-Higgs mechanism [38]. Consequently, the goldstino is removed from the physical spectrum and the gravitino acquires a mass (denoted by $m_{3/2}$). If $m_{3/2}$ is smaller than the mass of the lightest superpartner of the SM particles, then the gravitino is the LSP.

In processes with center-of-mass energy $E \gg m_{3/2}$, one can

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

employ the goldstino–gravitino equivalence theorem [39], which implies that the interactions of the helicity $\pm\frac{1}{2}$ gravitino (whose properties approximate those of the goldstino) dominate those of the helicity $\pm\frac{3}{2}$ gravitino. The interactions of gravitinos with other light fields can be described by a low-energy effective Lagrangian that is determined by fundamental principles [40].

### 89.2.3 *Hidden sectors and the structure of SUSY breaking*

It is very difficult (perhaps impossible) to construct a realistic model of spontaneously-broken weak-scale supersymmetry where the supersymmetry breaking arises solely as a consequence of the interactions of the particles of the MSSM. A more successful scheme posits a theory with at least two distinct sectors: a visible sector consisting of the particles of the MSSM [32] and a sector where SUSY breaking is generated. It is often (but not always) assumed that particles of the hidden sector are neutral with respect to the SM gauge group. The effects of the hidden sector supersymmetry breaking are then transmitted to the MSSM by some mechanism (often involving the mediation by particles that comprise an additional messenger sector). Two theoretical scenarios that exhibit this structure are gravity-mediated and gauge-mediated SUSY breaking.

Supergravity models provide a natural mechanism for transmitting the SUSY breaking of the hidden sector to the particle spectrum of the MSSM. In models of gravity-mediated supersymmetry breaking, gravity is the messenger of supersymmetry breaking [41–45]. More precisely, supersymmetry breaking is mediated by effects of gravitational strength (suppressed by inverse powers of the Planck mass). The soft-SUSY-breaking parameters with dimensions of mass arise as model-dependent multiples of the gravitino mass $m_{3/2}$. In this scenario, $m_{3/2}$ is of order the electroweak-symmetry-breaking scale, while the gravitino couplings are roughly gravitational in strength [3, 46]. However, such a gravitino typically plays no direct role in supersymmetric phenomenology at colliders (except perhaps indirectly in the case where the gravitino is the LSP [47]).

Under certain theoretical assumptions on the structure of the Kähler potential (the so-called sequestered form introduced in Ref. [48]), SUSY breaking is due entirely to the super-conformal (super-Weyl) anomaly, which is common to all supergravity models [48]. In particular, gaugino masses are radiatively generated at one-loop, and squark and slepton squared-mass matrices are flavor-diagonal. In sequestered scenarios, sfermion squared-masses arise at two-loops, which implies that gluino and sfermion masses are of the same order of magnitude. This approach is called anomaly-mediated SUSY breaking (AMSB). Indeed, anomaly mediation is more generic than originally conceived, and provides a ubiquitous source of SUSY breaking [49]. However in the simplest formulation of AMSB as applied to the MSSM, the squared-masses of the sleptons are negative (known as the tachyonic slepton problem). It may be possible to cure this otherwise fatal flaw in non-minimal extensions of the MSSM [50]. Alternatively, one can assert that anomaly mediation is not the sole source of SUSY breaking in the sfermion sector. In non-sequestered scenarios, sfermion squared-masses can arise at tree-level, in which case squark masses would be parametrically larger than the loop-suppressed gaugino masses [51].

In gauge-mediated supersymmetry breaking (GMSB), gauge forces transmit the supersymmetry breaking to the MSSM. A typical structure of such models involves a hidden sector where SUSY is broken, a messenger sector consisting of particles (messengers) with nontrivial SU(3)×SU(2)×U(1) quantum numbers, and the visible sector consisting of the fields of the MSSM [52–55]. The direct coupling of the messengers to the hidden sector generates a supersymmetry-breaking spectrum in the messenger sector. Supersymmetry breaking is then transmitted to the MSSM via the virtual exchange of the messenger fields. In models of direct gauge mediation, there is no separate hidden sector. In particular, the sector in which the SUSY breaking originates includes fields that carry nontrivial SM quantum numbers, which allows for the direct transmission of SUSY breaking to the MSSM [56].

In models of gauge-mediated SUSY breaking, the gravitino is the LSP [17], as its mass can range from a few eV (in the case of low SUSY breaking scales) up to a few GeV (in the case of high SUSY breaking scales). In particular, the gravitino is a potential dark matter candidate (for a review and guide to the literature, see Ref. [21]). Big bang nucleosynthesis (see Section 24) also provides some interesting constraints on the gravitino and the properties of the next-to-lightest supersymmetric particle that decays into the gravitino LSP [57]. The couplings of the helicity $\pm\frac{1}{2}$ components of $\widetilde{G}$ to the particles of the MSSM (which approximate those of the goldstino as previously noted in Sec. 89.2.2) are significantly stronger than gravitational strength and amenable to experimental collider analyses.

The concept of a hidden sector is more general than SUSY. Hidden valley models [58] posit the existence of a hidden sector of new particles and interactions that are very weakly coupled to particles of the SM. The impact of a hidden valley on supersymmetric phenomenology at colliders can be significant if the LSP lies in the hidden sector [59].

### 89.2.4 *SUSY and extra dimensions*

Approaches to SUSY breaking have also been developed in the context of theories in which the number of spatial dimensions is greater than three. In particular, a number of SUSY-breaking mechanisms have been proposed that are inherently extra-dimensional [60]. The size of the extra dimensions can be significantly larger than $M_{\rm P}^{-1}$; in some cases of order $(\text{TeV})^{-1}$ or even larger (see, *e.g.*, Sec. 86 or Ref. [61]).

For example, in one approach the fields of the MSSM live on some brane (a lower-dimensional manifold embedded in a higher-dimensional spacetime), while the sector of the theory that breaks SUSY lives on a second spatially-separated brane. Two examples of this approach are AMSB [48] and gaugino-mediated SUSY breaking [62]. In both cases, SUSY breaking is transmitted through fields that live in the bulk (the higher-dimensional space between the two branes). This setup has some features in common with both gravity-mediated and gauge-mediated SUSY breaking (*e.g.*, a hidden and visible sector and messengers).

Since a higher dimensional theory must be compactified to four spacetime dimensions, one can also generate a source of SUSY breaking by employing boundary conditions on the compactified space that distinguish between fermions and bosons. This is the so-called Scherk-Schwarz mechanism [63]. The phenomenology of such models can be strikingly different from that of the usual MSSM [64].

### 89.2.5 *Split-SUSY*

If SUSY is not connected with the origin of the electroweak scale, it may still be possible that some remnant of the superparticle spectrum survives down to the TeV-scale or below. This is the idea of split-SUSY [65, 66], in which scalar superpartners of the quarks and leptons are significantly heavier (perhaps by many orders of magnitude) than 1 TeV, whereas the fermionic superpartners of the gauge and Higgs bosons have masses on the order of 1 TeV or below. With the exception of a single light neutral scalar whose properties are practically indistinguishable from those of the SM Higgs boson, all other Higgs bosons are also assumed to be very heavy. Among the supersymmetric particles, only the fermionic superpartners may be kinematically accessible at the LHC.

In models of split SUSY, the top squark masses cannot be arbitrarily large, as these parameters enter in the radiative corrections to the mass of the observed Higgs boson [67, 68]. In the MSSM, a Higgs boson mass of 125 GeV (see Sec. 11) implies an upper bound on the top squark mass scale in the range of 10 to $10^8$ TeV [69–71], depending on the value of the ratio of the two neutral Higgs field vacuum expectation values, although this mass range can be somewhat extended by varying other relevant MSSM parameters. In some approaches, gaugino masses are one-loop suppressed relative to the sfermion masses, corresponding to the so-called mini-split SUSY spectrum [68, 72]. The higgsino mass scale may or may not be likewise suppressed depending on the details of the model [73].

The SUSY breaking required to produce such a split-SUSY spectrum would destabilize the gauge hierarchy, and thus would not provide an explanation for the scale of electroweak symmetry breaking. Nevertheless, models of split-SUSY can account for the dark matter (which is assumed to be the LSP gaugino or higgsino)

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

and gauge coupling unification, thereby preserving two of the desirable features of weak-scale SUSY. Finally, as a consequence of the very large squark and slepton masses, neutral flavor changing and CP-violating effects, which can be problematic in models with TeV-scale SUSY-breaking masses, are sufficiently reduced to avoid conflict with experimental observations.

## 89.3 Parameters of the MSSM

The parameters of the MSSM are conveniently described by considering separately the supersymmetry-conserving and the supersymmetry-breaking sectors. A careful discussion of the conventions used here in defining the tree-level MSSM parameters can be found in Refs. [74,75]. For simplicity, consider first the case of one generation of quarks, leptons, and their scalar superpartners.

### 89.3.1 *The SUSY-conserving parameters*

The parameters of the supersymmetry-conserving sector consist of: (i) gauge couplings, $g_s$, $g$, and $g'$, corresponding to the SM gauge group SU(3)×SU(2)×U(1) respectively; (ii) a supersymmetry-conserving higgsino mass parameter $\mu$; and (iii) Higgs-fermion Yukawa couplings, $\lambda_u$, $\lambda_d$, and $\lambda_e$, of one generation of left- and right-handed quarks and leptons, and their superpartners to the Higgs bosons and higgsinos. Because there is no right-handed neutrino/sneutrino in the MSSM as defined here, a Yukawa coupling $\lambda_\nu$ is not included. The complex $\mu$ parameter and Yukawa couplings enter via the most general renormalizable R-parity-conserving superpotential,

$$W = \lambda_d \hat{H}_d \hat{Q} \hat{D}^c - \lambda_u \hat{H}_u \hat{Q} \hat{U}^c + \lambda_e \hat{H}_d \hat{L} \hat{E}^c + \mu \hat{H}_u \hat{H}_d \,, \quad (89.1)$$

where the superfields are defined in Table 1 and the gauge group indices are suppressed.

### 89.3.2 *The SUSY-breaking parameters*

The supersymmetry-breaking sector contains the following sets of parameters: (i) three complex gaugino Majorana mass parameters, $M_3$, $M_2$, and $M_1$, associated with the SU(3), SU(2), and U(1) subgroups of the SM; (ii) five sfermion squared-mass parameters, $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$, and $M^2_{\widetilde{E}}$, corresponding to the five electroweak gauge multiplets, *i.e.*, superpartners of the left-handed fields $(u,d)_L$, $u^c_L$, $d^c_L$, $(\nu,\, e^-)_L$, and $e^c_L$, where the superscript $c$ indicates a charge-conjugated fermion field [24]; and (iii) three Higgs-squark-squark and Higgs-slepton-slepton trilinear interaction terms, with complex coefficients $T_U \equiv \lambda_u A_U$, $T_D \equiv \lambda_d A_D$, and $T_E \equiv \lambda_e A_E$ (which define the "$A$-parameters"). The notation $T_U$, $T_D$ and $T_E$ is employed in Ref. [75]. It is conventional to separate out the factors of the Yukawa couplings in defining the $A$-parameters (originally motivated by a simple class of gravity-mediated SUSY-breaking models [3,6]). If the $A$-parameters are parametrically of the same order (or smaller) relative to other SUSY-breaking mass parameters, then only the third generation $A$-parameters are phenomenologically relevant.

Finally, we have (iv) two real squared-mass parameters, $m_1^2$ and $m_2^2$ (also called $m^2_{H_d}$ and $m^2_{H_u}$, respectively, in the literature), and one complex squared-mass parameter, $m_{12}^2 \equiv \mu B$ (the latter defines the "$B$-parameter"), which appear in the MSSM tree-level scalar Higgs potential [28],

$$V = (m_1^2 + |\mu|^2) H_d^\dagger H_d + (m_2^2 + |\mu|^2) H_u^\dagger H_u + (m_{12}^2 H_u H_d + \text{h.c.}) + \frac{1}{8}(g^2 + g'^2)(H_d^\dagger H_d - H_u^\dagger H_u)^2 + \frac{1}{2} g^2 |H_d^\dagger H_u|^2 \,, \quad (89.2)$$

where the SU(2)-invariant combination, $H_u H_d \equiv H_u^+ H_d^- - H_u^0 H_d^0$. Note that the quartic Higgs couplings are related to the gauge couplings $g$ and $g'$ as a consequence of SUSY. The breaking of the SU(2)×U(1) electroweak symmetry group to $\mathrm{U(1)_{EM}}$ is only possible after incorporating the SUSY-breaking Higgs squared-mass parameters $m_1^2$, $m_2^2$ (which can be negative) and $m_{12}^2$. After minimizing the Higgs scalar potential, these three squared-mass parameters can be re-expressed in terms of the two Higgs vacuum expectation values, $\langle H_d^0 \rangle \equiv v_d/\sqrt{2}$ and $\langle H_u^0 \rangle \equiv v_u/\sqrt{2}$, and the CP-odd Higgs mass $m_A$ [cf. Eqs. (89.4) and (89.5) below]. One is always free to re-phase the Higgs doublet fields such that $v_d$ and $v_u$ (also called $v_1$ and $v_2$, respectively, in the literature) are both real and positive.

The quantity, $v_d^2 + v_u^2 = 4m_W^2/g^2 = (2G_F^2)^{-1/2} \simeq (246\ \text{GeV})^2$, is fixed by the Fermi constant, $G_F$, whereas the ratio

$$\tan\beta = v_u/v_d \quad (89.3)$$

is a free parameter such that $0 < \beta < \pi/2$. By employing the tree-level conditions resulting from the minimization of the scalar potential, one can eliminate the diagonal and off-diagonal Higgs squared-masses in favor of $m_Z^2 = \frac{1}{4}(g^2+g'^2)(v_d^2+v_u^2)$, the CP-odd Higgs mass $m_A$ and the parameter $\tan\beta$,

$$\sin 2\beta = \frac{2m_{12}^2}{m_1^2 + m_2^2 + 2|\mu|^2} = \frac{2m_{12}^2}{m_A^2} \,, \quad (89.4)$$

$$\frac{1}{2} m_Z^2 = -|\mu|^2 + \frac{m_1^2 - m_2^2 \tan^2\beta}{\tan^2\beta - 1} \,. \quad (89.5)$$

One must also guard against the existence of charge and/or color breaking global minima due to non-zero vacuum expectation values for the squark and charged slepton fields. This possibility can be avoided if the $A$-parameters are not unduly large [42, 76, 77]. Additional constraints must also be respected to avoid the possibility of directions in scalar field space in which the full tree-level scalar potential can become unbounded from below [77].

Note that SUSY-breaking mass terms for the fermionic superpartners of scalar fields and non-holomorphic trilinear scalar interactions (*i.e.*, interactions that mix scalar fields and their complex conjugates) have not been included above in the soft-SUSY-breaking sector. These terms can potentially destabilize the gauge hierarchy [11] in models with a gauge-singlet superfield. The latter is not present in the MSSM; hence as noted in Ref. [12], these so-called non-standard soft-SUSY-breaking terms are benign. The phenomenological impact of non-holomorphic soft SUSY-breaking terms has been reconsidered in Refs. [78–80]. However, in the most common approaches to constructing a fundamental theory of SUSY-breaking, the coefficients of these terms (which have dimensions of mass) are significantly suppressed compared to the TeV-scale [81]. Consequently, we follow the usual approach and omit these terms from further consideration.

### 89.3.3 *MSSM-124*

The total number of independent physical parameters that define the MSSM (in its most general form) is quite large, primarily due to the soft-supersymmetry-breaking sector. In particular, in the case of three generations of quarks, leptons, and their superpartners, $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$, and $M^2_{\widetilde{E}}$ are hermitian $3 \times 3$ matrices, and $A_U$, $A_D$, and $A_E$ are complex $3 \times 3$ matrices. In addition, $M_1$, $M_2$, $M_3$, $B$, and $\mu$ are in general complex parameters. Finally, as in the SM, the Higgs-fermion Yukawa couplings, $\lambda_f$ ($f = u$, $d$, and $e$), are complex $3 \times 3$ matrices that are related to the quark and lepton mass matrices via: $M_f = \lambda_f v_f/\sqrt{2}$, where $v_e \equiv v_d$ [with $v_u$ and $v_d$ as defined above Eq. (89.3)].

However, not all these parameters are physical. Some of the MSSM parameters can be eliminated by expressing interaction eigenstates in terms of the mass eigenstates, with an appropriate redefinition of the MSSM fields to remove unphysical degrees of freedom. The analysis of Ref. [82] shows that the MSSM possesses 124 independent real degrees of freedom. Of these, 18 correspond to SM parameters (including the QCD vacuum angle $\theta_{\rm QCD}$), one corresponds to a Higgs sector parameter (the analogue of the SM Higgs mass), and 105 are genuinely new parameters of the model. The latter include: five real parameters and three $CP$-violating phases in the gaugino/higgsino sector, 21 squark and slepton (sfermion) masses, 36 real mixing angles to define the sfermion mass eigenstates, and 40 $CP$-violating phases that can appear in sfermion interactions. The most general R-parity-conserving minimal supersymmetric extension of the SM (without additional theoretical assumptions) will be denoted henceforth as MSSM-124 [83].

## 89.4 The supersymmetric-particle spectrum

The supersymmetric particles (sparticles) differ in spin by half a unit from their SM partners. The superpartners of the gauge and

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

Higgs bosons are fermions, whose names are obtained by appending "ino" to the end of the corresponding SM particle name. The gluino is the color-octet Majorana fermion partner of the gluon with mass $M_{\widetilde{g}} = |M_3|$. The superpartners of the electroweak gauge and Higgs bosons (the gauginos and higgsinos) can mix due to SU(2)×U(1) breaking effects. As a result, the physical states of definite mass are model-dependent linear combinations of the charged or neutral gauginos and higgsinos, called charginos and neutralinos, respectively (sometimes collectively called electroweakinos). The neutralinos are Majorana fermions, which can lead to some distinctive phenomenological signatures [84,85]. The superpartners of the quarks and leptons are spin-zero bosons: the squarks, charged sleptons, and sneutrinos, respectively. A complete set of Feynman rules for the sparticles of the MSSM can be found in Ref. [86]. The MSSM Feynman rules also are implicitly contained in a number of amplitude generation and Feynman diagram software packages (see *e.g.*, Refs. [87–89]).

It should be noted that all mass formulae quoted below in this Section are tree-level results. Radiative loop corrections will modify these results and must be included in any precision study of supersymmetric phenomenology [90]. Beyond tree level, the definition of the supersymmetric parameters becomes convention-dependent. For example, one can define physical couplings or running couplings, which differ beyond the tree level. This provides a challenge to any effort that attempts to extract supersymmetric parameters from data. The SUSY Les Houches Accord (SLHA) [75,91] has been adopted, which establishes a set of conventions for specifying generic file structures for supersymmetric model specifications and input parameters, supersymmetric mass and coupling spectra, and decay tables. These provide a universal interface between spectrum calculation programs, decay packages, and high energy physics event generators.

### 89.4.1 *The charginos and neutralinos*

The mixing of the charged gauginos ($\widetilde{W}^{\pm}$) and charged higgsinos ($\widetilde{H}_u^+$ and $\widetilde{H}_d^-$) is described (at tree-level) by a $2 \times 2$ complex mass matrix [92, 93],

$$M_C \equiv \begin{pmatrix} M_2 & \frac{1}{\sqrt{2}} g v_u \\ \frac{1}{\sqrt{2}} g v_d & \mu \end{pmatrix} . \tag{89.6}$$

To determine the physical chargino states and their masses, one must perform a singular value decomposition [94, 95] of the complex matrix $M_C$:

$$U^* M_C V^{-1} = \mathrm{diag}(M_{\tilde{\chi}_1^+}\,,\, M_{\tilde{\chi}_2^+})\,, \tag{89.7}$$

where $U$ and $V$ are unitary matrices, and the right-hand side of Eq. (89.7) is the diagonal matrix of (real non-negative) chargino masses. The physical chargino states are denoted by $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_2^{\pm}$. These are linear combinations of the charged gaugino and higgsino states determined by the matrix elements of $U$ and $V$ [92,93] The chargino masses correspond to the singular values [94] of $M_C$, *i.e.*, the positive square roots of the eigenvalues of $M_C^\dagger M_C$:

$$M^2_{\tilde{\chi}_1^+,\tilde{\chi}_2^+} = \frac{1}{2}\Big\{ |\mu|^2 + |M_2|^2 + 2m_W^2 \mp \sqrt{\left(|\mu|^2 + |M_2|^2 + 2m_W^2\right)^2 - 4|\mu M_2 - m_W^2 \sin 2\beta|^2} \Big\}, \tag{89.8}$$

where the states are ordered such that $M_{\tilde{\chi}_1^+} \leq M_{\tilde{\chi}_2^+}$. The relative phase of $\mu$ and $M_2$ is physical and potentially observable. The mixing of the neutral gauginos ($\widetilde{B}$ and $\widetilde{W}^0$) and neutral higgsinos ($\widetilde{H}_d^0$ and $\widetilde{H}_u^0$) is described (at tree-level) by a $4 \times 4$ complex symmetric mass matrix [92, 93],

$$M_N \equiv \begin{pmatrix} M_1 & 0 & -\frac{1}{2}g' v_d & \frac{1}{2}g' v_u \\ 0 & M_2 & \frac{1}{2} g v_d & -\frac{1}{2} g v_u \\ -\frac{1}{2}g' v_d & \frac{1}{2} g v_d & 0 & -\mu \\ \frac{1}{2}g' v_u & -\frac{1}{2} g v_u & -\mu & 0 \end{pmatrix} . \tag{89.9}$$

To determine the physical neutralino states and their masses, one must perform an Autonne-Takagi factorization [94,96] (also called Takagi diagonalization [95,97]) of the complex symmetric matrix $M_N$:

$$W^T M_N W = \mathrm{diag}(M_{\tilde{\chi}_1^0}\,,\, M_{\tilde{\chi}_2^0}\,,\, M_{\tilde{\chi}_3^0}\,,\, M_{\tilde{\chi}_4^0})\,, \tag{89.10}$$

where $W$ is a unitary matrix and the right-hand side of Eq. (89.10) is the diagonal matrix of (real non-negative) neutralino masses. The physical neutralino states are denoted by $\widetilde{\chi}_i^0$ ($i = 1, \ldots 4$), where the states are ordered such that $M_{\tilde{\chi}_1^0} \leq M_{\tilde{\chi}_2^0} \leq M_{\tilde{\chi}_3^0} \leq M_{\tilde{\chi}_4^0}$. The $\widetilde{\chi}_i^0$ are the linear combinations of the neutral gaugino and higgsino states determined by the matrix elements of $W$ (which is denoted by $N^{-1}$ in Ref. [92]). The neutralino masses correspond to the singular values of $M_N$, *i.e.*, the positive square roots of the eigenvalues of $M_N^\dagger M_N$. Exact formulae for these masses can be found in Refs. [98] and [99]. A numerical algorithm for determining the mixing matrix $W$ has been given in Ref. [100].

If a chargino or neutralino state approximates a particular gaugino or higgsino state, it is convenient to employ the corresponding nomenclature. Specifically, if $|M_1|$ and $|M_2|$ are small compared to $m_Z$ and $|\mu|$, then the lightest neutralino $\widetilde{\chi}_1^0$ would be nearly a pure photino, $\widetilde{\gamma}$, the superpartner of the photon. If $|M_1|$ and $m_Z$ are small compared to $|M_2|$ and $|\mu|$, then the lightest neutralino would be nearly a pure bino, $\widetilde{B}$, the superpartner of the weak hypercharge gauge boson. If $|M_2|$ and $m_Z$ are small compared to $|M_1|$ and $|\mu|$, then the lightest chargino pair and neutralino would constitute a triplet of roughly mass-degenerate pure winos, $\widetilde{W}^{\pm}$, and $\widetilde{W}_3^0$, the superpartners of the weak SU(2) gauge bosons. Finally, if $|\mu|$ and $m_Z$ are small compared to $|M_1|$ and $|M_2|$, then the lightest chargino pair and neutralino would be nearly pure higgsino states, the superpartners of the Higgs bosons. Each of the above cases leads to a strikingly different phenomenology.

In the NMSSM, an additional Higgs singlet superfield is added to the MSSM. This superfield comprises two real Higgs scalar degrees of freedom and an associated neutral higgsino degree of freedom. Consequently, there are five neutralino mass eigenstates that are obtained by a Takagi-diagonalization of the $5 \times 5$ neutralino mass matrix. In many cases, the fifth neutralino state is dominated by its SU(2)×U(1) singlet component, and thus is very weakly coupled to the SM particles and their superpartners.

### 89.4.2 *The squarks and sleptons*

For a given Dirac fermion $f$, there are two superpartners, $\widetilde{f}_L$ and $\widetilde{f}_R$, where the $L$ and $R$ subscripts simply identify the scalar partners that are related by SUSY to the left-handed and right-handed fermions, $f_{L,R} \equiv \frac{1}{2}(1 \mp \gamma_5) f$, respectively. (There is no $\widetilde{\nu}_R$ in the MSSM.) However, $\widetilde{f}_L$–$\widetilde{f}_R$ mixing is possible, in which case $\widetilde{f}_L$ and $\widetilde{f}_R$ are not mass eigenstates. For three generations of squarks, one must diagonalize $6 \times 6$ matrices corresponding to the basis $(\widetilde{q}_{iL}, \widetilde{q}_{iR})$, where $i = 1, 2, 3$ are the generation labels. For simplicity, only the one-generation case is illustrated in detail below. (The effects of second and third generation squark mixing can be significant and are treated in Ref. [101].)

Using the notation of the third family, the one-generation tree-level squark squared-mass matrix is given by [102],

$$\mathcal{M}^2 = \begin{pmatrix} M^2_{\widetilde{Q}} + m_q^2 + L_q & m_q X_q^* \\ m_q X_q & M^2_{\widetilde{R}} + m_q^2 + R_q \end{pmatrix} , \tag{89.11}$$

where

$$X_q \equiv A_q - \mu^* (\cot\beta)^{2T_{3q}}\,, \tag{89.12}$$

and $T_{3q} = \frac{1}{2}$ [$-\frac{1}{2}$] for $q = t$ [$b$]. The diagonal squared-masses are governed by soft-SUSY-breaking squared-masses $M^2_{\widetilde{Q}}$ and $M^2_{\widetilde{R}} \equiv M^2_{\widetilde{U}}$ [$M^2_{\widetilde{D}}$] for $q = t$ [$b$], the corresponding quark masses $m_t$ [$m_b$] and the electroweak correction terms:

$$\begin{aligned} L_q &\equiv (T_{3q} - e_q \sin^2\theta_W) m_Z^2 \cos 2\beta\,, \\ R_q &\equiv e_q \sin^2\theta_W\, m_Z^2 \cos 2\beta\,, \end{aligned} \tag{89.13}$$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

where $e_q = \frac{2}{3}$ $[-\frac{1}{3}]$ for $q = t$ $[b]$. The off-diagonal squark squared-masses are proportional to the corresponding quark masses and depend on $\tan\beta$, the soft-SUSY-breaking $A$-parameters and the higgsino mass parameter $\mu$. Assuming that the $A$-parameters are parametrically of the same order (or smaller) relative to other SUSY-breaking mass parameters, it then follows that the first and second generation $\widetilde{q}_L$–$\widetilde{q}_R$ mixing is smaller than that of the third generation where mixing can be enhanced by factors of $m_t$ and $m_b \tan\beta$.

In the case of third generation $\widetilde{q}_L$–$\widetilde{q}_R$ mixing, the mass eigenstates (usually denoted by $\widetilde{q}_1$ and $\widetilde{q}_2$, with $m_{\tilde{q}_1} < m_{\tilde{q}_2}$) are determined by diagonalizing the $2\times 2$ matrix $\mathcal{M}^2$ given by Eq. (89.11). The corresponding squared-masses and mixing angle are given by [102]:

$$m^2_{\tilde{q}_{1,2}} = \frac{1}{2}\left[\mathrm{Tr}\,\mathcal{M}^2 \mp \sqrt{(\mathrm{Tr}\mathcal{M}^2)^2 - 4\det\mathcal{M}^2}\right],$$
$$\sin 2\theta_{\tilde{q}} = \frac{2m_q|X_q|}{m^2_{\tilde{q}_2} - m^2_{\tilde{q}_1}}. \qquad (89.14)$$

The one-generation results above also apply to the charged sleptons, with the obvious substitutions: $q \to \ell$ with $T_{3\ell} = -\frac{1}{2}$ and $e_\ell = -1$, and the replacement of the SUSY-breaking parameters: $M^2_{\underset{\sim}{Q}} \to M^2_{\underset{\sim}{L}}$, $M^2_{\underset{\sim}{D}} \to M^2_{\underset{\sim}{E}}$, and $A_q \to A_\tau$. For the neutral sleptons, $\widetilde{\nu}_R$ does not exist in the MSSM, so $\widetilde{\nu}_L$ is a mass eigenstate.

In the case of three generations, the SUSY-breaking scalar-squared masses [$M^2_{\underset{\sim}{Q}}$, $M^2_{\underset{\sim}{U}}$, $M^2_{\underset{\sim}{D}}$, $M^2_{\underset{\sim}{L}}$, and $M^2_{\underset{\sim}{E}}$] and the $A$-parameters [$A_U$, $A_D$, and $A_E$] are now $3\times 3$ matrices as noted in Sec. 89.3.3. The diagonalization of the $6\times 6$ squark mass matrices yields $\widetilde{f}_{iL}$–$\widetilde{f}_{jR}$ mixing. In practice, since the $\widetilde{f}_L$–$\widetilde{f}_R$ mixing is appreciable only for the third generation, this additional complication can often be neglected (although see Ref. [101] for examples in which the mixing between the second and third generation squarks is relevant).

## 89.5 The supersymmetric Higgs sector

Consider first the MSSM Higgs sector [27, 28, 103]. Despite the large number of potential $CP$-violating phases among the MSSM-124 parameters, the tree-level MSSM Higgs potential given by Eq. (89.2) is automatically $CP$-conserving. This follows from the fact that the only potentially complex parameter ($m^2_{12}$) of the MSSM Higgs potential can be chosen real and positive by rephasing the Higgs fields, in which case $\tan\beta$ is a real positive parameter. Consequently, the physical neutral Higgs scalars are $CP$-eigenstates (at tree-level). The MSSM Higgs sector contains five physical spin-zero particles: a charged Higgs boson pair ($H^\pm$), two $CP$-even neutral Higgs bosons (denoted by $h^0$ and $H^0$ where $m_h < m_H$), and one $CP$-odd neutral Higgs boson ($A^0$). The discovery of a SM-like Higgs boson at the LHC with a mass of 125 GeV (see Sec. 11) strongly suggests that this state should be identified with $h^0$, although the possibility that the 125 GeV state should be identified with $H^0$ cannot yet be completely ruled out [104].

In the NMSSM [33], the scalar component of the singlet Higgs superfield adds two additional neutral states to the Higgs sector. In this model, the tree-level Higgs sector can exhibit explicit CP-violation. If $CP$ is conserved, then the two extra neutral scalar states are $CP$-even and $CP$-odd, respectively. These states can potentially mix with the neutral Higgs states of the MSSM. If scalar states exist that are dominantly singlet, then they are weakly coupled to SM gauge bosons and fermions through their small mixing with the MSSM Higgs scalars. Consequently, it is possible that one (or both) of the singlet-dominated states is considerably lighter than the Higgs boson that was observed at the LHC.

### 89.5.1 *The tree-level Higgs sector*

The tree-level properties of the Higgs sector are determined by the Higgs potential given by Eq. (89.2). The quartic interaction terms are manifestly supersymmetric (although these are modified by SUSY-breaking effects at the loop level). In general, the quartic couplings arise from two sources: (i) the supersymmetric generalization of the scalar potential (the so-called "$F$-terms"), and (ii) interaction terms related by SUSY to the coupling of the scalar fields and the gauge fields, whose coefficients are proportional to the corresponding gauge couplings (the so-called "$D$-terms").

In the MSSM, $F$-term contributions to the quartic Higgs self-couplings are absent. As a result, the strengths of the MSSM quartic Higgs interactions are fixed in terms of the gauge couplings, as noted below Eq. (89.2). Consequently, all the tree-level MSSM Higgs-sector parameters depend only on two quantities: $\tan\beta$ [defined in Eq. (89.3)] and one Higgs mass usually taken to be $m_A$. From these two quantities, one can predict the values of the remaining Higgs boson masses, an angle $\alpha$ that measures the mixture of the hypercharge $\pm 1$ scalar fields, $H^0_u$ and $H^0_d$, in the physical $CP$-even neutral scalars, and the Higgs boson self-couplings. Moreover, the tree-level mass of the lighter $CP$-even Higgs boson is bounded, $m_h \leq m_Z|\cos 2\beta| \leq m_Z$ [27, 28]. This bound can be substantially modified when radiative corrections are included, as discussed in Sec. 89.5.2.

In the NMSSM, the superpotential contains a trilinear term that couples the two $Y = \pm 1$ Higgs doublet superfields and the singlet Higgs superfield. The coefficient of this term is denoted by $\lambda$. Consequently, the tree-level bound for the mass of the lightest $CP$-even MSSM Higgs boson is modified [105],

$$m^2_h \leq m^2_Z \cos^2 2\beta + \frac{1}{2}\lambda^2 v^2 \sin^2 2\beta\,, \qquad (89.15)$$

where $v \equiv (v^2_u + v^2_d)^{1/2} = 246$ GeV. If one demands that $\lambda$ should stay finite after renormalization-group evolution up to the Planck scale, then $\lambda$ is constrained to lie below about 0.7–0.8 at the electroweak scale [33] (although larger values of $\lambda$ have also been considered [106]).

The tree-level Higgs-quark and Higgs-lepton interactions of the MSSM are governed by the Yukawa couplings defined by the superpotential given in Eq. (89.1). In particular, the Higgs sector of the MSSM is a Type-II two-Higgs doublet model [107], in which one Higgs doublet ($H_d$) couples exclusively to the right-handed down-type quark (or lepton) fields and the second Higgs doublet ($H_u$) couples exclusively to the right-handed up-type quark fields. Consequently, the diagonalization of the fermion mass matrices simultaneously diagonalizes the matrix Yukawa couplings, resulting in flavor-diagonal tree-level couplings of the neutral Higgs bosons $h^0$, $H^0$ and $A^0$ to quark and lepton pairs.

### 89.5.2 *The radiatively-corrected Higgs sector*

When radiative corrections are incorporated, additional parameters of the supersymmetric model enter via virtual supersymmetric particles that appear in loops. The impact of these corrections can be significant [108]. The qualitative behavior of these radiative corrections can be most easily seen in the large top-squark mass limit, where in addition, both the splitting of the two diagonal entries and the off-diagonal entries of the top-squark squared-mass matrix [Eq. (89.11)] are small in comparison to the geometric mean of the two top-squark squared-masses, $M^2_{\rm S} \equiv M_{\underset{\sim}{t_1}} M_{\underset{\sim}{t_2}}$. In this case (assuming $\mathrm{m}_A > m_Z$), the predicted upper bound for $m_h$ is approximately given by

$$m^2_h \lesssim m^2_Z \cos^2 2\beta + \frac{3g^2 m^4_t}{8\pi^2 m^2_W}\left[\ln\left(\frac{M^2_{\rm S}}{m^2_t}\right) + \frac{X^2_t}{M^2_{\rm S}}\left(1 - \frac{X^2_t}{12M^2_{\rm S}}\right)\right], \qquad (89.16)$$

where $X_t \equiv A_t - \mu\cot\beta$ [cf. Eq. (89.12)] is proportional to the off-diagonal entry of the top-squark squared-mass matrix (where for simplicity, $A_t$ and $\mu$ are taken to be real). The Higgs mass upper limit specified by Eq. (89.16) is saturated when $\tan\beta$ is large (*i.e.*, $\cos^2 2\beta \sim 1$) and $X_t = \sqrt{6}\,M_S$, which defines the so-called maximal mixing scenario.

A more complete treatment of the radiative corrections shows that Eq. (89.16) somewhat overestimates the true upper bound of $m_h$. These more refined computations, which incorporate renormalization group improvement, the two loop and the leading three-loop contributions, yield $m_h \lesssim 135$ GeV in the region of large $\tan\beta$ (with an accuracy of a few GeV) for $m_t = 175$ GeV and $M_S \lesssim 2$ TeV [109].

In addition, one-loop radiative corrections can introduce $CP$-violating effects in the Higgs sector that depend on some of

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

the $CP$-violating phases among the MSSM-124 parameters [110]. This phenomenon is most easily understood in a scenario where $m_A \ll M_S$ (i.e., all five physical Higgs states are significantly lighter than the SUSY breaking scale). In this case, one can integrate out the heavy superpartners to obtain a low-energy effective theory with two Higgs doublets. The resulting effective two-Higgs doublet model will now contain all possible Higgs self-interaction terms (both CP-conserving and CP-violating) and Higgs-fermion interactions (beyond those of Type-II) that are consistent with electroweak gauge invariance [111].

In the NMSSM, the dominant radiative correction to Eq. (89.15) is the same as the one given in Eq. (89.16). However, in contrast to the MSSM, one does not need as large a boost from the radiative corrections to achieve a Higgs mass of 125 GeV in certain regimes of the NMSSM parameter space (*e.g.*, $\tan\beta \sim 2$ and $\lambda \sim 0.7$ [112]).

## 89.6 Restricting the MSSM parameter freedom

In Sections 89.4 and 89.5, we surveyed the parameters that comprise the MSSM-124. However, without additional restrictions on the choice of parameters, a generic parameter set within the MSSM-124 framework is not phenomenologically viable. In particular, a generic point of the MSSM-124 parameter space exhibits: (i) no conservation of the separate lepton numbers $L_e$, $L_\mu$, and $L_\tau$; (ii) unsuppressed flavor-changing neutral currents (FCNCs); and (iii) new sources of $CP$ violation that are inconsistent with the experimental bounds.

For example, the MSSM contains many new sources of $CP$ violation [113]. Indeed, for TeV-scale sfermion and gaugino masses, some combinations of the complex phases of the gaugino-mass parameters, the $A$-parameters, and $\mu$ must be less than about $10^{-2}$–$10^{-3}$ to avoid generating electric dipole moments for the neutron, electron, and atoms [114–116] in conflict with observed data [117]. The rarity of FCNCs [118–120] places additional constraints on the off-diagonal matrix elements of the squark and slepton soft-SUSY-breaking squared-masses and $A$-parameters (see Sec. 89.3.3).

The MSSM-124 is also theoretically incomplete as it provides no explanation for the fundamental origin of the supersymmetry-breaking parameters. The successful unification of the SM gauge couplings at very high energies close to the Planck scale [8, 66, 121–123] suggests that the high-energy structure of the theory may be considerably simpler than its low-energy realization. In a top-down approach, the dynamics that governs the more fundamental theory at high energies is used to derive the effective broken-supersymmetric theory at the TeV scale. A suitable choice for the high energy dynamics is one that yields a TeV-scale theory that satisfies all relevant phenomenological constraints.

In this Section, we examine a number of theoretical frameworks that potentially yield phenomenologically viable regions of the MSSM-124 parameter space. The resulting supersymmetric particle spectrum is then a function of a relatively small number of input parameters. This is accomplished by imposing a simple structure on the soft SUSY-breaking parameters at a common high-energy scale $M_X$ (typically chosen to be the Planck scale, $M_P$, the grand unification scale, $M_{\rm GUT}$, or the messenger scale, $M_{\rm mess}$). These serve as initial conditions for the MSSM renormalization group equations (RGEs), which are given in the two-loop approximation in Ref. [124] (an automated program to compute RGEs for the MSSM and other models of new physics beyond the SM has been developed in Ref. [125]). Solving these equations numerically, one can then derive the low-energy MSSM parameters relevant for phenomenology. A number of software packages exist that numerically calculate the spectrum of supersymmetric particles, consistent with theoretical conditions on SUSY breaking at high energies and some experimental data at low energies [126].

Examples of this scenario are provided by models of gravity-mediated, anomaly mediated and gauge-mediated SUSY breaking, to be discussed in more detail below. In some of these approaches, one of the diagonal Higgs squared-mass parameters is driven negative by renormalization group evolution [127]. In such models, electroweak symmetry breaking is generated radiatively, and the resulting electroweak symmetry-breaking scale is intimately tied to the scale of low-energy SUSY breaking.

### 89.6.1 *Gaugino mass relations*

One prediction of many supersymmetric grand unified models is the unification of the (tree-level) gaugino mass parameters at some high-energy scale, $M_X$,

$$M_1(M_X) = M_2(M_X) = M_3(M_X) = m_{1/2}\,. \tag{89.17}$$

Due to renormalization group running, in the one-loop approximation the effective low-energy gaugino mass parameters (at the electroweak scale) are related,

$$M_3 = (g_s^2/g^2)M_2 \simeq 3.5M_2\ , \qquad M_1 = (5g'^2/3g^2)M_2 \simeq 0.5M_2. \tag{89.18}$$

Eq. (89.18) can arise more generally in gauge-mediated SUSY-breaking models where the gaugino masses are generated at the messenger scale $M_{\rm mess}$ (which typically lies significantly below the unification scale where the gauge couplings unify). In this case, the gaugino mass parameters are proportional to the corresponding squared gauge couplings at the messenger scale.

When Eq. (89.18) is satisfied, the chargino and neutralino masses and mixing angles depend only on three unknown parameters: the gluino mass, $\mu$, and $\tan\beta$. It then follows that the lightest neutralino must be heavier than 46 GeV due to the non-observation of charginos at LEP [128]. If in addition $|\mu| \gg |M_1| \gtrsim m_Z$, then the lightest neutralino is nearly a pure bino, an assumption often made in supersymmetric particle searches at colliders. Although Eq. (89.18) is often assumed in many phenomenological studies, a truly model-independent approach would take the gaugino mass parameters, $M_i$, to be independent parameters to be determined by experiment. Indeed, an approximately massless neutralino *cannot* be ruled out at present by a model-independent analysis [129].

It is possible that the tree-level masses for the gauginos are zero. In this case, the gaugino mass parameters arise at one-loop and do not satisfy Eq. (89.18). For example, the gaugino masses in AMSB models arise entirely from a model-independent contribution derived from the super-conformal anomaly [48, 130]. In this case, Eq. (89.18) is replaced (in the one-loop approximation) by:

$$M_i \simeq \frac{b_i g_i^2}{16\pi^2} m_{3/2}\,, \tag{89.19}$$

where $m_{3/2}$ is the gravitino mass and the $b_i$ are the coefficients of the MSSM gauge beta-functions corresponding to the corresponding U(1), SU(2), and SU(3) gauge groups, $(b_1, b_2, b_3) = (\frac{33}{5}, 1, -3)$. Eq. (89.19) yields $M_1 \simeq 2.8M_2$ and $M_3 \simeq -8.3M_2$, which implies that the lightest chargino pair and neutralino comprise a nearly mass-degenerate triplet of winos, $\widetilde{W}^\pm$, $\widetilde{W}^0$ (cf. Table 1), over most of the MSSM parameter space. For example, if $|\mu| \gg m_Z, |M_2|$, then Eq. (89.19) implies that $M_{\tilde{\chi}^\pm} \simeq M_{\tilde{\chi}^0_1} \simeq M_2$ [131]. Alternatively, one can construct an AMSB model where $|\mu|, m_Z \ll M_2$, which yields an LSP that is an approximate higgsino state [132]. In both cases, the corresponding supersymmetric phenomenology differs significantly from the standard phenomenology based on Eq. (89.18) [133, 134].

Finally, it should be noted that the unification of gaugino masses (and scalar masses) can be accidental. In particular, the energy scale where unification takes place may not be directly related to any physical scale. One version of this phenomenon has been called mirage unification and can occur in certain theories of fundamental SUSY breaking [135].

### 89.6.2 *Constrained versions of the MSSM: mSUGRA, CMSSM, etc.*

In the minimal supergravity (mSUGRA) framework [3–6, 41–43], a form of the Kähler potential is employed that yields minimal kinetic energy terms for the MSSM fields [45]. As a result, the soft supersymmetry-breaking parameters at the high-energy scale $M_X$ take a particularly simple form in which the scalar squared-masses

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

and the $A$-parameters are flavor-diagonal and universal [43]:

$$\begin{aligned} &M^2_{\widetilde{Q}}(M_X) = M^2_{\widetilde{U}}(M_X) = M^2_{\widetilde{D}}(M_X) = m_0^2\mathbf{1}\,, \\ &M^2_{\widetilde{L}}(M_X) = M^2_{\widetilde{E}}(M_X) = m_0^2\mathbf{1}\,, \\ &m_1^2(M_X) = m_2^2(M_X) = m_0^2\,, \\ &A_U(M_X) = A_D(M_X) = A_E(M_X) = A_0\mathbf{1}\,, \end{aligned} \tag{89.20}$$

where $\mathbf{1}$ is a $3 \times 3$ identity matrix in generation space. As in the SM, this approach exhibits minimal flavor violation [136,137], whose unique source is the nontrivial flavor structure of the Higgs-fermion Yukawa couplings. The gaugino masses are also unified according to Eq. (89.17).

Renormalization group evolution is then used to derive the values of the supersymmetric parameters at the low-energy (electroweak) scale. For example, to compute squark masses, one should use the low-energy values for $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, and $M^2_{\widetilde{D}}$ in Eq. (89.11). Through the renormalization group running with boundary conditions specified in Eq. (89.18) and Eq. (89.20), one can show that the low-energy values of $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, and $M^2_{\widetilde{D}}$ depend primarily on $m_0^2$ and $m_{1/2}^2$. A number of useful approximate analytic expressions for superpartner masses in terms of the mSUGRA parameters can be found in Ref. [138].

In the mSUGRA approach, four flavors of squarks (with two squark eigenstates per flavor) are nearly mass-degenerate. If $\tan\beta$ is not very large, $\widetilde{b}_R$ is also approximately degenerate in mass with the first two generations of squarks. The $\widetilde{b}_L$ mass and the diagonal $\widetilde{t}_L$ and $\widetilde{t}_R$ masses are typically reduced relative to the common squark mass of the first two generations. In addition, there are six flavors of nearly mass-degenerate sleptons (with two slepton eigenstates per flavor for the charged sleptons and one per flavor for the sneutrinos); the sleptons are expected to be somewhat lighter than the mass-degenerate squarks. As noted below Eq. (89.11), third-generation squark masses and tau-slepton masses are sensitive to the strength of the respective $\widetilde{f}_L$–$\widetilde{f}_R$ mixing. The LSP is typically the lightest neutralino, $\tilde{\chi}^0_1$, which is dominated by its bino component. Regions of the mSUGRA parameter space in which the LSP is electrically charged do exist but are not phenomenologically viable [19].

One can count the number of independent parameters in the mSUGRA framework. In addition to 18 SM parameters (excluding the Higgs mass), one must specify $m_0$, $m_{1/2}$, $A_0$, the Planck-scale values for $\mu$ and $B$-parameters (denoted by $\mu_0$ and $B_0$), and the gravitino mass $m_{3/2}$. Without additional model assumptions, $m_{3/2}$ is independent of the parameters that govern the mass spectrum of the superpartners of the SM [43]. In principle, $A_0$, $B_0$, $\mu_0$, and $m_{3/2}$ can be complex, although in the mSUGRA approach, these parameters are taken (arbitrarily) to be real.

As previously noted, renormalization group evolution is used to compute the low-energy values of the mSUGRA parameters, which then fixes all the parameters of the low-energy MSSM. In particular, the two Higgs vacuum expectation values (or equivalently, $m_Z$ and $\tan\beta$) can be expressed as a function of the Planck-scale supergravity parameters. The most common procedure is to remove $\mu_0$ and $B_0$ in favor of $m_Z$ and $\tan\beta$ [the sign of $\mu_0$, denoted $\mathrm{sgn}(\mu_0)$ below, is not fixed in this process]. In this case, the MSSM spectrum and its interaction strengths are determined by five parameters:

$$m_0\,,\ A_0\,,\ m_{1/2}\,,\ \tan\beta\,,\ \text{and}\ \mathrm{sgn}(\mu_0)\,, \tag{89.21}$$

and an independent gravitino mass $m_{3/2}$ (in addition to the 18 parameters of the SM). In Ref. [139], this framework was dubbed the constrained minimal supersymmetric extension of the SM (CMSSM).

In the early literature, additional conditions were obtained by assuming a simplified form for the hidden sector that provides the fundamental source of SUSY breaking. Two additional relations emerged among the mSUGRA parameters [41,45]: $B_0 = A_0 - m_0$ and $m_{3/2} = m_0$. These relations characterize a theory that was called minimal supergravity when first proposed. In the subsequent literature, it has been more common to omit these extra conditions in defining the mSUGRA model (in which case the mSUGRA model and the CMSSM are synonymous). The authors of Ref. [140] advocate restoring the original nomenclature in which the mSUGRA model is defined with the extra conditions as originally proposed. Additional mSUGRA variations can also be considered where different relations among the CMSSM parameters are imposed.

One can also relax the universality of scalar masses by decoupling the squared-masses of the Higgs bosons and the squarks/sleptons. This leads to the non-universal Higgs mass models (NUHMs), thereby adding one or two new parameters to the CMSSM depending on whether the diagonal Higgs scalar squared-mass parameters ($m_1^2$ and $m_2^2$) are set equal (NUHM1 [141]) or taken to be independent (NUHM2 [142]) at the high energy scale $M_X^2$. Clearly, this modification preserves the minimal flavor violation of the mSUGRA approach. Nevertheless, the mSUGRA approach and its NUHM generalizations are probably too simplistic. Theoretical considerations suggest that the universality of Planck-scale soft SUSY-breaking parameters is not generic [143]. In particular, effective operators at the Planck scale exist that do not respect flavor universality, and it is difficult to find a theoretical principle that would forbid them.

In the framework of supergravity, if anomaly mediation is the sole source of SUSY breaking, then the gaugino mass parameters, diagonal scalar squared-mass parameters, and the SUSY-breaking trilinear scalar interaction terms (proportional to $\lambda_f A_F$) are determined in terms of the beta functions of the gauge and Yukawa couplings and the anomalous dimensions of the squark and slepton fields [48, 130, 134]. As noted in Sec. 89.2.3, this approach yields tachyonic sleptons in the MSSM unless additional sources of SUSY breaking are present. In the minimal AMSB (mAMSB) scenario, a universal squared-mass parameter, $m_0^2$, is added to the AMSB expressions for the diagonal scalar squared-masses [134]. Thus, the mAMSB spectrum and its interaction strengths are determined by four parameters, $m_0^2$, $m_{3/2}$, $\tan\beta$ and $\mathrm{sgn}(\mu_0)$.

The mAMSB scenario appears to be ruled out based on the observed value of the Higgs boson mass, assuming an upper limit on $M_S$ of a few TeV, since the mAMSB constraint on $A_F$ implies that the maximal mixing scenario cannot be achieved [cf. Eq. (89.16)]. Indeed, under the stated assumptions, the mAMSB Higgs mass upper bound lies below the observed Higgs mass value [144]. Thus within the AMSB scenario, either an additional SUSY-breaking contribution to $\lambda_f A_F$ and/or new ingredients beyond the MSSM are required.

### 89.6.3 *Gauge-mediated SUSY breaking*

In contrast to models of gravity-mediated SUSY breaking, the flavor universality of the fundamental soft SUSY-breaking squark and slepton squared-mass parameters is guaranteed in gauge-mediated SUSY breaking (GMSB) because the supersymmetry breaking is communicated to the sector of MSSM fields via gauge interactions [53,55]. In GMSB models, the mass scale of the messenger sector (or its equivalent) is sufficiently below the Planck scale such that the additional SUSY-breaking effects mediated by supergravity can be neglected.

In the minimal GMSB approach, there is one effective mass scale, $\Lambda$, that determines all low-energy scalar and gaugino mass parameters through loop effects, while the resulting $A$-parameters are suppressed. In order that the resulting superpartner masses be of order 1 TeV, one must have $\Lambda \sim \mathcal{O}(100\ \text{TeV})$. The origin of the $\mu$ and $B$-parameters is model-dependent, and lies somewhat outside the ansatz of gauge-mediated SUSY breaking [145].

The simplest GMSB models appear to be ruled out based on the observed value of the Higgs boson mass. Due to suppressed $A$ parameters, it is difficult to boost the contributions of the radiative corrections in Eq. (89.16) to obtain a Higgs mass as large as 125 GeV. However, this conflict can be alleviated in more complicated GMSB models [146]. To analyze these generalized GMSB models, it has been especially fruitful to develop model-independent techniques that encompass all known GMSB models [147]. These techniques are well-suited for a comprehensive analysis [148] of the phenomenological profile of gauge-mediated SUSY breaking.

The gravitino is the LSP in GMSB models, as noted in Sec. 89.2.3. As a result, the next-to-lightest supersymmetric par-

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

ticle (NLSP) now plays a crucial role in the phenomenology of supersymmetric particle production and decays. Note that unlike the LSP, the NLSP can be charged. In GMSB models, the most likely candidates for the NLSP are $\tilde{\chi}_1^0$ and $\widetilde{\tau}_R^{\pm}$. The NLSP will decay into its superpartner plus a gravitino (*e.g.*, $\tilde{\chi}_1^0 \to \gamma\widetilde{G}$, $\tilde{\chi}_1^0 \to Z\widetilde{G}$, $\tilde{\chi}_1^0 \to h^0\widetilde{G}$ or $\widetilde{\tau}_1^{\pm} \to \tau^{\pm}\widetilde{G}$), with lifetimes and branching ratios that depend on the model parameters. There are also GMSB scenarios in which there are several nearly degenerate co-NLSP's, any one of which can be produced at the penultimate step of a supersymmetric decay chain [149]. For example, in the slepton co-NLSP case, all three right-handed sleptons are close enough in mass and thus can each play the role of the NLSP.

Different choices for the identity of the NLSP and its decay rate lead to a variety of distinctive supersymmetric phenomenologies [55,150]. For example, a long-lived $\tilde{\chi}_1^0$-NLSP that decays outside collider detectors leads to supersymmetric decay chains with missing energy in association with leptons and/or hadronic jets (this case is indistinguishable from the standard phenomenology of the $\tilde{\chi}_1^0$-LSP). On the other hand, if $\tilde{\chi}_1^0 \to \gamma\widetilde{G}$ is the dominant decay mode, and the decay occurs inside the detector, then nearly *all* supersymmetric particle decay chains would contain a photon. In contrast, in the case of a $\widetilde{\tau}_1^{\pm}$-NLSP, the $\widetilde{\tau}_1^{\pm}$ would either be long-lived or would decay inside the detector into a $\tau$-lepton plus missing energy.

A number of attempts have been made to address the origins of the $\mu$ and $B$-parameters in GMSB models based on the field content of the MSSM (see, *e.g.*, Refs. [145, 151]). An alternative approach is to consider GMSB models based on the NMSSM [152]. The vacuum expectation value of the additional singlet Higgs superfield can be used to generate effective $\mu$ and $B$-parameters [153]. Such models provide an alternative GMSB framework for achieving a Higgs mass of 125 GeV, while still being consistent with LHC bounds on supersymmetric particle masses [154].

### 89.6.4 *The phenomenological MSSM*

Of course, any of the theoretical assumptions described in the previous three subsections must be tested experimentally and could turn out to be wrong. To facilitate the exploration of MSSM phenomena in a more model-independent way while respecting the constraints noted at the beginning of this Section, the phenomenological MSSM (pMSSM) has been introduced [155].

The pMSSM is governed by 19 independent real supersymmetric parameters: the three gaugino mass parameters $M_1$, $M_2$ and $M_3$, the Higgs sector parameters $m_A$ and $\tan\beta$, the Higgsino mass parameter $\mu$, five sfermion squared-mass parameters for the degenerate first and second generations ($M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$ and $M^2_{\widetilde{E}}$), the five corresponding sfermion squared-mass parameters for the third generation, and three third-generation $A$-parameters ($A_t$, $A_b$ and $A_\tau$). The first and second generation $A$-parameters are typically neglected in pMSSM studies, as their phenomenological consequences are negligible in most applications (one counterexample is the $A_\mu$ dependence of the anomalous magnetic moment of the muon, which can be as significant as other contributions due to superpartner mediated radiative corrections [156]). Since its initial proposal, the pMSSM approach has been extended to include CP-violating SUSY-breaking parameters in Ref. [157].

A comprehensive study of the 19-parameter pMSSM is computationally expensive. This is somewhat ameliorated in Ref. [158], where the number of pMSSM parameters is reduced to ten by assuming one common squark squared-mass parameter for the first two generations, a second common squark squared-mass parameter for the third generation, a common slepton squared-mass parameter and a common third generation $A$ parameter. Applications of the pMSSM approach to supersymmetric particle searches, and a discussion of the implications for past and future LHC and dark matter studies can be found in Refs. [158–160].

### 89.6.5 *Simplified models*

As Sec. 90 demonstrates, experiments present their searches for supersymmetric particles primarily in terms of simplified models. Simplified models for supersymmetric searches [161] are defined mostly by the empirical objects and kinematic variables involved in the search. Their interpretation by the experimental collaboration usually involves only a small number of supersymmetric particles (often two or three). Other supersymmetric particles are assumed to play no role (this may happen by virtue of them being too heavy to be produced). Experimental bounds from non-observation of a signal are usually presented in terms of the physical masses of the supersymmetric particles involved. Bounds may be presented on the relevant supersymmetric particle masses assuming a 100% branching ratio for a certain decay, or as an upper bound on signal production cross-section times branching ratio as a function of the relevant supersymmetric particle masses.

For example, consider a search for hadronic jets plus missing transverse momentum. One can match such a search to the simplified model of squark pair production followed by the subsequent decay of each squark into a quark (which appears as a jet) and a neutralino LSP that produces the missing transverse momentum, *i.e.* $\tilde{q}\tilde{q} \to (q\tilde{\chi}_1^0)(q\tilde{\chi}_1^0)$. Excluded regions resulting from the non-observation of a signal may be exhibited in the squark mass versus LSP mass plane.

Simplified models have the advantage that one makes fewer assumptions, compared to more complete supersymmetric models, where the larger number of free parameters makes it difficult to present excluded regions in any generality. It is hoped that simplified models may be a reasonable approximation over sizeable regions of parameter space of more complete models, within which the simplified model is embedded. On the other hand, as stressed in Sec. 90, simplified models have the disadvantage that the presentation of negative search limits tends to be overly strong when compared to the more complete models, particularly if 100% branching ratios are assumed. A contrast between supersymmetric particle search limits in the context of simplified models and the corresponding constraints obtained in the more complete pMSSM is provided in Ref. [162]. As long as one is able to dispel undue pessimism, simplified models remain an efficient vehicle for organizing and presenting the results of supersymmetric particle searches.

## 89.7 Experimental data confronts the MSSM

At present, there is no direct evidence for weak-scale SUSY from the data analyzed by the LHC experiments. Recent LHC data have been effectively employed in ruling out the existence of colored supersymmetric particles (primarily the gluino and the first generation of squarks) with masses below about 2 TeV (see Sec. 90). The precise mass limits are model dependent. For example, as Sec. 90 demonstrates, regions of the pMSSM parameter space can be identified in which lighter squarks and gluinos below 1 TeV cannot be definitely ruled out. Additional constraints arise from limits on the contributions of virtual supersymmetric particle exchange to a variety of SM processes [118–120].

In light of these negative results, one must confront the tension that exists between the theoretical expectations for the magnitude of the SUSY-breaking parameters and the non-observation of supersymmetric phenomena at colliders.

### 89.7.1 *Naturalness constraints and the little hierarchy*

In Sec. 89.1, weak-scale SUSY was motivated as a natural solution to the hierarchy problem, which could provide an understanding of the origin of the electroweak symmetry-breaking scale without a significant fine-tuning of the fundamental parameters that govern the MSSM. In this context, the weak scale soft supersymmetry-breaking masses must be generally of the order of 1 TeV or below [163]. This requirement is most easily seen in the determination of $m_Z$ by the scalar potential minimum condition. In light of Eq. (89.5), to avoid the fine-tuning of MSSM parameters, the soft SUSY-breaking squared-masses $m_1^2$ and $m_2^2$ and the higgsino squared-mass $|\mu|^2$ should all be roughly of $\mathcal{O}(m_Z^2)$. Many authors have proposed quantitative measures of fine-tuning [163–167]. One of the simplest measures is the one advocated by Barbieri and Giudice [163] (which was also introduced previously in Ref. [164]),

$$\Delta_i \equiv \left| \frac{\partial \ln m_Z^2}{\partial \ln p_i} \right| , \qquad \Delta \equiv \max\, \Delta_i \,, \tag{89.22}$$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

where the $p_i$ are the MSSM parameters at the high-energy scale $M_X$, which are set by the fundamental SUSY-breaking dynamics. The theory is more fine-tuned as $\Delta$ becomes larger. However, different measures of fine-tuning yield quantitatively different results; in particular, calculating minimal fine-tuning based on the high-scale parameters [as defined in Eq. (89.22)] yields a difference by a factor $\sim 10$ to fine-tuning based on TeV-scale parameters [168, 169].

One can apply the fine-tuning measure to any explicit model of SUSY breaking. For example, in the approaches discussed in Sec. 89.6, the $p_i$ are parameters of the model at the energy scale $M_X$ where the soft SUSY-breaking operators are generated by the dynamics of SUSY breaking. Renormalization group evolution then determines the values of the parameters appearing in Eq. (89.5) at the electroweak scale. In this way, $\Delta$ is sensitive to all the SUSY-breaking parameters of the model (see e.g. Ref. [170]). It should be noted that the computation of $\Delta$ is often based on Eq. (89.5), which is a tree-level condition. For example, an analysis in Ref. [80] shows that the fine tuning measure can be reduced by as much as a factor of two when loop corrections are included [171].

As anticipated, there is a tension between the present experimental lower limits on the masses of colored supersymmetric particles [172,173] and the expectation that supersymmetry-breaking is associated with the electroweak symmetry-breaking scale. Moreover, this tension is exacerbated [174] by the observed value of the Higgs mass ($m_h \simeq 125$ GeV), which is not far from the MSSM upper bound ($m_h \lesssim 135$ GeV) [which depends on the top-squark mass and mixing as noted in Sec. 89.5.2]. If $M_{\rm SUSY}$ characterizes the scale of supersymmetric particle masses, then one would crudely expect $\Delta \sim M^2_{\rm SUSY}/m^2_Z$. For example, if $M_{\rm SUSY} \sim 1$ TeV then one expects a $\Delta^{-1} \sim 1\%$ fine-tuning of the MSSM parameters to achieve the observed value of $m_Z$. This separation of the electroweak symmetry-breaking and SUSY-breaking scales is an example of the little hierarchy problem [175, 176].

The fine-tuning parameter $\Delta$ can depend quite sensitively on the structure of the SUSY-breaking dynamics, such as the value of $M_X$ and relations among SUSY-breaking parameters in the fundamental high energy theory [177]. For example, in so-called focus point SUSY models [166, 178], all squark masses can be as heavy as 5 TeV *without* significant fine-tuning. This can be attributed to a focusing behavior of the renormalization group evolution when certain relations hold among the high-energy values of the scalar squared-mass SUSY-breaking parameters. Although the focus point region of the CMSSM still yields an uncomfortably high value of $\Delta$ due to the observed Higgs mass of 125 GeV, one can achieve moderate values of $\Delta$ in models with NUHM2 boundary conditions for the scalar masses [174].

Among the colored superpartners, the third generation squarks typically have the most significant impact on the naturalness constraints [179], while their masses are the least constrained by the LHC data. Hence, in the absence of any relation between third generation squarks and those of the first two generations, the naturalness constraints due to present LHC data can be considerably weaker than those obtained in the CMSSM. Indeed, models with first and second generation squark masses in the multi-TeV range do not necessarily require significant fine tuning. Such models have the added benefit that undesirable FCNCs mediated by squark exchange are naturally suppressed [180]. Other MSSM mass spectra that are compatible with moderate fine tuning have been considered in Refs. [177] and [181].

The lower bounds on squark and gluino masses may not be as large as suggested by the experimental analyses based on the CMSSM or simplified models. For example, mass bounds for the gluino and the first and second generation squarks based on the CMSSM can often be evaded in alternative or extended MSSM models, *e.g.*, compressed SUSY [182] and stealth SUSY [183]. Moreover, the experimental upper limits for the third generation squark masses (which have a more direct impact on the fine-tuning measure) are weaker than the corresponding mass limits for other colored supersymmetric states.

Among the uncolored superpartners, the higgsinos are typically the most impacted by the naturalness constraints. Eq. (89.5) suggests that the masses of the two neutral higgsinos and charged higgsino pair (which are governed by $|\mu|$) should not be significantly larger than $m_Z$ to avoid an unnatural fine-tuning of the supersymmetric parameters, which would imply the existence of light higgsinos (whose masses are not well constrained, as they are difficult to detect directly at the LHC due to their soft decay products). Nevertheless, it may be possible to avoid the conclusion that $\mu \sim \mathcal{O}(m_Z)$ if additional correlations among the SUSY breaking mass parameters and $\mu$ are present. Such a scenario can be realized in models in which the boundary conditions for SUSY breaking are generated by approximately conformal strong dynamics. For example, in the so-called scalar-sequestering model of Ref. [184], values of $|\mu| > 1$ TeV can be achieved while naturally maintaining the observed value of $m_Z$.

Finally, one can also consider extensions of the MSSM in which the degree of fine-tuning is relaxed. For example, it has already been noted in Sec. 89.5 that it is possible to accommodate the observed Higgs mass more easily in the NMSSM due to contributions to $m^2_h$ proportional to the parameter $\lambda^2$. This means that we do not have to rely on a large contribution from the radiative corrections to boost the Higgs mass sufficiently above its tree-level bound. This allows for smaller top squark masses, which are more consistent with the demands of naturalness. The reduction of the fine-tuning in various NMSSM models was initially advocated in Ref. [185], and subsequently treated in more detail in Refs. [106, 186]. Naturalness can also be relaxed in extended supersymmetric models with vector-like quarks [187] and in gauge extensions of the MSSM [188].

The experimental absence of any new physics beyond the Standard Model at the LHC suggests that the principle of naturalness is presently under significant stress [189]. Nevertheless, one must be very cautious when drawing conclusions about the viability of weak-scale SUSY to explain the origin of electroweak symmetry breaking, since different measures of fine-tuning noted above can lead to different assessments [168, 169]. Moreover, the maximal value of $\Delta$ that determines whether weak-scale SUSY is a fine-tuned model (should it be $\Delta \sim 10$? 100? 1000?) is ultimately subjective. Thus, it is premature to conclude that weak-scale SUSY is on the verge of exclusion. However, it might be possible to sharpen the upper bounds on superpartner masses based on naturalness arguments, which ultimately will either confirm or refute the weak scale SUSY hypothesis [190]. Of course, if evidence for supersymmetric phenomena in the multi-TeV regime were to be established at a future collider facility (with an energy reach beyond the LHC [191]), it would be viewed as a spectacularly successful explanation of the large gauge hierarchy between the (multi-)TeV scale and Planck scale. In this case, the remaining little hierarchy, characterized by the somewhat large value of the fine-tuning parameter $\Delta$ discussed above, would be regarded as a less pressing issue.

### 89.7.2 *Constraints from virtual exchange of supersymmetric particles*

There are a number of low-energy measurements that are sensitive to the effects of new physics through indirect searches via supersymmetric loop effects. For example, the virtual exchange of supersymmetric particles can contribute to the muon anomalous magnetic moment, $a_\mu \equiv \frac{1}{2}(g-2)_\mu$, as reviewed in Ref. [192]. The SM prediction for $a_\mu$ exhibits a deviation in the range of 3—4$\sigma$ from the experimentally observed value [193]. This discrepancy is difficult to accommodate in the constrained SUSY models of Sec. 89.6.2 and 89.6.3 given the present sparticle mass bounds [173]. Nevertheless, there are regions of the more general pMSSM parameter space that are consistent with the observed value of $a_\mu$ [194]. An updated value of the fine structure constant has resulted in a new SM prediction [195] for the electron anomalous magnetic moment $a_e$ which is $2.4\sigma$ above the measurement [196]. Indeed, it is possible within the pMSSM to find allowed parameter space regions where the observed values of $a_\mu$ and $a_e$ are simultaneously accommodated [197].

The rare inclusive decay $b \to s\gamma$ also provides a sensitive probe to the virtual effects of new physics beyond the SM. The experimental measurements of $B \to X_s + \gamma$ [198] are in agreement with the theoretical SM predictions of Ref. [199]. Since supersymmet-

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

ric loop corrections can contribute an observable shift from the SM predictions, the absence of any significant deviation places useful constraints on the MSSM parameter space [200].

The rare decays $B_s \to \mu^+\mu^-$ and $B_d \to \mu^+\mu^-$ are especially sensitive to supersymmetric loop effects, with some loop contributions scaling as $\tan^6\beta$ when $\tan\beta \gg 1$ [201]. At present, a combination of the measurements of these rare decay modes [202] are in slight tension at the $2\sigma$ level [203] with the predicted SM rates [204]. Such a tension can be resolved by the aforementioned supersymmetric loop effects [201].

The decays $B^\pm \to \tau^\pm\nu_\tau$ and $B \to D^{(*)}\tau^-\overline{\nu}_\tau$ are noteworthy, since in models with extended Higgs sectors such as the MSSM, these processes possess tree-level charged Higgs exchange contributions that can compete with the dominant $W$-exchange. As Section 71 shows, experimental measurements of $B^\pm \to \tau^\pm\nu_\tau$ are currently consistent with SM expectations [205]. The BaBar Collaboration measured values of the rates for $\overline{B} \to D\tau^-\overline{\nu}_\tau$ and $\overline{B} \to D^*\tau^-\overline{\nu}_\tau$ [206] that showed a combined $3.4\sigma$ discrepancy from the SM predictions, which was also not compatible with the Type-II Higgs Yukawa couplings employed by the MSSM. Some subsequent measurements of the LHCb and Belle Collaborations [207] were consistent with the BaBar measurements, although more recent Belle measurements using a semi-leptonic tag are more consistent with SM expectations [208]. The combined difference between the measured and expected values of the $\overline{B} \to D\tau^-\overline{\nu}_\tau$ and $\overline{B} \to D^*\tau^-\overline{\nu}_\tau$ decay rates relative to the corresponding SM values has a significance of about three standard deviations [209]. There are a number of additional anomalies in $B$ decay data that have recently attracted some attention, although at present the observed deviations from SM expectations are mostly at the level of about two to three standard deviations (see, *e.g.*, Ref. [203]).

In summary, although there are a few hints of possible deviations from the SM in $B$ decays, none of the discrepancies by themselves are significant enough to conclusively imply the existence of new physics beyond the SM. The absence of definitive evidence for deviations in various $B$-physics observables from their SM predictions places useful constraints on the MSSM parameter space [120,172,210]. In contrast, if one or more of the $B$ anomalies referred to above were to be experimentally confirmed, it would require require significant modifications to the supersymmetric models treated in this review.

Finally, we note that the constraints from precision electroweak observables (see Sec. 10) and measurements of the $\epsilon'/\epsilon$ anomaly [211], if it persists [212], in the Kaon system are easily accommodated in models of TeV-scale SUSY [213, 214]. Thus, robust regions of the MSSM parameter space, compatible with the results of direct and indirect searches for SUSY, remain viable.

## 89.8 Massive neutrinos in weak-scale SUSY

In the minimal SM and its supersymmetric extension, there are no right-handed neutrinos, and Majorana mass terms for the left-handed neutrinos are absent. However, given the overwhelming evidence for neutrino masses and mixing (see Sec. 14 and Ref. [215]), any viable model of fundamental particles must provide a mechanism for generating neutrino masses [216]. In extended supersymmetric models, various mechanisms exist for producing massive neutrinos [217]. Although one can devise models for generating massive Dirac neutrinos [218], the most common approaches for incorporating neutrino masses are based on $L$-violating supersymmetric extensions of the MSSM, which generate massive Majorana neutrinos. Two classes of $L$-violating supersymmetric models will now be considered.

### 89.8.1 *The supersymmetric seesaw*

Neutrino masses can be incorporated into the SM by introducing SU(3)×SU(2)×U(1) singlet right-handed neutrinos ($\nu_R$) whose mass parameters are very large, typically near the grand unification scale. In addition, one must also include a standard Yukawa couplings between the lepton doublets, the Higgs doublet, and $\nu_R$. The Higgs vacuum expectation value then induces an off-diagonal $\nu_L$–$\nu_R$ mass on the order of the electroweak scale. Diagonalizing the neutrino mass matrix (in the three-generation model) yields three superheavy neutrino states, and three very light neutrino states that are identified with the light neutrinos observed in nature. This is the seesaw mechanism [219].

It is straightforward to construct a supersymmetric generalization of the seesaw model of neutrino masses [220, 221] by promoting the right-handed neutrino field to a superfield $\widehat{N}^c = (\widetilde{\nu}_R\,;\,\nu_R)$. Integrating out the heavy right-handed neutrino supermultiplet yields a new term in the superpotential [cf. Eq. (89.1)] of the form

$$W_{\rm seesaw} = \frac{f}{M_R}(\widehat{H}_U\widehat{L})(\widehat{H}_U\widehat{L})\,, \tag{89.23}$$

where $M_R$ is the mass scale of the right-handed neutrino sector and $f$ is a dimensionless constant. Note that lepton number is broken by two units, which implies that R-parity is conserved. The supersymmetric analogue of the Majorana neutrino mass term in the sneutrino sector leads to sneutrino–antisneutrino mixing phenomena [221, 222].

The SUSY Les Houches Accords [75, 91], mentioned at the end of the introduction to Sec. 89.4, have been extended to the supersymmetric seesaw (and other extensions of the MSSM) in Ref. [223].

### 89.8.2 *R-parity-violating SUSY*

It is possible to incorporate massive neutrinos in renormalizable supersymmetric models while retaining the minimal particle content of the MSSM by relaxing the assumption of R-parity invariance. The most general R-parity-violating (RPV) model involving the MSSM spectrum introduces many new parameters to both the SUSY-conserving and the SUSY-breaking sectors [75, 224]. Each new interaction term violates either $B$ or $L$ conservation. For example, starting from the MSSM superpotential given in Eq. (89.1) [suitably generalized to three generations of quarks, leptons and their superpartners], consider the effect of adding the following new terms:

$$\begin{aligned} W_{\rm RPV} =& (\lambda_L)_{pmn}\widehat{L}_p\widehat{L}_m\widehat{E}^c_n + (\lambda'_L)_{pmn}\widehat{L}_p\widehat{Q}_m\widehat{D}^c_n \\ &+ (\lambda_B)_{pmn}\widehat{U}^c_p\widehat{D}^c_m\widehat{D}^c_n + (\mu_L)_p\widehat{H}_u\widehat{L}_p\,, \end{aligned} \tag{89.24}$$

where $p$, $m$, and $n$ are generation indices, and gauge group indices are suppressed. Eq. (89.24) yields new scalar-fermion Yukawa couplings consisting of all possible combinations involving two SM fermions and one scalar superpartner.

Note that the term in Eq. (89.24) proportional to $\lambda_B$ violates $B$, while the other three terms violate $L$. The $L$-violating term in Eq. (89.24) proportional to $\mu_L$ is the RPV generalization of the $\mu\widehat{H}_u\widehat{H}_d$ term of the MSSM superpotential, in which the $Y = -1$ Higgs/higgsino supermultiplet $\widehat{H}_d$ is replaced by the slepton/lepton supermultiplet $\widehat{L}_p$.

Phenomenological constraints derived from data on various low-energy $B$- and $L$-violating processes can be used to establish limits on each of the coefficients $(\lambda_L)_{pmn}$, $(\lambda'_L)_{pmn}$, and $(\lambda_B)_{pmn}$ taken one at a time [224, 225]. If more than one coefficient is simultaneously non-zero, then the limits are in general more complicated [226]. All possible RPV terms cannot be simultaneously present and unsuppressed; otherwise the proton decay rate would be many orders of magnitude larger than the present experimental bound. One way to avoid proton decay is to impose $B$ or $L$ invariance (either one alone would suffice). Otherwise, one must accept the requirement that certain RPV coefficients must be extremely suppressed.

One particularly interesting class of RPV models is one in which $B$ is conserved, but $L$ is violated. It is possible to enforce baryon number conservation (and the stability of the proton), while allowing for lepton-number-violating interactions by imposing a discrete $\mathbf{Z_3}$ baryon triality symmetry on the low-energy theory [227], in place of the standard $\mathbf{Z_2}$ R-parity. Since the distinction between the Higgs and matter supermultiplets is lost in RPV models where $L$ is violated, the mixing of sleptons and Higgs bosons, the mixing of neutrinos and neutralinos, and the mixing of charged leptons and charginos are now possible, leading to more complicated mass matrices and mass eigenstates than in the MSSM. The treatment of neutrino masses and mixing in this framework can be found, *e.g.*, in Ref. [228].

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

Alternatively, one can consider imposing a lepton parity such that all lepton superfields are odd [227, 229]. In this case, only the $B$-violating term in Eq. (89.24) survives, and $L$ is conserved. Models of this type have been considered in Ref. [230]. Since $L$ is conserved in these models, the mixing of the lepton and Higgs superfields is forbidden. Moreover, neutrino masses (and mixing) are not generated if lepton parity is an exact symmetry. However, one expects that lepton parity cannot be exact due to quantum gravity effects. Remarkably, the standard $\mathbf{Z_2}$ R-parity and the $\mathbf{Z_3}$ baryon triality are stable with respect to quantum gravity effects, as they can be identified as residual discrete symmetries that arise from spontaneously broken non-anomalous gauge symmetries [227].

The symmetries employed above to either remove or suppress R-parity violating operators were flavour independent. In contrast, there exist a number of motivated scenarios based on flavor symmetries that can also yield the suppression as required by the experimental data (e.g., see Ref. [231]).

The supersymmetric phenomenology of the RPV models exhibits features that are distinct from that of the MSSM [224]. The LSP is no longer stable, which implies that not all supersymmetric decay chains must yield missing-energy events at colliders. A comprehensive examination of the phenomenology of the MSSM extended by a single R-parity violating coupling at the unification scale and its implications for LHC searches has been given in Ref. [232]. As an example, the sparticle mass bounds obtained in searches for R-parity-conserving SUSY can be considerably relaxed in certain RPV models due to the absence of large missing transverse momentum signatures [233]. This can alleviate some of the tension with naturalness discussed in Sec. 89.7.1.

Nevertheless, the loss of the missing-energy signature is often compensated by other striking signals (which depend on which R-parity-violating parameters are dominant). For example, supersymmetric particles in RPV models can be singly produced (in contrast to R-parity-conserving models where supersymmetric particles must be produced in pairs). The phenomenology of pair-produced supersymmetric particles is also modified in RPV models due to new decay chains not present in R-parity-conserving SUSY models [224].

In RPV models with lepton number violation (these include weak-scale SUSY models with baryon triality mentioned above), both $\Delta L = 1$ and $\Delta L = 2$ phenomena are allowed, leading to neutrino masses and mixing [234], neutrinoless double-beta decay [235], sneutrino-antisneutrino mixing [236], and resonant $s$-channel production of sneutrinos in $e^+e^-$ collisions [237] and charged sleptons in $p\bar{p}$ and $pp$ collisions [238].

## 89.9 Extensions beyond the MSSM

Extensions of the MSSM have been proposed to solve a variety of theoretical problems. One such problem involves the $\mu$ parameter of the MSSM. Although $\mu$ is a SUSY-*preserving* parameter, it must be of order the effective SUSY-breaking scale of the MSSM to yield a consistent supersymmetric phenomenology [239]. Any natural solution to the so-called $\mu$-problem must incorporate a symmetry that enforces $\mu = 0$ and a small symmetry-breaking parameter that generates a value of $\mu$ that is not parametrically larger than the effective SUSY-breaking scale [240]. A number of proposed mechanisms in the literature (*e.g.*, see Refs. [239–241]) provide concrete examples of a natural solution to the $\mu$-problem of the MSSM.

In extensions of the MSSM, new compelling solutions to the $\mu$-problem are possible. For example, one can replace $\mu$ by the vacuum expectation value of a new SU(3)×SU(2)×U(1) singlet scalar field. This is the NMSSM, which yields phenomena that were briefly discussed in Sections 89.4–89.7. The NMSSM superpotential consists only of trilinear terms whose coefficients are dimensionless. There are some advantages to extending the NMSSM further to the USSM [97] by adding a new broken U(1) gauge symmetry [242], under which the singlet field is charged.

Alternatively, one can consider a generalized version of the NMSSM (called the GNMSSM in Ref. [186]), where all possible renormalizable terms in the superpotential are allowed, which yields new supersymmetric mass terms (analogous to the $\mu$ term of the MSSM). A discussion of the parameters of the GNMSSM can be found in Ref. [75]. Although the GNMSSM does not solve the $\mu$-problem, it does exhibit regions of parameter space in which the degree of fine-tuning is relaxed, as discussed in Sec. 89.7.1.

The generation of the $\mu$ term may be connected with the solution to the strong CP problem [243]. Models of this type, which include new gauge singlet fields that are charged under the Peccei-Quinn (PQ) symmetry [244], were first proposed in Ref. [239]. The breaking of the PQ symmetry is thus intimately tied to SUSY breaking, while naturally yielding a value of $\mu$ that is of order the electroweak symmetry breaking scale [245].

It is also possible to add higher dimensional Higgs multiplets, such as Higgs triplet superfields [246], provided a custodial-symmetric model (in which the $\rho$-parameter of precision electroweak physics is close to 1, see Sec. 10) can be formulated. Such models can provide a rich phenomenology of new signals for future LHC studies.

All supersymmetric models discussed so far in this review possess self-conjugate fermions—the Majorana gluinos and neutralinos. However, it is possible to add additional chiral superfields in the adjoint representation. The spin-1/2 components of these new superfields can pair up with the gauginos to form Dirac gauginos [247,248]. Such states appear in models of so-called supersoft SUSY breaking [249], in some generalized GMSB models [250] and in R-symmetric SUSY [251,252]. Such approaches often lead to improved naturalness and/or significantly relaxed flavor constraints. The implications of models of Dirac gauginos on the observed Higgs boson mass and its properties are addressed in Ref. [253].

For completeness, we briefly note other MSSM extensions considered in the literature. These include an enlarged electroweak gauge group beyond SU(2)×U(1) [254]; and/or the addition of new (possibly exotic) matter supermultiplets such as vector-like fermions and their superpartners [187, 255].

# 90. Supersymmetry, Part II (Experiment)

Revised September 2019 by O. Buchmuller (Imperial Coll. London) and P. de Jong (NIKHEF).

## 90.1 Introduction

Supersymmetry (SUSY), a transformation relating fermions to bosons and vice versa [1–9] is one of the most compelling possible extensions of the Standard Model of particle physics (SM).

On theoretical grounds SUSY is motivated as a generalization of space-time symmetries. A low-energy realization of SUSY, *i.e.*, SUSY at the TeV scale, is, however, not a necessary consequence. Instead, low-energy SUSY is motivated by the possible cancellation of quadratic divergences in radiative corrections to the Higgs boson mass [10–15]. Furthermore, it is intriguing that a weakly interacting, (meta)stable supersymmetric particle might make up some or all of the dark matter in the universe [16–18]. In addition, SUSY predicts that gauge couplings, as measured experimentally at the electroweak scale, unify at an energy scale $\mathcal{O}(10^{16})$ GeV ("GUT scale") near the Planck scale [19–24].

In the minimal supersymmetric extension to the Standard Model, the so called MSSM [11,25,26], a supersymmetry transformation relates every chiral fermion and gauge boson in the SM to a supersymmetric partner with half a unit of spin difference, but otherwise with the same properties (such as mass) and quantum numbers. These are the "sfermions": squarks ($\tilde{q}$) and sleptons ($\tilde{\ell}$, $\tilde{\nu}$), and the "gauginos". The MSSM Higgs sector contains two doublets, for up-type quarks and for down-type quarks and charged leptons respectively. After electroweak symmetry breaking, five Higgs bosons arise, of which two are charged. The supersymmetric partners of the Higgs doublets are known as "higgsinos." The weak gauginos and higgsinos mix, giving rise to charged mass eigenstates called "charginos" ($\tilde{\chi}^{\pm}$), and neutral mass eigenstates called "neutralinos" ($\tilde{\chi}^0$). The SUSY partners of the gluons are known as "gluinos" ($\tilde{g}$). The fact that such particles are not yet observed leads to the conclusion that, if supersymmetry is realized, it is a broken symmetry. A description of SUSY in the form of an effective Lagrangian with only "soft" SUSY breaking terms and SUSY masses at the TeV scale maintains the cancellation of quadratic divergences of soft SUSY breaking scalar mass squared parameters.

The phenomenology of SUSY is to a large extent determined by the SUSY breaking mechanism and the SUSY breaking scale. This determines the SUSY particle masses, the mass hierarchy, the field contents of physical particles, and their decay modes. In addition, phenomenology crucially depends on whether the multiplicative quantum number of R-parity [26], $R = (-1)^{3(B-L)+2S}$, where $B$ and $L$ are baryon and lepton numbers and $S$ is the spin, is conserved or violated. If R-parity is conserved, SUSY particles (sparticles), which have odd R-parity, are produced in pairs and the decays of each SUSY particle must involve an odd number of lighter SUSY particles. The lightest SUSY particle (LSP) is then stable and often assumed to be a weakly interacting massive particle (WIMP). If R-parity is violated, new terms $\lambda_{ijk}$, $\lambda'_{ijk}$ and $\lambda''_{ijk}$ appear in the superpotential, where $ijk$ are generation indices; $\lambda$-type couplings appear between lepton superfields only, $\lambda''$-type are between quark superfields only, and $\lambda'$-type couplings connect the two. R-parity violation implies lepton and/or baryon number violation. More details of the theoretical framework of SUSY are discussed elsewhere in this volume [27].

Today, low-energy data from flavor physics experiments, high-precision electroweak observables as well as astrophysical data impose strong constraints on the allowed SUSY parameter space. Recent examples of such data include measurements of the rare B-meson decay $B_s \to \mu^+\mu^-$ [28,29], measurements of the anomalous magnetic moment of the muon [30], and accurate determinations of the cosmological dark matter relic density constraint [31, 32].

These indirect constraints are often more sensitive to higher SUSY mass scales than experiments searching for direct sparticle production at colliders, but the interpretation of these results is often strongly model dependent. In contrast, direct searches for sparticle production at collider experiments are less subject to interpretation ambiguities and therefore they play a crucial role in the search for SUSY.

The discovery of a Higgs boson with a mass around 125 GeV imposes constraints on SUSY models, which are discussed elsewhere [27, 33].

In this review we limit ourselves to direct searches, covering data analyses at LEP, HERA, the Tevatron and the LHC, with emphasis on the latter. For more details on LEP and Tevatron constraints, see earlier PDG reviews [34].

## 90.2 Experimental search program

The electron-positron collider LEP was operational at CERN between 1989 and 2000. In the initial phase, center-of-mass energies around the $Z$-peak were probed, but after 1995 the LEP experiments collected a significant amount of luminosity at higher center-of-mass energies, some 235 pb$^{-1}$ per experiment at $\sqrt{s} \geq 204$ GeV, with a maximum $\sqrt{s}$ of 209 GeV.

Searches for new physics at $e^+e^-$ colliders benefit from the clean experimental environment and the fact that momentum balance can be measured not only in the plane transverse to the beam, but also in the direction along the beam (up to the beam pipe holes), defined as the longitudinal direction. Searches at LEP are dominated by the data samples taken at the highest center-of-mass energies.

Constraints on SUSY have been set by the CDF and D0 experiments at the Tevatron, a proton-antiproton collider at a center-of-mass energy of up to 1.96 TeV. CDF and D0 collected integrated luminosities between 10 and 11 fb$^{-1}$ each up to the end of collider operations in 2011.

The electron-proton collider HERA provided collisions to the H1 and ZEUS experiments between 1992 and 2007, at a center-of-mass energy up to 318 GeV. A total integrated luminosity of approximately 0.5 fb$^{-1}$ was collected by each experiment. Since at HERA baryons collide with leptons, SUSY searches at HERA typically look for R-parity violating production of single SUSY particles.

The Large Hadron Collider (LHC) at CERN started proton-proton operation at a center-of-mass energy of 7 TeV in 2010. By the end of 2011 the experiments ATLAS and CMS had collected about 5 fb$^{-1}$ of integrated luminosity each, and the LHCb experiment had collected approximately 1 fb$^{-1}$. In 2012, the LHC operated at a center-of-mass energy of 8 TeV, and ATLAS and CMS collected approximately 20 fb$^{-1}$ each, whereas LHCb collected 2 fb$^{-1}$. In 2015, the LHC started Run 2, with a center-of-mass energy of 13 TeV. At the end of Run 2 in November 2018, ATLAS and CMS had both collected approximately 140 fb$^{-1}$, and LHCb had collected almost 6 fb$^{-1}$.

Proton-(anti)proton colliders produce interactions at higher center-of-mass energies than those available at LEP, and cross sections of QCD-mediated processes are larger, which is reflected in the higher sensitivity for SUSY particles carrying color charge: squarks and gluinos. Large background contributions from Standard Model processes, however, pose challenges to the trigger and analysis. Such backgrounds are dominated by multijet production processes, including, particularly at the LHC, those of top quark production, as well as jet production in association with vector bosons. The proton momentum is shared between its parton constituents, and in each collision only a fraction of the total center-of-mass energy is available in the hard parton-parton scattering. Since the parton momenta in the longitudinal direction are not known on an event-by-event basis, use of momentum conservation constraints in an analysis is restricted to the transverse plane, leading to the definition of transverse variables, such as the missing transverse momentum, and the transverse mass. Proton-proton collisions at the LHC differ from proton-antiproton collisions at the Tevatron in the sense that there are no valence anti-quarks in the proton, and that gluon-initiated processes play a more dominant role. The increased center-of-mass energy of the LHC compared to the Tevatron, as well as the increase at the LHC between Run 1 and Run 2, significantly extends the kinematic reach for SUSY searches. This is reflected foremost in the sensitivity for squarks and gluinos, but also for other SUSY particles.

The main production mechanisms of massive colored sparticles at hadron colliders are squark-squark, squark-gluino and gluino-

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

gluino production; when "squark" is used "antisquark" is also implied. Assuming R-parity conservation, the typical SUSY search signature at hadron colliders contains high-$p_{\mathrm{T}}$ jets, which are produced in the decay chains of heavy squarks and gluinos, and significant missing momentum originating from the two LSPs produced at the end of the decay chain, which escape experimental detection. Standard Model backgrounds with missing transverse momentum include leptonic $W/Z$-boson decays, heavy-flavor decays to neutrinos, and multijet events that may be affected by instrumental effects such as jet mismeasurement.

Selection variables designed to separate the SUSY signal from the Standard Model backgrounds include $H_{\mathrm{T}}$, $E_{\mathrm{T}}^{\mathrm{miss}}$, and $m_{\mathrm{eff}}$. The quantities $H_{\mathrm{T}}$ and $E_{\mathrm{T}}^{\mathrm{miss}}$ refer to the measured transverse energy and the missing transverse momentum in the event, respectively. They are usually defined as the scalar sum of the transverse jet momenta or calorimeter clusters transverse energies measured in the event ($H_{\mathrm{T}}$), or the magnitude ($E_{\mathrm{T}}^{\mathrm{miss}}$) of the negative vector sum of transverse momenta of reconstructed objects like jets and leptons in the event ($\vec{p}_{\mathrm{T}}^{\,\mathrm{miss}}$). The quantity $m_{\mathrm{eff}}$ is referred to as the effective mass of the event and is defined as $m_{\mathrm{eff}} = H_{\mathrm{T}} + E_{\mathrm{T}}^{\mathrm{miss}}$. The peak of the $m_{\mathrm{eff}}$ distribution for SUSY signal events correlates with the SUSY mass scale, in particular with the mass difference between the primary produced SUSY particle and the LSP [35], whereas the Standard Model backgrounds dominate at low $m_{\mathrm{eff}}$. Additional reduction of multijet backgrounds can be achieved by demanding isolated leptons or photons in the final states; in such events the lepton or photon transverse momentum may be added to $H_{\mathrm{T}}$ or $m_{\mathrm{eff}}$ for further signal-background separation.

At the LHC, alternative approaches have been developed to increase the sensitivity to pair production of heavy sparticles with TeV-scale masses focusing on the kinematics of their decays, and to further suppress the background from multijet production. Prominent examples of these new approaches are searches using the $\alpha_{\mathrm{T}}$ [36–40], *razor* [41], *stransverse mass* ($m_{\mathrm{T2}}$) [42], and *contransverse mass* ($m_{\mathrm{CT}}$) [43] variables. Recently, the topological event reconstruction methods have expanded with the *super-razor* [44] and *recursive jigsaw reconstruction* [45] techniques. Furthermore, frequently the searches for massive SUSY particles attempt to identify their decay into top quarks or vector bosons, which are themselves unstable. If these are produced with a significant boost, jets from their decay will typically overlap, and such topologies are searched for with *jet-substructure* [46] techniques.

## 90.3 Interpretation of results

Since the mechanism by which SUSY is broken is unknown, a general approach to SUSY via the most general soft SUSY breaking Lagrangian adds a significant number of new free parameters. For the minimal supersymmetric standard model, MSSM, *i.e.*, the model with the minimal particle content, these comprise 105 new real degrees of freedom. A phenomenological analysis of SUSY searches leaving all these parameters free is not feasible. For the practical interpretation of SUSY searches at colliders several approaches are taken to reduce the number of free parameters.

One approach is to assume a SUSY breaking mechanism and lower the number of free parameters through the assumption of additional constraints. Before the start of the LHC, interpretations of experimental results were predominately performed in constrained models of gravity mediated [50, 51], gauge-mediated [52–54], and anomaly mediated [55, 56] SUSY breaking. The most popular model was the constrained MSSM (CMSSM) [50, 57, 58], which in the literature is also referred to as minimal supergravity, or MSUGRA.

These constrained SUSY models are theoretically well motivated and provide a rich spectrum of experimental signatures. However, with universality relations imposed on the soft SUSY breaking parameters, they do not cover all possible kinematic signatures and mass relations of SUSY. In such scenarios the squarks are often nearly degenerate in mass, in particular for the first and second generation. The exclusion of parameter space in the CMSSM and in CMSSM-inspired models is mainly driven by first and second generation squark production together with gluino production. As shown in Fig. 90.1 [47–49] these processes possess

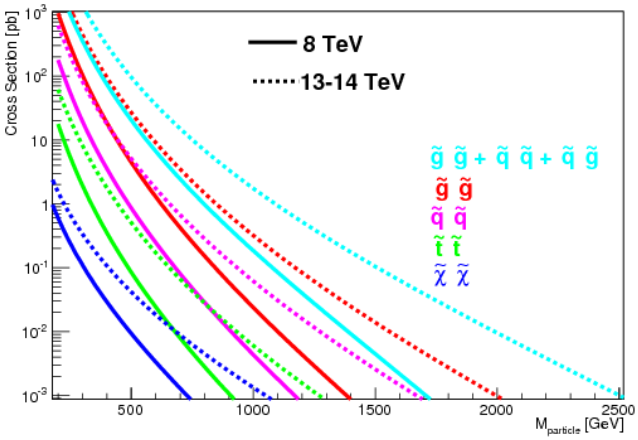

Figure 90.1: Cross sections for pair production of different sparticles as a function of their mass at the LHC for a center-of-mass energy of 8 TeV (solid curves) and 13-14 TeV (dotted curves), taken from Ref. [47]. Typically the production cross section of colored squarks and gluinos, calculated with NLL-FAST [48] at $\sqrt{s}$ =8 and 13 TeV, is several orders of magnitude larger than the one for electroweak gauginos, calculated with Prospino [49] at $\sqrt{s}$ =8 and 14 TeV for higgsino-like neutralinos. Except for the explicitly shown pair production of stops, production cross sections for squarks assumes mass degeneracy of left- and right-handed $u$, $d$, $s$, $c$ and $b$ squarks.

the largest production cross sections in proton-proton collisions, and thus the LHC searches typically provide the tightest mass limits on these colored sparticles. This, however, implies that the allowed parameter space of constrained SUSY models today has been restrained significantly by searches from ATLAS and CMS. Furthermore, confronting the remaining allowed parameter space with other collider and non-collider measurements, which are directly or indirectly sensitive to contributions from SUSY, the overall compatibility of these models with all data is significantly worse than in the pre-LHC era (see section II.8 for further discussion), indicating that very constrained models like the CMSSM are no longer good benchmark scenarios to solely characterize the results of SUSY searches at the LHC.

For these reasons, an effort has been made to complement the traditional constrained models with more flexible approaches.

One approach to study a broader and more comprehensive subset of the MSSM is via the phenomenological-MSSM, or pMSSM [59–61]. It is derived from the MSSM, using experimental data to eliminate parameters that are free in principle but have already been highly constrained by measurements of *e.g.*, flavor mixing and CP-violation. This effective approach reduces the number of free parameters in the MSSM to typically 19 or even less, making it a practical compromise between the full MSSM and highly constrained models such as the CMSSM.

Even less dependent on fundamental assumptions are interpretations in terms of so-called simplified models [62–65]. Such models assume a limited set of SUSY particle production and decay modes and leave open the possibility to vary masses and other parameters freely. Therefore, simplified models enable comprehensive studies of individual SUSY topologies, and are useful for optimization of the experimental searches over a wide parameter space without limitations on fundamental kinematic properties such as masses, production cross sections, and decay modes.

As a consequence, ATLAS and CMS have adopted simplified models as the primary framework to provide interpretations of their searches. In addition to using simplified models that describe prompt decays of SUSY particles, the experiments are now also focusing more on the use of simplified models that allow for decays of long-lived SUSY particles as they can arise in different SUSY scenarios (see Section 90.7 for further discussion). Today, almost every individual search provides interpretations of their results in one or even several simplified models that are characteristic of

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

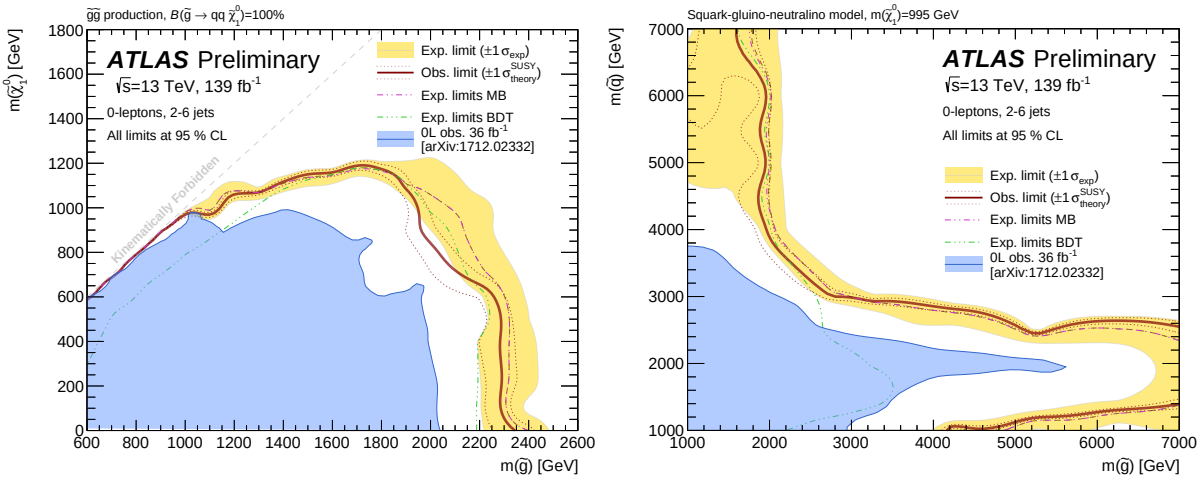

Figure 90.2: Left: lower mass limits, at 95% C.L., on gluino pair production and decay in a simplified model with $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$. Right: 95% C.L. mass limits on gluinos and squarks assuming gluino and squark production, and $m_{\tilde{\chi}_1^0} = 995$ GeV. Results of the ATLAS collaboration.

SUSY topologies probed by the analysis.

However, while these models are very convenient for the interpretation of individual SUSY production and decay topologies, care must be taken when applying these limits to more complex SUSY spectra. Therefore, in practice, simplified model limits are often used as an approximation of the constraints that can be placed on sparticle masses in more complex SUSY spectra. Yet, depending on the assumed SUSY spectrum, the sparticle of interest, and the considered simplified model limit, this approximation can lead to a significant mistake, typically an overestimation, in the assumed constraint on the sparticle mass (see for example [66]). Only on a case-by-case basis can it be determined whether the limit of a given simplified model represents a good approximation of the true underlying constraint that can be applied on a sparticle mass in a complex SUSY spectrum. In the following, we will point out explicitly the assumptions that have entered the limits when quoting interpretations from simplified models.

This review covers results up to September 2019 and since none of the searches performed so far have shown significant excess above the SM background prediction, the interpretation of the presented results are exclusion limits on SUSY parameter space. Unless stated differently, all quoted exclusion limits are at 95% confidence level.

## 90.4 Exclusion limits on gluino and squark masses

Gluinos and squarks are the SUSY partners of gluons and quarks, and thus carry color charge. Limits on squark masses of the order 100 GeV have been set by the LEP experiments [67], in the decay to quark plus neutralino, and for a mass difference between squark and quark plus neutralino of typically at least a few GeV. However, due to the colored production of these particles at hadron colliders (see e.g. Fig. 90.1), hadron collider experiments are able to set much tighter mass limits.

Pair production of these massive colored sparticles at hadron colliders usually involve both the s-channel and t-channel parton-parton interactions. Since there is a negligible amount of bottom and top quark content in the proton, top- and bottom squark production proceeds through s-channel diagrams only. In the past, experimental analyses of squark and/or gluino production typically assumed the first and second generation squarks to be approximately degenerate in mass. However, in order to have even less model dependent interpretations of the searches, the experiments have started to also provide simplified model limits on individual first or second generation squarks.

Assuming R-parity conservation and assuming gluinos to be heavier than squarks, squarks will predominantly decay to a quark and a neutralino or chargino, if kinematically allowed. The decay may involve the lightest neutralino (typically the LSP) or chargino, but, depending on the masses and couplings of the gauginos, may involve heavier neutralinos or charginos. For pair production of first and second generation squarks, the simplest decay modes involve two jets and missing momentum, with potential extra jets stemming from initial state or final state radiation (ISR/FSR) or from decay modes with longer decay chains (cascades). Similarly, gluino pair production leads to four jets and missing momentum, and possibly additional jets from ISR/FSR or cascades. Associated production of a gluino and a (anti-)squark is also possible, in particular if squarks and gluinos have similar masses, typically leading to three or more jets in the final state. In cascades, isolated photons or leptons may appear from the decays of sparticles such as neutralinos or charginos. Final states are thus characterized by significant missing transverse momentum, and at least two, and possibly many more high $p_{\mathrm{T}}$ jets, which can be accompanied by one or more isolated objects like photons or leptons, including $\tau$ leptons, in the final state. Table 90.1 shows a schematic overview of characteristic final state signatures of gluino and squark production for different mass hierarchy hypotheses and assuming decays involving the lightest neutralino.

**Table 90.1:** Typical search signatures at hadron colliders for direct gluino and first- and second-generation squark production assuming different mass hierarchies.

| Mass Hierarchy | Main Production | Dominant Decay | Typical Signature |
|---|---|---|---|
| $m_{\tilde{q}} \ll m_{\tilde{g}}$ | $\tilde{q}\tilde{q}, \tilde{q}\bar{\tilde{q}}$ | $\tilde{q} \to q\tilde{\chi}_1^0$ | $\geq 2$ jets + $E_{\mathrm{T}}^{\mathrm{miss}}$ + X |
| $m_{\tilde{q}} \approx m_{\tilde{g}}$ | $\tilde{q}\tilde{g}, \tilde{q}\bar{\tilde{g}}$ | $\tilde{q} \to q\tilde{\chi}_1^0$ | $\geq 3$ jets + $E_{\mathrm{T}}^{\mathrm{miss}}$ + X |
| | | $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$ | |
| $m_{\tilde{q}} \gg m_{\tilde{g}}$ | $\tilde{g}\tilde{g}$ | $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$ | $\geq 4$ jets + $E_{\mathrm{T}}^{\mathrm{miss}}$ + X |

### 90.4.1 *Exclusion limits on the gluino mass*

Limits set by the Tevatron experiments on the gluino mass assume the framework of the CMSSM, with $\tan\beta = 5$ (CDF) or $\tan\beta = 3$ (D0), where $\tan\beta$ is the ratio of vacuum expectation values of the Higgs fields for up-type and down-type fermions. Furthermore, $A_0 = 0$ and $\mu < 0$ is assumed, and the resulting lower mass limits are about 310 GeV for all squark masses, or 390 GeV for the case $m_{\tilde{q}} = m_{\tilde{g}}$ [68, 69]. These limits have been superseded by those provided by ATLAS and CMS, and the tightest constraints have been set with up to approximately 140 fb$^{-1}$ of data recorded at the LHC at a center-of-mass energy of 13 TeV.

Limits on the gluino mass have been established in the framework of simplified models. Assuming only gluino pair production, in particular three primary decay chains of the gluino have been

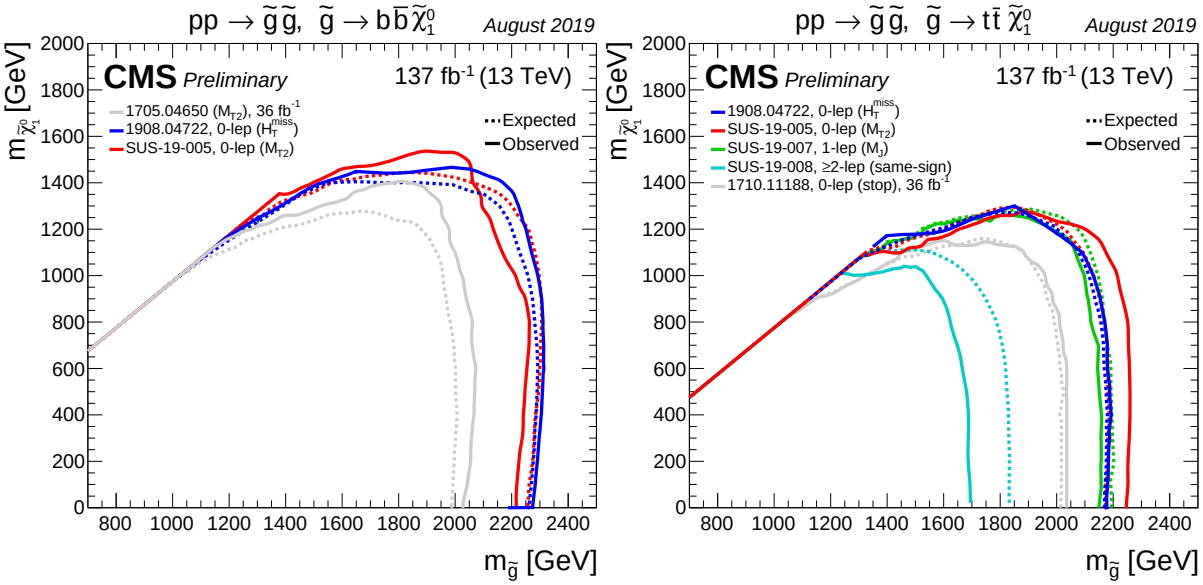

Figure 90.3: Lower mass limits, at 95% C.L., on gluino pair production for various decay chains in the framework of simplified models. Left: $\tilde{g} \to b\bar{b}\tilde{\chi}_1^0$. Right: $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$. Results of the CMS collaboration.

considered by the LHC experiments for interpretations of their search results. The first decay chain $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$ assumes gluino mediated production of first and second generation squarks (on-shell or off-shell) which leads to four light flavor quarks in the final state. Therefore, inclusive all-hadronic analyses searching for multijet plus $E_{\mathrm{T}}^{\mathrm{miss}}$ final states are utilized to put limits on this simplified model. These limits are derived as a function of the gluino and neutralino (LSP) mass. As shown in Fig. 90.2 (left), using the cross section from next-to-leading order QCD corrections and the resummation of soft gluon emission at next-to-leading-logarithmic accuracy as reference [48], the ATLAS collaboration [70] excludes in this simplified model gluino masses below approximately 2.3 TeV, for a massless neutralino. In scenarios where neutralinos are not very light, the efficiency of the analyses is reduced by the fact that jets are less energetic, and there is less missing transverse momentum in the event. This leads to weaker limits when the mass difference $\Delta m = m_{\tilde{g}} - m_{\tilde{\chi}_1^0}$ is reduced. For example, for neutralino masses above about 1.2 TeV no limit on the gluino mass can be set for this decay chain. Therefore, limits on gluino masses are strongly affected by the assumption of the neutralino mass. Similar results for this simplified model have been obtained by CMS [71].

The second important decay chain of the gluino considered for interpretation in a simplified model is $\tilde{g} \to b\bar{b}\tilde{\chi}_1^0$. Here the decay is mediated via bottom squarks and thus leads to four jets from $b$ quarks and $E_{\mathrm{T}}^{\mathrm{miss}}$ in the final state. Also for this topology inclusive all-hadronic searches provide the highest sensitivity. However, with four $b$ quarks in the final state, the use of secondary vertex reconstruction for the identification of jets originating from $b$ quarks provides a powerful handle on the SM background. Therefore, in addition to a multijet plus $E_{\mathrm{T}}^{\mathrm{miss}}$ signature these searches also require several jets to be tagged as $b$-jets. As shown in Fig. 90.3 (left), for this simplified model CMS [71] excludes gluino masses below $\approx 2.3$ TeV for a massless neutralino, while for neutralino masses above $\approx 1.5$ TeV no limit on the gluino mass can be set. Comparable limits for this simplified model are provided by searches from ATLAS [72].

Gluino decays are not limited to first and second generation squarks or bottom squarks; if kinematically allowed, decays to top squarks via $\tilde{g} \to \tilde{t}t$ are also possible. This leads to a "four tops" final state $tttt\tilde{\chi}_1^0\tilde{\chi}_1^0$ and defines the third important simplified model, $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$, characterizing gluino pair production. The topology of this decay is very rich in different experimental signatures: as many as four isolated leptons, four $b$-jets, several light flavor quark jets, and significant missing momentum from the neutrinos in the $W$ decay and from the two neutralinos. As shown in Fig. 90.3 (right), the CMS search based on the $m_{\mathrm{T2}}$ variable [73] rules out gluinos with masses below $\approx 2.25$ TeV for massless neutralinos in this model. For neutralino masses above $\approx 1.3$ TeV, no limit can be placed on the gluino mass. The ATLAS multiple b-jets search [72] obtains similar limits.

The ATLAS collaboration also provides limits in a pMSSM-inspired model with only gluinos and first and second generation squarks, and a bino-like $\tilde{\chi}_1^0$ [70]. As shown in Fig. 90.2 (right), assuming $m_{\tilde{\chi}_1^0} = 995$ GeV, gluinos with masses below $\approx 1.6$ TeV are excluded for any squark mass. For $m_{\tilde{q}} \approx m_{\tilde{g}}$, the mass exclusion is about 3.0 TeV. The dependence of these limits on $m_{\tilde{\chi}_1^0}$ is illustrated in Ref. [70]. For massless $\tilde{\chi}_1^0$, gluino masses below 2.2 TeV are excluded for all squark masses.

R-parity violating gluino decays are searched for in a number of final states. Searches in multilepton final states set lower mass limits of 1 to 1.4 TeV, depending on neutralino mass and lepton flavor, on decays mediated by $\lambda$ and $\lambda'$ couplings [74–78], assuming prompt decays. Searches for displaced vertices are sensitive to non-prompt decays [79–82]. Multijet final states have been used to search for fully hadronic gluino decays involving $\lambda''$, by CDF [83], ATLAS [79, 84–86] and CMS [87–89]. Lower gluino mass limits range between 600 and 2000 GeV depending on neutralino mass and flavor content of the final state.

### 90.4.2 *Exclusion limits on squark masses*

Limits on first and second generation squark masses set by the Tevatron experiments assume the CMSSM, and amount to lower limits of about 380 GeV for all gluino masses, or 390 GeV for the case $m_{\tilde{q}} = m_{\tilde{g}}$ [68, 69].

At the LHC, limits on squark masses have been set using up to approximately 140 fb$^{-1}$ of data at 13 TeV. Interpretations in simplified models typically characterize squark pair production with only one decay chain of $\tilde{q} \to q\tilde{\chi}_1^0$. Here it is assumed that the left and right-handed $\tilde{u}$, $\tilde{d}$, $\tilde{s}$ and $\tilde{c}$ squarks are degenerate in mass. Furthermore, it is assumed that the mass of the gluino is very high and thus contributions of the corresponding t-channel diagrams to squark pair production are negligible. Therefore, the total production cross section for this simplified model is eight times the production cross section of an individual squark (e.g. $\tilde{u}_L$). Under these assumptions, ATLAS obtains a lower squark mass limit of $\approx 1.9$ TeV for light neutralinos [70], as shown in Fig. 90.4 (left). The effects of heavy neutralinos on squark limits are similar to those discussed in the gluino case (see Section 90.4.1), and only for neutralino masses below $\approx 800$ GeV can any squark masses

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

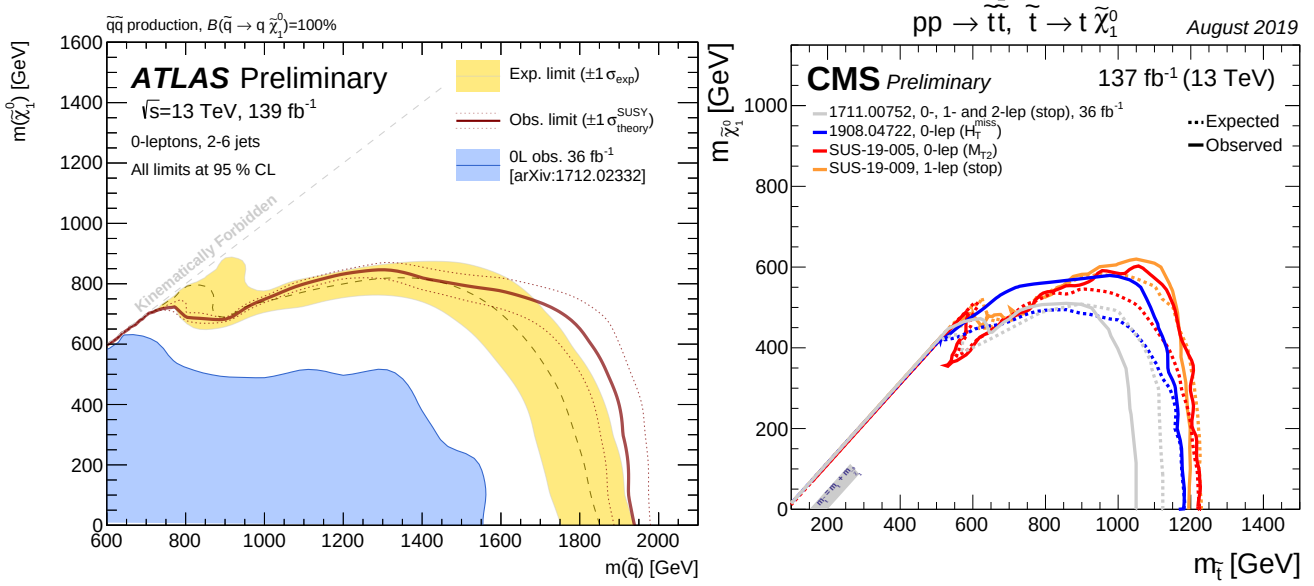

Figure 90.4: Left: 95% C.L. exclusion contours in the squark-neutralino mass plane defined in the framework of simplified models assuming a single decay chain of $\tilde{q} \to q\tilde{\chi}_1^0$, obtained by ATLAS. Right: the 95% C.L. exclusion contours in the stop-neutralino mass plane defined in the framework of a simplified model assuming a single decay chain of $\tilde{t} \to t\tilde{\chi}_1^0$ as obtained by CMS.

be excluded.

For the same analysis ATLAS also provides an interpretation of their search result in the aforementioned pMSSM-inspired model with only gluinos and first and second generation squarks, and a bino-like $\tilde{\chi}_1^0$ [70], as shown in Fig. 90.2 (right). In this model, squark production can take place with non-decoupled gluinos, enhancing the squark production cross section through gluino exchange diagrams.

If the assumption of mass degenerate first and second generation squarks is dropped and only the production of a single light squark is assumed, the limits weaken significantly. For example, the CMS limit on degenerate squarks of 1750 GeV for light neutralinos drops to $\approx$ 1300 GeV for pair production of a single light squark, and for neutralinos heavier than $\approx$ 600 GeV no squark mass limit can be placed [73]. It should be noted that this limit is not a result of a simple scaling of the above mentioned mass limits assuming eightfold mass degeneracy but it also takes into account that for an eight times lower production cross section the analyses must probe kinematic regions of phase space that are closer to the ones of SM background production. Since signal acceptance and the ratio of expected signal to SM background events of the analyses are typically worse in this region of phase space not only the 1/8 reduction in production cross section but also a worse analysis sensitivity are responsible for the much weaker limit on single squark pair production.

For single light squarks ATLAS also reports results of a dedicated search for pair production of scalar partners of charm quarks [90]. Assuming that the scalar-charm state exclusively decays into a charm quark and a neutralino, scalar-charm masses up to 800 GeV are excluded for neutralino masses below 260 GeV.

Besides placing stringent limits on first and second generation squark masses, the LHC experiments also search for the production of third generation squarks. SUSY at the TeV-scale is often motivated by naturalness arguments, most notably as a solution to cancel quadratic divergences in radiative corrections to the Higgs boson mass. In this context, the most relevant terms for SUSY phenomenology arise from the interplay between the masses of the third generation squarks and the Yukawa coupling of the top quark to the Higgs boson. This motivates a potential constraint on the masses of the top squarks and the left-handed bottom squark. Due to the large top quark mass, significant mixing between $\tilde{t}_L$ and $\tilde{t}_R$ is expected, leading to a lighter mass state $\tilde{t}_1$ and a heavier mass state $\tilde{t}_2$. In the MSSM, the lightest top squark ($\tilde{t}_1$) can be the lightest squark.

Bottom squarks are expected to decay predominantly to $b\tilde{\chi}^0$ giving rise to the characteristic multi $b$-jet and $E_T^{miss}$ signature. Direct production of bottom squark pairs has been searched for at the Tevatron and at the LHC. Limits from the Tevatron are $m_{\tilde{b}} > 247$ GeV for a massless neutralino [91] [92]. The LHC experiments have surpassed these limits, and the latest results are based on up to 140 fb$^{-1}$ of data collected at $\sqrt{s} = 13$ TeV. CMS has set a lower limit of $m_{\tilde{b}} >\approx 1250$ GeV for massless neutralinos in this model [73]. For $m_{\tilde{\chi}_1^0} \approx 700$ GeV or higher no limit can be placed on direct bottom squark pair production in this simplified model. Limits from ATLAS are comparable [93]. Further bottom squark decay modes have also been searched for by ATLAS [94,95] and CMS [71,76,96].

The top squark decay modes depend on the SUSY mass spectrum, and on the $\tilde{t}_L$-$\tilde{t}_R$ mixture of the top squark mass eigenstate. If kinematically allowed, the two-body decays $\tilde{t} \to t\tilde{\chi}^0$ (which requires $m_{\tilde{t}} - m_{\tilde{\chi}^0} > m_t$) and $\tilde{t} \to b\tilde{\chi}^{\pm}$ (which requires $m_{\tilde{t}} - m_{\tilde{\chi}^{\pm}} > m_b$) are expected to dominate. If not, the top squark decay may proceed either via the two-body decay $\tilde{t} \to c\tilde{\chi}^0$ or through $\tilde{t} \to bf\bar{f}'\tilde{\chi}^0$ (where $f$ and $\bar{f}'$ denote a fermion-antifermion pair with appropriate quantum numbers). For $m_{\tilde{t}} - m_{\tilde{\chi}^0} > m_b$ the latter decay chain represents a four-body decay with a $W$ boson, charged Higgs $H$, slepton $\tilde{\ell}$, or light flavor squark $\tilde{q}$, exchange. If the exchanged $W$ boson and/or sleptons are kinematically allowed to be on-shell ($(m_{\tilde{t}} - m_{\tilde{\chi}^{\pm}}) > (m_b + m_W)$ and/or $(m_{\tilde{t}} - m_{\tilde{\ell}}) > m_b$), the three-body decays $\tilde{t} \to Wb\tilde{\chi}^0$ and/or $\tilde{t} \to bl\tilde{\ell}$ will become dominant. For further discussion on top squark decays see for example Ref. [97].

Limits from LEP on the $\tilde{t}_1$ mass are $m_{\tilde{t}} > 96$ GeV in the charm plus neutralino final state, and $> 93$ GeV in the lepton, b-quark and sneutrino final state [67].

The Tevatron experiments have performed a number of searches for top squarks, often assuming direct pair production. In the $b\ell\tilde{\nu}$ decay channel, and assuming a 100% branching fraction, limits are set as $m_{\tilde{t}} > 210$ GeV for $m_{\tilde{\nu}} < 110$ GeV and $m_{\tilde{t}} - m_{\tilde{\nu}} > 30$ GeV, or $m_{\tilde{t}} > 235$ GeV for $m_{\tilde{\nu}} < 50$ GeV [98] [99]. In the $\tilde{t} \to c\tilde{\chi}_1^0$ decay mode, a top squark with a mass below 180 GeV is excluded for a neutralino lighter than 95 GeV [100] [101]. In both analyses, no limits on the top squark can be set for heavy sneutrinos or neutralinos. In the $\tilde{t} \to b\tilde{\chi}_1^{\pm}$ decay channel, searches for a relatively light top squark have been performed in the dilepton final state [102] [103]. The CDF experiment sets limits in the $\tilde{t} - \tilde{\chi}_1^0$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

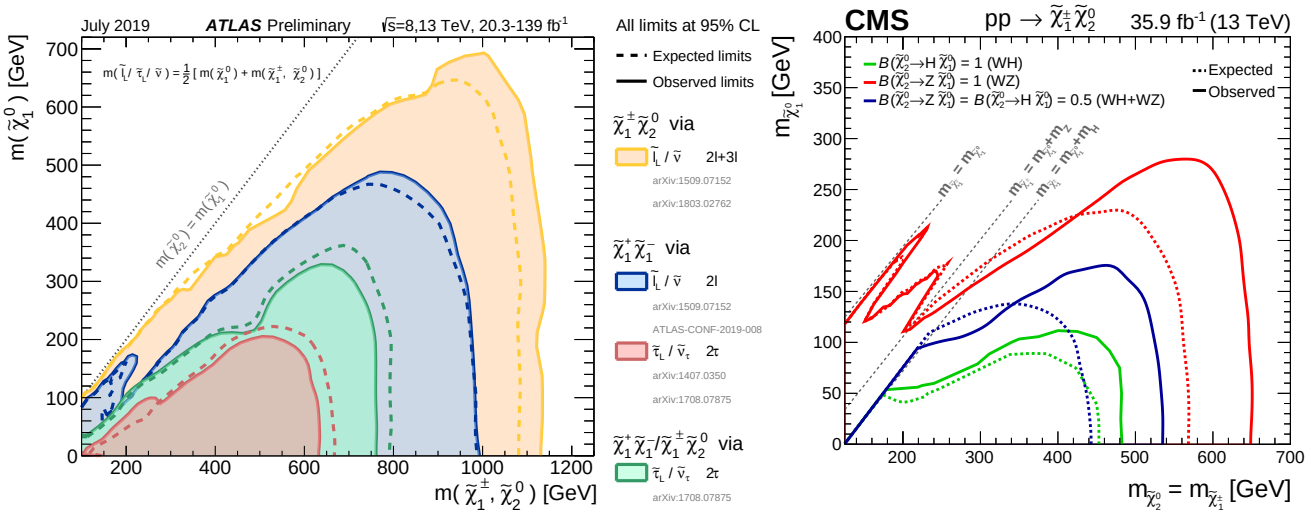

Figure 90.5: LHC exclusion limits on chargino and neutralino masses in a number of simplified models. Left: limits on chargino and neutralino masses for pair production of charginos, pair production of heavier neutralinos, or pair production of chargino and neutralino, under the assumption of light sleptons mediating the decays. Right: limits on chargino and neutralino masses for pair production of chargino and neutralino, under the assumption of decoupled sleptons, and chargino/neutralino decay through $W^*$, $Z^*$ or $H$.

mass plane for various branching fractions of the chargino decay to leptons and for two value of $m_{\tilde{\chi}_1^\pm}$. For $m_{\tilde{\chi}_1^\pm} = 105.8$ GeV and $m_{\tilde{\chi}_1^0} = 47.6$ GeV, top squarks between 128 and 135 GeV are excluded for $W$-like leptonic branching fractions of the chargino.

The LHC experiments have improved these limits substantially. As shown in the right plot of Fig. 90.4, limits on the top squark mass assuming a simplified model with a single decay chain of $\tilde{t} \to t\tilde{\chi}_1^0$ now surpass 1 TeV. The most important searches for this top squark decay topology are dedicated searches requiring zero or one isolated lepton, modest $E_{\mathrm{T}}^{\mathrm{miss}}$, and four or more jets out of which at least one jet must be reconstructed as a $b$-jet [71,73,104–106]. For example, CMS excludes top squarks with masses below about 1200 GeV in this model for massless neutralinos, while for $m_{\tilde{\chi}_1^0} > 600$ GeV no limits can be provided.

Assuming that the top squark decay exclusively proceeds via the chargino mediated decay chain $\tilde{t} \to b\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^{\pm(*)}\tilde{\chi}_1^0$ yields stop mass exclusion limits that vary strongly with the assumptions made on the $\tilde{t} - \tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ mass hierarchy. For example, for $m_{\tilde{\chi}_1^\pm} = (m_{\tilde{t}} + m_{\tilde{\chi}_1^0})/2$, a stop mass below $\approx 1150$ GeV for a light $\tilde{\chi}_1^0$ is excluded, while no limit can be placed for $m_{\tilde{\chi}_1^0} > 550$ GeV [104]. These limits, however, can weaken significantly when other assumptions about the mass hierarchy or the decay of the charginos are imposed [104,106–108].

If the decays $\tilde{t} \to t\tilde{\chi}_1^0$ and $\tilde{t} \to b\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^{\pm(*)}\tilde{\chi}_1^0$ are kinematically forbidden, the decay chains $\tilde{t} \to Wb\tilde{\chi}^0$ and $\tilde{t} \to c\tilde{\chi}^0$ can become important. The one-lepton ATLAS search provides for the kinematic region $m_{\tilde{t}} - m_{\tilde{\chi}^\pm} > m_b + m_W$ lower limits on the top squark mass of $\approx 700$ GeV for a neutralino lighter than $\approx 570$ GeV [109]. Other analyses with zero, one or two leptons also target this kinematic region [105,106,110–114].

For the kinematic region in which even the production of real $W$ bosons is not allowed, ATLAS and CMS improve the Tevatron limit on $\tilde{t} \to c\tilde{\chi}^0$ substantially. Based on a monojet analysis [115] ATLAS excludes top squark masses below $m_{\tilde{\chi}_1^0} \approx 450$ GeV along the kinematic boundary for the $\tilde{t} \to c\tilde{\chi}^0$ decay. A dedicated analysis for $\tilde{t} \to c\tilde{\chi}^0$ excludes stop masses below 500 GeV for $m_{\tilde{\chi}_1^0}$ below 420 GeV [90]. The CMS collaboration uses the hadronic searches [111,113] to place constraints on this particular stop decay and excludes $m_{\tilde{t}} \approx 550$ GeV for $m_{\tilde{\chi}_1^0}$ below 450 GeV. The exclusion at $m_{\tilde{t}} \approx m_{\tilde{\chi}_1^0}$ is also about 550 GeV.

The other decay chain relevant in this phase region is $\tilde{t} \to bf\bar{f}'\tilde{\chi}^0$. Here the ATLAS one-lepton [106] and two-lepton [110] searches exclude up to $m_{\tilde{t}} \approx 440$ GeV for $m_{\tilde{\chi}_1^0}$ below 340 GeV, while the monojet analysis [115] excludes at the kinematic boundary top squarks below 400 GeV. As for the $\tilde{t} \to c\tilde{\chi}^0$ decay, CMS uses the zero-lepton searches [111,113] to also place constraints on $\tilde{t} \to bf\bar{f}'\tilde{\chi}^0$. Also in this case CMS excludes $m_{\tilde{t}} \approx 550$ GeV for $m_{\tilde{\chi}_1^0}$ below 450 GeV.

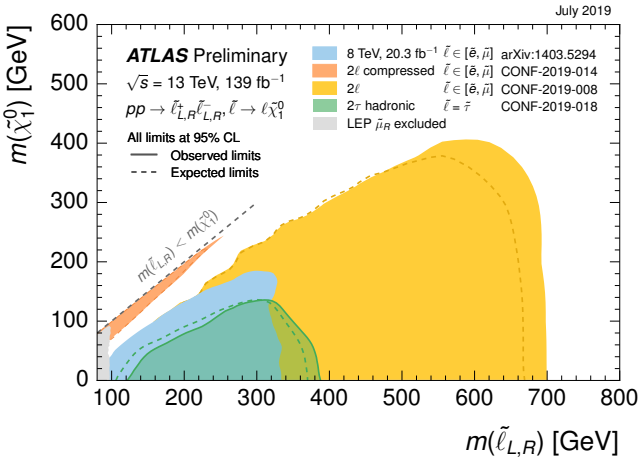

Figure 90.6: LHC exclusion limits on slepton (selectron and smuon) masses, assuming equal masses of selectrons and smuons, degeneracy of $\tilde{\ell}_{\mathrm{L}}$ and $\tilde{\ell}_{\mathrm{R}}$, and a 100% branching fraction for $\tilde{\ell} \to \ell\tilde{\chi}_1^0$.

In general, the variety of top squark decay chains in the phase space region where $\tilde{t} \to t\tilde{\chi}_1^0$ is kinematically forbidden represents a challenge for the experimental search program and more data and refined analyses will be required to further improve the sensitivity in this difficult but important region of SUSY parameter space.

R-parity violating production of single squarks via a $\lambda'$-type coupling has been studied at HERA. In such models, a lower limit on the squark mass of the order of 275 GeV has been set for electromagnetic-strength-like couplings $\lambda' = 0.3$ [116]. At the LHC, both prompt [75,78,117] and non-prompt [80,118] R-parity violating squark decays have been searched for, but no signal was found. Squark mass limits are very model-dependent.

R-parity violating production of single top squarks has been

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

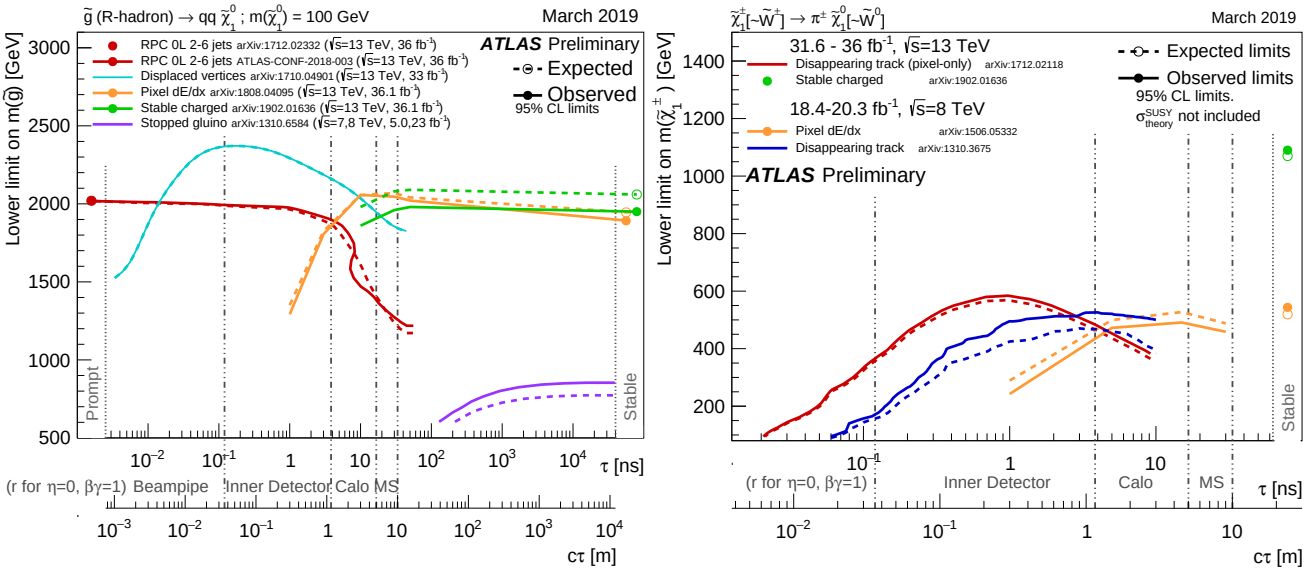

Figure 90.7: Limits at 95% C.L. on the gluino mass in R-hadron models (left), and on the chargino mass in a model where the wino-like chargino is almost degenerate with the LSP (right), as a function of gluino or chargino lifetime, as obtained by ATLAS.

searched for at LEP, HERA, and the Tevatron. For example, an analysis from the ZEUS collaboration [119] makes an interpretation of its search result assuming top squarks to be produced via a $\lambda'$ coupling and decay either to $b\tilde{\chi}_1^{\pm}$ or R-parity-violating to a lepton and a jet. Limits are set on $\lambda'_{131}$ as a function of the top squark mass in an MSSM framework with gaugino mass unification at the GUT scale.

The search for top squark pair production in the context of R-parity violating supersymmetry has now also become a focus point for searches at the LHC. CMS and ATLAS have performed searches for top squarks using a variety of multilepton final states [75, 120]. The $\lambda'$-mediated top squark decay $\tilde{t} \to b\ell$ has been studied by ATLAS for prompt decays [121], and by ATLAS and CMS for non-prompt decays [122–124], setting limits up to 1.4 – 1.6 TeV in simplified models for this mode. CMS also searched for the $\lambda'$-mediated decay $\tilde{t} \to b\ell qq$, setting lower stop mass limits of 890 GeV ($e$) or 1000 GeV ($\mu$) [125]. The fully hadronic R-parity violating top squark decays $\tilde{t} \to bs$, $\tilde{t} \to ds$, and $\tilde{t} \to bd$, involving $\lambda''$, have been searched for by ATLAS [75, 79, 94, 126], and CMS [127, 128], and lower top squark mass limits up to 610 GeV were set.

It should be noted that limits discussed in this section belong to different top and bottom squark decay channels, different sparticle mass hierarchies, and different simplified decay scenarios. Therefore, care must be taken when interpreting these limits in the context of more complete SUSY models.

### 90.4.3 *Summary of exclusion limits on squarks and gluinos assuming R-Parity conservation*

A summary of the most important squark and gluino mass limits for different interpretation approaches assuming R-parity conservation is shown in Table 90.2.

For gluino masses rather similar limits of about 2.3 TeV are obtained from different model assumptions, indicating that the LHC is indeed probing direct gluino production at the TeV scale and beyond. However, for neutralino masses above approximately 1 to 1.4 TeV, in the best case scenarios, ATLAS and CMS searches do not place any limits on the gluino mass.

Limits on direct squark production, on the other hand, depend strongly on the chosen model. Especially for direct production of top squarks there are still large regions in parameter space where masses below 1 TeV cannot be excluded. This is also true for first and second generation squarks when only one single squark is considered. Furthermore, for neutralino masses above $\approx 500$ GeV no limits on any direct squark production scenario are placed by the LHC.

## 90.5 Exclusion limits on the masses of charginos and neutralinos

Charginos and neutralinos result from mixing of the charged wino and higgsino states, and the neutral bino, wino and higgsino states, respectively. The mixing is determined by a limited number of parameters. For charginos these are the wino mass parameter $M_2$, the higgsino mass parameter $\mu$, and $\tan\beta$, and for neutralinos these are the same parameters plus the bino mass parameter $M_1$. If any of the parameters $M_1$, $M_2$ or $\mu$ happened to be substantially smaller than the others, the chargino/neutralino composition would be dominated by specific states, which are referred to as bino-like ($M_1 \ll M_2, \mu$), wino-like ($M_2 \ll M_1, \mu$), or higgsino-like ($\mu \ll M_1, M_2$). If gaugino mass unification at the GUT scale is assumed, a relation between $M_1$ and $M_2$ at the electroweak scale follows: $M_1 = 5/3 \tan^2\theta_W M_2 \approx 0.5 M_2$, with $\theta_W$ the weak mixing angle. Charginos and neutralinos carry no color charge.

### 90.5.1 *Exclusion limits on chargino masses*

If kinematically allowed, two body decay modes such as $\tilde{\chi}^{\pm} \to \tilde{f}\bar{f}'$ (including $\ell\tilde{\nu}$ and $\tilde{\ell}\nu$) are dominant. If not, three body decays $\tilde{\chi}^{\pm} \to f\bar{f}'\tilde{\chi}^0$, mediated through virtual $W$ bosons or sfermions, become dominant. If sfermions are heavy, the $W$ mediation dominates, and $f\bar{f}'$ are distributed with branching fractions similar to $W$ decay products (barring phase space effects for small mass gaps between $\tilde{\chi}^{\pm}$ and $\tilde{\chi}^0$). If, on the other hand, sleptons are light enough to play a significant role in the decay, leptonic final states will be enhanced.

At LEP, charginos have been searched for in fully-hadronic, semi-leptonic and fully leptonic decay modes [129] [130]. A general lower limit on the lightest chargino mass of 103.5 GeV is derived, except in corners of phase space with low electron sneutrino mass, where destructive interference in chargino production, or two-body decay modes, play a role. The limit is also affected if the mass difference between $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_1^0$ is small; dedicated searches for such scenarios set a lower limit of 92 GeV.

At the Tevatron, charginos have been searched for via associated production of $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0$ [131] [132]. Decay modes involving multilepton final states provide the best discrimination against the large multijet background. Analyses have looked for at least three charged isolated leptons, for two leptons with missing transverse momentum, or for two leptons with the same charge. Depending on the $(\tilde{\chi}_1^{\pm} - \tilde{\chi}_1^0)$ and/or $(\tilde{\chi}_2^0 - \tilde{\chi}_1^0)$ mass differences, leptons may be soft.

At the LHC, the search strategy is similar to that at the Teva-

tron. As shown in Fig. 90.1, the cross section of pair production of electroweak gauginos at the LHC, for masses of several hundreds of GeV, is at least two orders of magnitude smaller than for colored SUSY particles (e.g. top squark pair production). For this reason a large data sample is required to improve the sensitivity of LEP and Tevatron searches for direct chargino/neutralino production. With the full LHC Run 1 and Run 2 data sets, ATLAS and CMS have surpassed the limits from LEP and Tevatron in regions of SUSY parameter space.

Chargino pair production is searched for in the dilepton plus missing momentum final state. In a simplified model interpretation of the results, assuming mediation of the chargino decay by light sleptons ($\tilde{e}$ and $\tilde{\mu}$), ATLAS [133] and CMS [134] set limits on the chargino mass up to 1 TeV for massless LSPs, but no limits on the chargino mass can be set for $\tilde{\chi}_1^0$ heavier than 480 GeV. Limits are fairly robust against variation of the slepton mass, unless the mass gap between chargino and slepton becomes small. For decays mediated through $\tilde{\tau}$ or $\tilde{\nu}_\tau$, limits of 630 GeV are set by ATLAS [135] for LSPs not heavier than 200 GeV. The CMS experiment provides similar limits [136]. ATLAS also sets limits on charginos decaying via a $W$ boson [133]: chargino masses below 420 GeV are excluded for massless LSPs, but no limits are set for LSPs heavier than 120 GeV.

The trilepton plus missing momentum final state is used to set limits on $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ production, assuming wino-like $\tilde{\chi}^\pm$ and $\tilde{\chi}_2^0$, bino-like $\tilde{\chi}_1^0$, and $m_{\tilde{\chi}^\pm} = m_{\tilde{\chi}_2^0}$, leaving $m_{\tilde{\chi}^\pm}$ and $m_{\tilde{\chi}_1^0}$ free. Again, the branching fraction of leptonic final states is determined by the slepton masses. If the decay is predominantly mediated by a light $\tilde{\ell}_\mathrm{L}$, i.e. $\tilde{\ell}_\mathrm{R}$ is assumed to be heavy, the three charged-lepton flavors will be produced in equal amounts. It is assumed that $\tilde{\ell}_\mathrm{L}$ and sneutrino masses are equal, and diagrams with sneutrinos are included. In this scenario, ATLAS [137] and CMS [138] exclude chargino masses below 1140 GeV for massless LSPs; no limits are set for LSP masses above 700 GeV. If the decay is dominated by a light $\tilde{\ell}_\mathrm{R}$, the chargino cannot be a pure wino but needs to have a large higgsino component, preferring the decays to tau leptons. Limits are set in various scenarios. If, like for $\tilde{\ell}_\mathrm{L}$, a flavor-democratic scenario is assumed, CMS sets limits of 1060 GeV on the chargino mass for massless LSPs, but under the assumption that both $\tilde{\chi}^\pm$ and $\tilde{\chi}_2^0$ decay leads to tau leptons in the final state, the chargino mass limit deteriorates to 620 GeV for massless LSPs [138]. ATLAS assumes a simplified model in which staus are significantly lighter than the other sleptons in order to search for a similar multi-tau final state, and sets a lower limit on the chargino mass of 760 GeV in this model [135]. The CMS experiment provides similar limits [136].

If sleptons are heavy, the chargino is assumed to decay to a $W$ boson plus LSP, and the $\tilde{\chi}_2^0$ into $Z$ plus LSP or $H$ plus LSP. In the $WZ$ channel, ATLAS [137, 139] and CMS [140] limits on the chargino mass reach 650 GeV for massless LSPs, but no limits are set for LSPs heavier than 300 GeV. In the $WH$ channel, for $m_H$ = 125 GeV and using various Higgs decay modes, ATLAS [141–143] and CMS [140] set lower limits on the chargino mass up to 740 GeV for massless LSPs, but vanish for LSP masses above 240 GeV.

The results on electroweak gaugino searches interpreted in sim-

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

plified models are summarized in Fig. 90.5 for the two cases of light or decoupled sleptons. For both cases, ATLAS and CMS have comparable limits.

In both the wino region (a characteristic of anomaly-mediated SUSY breaking models) and the higgsino region of the MSSM, the mass splitting between $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^0$ is small. The chargino decay products are very soft and may escape detection. These compressed spectra are hard to detect, and have triggered dedicated search strategies. ATLAS has performed a search for charginos and neutralinos in a compressed mass spectrum using initial state radiation [144]. For wino-like charginos, assuming degenerate $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$, exclusion contours in the chargino-mass versus $\Delta m(\tilde{\chi}_1^\pm - \tilde{\chi}_1^0)$ plane are derived. As an example, such charginos are excluded below 200 GeV for $\Delta m(\tilde{\chi}_1^\pm - \tilde{\chi}_1^0) = 10$ GeV. CMS has searched for chargino-pair production through vector-boson-fusion [145], also targetting compressed mass spectra. Assuming degenerate $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$, charginos with a mass below 112 GeV are excluded for $\Delta m(\tilde{\chi}_1^\pm - \tilde{\chi}_1^0) = 1$ GeV. CMS has published further searches for such compressed spectra with soft leptons [146] or a soft tau lepton [147].

### 90.5.2 *Exclusion limits on neutralino masses*

In a considerable part of the MSSM parameter space, and in particular when demanding that the LSP carries no electric or color charge, the lightest neutralino $\tilde{\chi}_1^0$ is the LSP. If R-parity is conserved, such a $\tilde{\chi}_1^0$ is stable. Since it is weakly interacting, it will typically escape detectors unseen. Limits on the invisible width of the $Z$ boson apply to neutralinos with a mass below 45.5 GeV, but depend on the $Z$-neutralino coupling. Such a coupling could be small or even absent; in such a scenario there is no general lower limit on the mass of the lightest neutralino [148]. In models with gaugino mass unification and sfermion mass unification at the GUT scale, a lower limit on the neutralino mass is derived from limits from direct searches, notably for charginos and sleptons, and amounts to 47 GeV [149]. Assuming a constrained model like the CMSSM, this limit increases to 50 GeV at LEP; however the strong constraints now set by the LHC increase such CMSSM-derived $\tilde{\chi}_1^0$ mass limits to well above 200 GeV [150–152].

In gauge-mediated SUSY breaking models (GMSB), the LSP is typically a gravitino, and the phenomenology is determined by the nature of the next-to-lightest supersymmetric particle (NLSP). A NLSP neutralino will decay to a gravitino and a SM particle whose nature is determined by the neutralino composition. Final states with two high $p_{\mathrm{T}}$ photons and missing momentum are searched for, and interpreted in gauge mediation models with bino-like neutralinos [153–158].

Assuming the production of at least two neutralinos per event, neutralinos with large non-bino components can also be searched for by their decay in final states with missing momentum plus any two bosons out of the collection $\gamma, Z, H$. A number of searches at the LHC have tried to cover the rich phenomenology of the various $Z$ and $H$ decay modes [74, 96, 138, 140, 142, 156, 159–165].

Heavier neutralinos, in particular $\tilde{\chi}_2^0$, have been searched for in their decays to the lightest neutralino plus a $\gamma$, a $Z$ boson or a Higgs boson. Limits on electroweak production of $\tilde{\chi}_2^0$ plus $\tilde{\chi}_1^\pm$ from trilepton analyses have been discussed in the section on charginos; the assumption of equal mass of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ make the limits on chargino masses apply to $\tilde{\chi}_2^0$ as well. Multilepton analyses have also been used to set limits on $\tilde{\chi}_2^0\tilde{\chi}_3^0$ production; assuming equal mass and decay through light sleptons, limits are set up to 680 GeV for massless LSPs [166]. Again, compressed spectra with small mass differences between the heavier neutralinos and the LSP form the most challenging region.

In $\tilde{\chi}_2^0$ decays to $\tilde{\chi}_1^0$ and a lepton pair, the lepton pair invariant mass distribution may show a structure that can be used to measure the $\tilde{\chi}_2^0 - \tilde{\chi}_1^0$ mass difference in case of a signal [35]. This structure, however, can also be used in the search strategy itself, as demonstrated by ATLAS [167, 168] and CMS [96, 169].

In models with R-parity violation, the lightest neutralino can decay even if it is the lightest supersymmetric particle. If the decay involves a non-zero $\lambda$ coupling, the final state will be a multi-lepton one. Searches for events with four or more isolated charged leptons by ATLAS [74] and CMS [78] are interpreted in such models. With very small coupling values, the neutralino would be long-lived, leading to lepton pairs with a displaced vertex, which have also been searched for [118, 124, 170].

Various searches, including searches for multi-lepton and lepton plus jets events, and searches for events with a displaced hadronic vertex, with or without a matched lepton, are interpreted in a model with R-parity violating neutralino decays involving a non-zero $\lambda'$ coupling [75, 80, 86, 171]. Neutralino decays involving non-zero $\lambda''$ lead to fully hadronic final states, and searches for multi-jet events and jet-pair resonances are used to set limits, typically on the production of colored particles like top squarks or gluinos, which are assumed to be the primary produced sparticles in these interpretations, as discussed earlier [79, 84, 86].

The limits on weak gauginos in simplified models are summarized in Table 90.3. Interpretations of the search results outside simplified models, such as in the phenomenological MSSM [172–176], show that the simplified model limits must be interpreted with care. Electroweak gauginos in models that are compatible with the relic density of dark matter in the universe, for example, have particularly tuned mixing parameters and mass spectra, which are not always captured by the simplified models used.

**Table 90.3:** Summary of weak gaugino mass limits in simplified models, assuming R-parity conservation. Masses in the table are provided in GeV. Further details about assumptions and analyses from which these limits are obtained are discussed in the text.

| Assumption | $m_\chi$ |
|---|---|
| $\tilde{\chi}_1^\pm$, all $\Delta m(\tilde{\chi}_1^\pm, \tilde{\chi}_1^0)$ | $> 92$ |
| $\tilde{\chi}_1^\pm$ $\Delta m > 5$, $m_{\tilde{\nu}} > 300$ | $> 103.5$ |
| $\tilde{\chi}_1^\pm$, $m_{(\tilde{\ell},\tilde{\nu})} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$ | |
| $m_{\tilde{\chi}_1^0} \approx 0$ | $> 1000$ |
| $\tilde{\chi}_1^\pm$, $m_{\tilde{\chi}_1^0} > 480$ | no LHC limit |
| $\tilde{\chi}_1^\pm$, $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$ | |
| $m_{\tilde{\chi}_1^0} \approx 0$ | $> 420$ |
| $\tilde{\chi}_1^\pm$, $m_{\tilde{\chi}_1^0} > 120$ | no LHC limit |
| $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}_\mathrm{L}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$ | |
| $m_{\tilde{\chi}_1^0} \approx 0$ | $> 1140$ |
| $m_{\tilde{\chi}_1^0} > 700$ | no LHC limit |
| $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}_\mathrm{R}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$ | flavor-democratic |
| $m_{\tilde{\chi}_1^0} \approx 0$ | $> 1060$ |
| $m_{\tilde{\chi}_1^0} > 600$ | no LHC limit |
| $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\tau}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$ | $\tilde{\tau}$-dominated |
| $m_{\tilde{\chi}_1^0} \approx 0$ | $> 620$ |
| $m_{\tilde{\chi}_1^0} > 260$ | no LHC limit |
| $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$, BF$(WZ) = 1$ | |
| $m_{\tilde{\chi}_1^0} \approx 0$ | $> 650$ |
| $m_{\tilde{\chi}_1^0} > 300$ | no LHC limit |
| $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$, BF$(WH) = 1$ | |
| $m_{\tilde{\chi}_1^0} \approx 0$ | $> 740$ |
| $m_{\tilde{\chi}_1^0} > 240$ | no LHC limit |

## 90.6 Exclusion limits on slepton masses

In models with slepton and gaugino mass unification at the GUT scale, the right-handed slepton, $\tilde{\ell}_\mathrm{R}$, is expected to be lighter than the left-handed slepton, $\tilde{\ell}_\mathrm{L}$. For tau sleptons there may be considerable mixing between the L and R states, leading to a significant mass difference between the lighter $\tilde{\tau}_1$ and the heavier $\tilde{\tau}_2$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

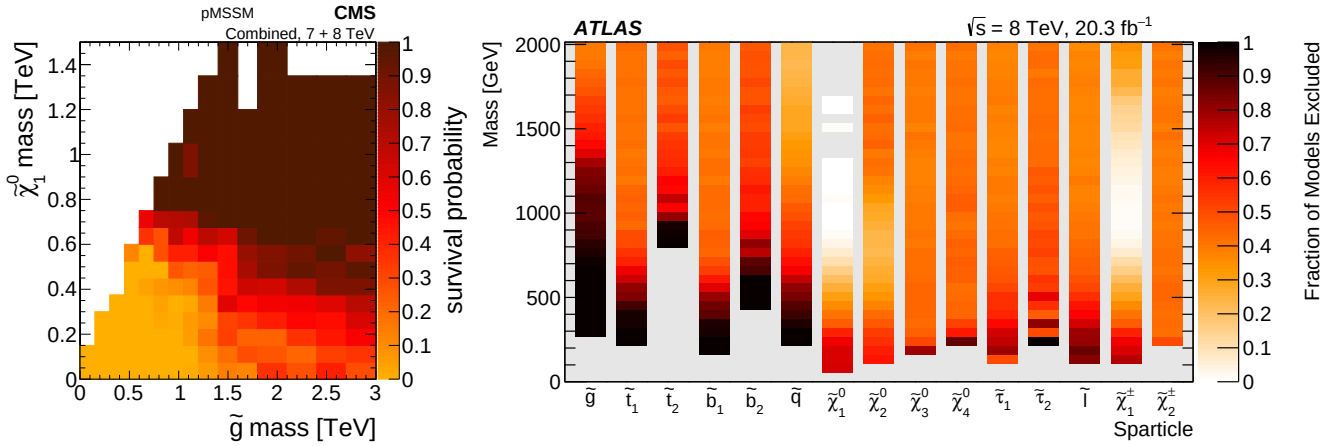

Figure 90.9: The plot on the left shows the survival probability of a pMSSM parameter space model in the gluino-neutralino mass plane after the application of the relevant CMS search results. The plot on the right shows a graphical representation of the ATLAS exclusion power in a pMSSM model. Each vertical bar is a one-dimensional projection of the fraction of models points excluded for each sparticle by ATLAS analyses. The experimental results are obtained from data taken at $\sqrt{s} = 7$ and 8 TeV.

### 90.6.1 *Exclusion limits on the masses of charged sleptons*

The most model-independent searches for selectrons, smuons and staus originate from the LEP experiments [177]. Smuon production only takes place via s-channel $\gamma^*/Z$ exchange. Search results are often quoted for $\tilde{\mu}_R$, since it is typically lighter than $\tilde{\mu}_L$ and has a weaker coupling to the $Z$ boson; limits are therefore conservative. Decays are expected to be dominated by $\tilde{\mu}_R \to \mu\tilde{\chi}_1^0$, leading to two non-back-to-back muons and missing momentum. Slepton mass limits are calculated in the MSSM under the assumption of gaugino mass unification at the GUT scale, and depend on the mass difference between the smuon and $\tilde{\chi}_1^0$. A $\tilde{\mu}_R$ with a mass below 94 GeV is excluded for $m_{\tilde{\mu}_R} - m_{\tilde{\chi}_1^0} > 10$ GeV. The selectron case is similar to the smuon case, except that an additional production mechanism is provided by t-channel neutralino exchange. The $\tilde{e}_R$ lower mass limit is 100 GeV for $m_{\tilde{\chi}_1^0} < 85$ GeV. Due to the t-channel neutralino exchange, $\tilde{e}_R\tilde{e}_L$ pair production was possible at LEP, and a lower limit of 73 GeV was set on the selectron mass regardless of the neutralino mass by scanning over MSSM parameter space [178]. The potentially large mixing between $\tilde{\tau}_L$ and $\tilde{\tau}_R$ not only makes the $\tilde{\tau}_1$ light, but can also make its coupling to the $Z$ boson small. LEP lower limits on the $\tilde{\tau}$ mass range between 87 and 93 GeV depending on the $\tilde{\chi}_1^0$ mass, for $m_{\tilde{\tau}} - m_{\tilde{\chi}_1^0} > 7$ GeV [177].

At the LHC, pair production of sleptons is not only heavily suppressed with respect to pair production of colored SUSY particles but the cross section is also almost two orders of magnitude smaller than the one of pair production of charginos and neutralinos. With the full data sets of Run 1 and Run 2, however, ATLAS and CMS have surpassed the sensitivity of the LEP analyses under certain assumptions.

**Table 90.4:** Summary of slepton mass limits from LEP and LHC, assuming R-parity conservation and 100% branching fraction for $\tilde{\ell} \to \ell\tilde{\chi}_1^0$. Masses in this table are provided in GeV.

| Assumption | $m_{\tilde{\ell}}$ |
|---|---|
| $\tilde{\mu}_R$, $\Delta m(\tilde{\mu}_R, \tilde{\chi}_1^0) > 10$ | $> 94$ |
| $\tilde{e}_R$, $\Delta m(\tilde{e}_R, \tilde{\chi}_1^0) > 10$ | $> 94$ |
| $\tilde{e}_R$, any $\Delta m$ | $> 73$ |
| $\tilde{\tau}_R$, $\Delta m(\tilde{\tau}_R, \tilde{\chi}_1^0) > 7$ | $> 87$ |
| $\tilde{\nu}_e$, $\Delta m(\tilde{e}_R, \tilde{\chi}_1^0) > 10$ | $> 94$ |
| $m_{\tilde{e}_{L,R}} = m_{\tilde{\mu}_{L,R}}$, $m_{\tilde{\chi}_1^0} \approx 0$ | $> 700$ |
| $m_{\tilde{\chi}_1^0} >\approx 400$ | no LHC limit |
| $m_{\tilde{\tau}_L} = m_{\tilde{\tau}_R}$, $m_{\tilde{\chi}_1^0} \approx 0$ | $> 390$ |
| $m_{\tilde{\chi}_1^0} >\approx 130$ | no LHC limit |

ATLAS and CMS have searched for direct production of selectron pairs and smuon pairs at the LHC, with each slepton decaying to its corresponding SM partner lepton and the $\tilde{\chi}_1^0$ LSP. In simplified models, ATLAS [133] and CMS [179] set lower mass limits on sleptons of 700 GeV for degenerate $\tilde{\ell}_L$ and $\tilde{\ell}_R$, for a massless $\tilde{\chi}_1^0$ and assuming equal selectron and smuon masses, as shown in Fig. 90.6. The limits deteriorate with increasing $\tilde{\chi}_1^0$ mass due to decreasing missing momentum and lepton momentum. As a consequence, no limits are set for $\tilde{\chi}_1^0$ masses above 400 GeV. Limits are also derived without the assumption of slepton mass degeneracy [133, 179]. A dedicated search for sleptons with small mass difference between $\tilde{\ell}$ and $\tilde{\chi}_1^0$ is performed by ATLAS [144] demanding the presence of ISR jets.

ATLAS and CMS have also searched for $\tilde{\tau}$-pair production. In simplified models, ATLAS excludes $\tilde{\tau}$ masses between 120 and 390 GeV assuming light $\tilde{\chi}_1^0$, combining the production of degenerate left- and right-handed $\tilde{\tau}$s [180]. The CMS analysis [181] covers lower masses and closes the mass gap with LEP. No limits are set for $\tilde{\chi}_1^0$ masses above 130 GeV.

In gauge-mediated SUSY breaking models, sleptons can be (co-)NLSPs, *i.e.*, the next-to-lightest SUSY particles and almost degenerate in mass, decaying to a lepton and a gravitino. This decay can either be prompt, or the slepton can have a non-zero lifetime. Combining several analyses, lower mass limits on $\tilde{\mu}_R$ of 96.3 GeV and on $\tilde{e}_R$ of 66 GeV are set for all slepton lifetimes at LEP [182]. In a considerable part of parameter space in these models, the $\tilde{\tau}$ is the NLSP. The LEP experiments have set lower limits on the mass of such a $\tilde{\tau}$ between 87 and 97 GeV, depending on the $\tilde{\tau}$ lifetime. ATLAS and CMS have searched for final states with $\tau$s, jets and missing transverse momentum, and has interpreted the results in GMSB models setting limits on the model parameters [183, 184]. CMS has interpreted a multilepton analysis in terms of limits on gauge mediation models with slepton NLSP [185]. CDF has put limits on gauge mediation models at high $\tan\beta$ and slepton NLSP using an analysis searching for like-charge light leptons and taus [186].

Limits also exist on sleptons in R-parity violating models, both from LEP and the Tevatron experiments. From LEP, lower limits on $\tilde{\mu}_R$ and $\tilde{e}_R$ masses in such models are 97 GeV, and the limits on the stau mass are very close: 96 GeV [187]. CMS has searched for resonant smuon production in a modified CMSSM scenario [188], putting limits on $\lambda'_{211}$ as a function of $m_0, m_{1/2}$.

### 90.6.2 *Exclusion limits on sneutrino masses*

The invisible width of the $Z$ boson puts a lower limit on the sneutrino mass of about 45 GeV. Tighter limits are derived from other searches, notably for gauginos and sleptons, under the assumption of gaugino and sfermion mass universality at the GUT scale, and amount to approximately 94 GeV in the MSSM [189].

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

It is possible that the lightest sneutrino is the LSP; however, a left-handed sneutrino LSP is ruled out as a cold dark matter candidate [190, 191].

Production of pairs of sneutrinos in R-parity violating models has been searched for at LEP [187]. Assuming fully leptonic decays via $\lambda$-type couplings, lower mass limits between 85 and 100 GeV are set. At the Tevatron [192, 193] and at the LHC [188, 194–196], searches have focused on scenarios with resonant production of a sneutrino, decaying to $e\mu$, $\mu\tau$ and $e\tau$ final states. No signal has been seen, and limits have been set on sneutrino masses as a function of the value of relevant RPV couplings. As an example, the LHC experiments exclude a resonant tau sneutrino with a mass below 2.3 TeV for $\lambda_{312} = \lambda_{321} > 0.07$ and $\lambda'_{311} > 0.11$.

The limits on sleptons in simplified models are summarized in Table 90.4.

## 90.7 Exclusion limits on long-lived sparticles

Long-lived sparticles arise in many different SUSY models. In particular in co-annihilation scenarios, where the NLSP and LSP are nearly mass-degenerate, this is rather common in order to obtain the correct Dark Matter relic density. Prominent examples are scenarios featuring stau co-annihilation, or models of SUSY breaking, e.g. minimal anomaly-mediated SUSY breaking (AMSB), in which the appropriate Dark Matter density is obtained by co-annihilation of the LSP with an almost degenerate long-lived wino. However, in general, also other sparticles can be long-lived and it is desirable to establish a comprehensive search program for these special long-lived cases, which lead to distinct experimental search signatures, including displaced vertices or disappearing tracks, etc.

Past experiments have performed dedicated searches for long-lived SUSY signatures, but given the absence of any experimental evidence for SUSY so far, more effort and focus has gone into such searches at the LHC recently. As for the interpretation of more standard searches for e.g. R-parity conserving SUSY, simplified models are also a convenient tool to benchmark long-lived scenarios (see e.g. [197, 198]).

If the decay of gluinos is suppressed, for example if squark masses are high, gluinos may live longer than typical hadronization times. It is expected that such gluinos will hadronize to long-living strongly interacting particles known as R-hadrons. In particular, if the suppression of the gluino decay is strong, as in the case that the squark masses are much higher than the TeV scale, these R-hadrons can be (semi-)stable in collider timescales. Searches for such R-hadrons exploit the typical signature of stable charged massive particles in the detector. R-hadrons decaying in the detector are searched for using $dE/dx$ measurements and searches for displaced vertices. As shown in the left plot of Fig. 90.7, the ATLAS experiment excludes semi-stable gluino R-hadrons with masses below $1.9 - 2.3$ TeV for all lifetimes in a simplified model where such gluinos always form R-hadrons, and decay into jets and a light neutralino, by combining a number of analyses [79, 199–201]. A combination of CMS searches for long-lived particles, as shown in Fig. 90.8, reaches similar limits [82, 202–204].

Alternatively, since such R-hadrons are strongly interacting, they may be stopped in the calorimeter or in other material, and decay later into energetic jets. These decays are searched for by identifying the jets [205–207] or muons [207] outside the time window associated with bunch-bunch collisions. As shown in Fig. 90.8, the CMS collaboration sets limits on such stopped R-hadrons over 13 orders of magnitude in gluino lifetime, up to masses of 1390 GeV [207].

Top squarks can also be long-lived and hadronize to a R-hadron, for example in the scenario where the top squark is the next-to-lightest SUSY particle (NLSP), with a small mass difference to the LSP. Searches for massive stable charged particles are sensitive to such top squarks. Tevatron limits are approximately $m_{\tilde{t}} > 300$ GeV [208, 209]. ATLAS sets a limit of 1340 GeV on such top squarks [200], the CMS limits are comparable [204].

In addition to colored sparticles, also sparticles like charginos may be long-lived, especially in scenarios with compressed mass spectra. Charginos decaying in the detectors away from the primary vertex could lead to signatures such as kinked-tracks, or apparently disappearing tracks, since, for example, the pion in $\tilde{\chi}_1^{\pm} \to \pi^{\pm}\tilde{\chi}_1^0$ might be too soft to be reconstructed. At the LHC, searches have been performed for such disappearing tracks, and interpreted within anomaly-mediated SUSY breaking models [210–212]. The right plot of Fig. 90.7 shows constraints for different ATLAS searches on the chargino mass-vs-lifetime plane for an AMSB model ($\tan\beta = 5$, $\mu > 0$) in which a wino-like $\tilde{\chi}^{\pm}$ decays to a soft pion and an almost mass-degenerated wino-like $\tilde{\chi}_1^0$ [200,201,211,212]. For a similar model, CMS excludes $c\tau$ values between 0.15 and 18 m for a chargino mass of 505 GeV [210], see Fig. 90.8. Charginos with a lifetime longer than the time needed to pass through the detector appear as charged stable massive particles. Limits have been derived by the LEP experiments [213], by D0 at the Tevatron [209], and by the LHC experiments [200, 214], and such charginos with mass below 1090 GeV are excluded.

In gauge mediation models, NLSP neutralino decays need not be prompt, and experiments have searched for late decays with photons in the final state. CDF have searched for delayed $\tilde{\chi}_1^0 \to \gamma\tilde{G}$ decays using the timing of photon signals in the calorimeter [215]. CMS has used the same technique at the LHC [216]. Results are given as exclusion contours in the neutralino mass versus lifetime plane, and for example in a GMSB model with a neutralino mass of 300 GeV, $c\tau$ values between 10 and 2000 cm are excluded [216]. D0 has looked at the direction of showers in the electromagnetic calorimeter with a similar goal [217], and ATLAS has searched for photon candidates that do not point back to the primary vertex, as well as for delayed photons [218].

Charged slepton decays may be kinematically suppressed, for example in the scenario of a NLSP slepton with a very small mass difference to the LSP. Such a slepton may appear to be a stable charged massive particle. Interpretation of searches at LEP for such signatures within GMSB models with stau NLSP or slepton co-NLSP exclude masses up to 99 GeV [213]. Searches of stable charged particles at the Tevatron [208, 209] and at the LHC [200, 204] are also interpreted in terms of limits on stable charged sleptons. The limits obtained at the LHC exclude stable staus with masses below 430 GeV when produced directly in pairs, and below 660 GeV when staus are produced both directly and indirectly in the decay of other particles in a GMSB model.

## 90.8 Global interpretations

Apart from the interpretation of direct searches for sparticle production at colliders in terms of limits on masses of individual SUSY particles, model-dependent interpretations of allowed SUSY parameter space are derived from global SUSY fits. Typically these fits combine the results from collider experiments with indirect constraints on SUSY as obtained from low-energy experiments, flavor physics, high-precision electroweak results, and astrophysical data.

In the pre-LHC era these fits were mainly dominated by indirect constraints. Even for very constrained models like the CMSSM, the allowed parameter space, in terms of squark and gluino masses, ranged from several hundreds of GeV to a few TeV. Furthermore, these global fits indicated that squarks and gluino masses in the range of 500 to 1000 GeV were the preferred region of parameter space, although values as high as few TeV were allowed with lower probabilities [219–226].

With ATLAS and CMS now probing mass scales around 1 TeV and beyond, the importance of the direct searches for global analyses of allowed SUSY parameter space has increased. For example, imposing the new experimental limits on constrained supergravity models pushes the most likely values of first generation squark and gluino masses significantly beyond 2 TeV, typically resulting in overall values of fit quality much worse than those in the pre-LHC era [150–152, 174, 227–234]. Also the measured value of $m_h$ pushes the sparticle masses upwards. Although these constrained models are not yet ruled out, the extended experimental limits impose very tight constraints on the allowed parameter space.

For this reason, the emphasis of global SUSY fits has shifted towards less-constrained SUSY models. Especially interpretations in the pMSSM [172–176, 214, 227] but also in simplified models have been useful to generalize SUSY searches, for example to re-

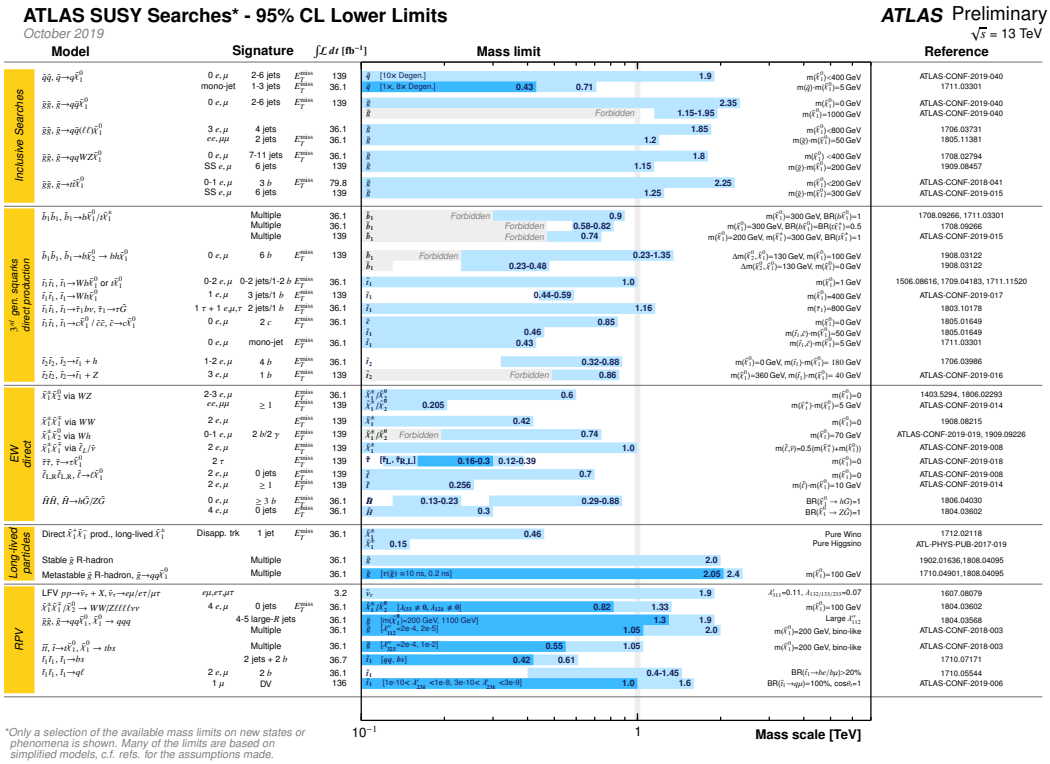

Figure 90.10: Overview of the current landscape of SUSY searches at the LHC. The plot shows exclusion mass limits of ATLAS for different searches and interpretation assumptions. The corresponding results of the CMS experiment are similar.

design experimental analyses in order to increase their sensitivity for compressed spectra, where the mass of the LSP is much closer to squark and gluino masses than predicted, for example, by the CMSSM. As shown in Table 90.2, for neutralino masses above $0.5 - 1$ TeV the current set of ATLAS and CMS searches, interpreted in simplified models, cannot exclude the existence of squarks or gluinos with masses only marginally above the neutralino mass. However, as these exclusion limits are defined in the context of simplified models, they are only valid for the assumptions in which these models are defined.

As an alternative approach, both ATLAS [172] and CMS [173] have performed an analysis of the impact of their searches on the parameter space of the pMSSM. Fig. 90.9 shows graphically the LHC exclusion power in the pMSSM based on searches performed at $\sqrt{s} = 7$ and 8 TeV. The plot on the left shows the survival probability in the gluino-neutralino mass plane, which is a measure of the parameter space that remains after inclusion of the relevant CMS search results. As can be seen, gluino masses below about 1.2 TeV are almost fully excluded. This result agrees well with the typical exclusion obtained at 8 TeV in simplified models for gluino production. However, as shown in the right plot of Fig. 90.9, when a similar analysis for other sparticles is performed it becomes apparent that exclusions on the pMSSM parameter can be significantly less stringent than simplified model limits might suggest. This is especially apparent for the electroweak sector, where even at rather low masses several of the pMSSM test points still survive the constraint of ATLAS searches at $\sqrt{s} = 7$ and 8 TeV. This again indicates that care must be taken when interpreting results from the LHC searches and there are still several scenarios where sparticles below the 1 TeV scale are not excluded, even when considering the most recent results at $\sqrt{s} = 13$ TeV.

Furthermore, the discovery of a Higgs boson with a mass around 125 GeV has triggered many studies regarding the compatibility of SUSY parameter space with this new particle. Much of it is still work in progress and it will be interesting to see how the interplay between the results from direct SUSY searches and more precise measurements of the properties of the Higgs boson will unfold in the future.

## 90.9 Summary and Outlook

The absence of any observation of new phenomena at the first run of the LHC at $\sqrt{s} = 7/8$ TeV, and after the second run at $\sqrt{s} = 13$ TeV, place significant constraints on SUSY parameter space. Today, inclusive searches probe production of gluinos at about 2.3 TeV, first and second generation squarks in the range of about 1 to 1.9 TeV, third generation squarks at scales around 600 GeV to 1.2 TeV, electroweak gauginos at scales around $400 - 1100$ GeV, and sleptons around 700 GeV. However, depending on the assumptions made on the underlying SUSY spectrum these limits can also weaken considerably.

With the LHC having reached almost its maximum energy of about $\sqrt{s} = 14$ TeV, future sensitivity improvement will have to originate from more data, the improvement of experimental analysis techniques and the focus of special signatures like the one arising in long-lived sparticle decays. Therefore, it is expected that the current landscape of SUSY searches and corresponding exclusion limits at the LHC, as, for example, shown in Fig. 90.10 from the ATLAS experiment [235] (CMS results are similar [236]), will not change as rapidly anymore as it did in the past, when the LHC underwent several successive increases of collision energy.

The interpretation of results at the LHC has moved away from constrained models like the CMSSM towards a large set of simplified models, or the pMSSM. On the one hand this move is because the LHC limits have put constrained models like the CMSSM under severe pressure, while on the other hand simplified models leave more freedom to vary parameters and form a better representation of the underlying sensitivity of analyses. However, these interpretations in simplified models do not come without a price: the decomposition of a potentially complicated reality in a limited set of individual decay chains can be significantly incomplete. Therefore, quoted limits in simplified models are only valid under the explicit assumptions made in these models. The recent addition of more comprehensive interpretations in the pMSSM will complement those derived from simplified models and, thus, will enable an even more refined understanding of the probed SUSY parameter space.

In this context, the limit range of $1.5 - 2.3$ TeV on generic

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

colored SUSY particles only holds for light neutralinos, in the R-parity conserving MSSM. Limits on third generation squarks and electroweak gauginos also only hold for light neutralinos, and under specific assumptions for decay modes and slepton masses.

The next LHC runs at $\sqrt{s} = 13$ or 14 TeV with significantly larger integrated luminosities (notably the High-Luminosity LHC), will provide a large data sample for future SUSY searches. As mentioned above, the improvement in sensitivity will largely have to come from a larger data set, and evolution of trigger and analysis techniques, since there will be no significant energy increase at the LHC anymore. Although the sensitivity for colored sparticles will increase somewhat as well, the expanded data set will be particularly beneficial for electroweak gaugino searches, and for the more difficult final states presented by compressed particle spectra, stealth SUSY, long-lived sparticles, or R-parity violating scenarios.

# 91. Axions and Other Similar Particles

Revised October 2019 by A. Ringwald (DESY, Hamburg), L.J. Rosenberg (U. Washington) and G. Rybka (U. Washington).

## 91.1 Introduction

In this section, we list coupling-strength and mass limits for light neutral scalar or pseudoscalar bosons that couple weakly to normal matter and radiation. Such bosons may arise from the spontaneous breaking of a global U(1) symmetry, resulting in a massless Nambu-Goldstone (NG) boson. If there is a small explicit symmetry breaking, either already in the Lagrangian or due to quantum effects such as anomalies, the boson acquires a mass and is called a pseudo-NG boson. Typical examples are axions ($A^0$) [1–4] and majorons [5], associated, respectively, with a spontaneously broken Peccei-Quinn and lepton-number symmetry.

A common feature of these light bosons $\phi$ is that their coupling to Standard-Model particles is suppressed by the energy scale that characterizes the symmetry breaking, *i.e.*, the decay constant $f$. The interaction Lagrangian is

$$\mathcal{L} = f^{-1} J^\mu \partial_\mu \phi \,, \tag{91.1}$$

where $J^\mu$ is the Noether current of the spontaneously broken global symmetry. If $f$ is very large, these new particles interact very weakly. Detecting them would provide a window to physics far beyond what can be probed at accelerators.

Axions are of particular interest because the Peccei-Quinn (PQ) mechanism remains perhaps the most credible scheme to preserve CP-symmetry in QCD. Moreover, the cold dark matter (CDM) of the universe may well consist of axions and they are searched for in dedicated experiments with a realistic chance of discovery.

Originally it was assumed that the PQ scale $f_A$ was related to the electroweak symmetry-breaking scale $v_{\rm EW} = (\sqrt{2} G_{\rm F})^{-1/2} = 247$ GeV. However, the associated "standard" and "variant" axions were quickly excluded—we refer to the Listings for detailed limits. Here we focus on "invisible axions" with $f_A \gg v_{\rm EW}$ as the main possibility.

Axions have a characteristic two-photon vertex, inherited from their mixing with $\pi^0$ and $\eta$. This coupling allows for the main search strategy based on axion-photon conversion in external magnetic fields [6], an effect that also can be of astrophysical interest. While for axions the product "$A\gamma\gamma$ interaction strength × mass" is essentially fixed by the corresponding $\pi^0$ properties, one may consider a more general class of axion-like particles (ALPs) where the two parameters (coupling and mass) are independent. A number of experiments explore this more general parameter space. ALPs populating the latter are predicted to arise generically, in addition to the axion, in low-energy effective field theories emerging from string theory [7–14]. The latter often contain also very light Abelian vector bosons under which the Standard-Model particles are not charged: so-called hidden-sector photons, dark photons or paraphotons. They share a number of phenomenological features with the axion and ALPs, notably the possibility of hidden photon to photon conversion. Their physics cases and the current constraints are compiled in Refs. [15–17].

## 91.2 Theory

### 91.2.1 *Peccei-Quinn mechanism and axions*

The QCD Lagrangian includes a CP-violating term $\mathcal{L}_\Theta = -\bar{\Theta}\,(\alpha_s/8\pi)\, G^{\mu\nu a} \tilde{G}^a_{\mu\nu}$, where $-\pi \le \bar{\Theta} \le +\pi$ is the effective $\Theta$ parameter after diagonalizing quark masses, $G^a_{\mu\nu}$ is the color field strength tensor, and $\tilde{G}^{a,\mu\nu} \equiv \epsilon^{\mu\nu\lambda\rho} G^a_{\lambda\rho}/2$, with $\varepsilon^{0123} = 1$, its dual. Limits on the neutron electric dipole moment [18] imply $|\bar{\Theta}| \lesssim 10^{-10}$ even though $\bar{\Theta} = \mathcal{O}(1)$ is otherwise completely satisfactory. The spontaneously broken global Peccei-Quinn symmetry $\mathrm{U(1)_{PQ}}$ was introduced to solve this "strong CP problem" [1, 2], the axion being the pseudo-NG boson of $\mathrm{U(1)_{PQ}}$ [3,4]. This symmetry is broken due to the axion's anomalous triangle coupling to gluons,

$$\mathcal{L} = \left(\frac{\phi_A}{f_A} - \bar{\Theta}\right) \frac{\alpha_s}{8\pi}\, G^{\mu\nu a} \tilde{G}^a_{\mu\nu} \,, \tag{91.2}$$

where $\phi_A$ is the axion field and $f_A$ the axion decay constant. Color anomaly factors have been absorbed in the normalization of $f_A$ which is defined by this Lagrangian. Thus normalized, $f_A$ is the quantity that enters all low-energy phenomena [19]. Nonperturbative topological fluctuations of the gluon fields in QCD induce a potential for $\phi_A$ whose minimum is at $\phi_A = \bar{\Theta}\, f_A$, thereby canceling the $\bar{\Theta}$ term in the QCD Lagrangian and thus restoring CP symmetry.

The resulting axion mass, in units of the PQ scale $f_A$, is identical to the square root of the topological susceptibility in QCD, $m_A f_A = \sqrt{\chi}$. The latter can be evaluated further [20,21], exploiting the chiral limit (masses of up and down quarks much smaller than the scale of QCD), yielding $m_A f_A = \sqrt{\chi} \approx f_\pi m_\pi$, where $m_\pi = 135$ MeV and $f_\pi \approx 92$ MeV. In more detail one finds, to next-to-next-to-leading order in chiral perturbation theory [22],

$$m_A = 5.691(51) \left(\frac{10^9\ \mathrm{GeV}}{f_A}\right) \mathrm{meV} \,. \tag{91.3}$$

A direct calculation of the topological susceptibility via QCD lattice simulations finds almost the same central value, albeit with an about five times larger error bar [23].

Axions with $f_A \gg v_{\rm EW}$ evade all current experimental limits. One generic class of models invokes "hadronic axions" where new heavy quarks carry $\mathrm{U(1)_{PQ}}$ charges, leaving ordinary quarks and leptons without tree-level axion couplings. The archetype is the KSVZ model [24], where in addition the heavy new quarks are electrically neutral. Another generic class requires at least two Higgs doublets and ordinary quarks and leptons carry PQ charges, the archetype being the DFSZ model [25]. All of these models contain at least one electroweak singlet scalar that acquires a vacuum expectation value and thereby breaks the PQ symmetry. The KSVZ and DFSZ models are frequently used as benchmark examples, but other models exist where both heavy quarks and Higgs doublets carry PQ charges. In supersymmetric models, the axion is part of a supermultiplet and thus inevitably accompanied by a spin-0 saxion and a spin-1 axino, which both also have couplings suppressed by $f_A$ and are expected to have large masses due to supersymmetry breaking [26].

### 91.2.2 *Model-dependent axion couplings*

Although the generic axion interactions scale approximately with $f_\pi/f_A$ from the corresponding $\pi^0$ couplings, there are non-negligible model-dependent factors and uncertainties. The axion's two-photon interaction plays a key role for many searches,

$$\mathcal{L}_{A\gamma\gamma} = -\frac{g_{A\gamma\gamma}}{4}\, F_{\mu\nu} \tilde{F}^{\mu\nu} \phi_A = g_{A\gamma\gamma} \mathbf{E}\cdot\mathbf{B}\, \phi_A \,, \tag{91.4}$$

where $F$ is the electromagnetic field-strength tensor and $\tilde{F}^{\mu\nu} \equiv \epsilon^{\mu\nu\lambda\rho} F_{\lambda\rho}/2$, with $\varepsilon^{0123} = 1$, its dual. The coupling constant is [27]

$$g_{A\gamma\gamma} = \frac{\alpha}{2\pi f_A} \left(\frac{E}{N} - 1.92(4)\right) = \left(0.203(3)\frac{E}{N} - 0.39(1)\right) \frac{m_A}{\mathrm{GeV}^2} \,, \tag{91.5}$$

where $E$ and $N$ are the electromagnetic and color anomalies of the axial current associated with the axion. In grand unified models, and notably for DFSZ [25], $E/N = 8/3$, whereas for KSVZ [24] $E/N = 0$ if the electric charge of the new heavy quark is taken to vanish. In general, a broad range of $E/N$ values is possible [28, 29], as indicated by the diagonal yellow band in Fig. 91.1. However, this band still does not exhaust all the possibilities. In fact, there exist classes of QCD axion models whose photon couplings populate the entire still allowed region above the yellow band in Fig. 91.1, motivating axion search efforts over a wide range of masses and couplings [30, 31].

The two-photon decay width is

$$\Gamma_{A\to\gamma\gamma} = \frac{g^2_{A\gamma\gamma} m_A^3}{64\,\pi} = 1.1 \times 10^{-24}\ \mathrm{s}^{-1} \left(\frac{m_A}{\mathrm{eV}}\right)^5 . \tag{91.6}$$

The second expression uses Eq. (91.5) with $E/N = 0$. Axions decay faster than the age of the universe if $m_A \gtrsim 20$ eV. The interaction with fermions $f$ has derivative form and is invariant under a shift $\phi_A \to \phi_A + \phi_0$ as behooves a NG boson,

$$\mathcal{L}_{Aff} = \frac{C_f}{2 f_A}\, \bar{\Psi}_f \gamma^\mu \gamma_5 \Psi_f \partial_\mu \phi_A \,. \tag{91.7}$$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

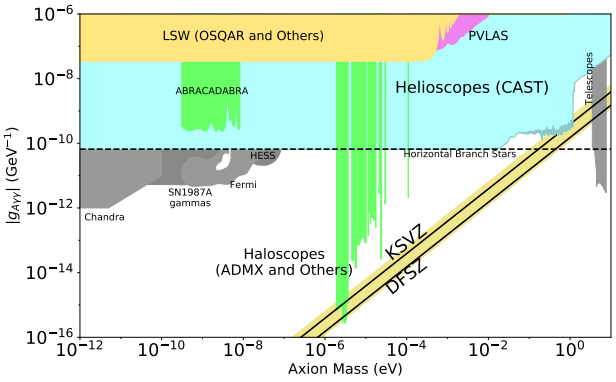

Figure 91.1: Exclusion plot for ALPs as described in the text.

Here, $\Psi_f$ is the fermion field, $m_f$ its mass, and $C_f$ a model-dependent coefficient. The dimensionless combination $g_{Aff} \equiv C_f m_f/f_A$ plays the role of a Yukawa coupling and $\alpha_{Aff} \equiv g_{Aff}^2/4\pi$ of a "fine-structure constant." The often-used pseudoscalar form $\mathcal{L}_{Aff} = -\mathrm{i}\,(C_f m_f/f_A)\,\bar{\Psi}_f\gamma_5\Psi_f\phi_A$ need not be equivalent to the appropriate derivative structure, for example when two NG bosons are attached to one fermion line as in axion emission by nucleon bremsstrahlung [32].

In the DFSZ model [25], the tree-level coupling coefficient to electrons is [33]

$$C_e = \frac{\sin^2\beta}{3}\,, \tag{91.8}$$

where $\tan\beta$ is the ratio of the vacuum expectation values of the two Higgs doublets giving masses to the up- and down-type quarks, respectively: $\tan\beta = v_u/v_d$.

For nucleons, $C_{p,n}$ have been determined as [27]

$$\begin{aligned} C_p &= -0.47(3) + 0.88(3)C_u - 0.39(2)C_d - 0.038(5)C_s \\ &\quad - 0.012(5)C_c - 0.009(2)C_b - 0.0035(4)C_t\,, \\ C_n &= -0.02(3) + 0.88(3)C_d - 0.39(2)C_u - 0.038(5)C_s \\ &\quad - 0.012(5)C_c - 0.009(2)C_b - 0.0035(4)C_t\,, \end{aligned} \tag{91.9}$$

in terms of the corresponding model-dependent quark couplings $C_q$, $q = u, d, s, c, b, t$.

For hadronic axions with $C_q = 0$, $C_n$ is compatible with zero whereas $C_p$ does not vanish. In the DFSZ model, on the other hand, $C_u = C_c = C_t = \frac{1}{3}\cos^2\beta$ and $C_d = C_s = C_b = \frac{1}{3}\sin^2\beta$, and $C_p$ and $C_n$, as functions of $\beta$,

$$\begin{aligned} C_p &= -0.435\sin^2\beta + (-0.182 \pm 0.025)\,, \\ C_n &= 0.414\sin^2\beta + (-0.160 \pm 0.025)\,, \end{aligned} \tag{91.10}$$

do not vanish simultaneously.

The axion-pion interaction is given by the Lagrangian [34]

$$\mathcal{L}_{A\pi} = \frac{C_{A\pi}}{f_\pi f_A}\left(\pi^0\pi^+\partial_\mu\pi^- + \pi^0\pi^-\partial_\mu\pi^+ - 2\pi^+\pi^-\partial_\mu\pi^0\right)\partial_\mu\phi_A\,, \tag{91.11}$$

where $C_{A\pi} = (1-z)/[3(1+z)]$ in hadronic models, with $0.38 < z = m_u/m_d < 0.58$ [35, 36]. The chiral symmetry-breaking Lagrangian provides an additional term $\mathcal{L}'_{A\pi} \propto (m_\pi^2/f_\pi f_A)\,(\pi^0\pi^0 + 2\pi^-\pi^+)\,\pi^0\phi_A$. For hadronic axions it vanishes identically, in contrast to the DFSZ model (Roberto Peccei, private communication).

## 91.3 Laboratory Searches

### 91.3.1 *Light shining through walls*

Searching for "invisible axions" is extremely challenging due to its extraordinarily feeble coupling to normal matter and radiation. Currently, the most promising approaches rely on the axion-two-photon interaction, allowing for axion-photon conversion in external electric or magnetic fields [6]. For the Coulomb field of a charged particle, the conversion is best viewed as a scattering process, $\gamma + Ze \leftrightarrow Ze + A$, called Primakoff effect [37]. In the other extreme of a macroscopic field, usually a large-scale $B$-field, the momentum transfer is small, the interaction is coherent over a large distance, and the conversion is best viewed as an axion-photon oscillation phenomenon in analogy to neutrino flavor oscillations [38].

Photons propagating through a transverse magnetic field, with incident $\mathbf{E}_\gamma$ and magnetic field $\mathbf{B}$ parallel, may convert into axions. For $m_A^2 L/2\omega \ll 2\pi$, where $L$ is the length of the $B$ field region and $\omega$ the photon energy, the resultant axion beam is coherent with the incident photon beam and the conversion probability is $\Pi \sim (1/4)(g_{A\gamma\gamma}BL)^2$. A practical realization uses a laser beam propagating down the bore of a superconducting dipole magnet (like the bending magnets in high-energy accelerators). If another magnet is in line with the first, but shielded by an optical barrier, then photons may be regenerated from the pure axion beam [39, 40]. The overall probability is $P(\gamma \to A \to \gamma) = \Pi^2$.

The first such Light-Shining-through-Walls (LSW) experiment was performed by the BFRT collaboration. It utilized two magnets of length $L = 4.4$ m and $B = 3.7$ T and found $|g_{A\gamma\gamma}| < 6.7\times10^{-7}$ GeV$^{-1}$ at 95% CL for $m_A < 1$ meV [41]. More recently, several such experiments were performed (see Listings) [42–48]. The current best limit, $|g_{A\gamma\gamma}| < 3.5\times10^{-8}$ GeV$^{-1}$ at 95% CL for $m_A \lesssim 0.3$ meV (see Fig. 91.1), has been achieved by the OSQAR (Optical Search for QED Vacuum Birefringence, Axions, and Photon Regeneration) experiment, which exploited two 9 T LHC dipole magnets and an 18.5 W continuous wave laser emitting at the wavelength of 532 nm [48]. Some of these experiments have also reported limits for scalar bosons where the photon $\mathbf{E}_\gamma$ must be chosen perpendicular to the magnetic field $\mathbf{B}$.

The concept of resonantly enhanced photon regeneration may open unexplored regions of coupling strength [49, 50]. In this scheme, both the production and detection magnets are within Fabry-Perot optical cavities and actively locked in frequency. The $\gamma \to A \to \gamma$ rate is enhanced by a factor $\mathcal{F}\mathcal{F}'/\pi^2$ relative to a single-pass experiment, where $\mathcal{F}$ and $\mathcal{F}'$ are the finesses of the two cavities. The resonant enhancement could be of order $10^{(10-12)}$, improving the $g_{A\gamma\gamma}$ sensitivity by $10^{(2.5-3)}$. The experiment ALPS II (Any Light Particle Search II) is based on this concept and aims at an improvement of the current laboratory bound on $g_{A\gamma\gamma}$ by a factor $\sim 10^3$ in the year 2020 [51].

Resonantly enhanced photon regeneration has already been exploited in experiments searching for 'radiowaves shining through a shielding' [52–55]. For $m_A \lesssim 10^{-5}$ eV, the upper bound on $g_{A\gamma\gamma}$ established by the CROWS (CERN Resonant Weakly Interacting sub-eV Particle Search) experiment [56] is slightly less stringent than the one set by OSQAR.

### 91.3.2 *Photon polarization*

An alternative to regenerating the lost photons is to use the beam itself to detect conversion: the polarization of light propagating through a transverse $B$ field suffers dichroism and birefringence [57]. Dichroism: The $E_\parallel$ component, but not $E_\perp$, is depleted by axion production, causing a small rotation of linearly polarized light. For $m_A^2 L/2\omega \ll 2\pi$, the effect is independent of $m_A$. For heavier axions, it oscillates and diminishes as $m_A$ increases, and it vanishes for $m_A > \omega$. Birefringence: This effect occurs because there is mixing of virtual axions in the $E_\parallel$ state, but not for $E_\perp$. Hence, linearly polarized light will develop elliptical polarization. Higher-order QED also induces vacuum magnetic birefringence (VMB). A search for these effects was performed in the same dipole magnets of the BFRT experiment mentioned before [58]. The dichroic rotation gave a stronger limit than the ellipticity rotation: $|g_{A\gamma\gamma}| < 3.6\times10^{-7}$ GeV$^{-1}$ at 95% CL, for $m_A < 5\times10^{-4}$ eV. The ellipticity limits are better at higher masses, as they fall off smoothly and do not terminate at $m_A$.

In 2006, the PVLAS collaboration reported a signature of magnetically induced vacuum dichroism that could be interpreted as the effect of a pseudoscalar with $m_A = 1$–$1.5$ meV and $|g_{A\gamma\gamma}| = (1.6$–$5)\times10^{-6}$ GeV$^{-1}$ [59]. Later, it turned out that these findings are due to instrumental artifacts [60]. This particle interpretation is also excluded by the above photon regeneration searches that were inspired by the original PVLAS result. The fourth generation setup of the PVLAS experiment has published results on searches for VMB (see Fig. 91.1) and dichroism [61].

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

The bounds from the non-observation of the latter on $g_{A\gamma\gamma}$ are slightly weaker than the ones from OSQAR.

#### 91.3.3 *Long-range forces*

New bosons would mediate long-range forces, which are severely constrained by "fifth force" experiments [62]. Those looking for new mass-spin couplings provide significant constraints on pseudoscalar bosons [63]. Presently, the most restrictive limits are obtained from combining long-range force measurements with stellar cooling arguments [64]. For the moment, any of these limits are far from realistic values expected for axions. Still, these efforts provide constraints on more general low-mass bosons.

In Ref. [65], a method was proposed that can extend the search for axion-mediated spin-dependent forces by several orders of magnitude. By combining techniques used in nuclear magnetic resonance and short-distance tests of gravity, this method appears to be sensitive to axions in the $\mu$eV – meV mass range, independent of the cosmic axion abundance, if axions have a CP-violating interaction with nuclei as large as the current experimental bound on the electric dipole moment of the neutron allows. Experimental tests to demonstrate the requirements of ARIADNE (Axion Resonant InterAction DetectioN Experiment) are under way [66].

## 91.4 Axions from Astrophysical Sources

#### 91.4.1 *Stellar energy-loss limits*

Low-mass weakly-interacting particles (neutrinos, gravitons, axions, baryonic or leptonic gauge bosons, *etc.*) are produced in hot astrophysical plasmas, and can thus transport energy out of stars. The coupling strength of these particles with normal matter and radiation is bounded by the constraint that stellar lifetimes or energy-loss rates are not in conflict with observation [67, 68].

We begin this discussion with our Sun and concentrate on hadronic axions. They are produced predominantly by the Primakoff process $\gamma + Ze \to Ze + A$. Integrating over a standard solar model yields the axion luminosity [69]

$$L_A = g_{10}^2 \times 1.85 \times 10^{-3}\, L_\odot\,, \tag{91.12}$$

where $g_{10} = |g_{A\gamma\gamma}| \times 10^{10}$ GeV. The maximum of the spectrum is at 3.0 keV, the average at 4.2 keV, and the number flux at Earth is $g_{10}^2 \times 3.75 \times 10^{11}$ cm$^{-2}$ s$^{-1}$. The solar photon luminosity is fixed, so energy losses due to the Primakoff process require enhanced nuclear energy production and thus enhanced neutrino fluxes. The all-flavor measurements by SNO (Solar Neutrino Observatory), together with a standard solar model, imply $L_A \lesssim 0.10\, L_\odot$, corresponding to $g_{10} \lesssim 7$ [70], mildly superseding a similar limit from helioseismology [71]. In Ref. [72], this limit was improved to $g_{10} < 4.1$ (at $3\,\sigma$), exploiting a new statistical analysis that combined helioseismology (sound speed, surface helium and convective radius) and solar neutrino observations, including theoretical and observational errors, and accounting for tensions between input parameters of solar models, in particular the solar element abundances.

A more restrictive limit derives from globular-cluster (GC) stars that allow for detailed tests of stellar-evolution theory. The stars on the horizontal branch (HB) in the color-magnitude diagram have reached helium burning with a core-averaged energy release of about 80 erg g$^{-1}$ s$^{-1}$, compared to Primakoff axion losses of $g_{10}^2\, 30$ erg g$^{-1}$ s$^{-1}$. The accelerated consumption of helium reduces the HB lifetime by about $80/(80{+}30\, g_{10}^2)$. Number counts of HB stars in a large sample of 39 Galactic GCs compared with the number of red giants (that are not much affected by Primakoff losses) give a weak indication of non-standard losses which may be accounted by Primakoff-like axion emission, if the photon coupling is in the range $|g_{A\gamma\gamma}| = (2.9 \pm 1.8) \times 10^{-11}$ GeV$^{-1}$ [73, 74]. Still, the upper bound found in this analysis,

$$|g_{A\gamma\gamma}| < 6.6 \times 10^{-11}\,\text{GeV}^{-1}\ (95\%\,\text{CL}), \tag{91.13}$$

represents the strongest limit on $g_{A\gamma\gamma}$ for a wide mass range, see Fig. 91.1. The conservative constraint, Eq. (91.13), on $g_{A\gamma\gamma}$ may be translated to $f_A > 3.4 \times 10^7$ GeV ($m_A < 0.2$ eV), using $E/N = 0$ as in the KSVZ model, or to $f_A > 1.3 \times 10^7$ GeV ($m_A < 0.5$ eV), for the DFSZ axion model, with $E/N = 8/3$, see Fig. 91.1.

If axions couple directly to electrons, the dominant emission processes are atomic axio-recombination and axio-deexcitation, axio-bremsstrahlung in electron-ion or electron-electron collisions, and Compton scattering [75]. Stars in the red giant (RG) branch of the color-magnitude diagram of GCs are particularly sensitive to these processes. In fact, they would lead to an extension of the latter to larger brightness. Reference [76] provided high-precision photometry for the Galactic globular cluster M5 (NGC 5904), allowing for a detailed comparison between the observed tip of the RG branch with predictions based on state-of-the-art stellar evolution theory. It was found that, within the uncertainties, the observed and predicted tip of the RG branch brightness agree reasonably well, leading to the bound

$$|g_{Aee}| < 4.3 \times 10^{-13} \quad (95\%\ \text{CL}), \tag{91.14}$$

implying an upper bound on the axion mass in the DFSZ model,

$$m_A \sin^2\beta < 15\ \text{meV} \quad (95\%\ \text{CL}), \tag{91.15}$$

see Fig. 91.2 (left panel). Intriguingly, the agreement would improve with a small amount of extra cooling that slightly postpones helium ignition, prefering an electron coupling around $|g_{Aee}| \sim 1.9 \times 10^{-13}$, corresponding to $m_A \sin^2\beta \sim 7$ meV.

Bremsstrahlung is also efficient in white dwarfs (WDs), where the Primakoff and Compton processes are suppressed by the large plasma frequency. A comparison of the predicted and observed luminosity function of WDs can be used to put limits on $|g_{Aee}|$ [78]. A recent analysis, based on detailed WD cooling treatment and new data on the WD luminosity function (WDLF) of the Galactic Disk, found that electron couplings above $|g_{Aee}| \gtrsim 3 \times 10^{-13}$, corresponding to a DFSZ axion mass $m_A \sin^2\beta \gtrsim 10$ meV, are disfavoured [79], see Fig. 91.2 (left panel). Lower couplings cannot be discarded from the current knowledge of the WDLF of the Galactic Disk. On the contrary, features in some WDLFs can be interpreted as suggestions for electron couplings in the range $7.2 \times 10^{-14} \lesssim |g_{Aee}| \lesssim 2.2 \times 10^{-13}$, corresponding to 2.5 meV $\lesssim m_A \sin^2\beta \lesssim 7.5$ meV [79, 80]. This hypothesis will be further scrutinized by the Large Synoptic Survey Telescope (LSST) which is expected to increase the sample of WDs in the Galactic halo to hundreds of thousands [81]. This will allow for the determination of independent WDLFs from different Galactic populations, greatly reducing the uncertainties related to star formation histories. For pulsationally unstable WDs (ZZ Ceti stars), the period decrease $\dot{P}/P$ is a measure of the cooling speed. The corresponding observations of the pulsating WDs G117-B15A and R548 imply additional cooling that can be interpreted also in terms of similar axion losses [82, 83].

Recently, it has been pointed out that the hints of excessive cooling of WDs, RGs and HB stars can be explained at one stroke by an ALP coupling to electrons and photons, with couplings $|g_{Aee}| \sim 1.5 \times 10^{-13}$ and $|g_{A\gamma\gamma}| \sim 1.4 \times 10^{-11}\,\text{GeV}^{-1}$, respectively [84, 85]. Intriguingly, good fits to the data can be obtained employing the DFSZ axion with a mass in the range $4\,\text{meV} \lesssim m_A \lesssim 250\,\text{meV}$ [84].

Similar constraints derive from the measured duration of the neutrino signal of the supernova SN 1987A. Numerical simulations for a variety of cases, including axions and Kaluza-Klein gravitons, reveal that the energy-loss rate of a nuclear medium at the density $3 \times 10^{14}$ g cm$^{-3}$ and temperature 30 MeV should not exceed about $1{\times}10^{19}$ erg g$^{-1}$ s$^{-1}$ [86]. The energy-loss rate from nucleon bremsstrahlung, $N{+}N \to N{+}N{+}A$, is $(C_N/2f_A)^2(T^4/\pi^2 m_N)\, F$. Here $F$ is a numerical factor that represents an integral over the dynamical spin-density structure function because axions couple to the nucleon spin. For realistic conditions, even after considerable effort, one is limited to a heuristic estimate leading to $F \approx 1$ [68]. The SN 1987A limits are of particular interest for hadronic axions where the bounds on $|g_{Aee}|$ are moot. Using a proton fraction of 0.3, $g_{Ann} = 0$, $F = 1$, and $T = 30$ MeV, one finds $f_A \gtrsim 4{\times}10^8$ GeV and $m_A \lesssim 16$ meV [68], see Fig. 91.2 (right panel). A more detailed numerical calculation [87] with state of the art SN models, again assuming $g_{Ann} = 0$, found that a coupling larger than $|g_{App}| \gtrsim 6 \times 10^{-10}$, would shorten significantly the timescale of the neutrino emission. This result is, not surprisingly, rather close to the estimate in Ref. [68]. Improving the

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

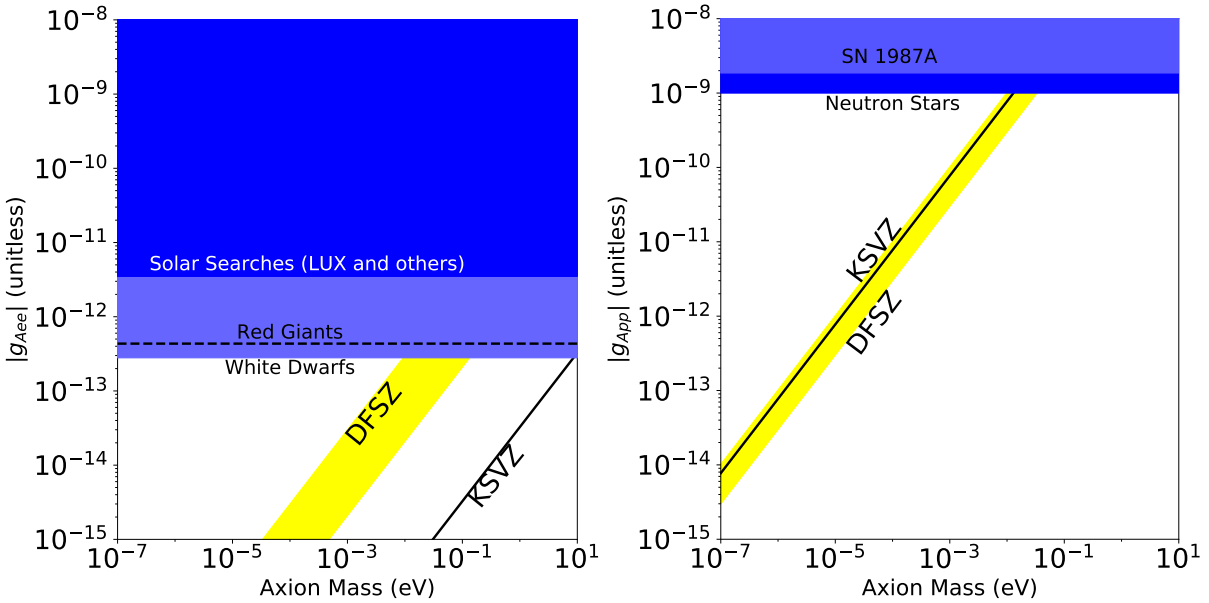

Figure 91.2: Exclusion plots for ALPs as described in the text. For the DFSZ range we have taken into account the constraint $0.28 \lesssim \tan\beta \lesssim 140$ [77] arising from the requirement of perturbative unitarity of the Yukawa couplings of Standard Model fermions.

calculation of axion emission via nucleon-nucleon bremsstrahlung beyond the basic one-pion exchange approximation appears to losen the bound [88, 89]. The latter analysis finds a reduction of the axion emissivity by an order of magnitude if one takes into account the non-vanishing mass of the exchanged pion, the contribution from two-pion exchange, effective in-medium nucleon masses and multiple nucleon scattering, leading to a looser bound (Maurizio Giannotti and Alessandro Mirizzi, private communication)

$$g_{Ann}^2 + 0.29\, g_{App}^2 + 0.27\, g_{Ann}\, g_{App} < 3.25 \times 10^{-18}. \quad (91.16)$$

However, with the present understanding of SNe (current lack of self-consistent 3D SN simulations) and the sparse data from SN 1987A, the constraint on the axion-nucleon couplings from SN 1987A should be considered more as indicative than as a sharp bound [87].

If axions interact sufficiently strongly they are trapped. Only about three orders of magnitude in $g_{ANN}$ or $m_A$ are excluded. For even larger couplings, the axion flux would have been negligible, yet it would have triggered additional events in the detectors, excluding a further range [90]. A possible gap between these two SN 1987A arguments was discussed as the "hadronic axion window" under the assumption that $g_{A\gamma\gamma}$ was anomalously small [91]. This range is now excluded by hot dark matter (HDM) bounds (see below).

There is another hint for excessive stellar energy losses from the neutron star (NS) in the supernova remnant Cassiopeia A (Cas A): its surface temperature measured over 10 years reveals an unusually fast cooling rate. This rapid cooling of the Cas A NS may be explained by NS minimal cooling with neutron superfluidity and proton superconductivity [92, 93]. The rapid cooling may also arise from a phase transition of the neutron condensate into a multicomponent state [94]. Recently, Ref. [95] analyzed Cas A NS cooling in the presence of axion emission and obtained

$$g_{App}^2 + 1.6 g_{Ann}^2 < 1 \times 10^{-18}, \quad (91.17)$$

which is comparable to the SN 1987A bound. Refs. [96] put a more conservative bound without an attempt to fit a transient behavior of Cas A,

$$g_{App}^2 < (1-6) \times 10^{-17} (\text{or } f_A > (5-10) \times 10^7 \text{ GeV}), \quad (91.18)$$

from the temperatures of Cas A and other NSs. The Cas A NS cooling may also be interpreted as a hint for extra cooling caused by the emission of axions from the breaking and re-formation of neutron triplet Cooper pairs [97], requiring a coupling to the neutron of

$$g_{Ann}^2 = (1.4 \pm 0.5) \times 10^{-19}, \quad (91.19)$$

corresponding to an axion mass

$$m_A = (2.3 \pm 0.4)\, \text{meV}/C_n. \quad (91.20)$$

On the other hand, Ref. [98] considered another hot young NS in the supernova remnant HESS J1731-347. Its high temperature implies that all the neutrino emission processes except neutron-neutron bremsstrahlung must be strongly suppressed, which can be realized with a negligible neutron triplet gap and a large proton singlet gap. In this setup, the bremsstrahlung from neutrons is the dominant channel for axion emission, from which one obtains a limit

$$g_{Ann}^2 < 7.7 \times 10^{-20}, \quad (91.21)$$

see Fig. 91.3 (left panel).

Finally, let us note that if the interpretation of the various hints for additional cooling of stars reported in this section in terms of emission of axions with $m_A \sim$ meV were correct, SNe would lose a large fraction of their energy as axions. This would lead to a diffuse SN axion background in the universe with an energy density comparable to the extra-galactic background light [99]. However, there is no apparent way of detecting it or the axion burst from the next nearby SN. On the other hand, neutrino detectors such as IceCube, Super-Kamiokande or a future mega-ton water Cherenkov detector will probe exactly the mass region of interest by measuring the neutrino pulse duration of the next galactic SN [87].

### 91.4.2 *Searches for solar axions and ALPs*

Instead of using stellar energy losses to derive axion limits, one can also search directly for these fluxes, notably from the Sun. The main focus has been on ALPs with a two-photon vertex. They are produced by the Primakoff process with a flux given by Eq. (91.12) and an average energy of 4.2 keV, and can be detected at Earth with the reverse process in a macroscopic $B$-field ("axion helioscope") [6]. In order to extend the sensitivity in mass towards larger values, one can endow the photon with an effective mass in a gas, $m_\gamma = \omega_{\rm plas}$, thus matching the axion and photon dispersion relations [100].

An early implementation of these ideas used a conventional dipole magnet, with a conversion volume of variable-pressure gas with a xenon proportional chamber as x-ray detector [101]. The

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

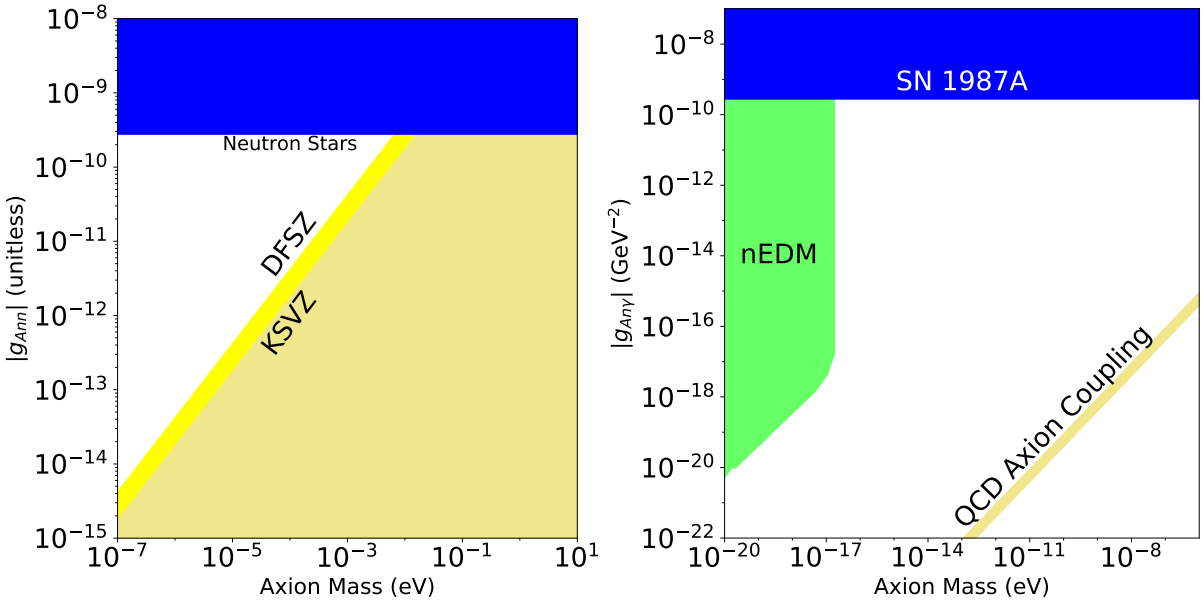

Figure 91.3: Exclusion plots for ALPs as described in the text.

conversion magnet was fixed in orientation and collected data for about 1000 s/day. Axions were excluded for $|g_{A\gamma\gamma}| < 3.6 \times 10^{-9}$ GeV$^{-1}$ for $m_A < 0.03$ eV, and $|g_{A\gamma\gamma}| < 7.7 \times 10^{-9}$ GeV$^{-1}$ for $0.03 < m_A < 0.11$ eV at 95% CL.

Later, the Tokyo axion helioscope used a superconducting magnet on a tracking mount, viewing the Sun continuously. They reported $|g_{A\gamma\gamma}| < 6 \times 10^{-10}$ GeV$^{-1}$ for $m_A < 0.3$ eV [102]. This experiment was recommissioned and a similar limit for masses around 1 eV was reported [103].

The most recent helioscope CAST (CERN Axion Solar Telescope) uses a decommissioned LHC dipole magnet on a tracking mount. The hardware includes grazing-incidence x-ray optics with solid-state x-ray detectors, as well as novel x-ray Micromegas position-sensitive gaseous detectors. Exploiting a IAXO (see below) pathfinder system, CAST has established the limit

$$|g_{A\gamma\gamma}| < 6.6 \times 10^{-11} \text{ GeV}^{-1} \quad (95\% \text{ CL}), \tag{91.22}$$

for $m_A < 0.02$ eV [104]. To cover larger masses, the magnet bores are filled with a gas at varying pressure. The runs with $^4$He cover masses up to about 0.4 eV [105], providing the $^4$He limits shown in Fig. 91.1. To cover yet larger masses, $^3$He was used to achieve a larger pressure at cryogenic temperatures. Limits up to 1.17 eV allowed CAST to "cross the axion line" for the KSVZ model [106], see Fig. 91.1.

Going to yet larger masses in a helioscope search is not well motivated because of the cosmic HDM bound of $m_A \lesssim 1$ eV (see below). Sensitivity to significantly smaller values of $g_{A\gamma\gamma}$ can be achieved with a next-generation axion helioscope with a much larger magnetic-field cross section. Realistic design options for this "International Axion Observatory" (IAXO) have been studied in some detail [107] and its physics potential has been reviewed recently [108]. Such a next-generation axion helioscope may also push the sensitivity in the product of couplings to photons and to electrons, $g_{A\gamma\gamma}g_{Aee}$, into a range beyond stellar energy-loss limits and test the hypothesis that WD, RG, and HB cooling is dominated by axion emission [84, 109]. As a first step towards IAXO, an intermediate experimental stage called BabyIAXO is currently under preparation at DESY (for a short introduction, see Ref. [108]).

Other Primakoff searches for solar axions and ALPs have been carried out using crystal detectors, exploiting the coherent conversion of axions into photons when the axion angle of incidence satisfies a Bragg condition with a crystal plane [110]. However, none of these limits is more restrictive than the one derived from the constraint on the solar axion luminosity ($L_A \lesssim 0.10\, L_\odot$) discussed earlier.

Another idea is to look at the Sun with an x-ray satellite when the Earth is in between. Solar axions and ALPs would convert in the Earth magnetic field on the far side and could be detected [111]. The sensitivity to $g_{A\gamma\gamma}$ could be comparable to CAST, but only for much smaller $m_A$. Deep solar x-ray measurements with existing satellites, using the solar magnetosphere as conversion region, have reported preliminary limits on $g_{A\gamma\gamma}$ [112].

Direct detection experiments searching for dark matter (DM) consisting of weakly interacting massive particles, such as EDELWEISS-II, LUX, and XENON100, have also the capability to search for solar axions and ALPs [113,114]. Recently, the LUX experiment [114] has put a bound on the axion-electron coupling constant by exploiting the axio-electric effect in liquid xenon,

$$|g_{Aee}| < 3.5 \times 10^{-12} \quad (90\% \text{ CL}), \tag{91.23}$$

excluding the DFSZ model with $m_A \sin^2\beta > 0.12\,\text{eV}$, cf. see Fig. 91.2 (left panel). However, as obvious from the same figure, this technique has not reached the sensitivity of energy-loss considerations in stars (RGs and WDs).

### 91.4.3 *Conversion of astrophysical photon fluxes*

Large-scale $B$ fields exist in astrophysics that can induce axion-photon oscillations. In practical cases, $B$ is much smaller than in the laboratory, whereas the conversion region $L$ is much larger. Therefore, while the product $BL$ can be large, realistic sensitivities are usually restricted to very low-mass particles, far away from the "axion band" in a plot like Fig. 91.1.

One example is SN 1987A, which would have emitted a burst of ALPs due to the Primakoff production in its core. They would have partially converted into $\gamma$-rays in the galactic $B$-field. The lack of a gamma-ray signal in the GRS instrument of the SMM satellite in coincidence with the observation of the neutrinos emitted from SN 1987A therefore provides a strong bound on their coupling to photons [115]. This bound has been revisited and the underlying physics has been brought to the current state-of-the-art, as far as modelling of the supernova and the Milky-Way magnetic field are concerned, resulting in the limit [116]

$$|g_{A\gamma\gamma}| < 5.3 \times 10^{-12} \text{ GeV}^{-1}, \text{ for } m_A \lesssim 4.4 \times 10^{-10} \text{ eV}, \tag{91.24}$$

see Fig. 91.1. Magnetically induced oscillations between photons and ALPs can modify the photon fluxes from distant sources in various ways, featuring (i) frequency-dependent dimming, (ii) modified polarization, and (iii) avoiding absorption by propagation in the form of axions.

For example, dimming of SNe Ia could influence the interpretation in terms of cosmic acceleration [117], although it has become

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

clear that photon-ALP conversion could only be a subdominant effect [118]. Searches for linearly polarised emission from magnetised white dwarfs [119] and changes of the linear polarisation from radio galaxies (see, e.g., Ref. [120]) provide limits close to $g_{A\gamma\gamma} \sim 10^{-11}$ GeV$^{-1}$, for masses $m_A \lesssim 10^{-7}$ eV and $m_A \lesssim 10^{-15}$ eV, respectively, albeit with uncertainties related to the underlying assumptions. Even stronger limits, $g_{A\gamma\gamma} \lesssim 2 \times 10^{-13}$ GeV$^{-1}$, for $m_A \lesssim 10^{-14}$ eV, have been obtained by exploiting high-precision measurements of quasar polarisations [121].

Remarkably, it appears that the universe could be too transparent to TeV $\gamma$-rays that should be absorbed by pair production on the extra-galactic background light [122–126]. The situation is not conclusive at present [127–129], but the possible role of photon-ALP oscillations in TeV $\gamma$-ray astronomy is tantalizing [130]. Fortunately, the region in ALP parameter space, $g_{A\gamma\gamma} \sim 10^{-12} - 10^{-10}$ GeV$^{-1}$ for $m_A \lesssim 10^{-7}$ eV [131], required to explain the anomalous TeV transparency of the universe, could be conceivably probed by the next generation of laboratory experiments (ALPS II) and helioscopes (IAXO) mentioned above. This parameter region can also be probed by searching for an irregular behavior of the gamma ray spectrum of distant active galactic nuclei (AGN), expected to arise from photon-ALP mixing in a limited energy range. The H.E.S.S. collaboration has set a limit of $|g_{A\gamma\gamma}| \lesssim 2.1 \times 10^{-11}$ GeV$^{-1}$, for $1.5 \times 10^{-8}$ eV $\lesssim m_A \lesssim 6.0 \times 10^{-8}$ eV, from the non-observation of an irregular behavior of the spectrum of the AGN PKS 2155-304 [132], see Fig. 91.1. The Fermi-LAT collaboration has put an even more stringent limit on the ALP-photon coupling [133] from observations of the gamma ray spectrum of NGC 1275, the central galaxy of the Perseus cluster, see Fig. 91.1. A similar analysis has been carried out in Ref. [134] using Fermi-LAT data of PKS 2155-304.

Evidence for spectral irregularities has been reported in Galactic sources, such as pulsars and supernova remnants, and has been interpreted as hints for ALPs [135, 136]. However, the inferred ALP parameters are in tension with the CAST helioscope bounds. It should also be noted that the high signal-to-noise spectra of Galactic gamma-ray sources are dominated by uncertainties of the instrumental systematics rather than statistical errors. Furthermore, it has been shown that additional care has to be taken when deriving confidence intervals on ALP parameters based on Wilks' theorem [137], since it has been shown that it does not apply for testing the ALP hypothesis [133].

At smaller masses, $m_A \lesssim 10^{-12}$ eV, galaxy clusters become highly efficient at interconverting ALPs and photons at x-ray energies. Constraints on spectral irregularities in the spectra of luminous x-ray sources (Hydra A, M87, NGC 1275, NGC 3862, Seyfert galaxy 2E3140; taken by Chandra and XMM-Newton) located in or behind galaxy clusters then lead to stringent upper limits on the ALP-photon coupling [138–143]. In this type of studies, the uncertainty in the cluster magnetic field needs to be taken into account. This typically leads to a range of limits on the ALP-photon coupling that depend on the modelling assumptions. Reference [143] recently performed the most sensitive x-ray searches for ALPs to date by employing Chandra's High-Energy Transmission Gratings that allow for an unsurpassed spectral resolution. New observations of the AGN NGC 1275 then led to the bound

$$|g_{A\gamma\gamma}| < 8 \times 10^{-13}\,\text{GeV}^{-1} \quad (99.7\%\ \text{CL}) \tag{91.25}$$

for light ALPs, see Fig. 91.1.

#### 91.4.4 *Superradiance of black holes*

Light bosonic fields such as axions or ALPs can affect the dynamics and gravitational wave emission of rapidly rotating astrophysical black holes through the superradiance mechanism. When their Compton wavelength is of order of the black hole size, they form gravitational bound states around the black hole. Their occupation number grows exponentially by extracting energy and angular momentum from the black hole, forming a coherent axion or ALP bound state emitting gravitational waves. When accretion cannot replenish the spin of the black hole, superradiance dominates the black hole spin evolution; this is true for both supermassive and stellar mass black holes. The existence of destabilizing light bosonic fields thus leads to gaps in the mass vs. spin plot of rotating black holes. Stellar black hole spin measurements – exploiting well-studied binaries and two independent techniques – exclude a mass range $6 \times 10^{-13}\,\text{eV} < m_A < 2 \times 10^{-11}\,\text{eV}$ at $2\,\sigma$, which for the axion excludes $3 \times 10^{17}\,\text{GeV} < f_A < 1 \times 10^{19}\,\text{GeV}$ [11, 144, 145]. These bounds apply when gravitational interactions dominate over the axion self-interaction, which is true for the QCD axion in this mass range. Long lasting, monochromatic gravitational wave signals, which can be distinguished from ordinary astrophysical sources by their clustering in a narrow frequency range, are expected to be produced by axions or ALPs annihilating to gravitons. Gravitational waves could also be sourced by axions/ALPs transitioning between gravitationally bound levels. Accordingly, the gravitational wave detector Advanced LIGO should be sensitive to the axion in the $m_A \lesssim 10^{-10}\,\text{eV}$ region. LIGO measurements of black hole spins in binary merger events could also provide statistical evidence for the presence of an axion [146, 147]. Similar signatures could arise for supermassive black holes for particle with masses $\lesssim 10^{-15}\,\text{eV}$. Gravitational waves from such sources could be detected at lower-frequency observatories such as LISA.

## 91.5 Cosmic Axions

#### 91.5.1 *Cosmic axion populations*

In the early universe, axions are produced by processes involving quarks and gluons [148]. After color confinement, the dominant thermalization process is $\pi + \pi \leftrightarrow \pi + A$ [34]. The resulting axion population would contribute an HDM component in analogy to massive neutrinos. Cosmological precision data provide restrictive constraints on a possible HDM fraction that translate into $m_A \lesssim 1$ eV [149], but in detail depend on the used data set and assumed cosmological model. In the future, data from a EUCLID-like survey combined with Planck CMB data can detect HDM axions with a mass $m_A \gtrsim 0.15\,\text{eV}$ at very high significance [150].

For $m_A \gtrsim 20$ eV, axions decay fast on a cosmic time scale, removing the axion population while injecting photons. This excess radiation provides additional limits up to very large axion masses [151]. An anomalously small $g_{A\gamma\gamma}$ provides no loophole because suppressing decays leads to thermal axions overdominating the mass density of the universe.

The main cosmological interest in axions derives from their possible role as CDM. In addition to thermal processes, axions are abundantly produced by the vacuum re-alignment (VR) mechanism [152].

The axion DM abundance crucially depends on the cosmological history. Let us first consider the so called *pre-inflationary PQ symmetry breaking scenario*, in which the PQ symmetry is broken before and during inflation and not restored afterwards. After the breakdown of the PQ symmetry, the axion field relaxes somewhere in the bottom of the "wine-bottle-bottom" potential. Near the QCD epoch, topological fluctuations of the gluon fields such as instantons explicitly break the PQ symmetry. This tilting of the "wine-bottle-bottom" drives the axion field toward the CP-conserving minimum, thereby exciting coherent oscillations of the axion field that ultimately represent a condensate of CDM. The fractional cosmic mass density in this homogeneous field mode, created by the VR mechanism, is [23, 153–155],

$$\begin{aligned}\Omega_A^{\text{VR}} h^2 &\approx 0.12 \left(\frac{f_A}{9 \times 10^{11}\ \text{GeV}}\right)^{1.165} F\,\Theta_{\text{i}}^2 \\ &\approx 0.12 \left(\frac{6\ \mu\text{eV}}{m_A}\right)^{1.165} F\,\Theta_{\text{i}}^2\,,\end{aligned} \tag{91.26}$$

where $h$ is the present-day Hubble expansion parameter in units of 100 km s$^{-1}$ Mpc$^{-1}$, and $-\pi \le \Theta_{\text{i}} \le \pi$ is the initial "misalignment angle" relative to the CP-conserving position attained in the causally connected region which evolved into today's observable universe. $F = F(\Theta_{\text{i}}, f_A)$ is a factor accounting for anharmonicities in the axion potential. For $F\Theta_{\text{i}}^2 = \mathcal{O}(1)$, $m_A$ should be above $\sim 6\,\mu$eV in order that the cosmic axion density does not exceed the observed CDM density, $\Omega_{\text{CDM}} h^2 = 0.12$. However, much smaller

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

axion masses (much higher PQ scales) are still possible if the initial value $\Theta_{\rm i}$ just happens to be small enough in today's observable universe ("anthropic axion window" [156]). In this cosmological scenario, however, quantum fluctuations of the axion field during inflation are expected to lead to isocurvature density fluctuations which get imprinted to the temperature fluctuations of the CMB [157,158]. Their non-observation puts severe constraints on the Hubble expansion rate $H_I$ during inflation [159–163], which read, in the simplest cosmological inflationary scenario,

$$H_I \lesssim 5.7\times 10^8\,{\rm GeV}\left(\frac{5\,{\rm neV}}{m_a}\right)^{0.4175}\,, \tag{91.27}$$

if axions represent all of DM.

In the *post-inflationary PQ symmetry breaking scenario*, on the other hand, $\Theta_{\rm i}$ will take on different values in different patches of the present universe. The average contribution is [23, 153–155]

$$\Omega_A^{\rm VR}h^2 \approx 0.12\,\left(\frac{30\ \mu{\rm eV}}{m_A}\right)^{1.165}\,. \tag{91.28}$$

The decay of cosmic strings and domain walls gives rise to a further population of CDM axions, whose abundance suffers from significant uncertainties [154, 155, 164–172] which arise from the difficulty in understanding the energy loss process of topological defects and the generated axion spectrum in a quantitative way. In fact, in the present state-of-the-art it is still possible that the CDM contribution from the decay of topological defects is subdominant or overwhelmingly large in comparison to the one from the VR mechanism. Correspondingly, the plausible range of axion masses providing all of CDM in scenarios with postinflationary PQ symmetry breaking is still rather large, namely

$$m_A \approx 25\ \mu{\rm eV} - 4.4\ {\rm meV}, \tag{91.29}$$

for models with short-lived (requiring unit color anomaly $N = 1$) domain walls, such as the KSVZ model. For models with long-lived ($N > 1$) domain walls, such as an accidental DFSZ model [173], where the PQ symmetry is broken by higher dimensional Planck suppressed operators, the mass is predicted to be significantly higher [168, 173, 174],

$$m_A \approx (0.58 - 130)\,{\rm meV}\,. \tag{91.30}$$

However, the upper part of the predicted range is in conflict with stellar energy-loss limits on the axion, cf. Fig. 91.2 (right panel) and Fig. 91.3 (left panel).

In this post-inflationary PQ symmetry breakdown scenario, the spatial axion density variations are large at the QCD transition and they are not erased by free streaming. Gravitationally bound "axion miniclusters" form before and around matter-radiation equality [175–177]. A significant fraction of CDM axions can reside in these bound objects [171,178]. Remarkably, the minicluster fraction can be bounded by gravitational lensing [179–181].

In the above predictions of the fractional cosmic mass density in axions, the exponent, 1.165, arises from the non-trivial temperature dependence of the topological susceptibility $\chi(T) = m_A^2(T)f_A^2$ at temperatures slighty above the QCD quark-hadron phase transition. Lattice QCD calculations of this exponent [23, 182–186], but also Ref. [187], found it to be remarkably close to the prediction of the dilute instanton gas approximation [188] which was previously exploited. Therefore, the state-of-the-art prediction of the axion mass relevant for DM for a fixed initial misalignment angle $\Theta_{\rm i}$ differs from the previous prediction by just a factor of order one.

The non-thermal production mechanisms attributed to axions are generic to light bosonic weakly interacting particles such as ALPs [189]. The relic abundance is set by the epoch when the axion mass becomes significant, $3H(t) \approx m_A(t)$, and ALP field oscillations begin. For ALPs to contribute to the DM density this epoch must precede that of matter radiation equality. For a temperature independent ALP mass this leads to the bound:

$$m_A \gtrsim 7\times 10^{-28}\,{\rm eV}\left(\frac{\Omega_m\,h^2}{0.15}\right)^{1/2}\left(\frac{1+z_{\rm eq}}{3.4\times 10^3}\right)^{3/2}\,. \tag{91.31}$$

ALPs lighter than this bound are allowed if their cosmic energy density is small, but they are quite distinct from other forms of DM [190]. Ignoring anharmonicities in the ALP potential, and taking the ALP mass to be temperature independent, the relic density in DM ALPs due to the VR mechanism is given by

$$\Omega_{\rm ALP}^{\rm VR}h^2 = 0.12\left(\frac{m_A}{4.7\times 10^{-19}\,{\rm eV}}\right)^{1/2}\left(\frac{f_A}{10^{16}\,{\rm GeV}}\right)^2 \times \left(\frac{\Omega_m h^2}{0.15}\right)^{3/4}\left(\frac{1+z_{\rm eq}}{3.4\times 10^3}\right)^{-3/4}\Theta_{\rm i}^2\,. \tag{91.32}$$

An ALP decay constant near the GUT scale gives the correct relic abundance for *ultralight ALPs* (ULAs), which we now define. Extended discussions of ULAs can be found in Refs. [191, 192].

The standard CDM model treats DM as a distribution of cold, collisionless particles interacting only via gravity. Below the Compton wavelength, $\lambda_c = 2\pi/m_A$, the particle description of ALPs breaks down. For large occupation numbers we can model ALPs below the Compton wavelength as a coherent classical field. Taking as a reference length scale the Earth radius, $R_\oplus = 6371\,{\rm km}$, we define ULAs to be those axions with $\lambda_c > R_\oplus$, leading to the defining bound

$$m_{\rm ULA} < 2\times 10^{-13}\,{\rm eV}\,. \tag{91.33}$$

ULAs encompass the entire Earth in a single coherent field. The coherence time of the ULA field on Earth can be estimated from the crossing time of the de Broglie wavelength at the virial velocity in the Milky Way, $\tau_{\rm coh.} \sim 1/m_{\rm ULA}v_{\rm vir.}^2$.

We notice that by the definition, Eq. (91.33), an ultralight QCD axion must have a super-Planckian decay constant, $f_A > 3\times 10^{19}\,{\rm GeV}$ and would require fine tuning of $\theta_i$ to provide the relic abundance. Natural models for ULAs can be found in string and M-theory compactifications [7–14], in field theory with accidental symmetries [193], or new hidden strongly coupled sectors [194].

In addition to the gravitational potential energy, the ULA field also carries gradient energy. On scales where the gradient energy is non-negligible, ULAs acquire an effective pressure and do not behave as CDM. The gradient energy opposes gravitational collapse, leading to a Jeans scale below which perturbations are stable [195]. The Jeans scale suppresses linear cosmological structure formation relative to CDM [196]. The Jeans scale at matter-radiation equality in the case that ULAs make up all of CDM is:

$$k_{\rm J,eq} = 8.7\,{\rm Mpc}^{-1}\left(\frac{1+z_{\rm eq}}{3.4\times 10^3}\right)^{-1/4}\left(\frac{\Omega_{\rm ALP}^{\rm VR}}{0.12}\right)^{1/4} \times \left(\frac{m_{\rm ULA}}{10^{-22}\,{\rm eV}}\right)^{1/2}\,. \tag{91.34}$$

On non-linear scales the gradient energy leads to the existence of a class of pseudo-solitons known as oscillatons, or axion stars [197].

Cosmological and astrophysical observations are consistent with the CDM model, and departures from it are only allowed on the scales of the smallest observed DM structures with $M \sim 10^{6-8}M_\odot$. The CMB power spectrum and galaxy autocorrelation power spectrum limit the ULA mass to $m_{\rm ULA} > 10^{-24}\,{\rm eV}$ from linear theory of structure formation [190, 198]. Analytic models [199] and $N$-body simulations [200] for non-linear structures show that halo formation is suppressed in ULA models relative to CDM. This leads to constraints on the ULA mass of $m_{\rm ULA} > 10^{-22}\,{\rm eV}$ from observations of high-$z$ galaxies [200, 201], and $m_{\rm ULA} > 10^{-21}\,{\rm eV}$ from the Lyman-alpha forest flux power spectrum [202]. Including the effects of anharmonicities on structure formation with ALPs can weaken these bounds if the misalignment angle $\Theta_{\rm i} \approx \pi$ [203]. Cosmological simulations that treat gradient energy in the ULA field beyond the $N$-body approximation have just recently become available [204, 205], and show, among other things, evidence for the formation of axion stars in the centres of ULA halos (various consequences of axion stars are considered in Refs. [206]). These central axion stars have been conjectured to play a role in the apparently cored density

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

profiles of dwarf spheroidal galaxies, and other central galactic regions [204, 207–209]. However, the relationship between the halo mass and the axion star mass [210] leads to problems with this scenario in some galaxies [211–213]. It should be emphasised that many of the conclusions about the role of ULA axion stars in galactic dynamics are based on use of simulation results that do not contain baryons (however, see Ref. [214]), and feedback [215] could be important.

Inside DM halos the axion gradient energy causes coherence on the de Broglie wavelength and fluctuations on the coherence time [204,216]. These fluctuations can be thought of as short-lived quasiparticles and lead to relaxation processes that can be described statistically [192,217] (this relaxation processes also leads to the gravitational condensation of axion stars [218]). The typical relaxation time is:

$$t \sim 10^{10}\ \text{years} \left(\frac{m_{\rm ULA}}{10^{-22}\ \text{eV}}\right)^3 \left(\frac{v}{100\ \text{km s}^{-1}}\right)^2 \left(\frac{r}{5\ \text{kpc}}\right)^4 , \tag{91.35}$$

where $v$ and $r$ are the velocity and radius of the orbit in the host DM halo.

Relaxation processes such as these are not observed in galaxies, though there are some circumstances where they may be desirable [192]. An absence of observed relaxation can be used to set limits on the ULA mass. An absence of Milky Way disk thickening excludes $m_{\rm ULA} > 0.6 \times 10^{-22}$ eV [219], while stellar streams give the stronger bound $m_{\rm ULA} > 1.5 \times 10^{-22}$ eV [220]. The survival of the old star cluster in Eridanus II [221] excludes the range of masses $10^{-21}$ eV $\lesssim m_{\rm ULA} \lesssim 10^{-19}$ eV [222]. As in the case of ULA axion stars, current constraints from heating do not fully account for the possible role of baryons.

Finally, one should note that the beyond-CDM physics of ULAs (Jeans scale, relaxation, axion star formation) of course also applies to the QCD axion on smaller length scales. This is of particular interest inside axion miniclusters [175, 176, 218, 223].

### 91.5.2 *Telescope searches*

The two-photon decay is extremely slow for axions with masses in the CDM regime, but could be detectable for eV masses. The signature would be a quasi-monochromatic emission line from galaxies and galaxy clusters. The expected optical line intensity for DFSZ axions is similar to the continuum night emission. An early search in three rich Abell clusters [224] and a recent search in two rich Abell clusters [225] exclude the "Telescope" range in Fig. 91.1. Of course, axions in this mass range would anyway provide an excessive hot DM contribution.

Very low-mass axions in halos produce a weak quasi-monochromatic radio line. Virial velocities in undisrupted dwarf galaxies are very low, and the axion decay line would therefore be extremely narrow. A search with the Haystack radio telescope on three nearby dwarf galaxies provided a limit $|g_{A\gamma\gamma}| < 1.0\times10^{-9}$ GeV$^{-1}$ at 96% CL for $298 < m_A < 363\ \mu$eV [226]. However, this combination of $m_A$ and $g_{A\gamma\gamma}$ does not exclude plausible axion models.

A monochromatic signal is also produced in the conversion of DM axions in the background of slowly varying galactic $B$-fields [227]. The signal is, however, sensitive to magnetic field power on the scale of the axion mass [228]. Present and future radio telescopes appear to be able to probe ALP DM in the mass range $0.1 - 100\ \mu$eV for couplings $g_{A\gamma\gamma} \gtrsim 10^{-13}$ GeV$^{-1}$ [228] – unfortunately not reaching down to the benchmark QCD axion sensitivity.

Resonant conversion of QCD axion DM in neutron star magnetospheres may give a detectable signal from individual neutron stars for axion masses in the $\mu$eV range [229]. Furthermore, stimulated ALP decays in high radiation environments may be detectable, by next-generation radio telescopes such as the Square Kilometer Array, down to $g_{A\gamma\gamma} \gtrsim 10^{-11}\,\text{GeV}^{-1}$, for masses between $\mu$eV and 0.1 meV [230].

Photon propagation on an ULA DM background can induce birefringence that can be compared with upper limits from the CMB [231] and may also be probed with other sources such as pulsars [232].

### 91.5.3 *Microwave cavity experiments*

In a big part of the plausible $m_A$ range for CDM, galactic halo axions may be detected by their resonant conversion into a quasi-monochromatic microwave signal in a high-Q electromagnetic cavity permeated by a strong static $B$ field [6,233,234]. The cavity frequency is tunable, and the signal is maximized when the frequency is the total axion energy, rest mass plus kinetic energy, of $\nu = (m_A/2\pi)\,[1 + \mathcal{O}(10^{-6})]$, the width above the rest mass representing the virial distribution in the galaxy. The frequency spectrum may also contain finer structure from axions more recently fallen into the galactic potential and not yet completely virialized [235, 236].

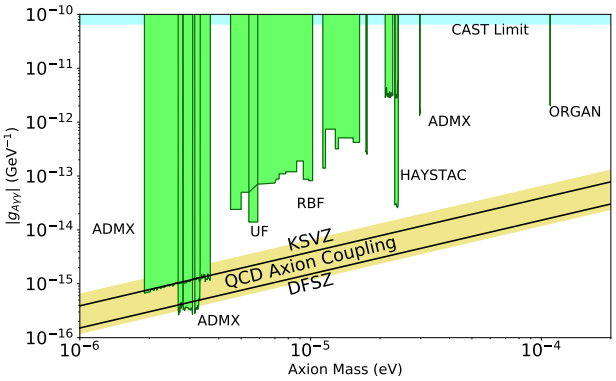

Figure 91.4: Exclusion plot for ALPs as described in the text.

The feasibility of this technique was established in early experiments (RBF and UF) of relatively small sensitive volume, $\mathcal{O}$(1 liter), with HFET-based amplifiers, setting limits in the range $4.5 < m_A < 16.3\ \mu$eV [237], but lacking by 2–3 orders of magnitude the sensitivity required to detect realistic axions, see Fig. 91.4. Later, ADMX ($B \sim 8$ T, $V \sim 200$ liters) has achieved sensitivity to KSVZ axions, assuming they saturate the local DM density and are well virialized, over the mass range 1.9–3.3 $\mu$eV [238]. Should halo axions have a significant component not yet virialized, ADMX is sensitive to DFSZ axions over the entire mass range [239]. The corresponding 90% CL exclusion regions shown in Fig. 91.4 are normalized to an assumed local CDM density of $7.5 \times 10^{-25}$ g cm$^{-3}$ (450 MeV cm$^{-3}$). More recently, the ADMX experiment commissioned an upgrade [240] that replaces the microwave HFET amplifiers by near quantum-limited low-noise dc SQUID microwave amplifiers [241]. It has reached an unprecedented axion DM sensitivity in the mass range between 2.66 and 3.31 $\mu$eV [242,243], down to the DFSZ benchmark axion-photon coupling, see Fig. 91.4. This apparatus is also sensitive to other hypothetical light bosons, such as hidden photons or chameleons, over a limited parameter space [189,244,245]. ADMX has also done a testbed experiment to probe higher masses. This experiment lives inside of and operates in tandem with the main ADMX experiment, searches in three widely spaced frequency ranges (4202–4249 MHz, 5086–5799 MHz and 7173–7203 MHz), uses both the $\text{TM}_{010}$ and $\text{TM}_{020}$ cavity modes, and demonstrates the successful use of a piezoelectric actuator for cavity tuning [246]. Recently, the HAYSTAC experiment reported on first results from a new microwave cavity search for DM axions with masses above 20 $\mu$eV. They exclude axions with two-photon coupling $|g_{A\gamma\gamma}| \gtrsim 2\times10^{-14}\,\text{GeV}^{-1}$ over the range $23.15\,\mu\text{eV} < m_A < 24.0\,\mu\text{eV}$ [247,248], a factor of 2.7 above the KSVZ benchmark, see Fig. 91.4. Exploiting a Josephson parametric amplifier, this experiment has demonstrated total noise approaching the standard quantum limit for the first time in an axion search. A Rydberg atom single-photon detector [249], like any photon counter, can in principle evade the standard quantum limit for coherent photon detection. The ORGAN experiment is designed to probe axions in the mass range $60\,\mu\text{eV} < m_A < 210\,\mu\text{eV}$. In a pathfinding run, it has set the limit $|g_{A\gamma\gamma}| < 2 \times 10^{-12}\,\text{GeV}^{-1}$ at 110 $\mu$eV, in a span of 2.5 neV [250]. There are further microwave cavity axion DM experiments recently in operation (CULTASK [251]), under construction (RADES [252]) or proposed (KLASH [253]).

### 91.5.4 *New concepts for axion DM direct detection*

Other new concepts for searching for axion DM are also being investigated. An alternative to the microwave cavity technique is based on a novel detector architecture consisting of an open, Fabry-Perot resonator and a series of current-carrying wire planes [254]. The Orpheus detector has demonstrated this new technique, excluding DM ALPs with masses between 68.2 and 76.5 $\mu$eV and axion-photon couplings greater than $4 \times 10^{-7}\,\mathrm{GeV}^{-1}$. This technique may be able to probe DM axions in the mass range from 40 to 700 $\mu$eV. Another detector concept exploits the fact that a magnetized mirror would radiate photons in the background of axion DM, which could be collected like in a dish antenna [255]. Searches for hidden photon DM exploiting this technique are already underway [256]. The proposed MADMAX experiment will place a stack of dielectric layers in a magnetic field in order to resonantly enhance the photon signal, aiming a sensitivity to probe the mass range $40\,\mu\mathrm{eV} \lesssim m_A \lesssim 200\,\mu\mathrm{eV}$ [257,258]. Optical dielectric haloscopes with single photon signal detection have been proposed to search for axions in the 50 meV – 10 eV mass range [259]. Absorption of axions on molecular transitions can be sensitive to the axion pseudoscalar coupling $g_{ANN}$ to nucleons or the pseudoscalar coupling $g_{Aee}$ to electrons in the 0.5 – 20 eV range [260]. Another proposed axion DM search method sensitive in the 100 $\mu$eV mass range is to cool a kilogram-sized sample to mK temperatures and count axion induced atomic transitions using laser techniques [261].

The oscillating galactic DM axion field induces oscillating nuclear electric dipole moments (EDMs) [262],

$$d_N(t) = g_{AN\gamma}\sqrt{2\rho_{\mathrm{ADM}}}\cos(m_A\,t)/m_A\,, \tag{91.36}$$

where $g_{AN\gamma}$ is the coupling of the axion to the nucleon EDM operator,

$$\mathcal{L}_A \supset -\frac{i}{2} g_{AN\gamma}\, A\,\overline{\Psi}_N \sigma_{\mu\nu}\gamma_5 \Psi_N F^{\mu\nu}\,. \tag{91.37}$$

For the QCD axion, this coupling is predicted as [263]

$$\begin{aligned} g_{An\gamma} = -g_{Ap\gamma} &= (3.7 \pm 1.5)\times 10^{-3}\left(\frac{1}{f_A}\right)\frac{1}{\mathrm{GeV}} = \\ &= (6.5 \pm 2.6)\times 10^{-13}\left(\frac{m_A}{\mathrm{meV}}\right)\frac{1}{\mathrm{GeV}^2} \end{aligned} \tag{91.38}$$

and plotted as a yellow diagonal band in Fig. 91.3 (right panel). An analysis of the ratio of spin-precession frequencies of stored ultracold neutrons and $^{199}$Hg atoms measured by neutron EDM experiments for an axion-induced oscillating neutron EDM revealed no signal consistent with axion DM, excluding a sizeable region of parameter space in the mass region $10^{-24}\,\mathrm{eV} \le m_A \le 10^{-17}\,\mathrm{eV}$ [264], which surpass the limits on anomalous energy loss of SN 1987A [262] by more than seven orders of magnitude, but are still a few orders of magnitude above the QCD axion expectations, see Fig. 91.3 (right panel). The oscillating EDMs cause also the precession of nuclear spins in a nucleon spin polarized sample in the presence of an electric field. The resulting transverse magnetization can be searched for by exploiting magnetic-resonance (MR) techniques, which are most sensitive in the range of low oscillation frequencies corresponding to sub-neV axion masses. The aim of the corresponding Cosmic Axion Spin Precession Experiment (CASPEr) [265] is to probe axion DM in the anthropic window, $f_A \gtrsim 10^{15}\,\mathrm{GeV}$ ($m_A \lesssim$ neV), motivated from Grand Unification [266–269]. Sub-$\mu$eV ALP masses can also be probed by using the storage ring EDM method proposed in Ref. [270] which exploits a combination of B and E-fields to produce a resonance between the $g-2$ spin precession frequency and the DM ALP field oscillation frequency. This method, however, does not reach the sensitivity to probe the QCD axion prediction for $g_{AN\gamma}$.

In the intermediate mass region, $\mathrm{neV} \lesssim m_A \lesssim 0.1\,\mu\mathrm{eV}$, one may exploit a cooled LC circuit and precision magnetometry to search for the oscillating electric current induced by DM axions in a strong magnetic field [271]. A similar approach is followed by the proposed ABRACADABRA [272] and DM-Radio Pathfinder [273] experiments. Recently, ABRACADABRA-10 cm – a small-scale prototype for a future detector that could be sensitive to the QCD axion – established upper limits on the axion-photon coupling in the mass range $3.1 \times 10^{-10}\,\mathrm{eV} - 8.3 \times 10^{-9}\,\mathrm{eV}$ [274], which are, however, not competitive yet with other limits in this mass range, see Fig. 91.1.

An eventually non-zero axion electron coupling $g_{Aee}$ will lead to an electron spin precession about the axion DM wind [275]. The QUAX (QUaerere AXions) experiment aims at exploiting MR inside a magnetized material [276]. Because of the higher Larmor frequency of the electron, it is sensitive in the classic window.

## 91.6 Conclusions

There is a strengthening physics case for very weakly coupled light particles beyond the Standard Model. The elegant solution of the strong CP problem proposed by Peccei and Quinn yields a particularly strong motivation for the axion. In many theoretically appealing ultraviolet completions of the Standard Model axions and ALPs occur automatically. Moreover, they are natural CDM candidates. Perhaps the first hints of their existence have already been seen in the anomalous excessive cooling of stars and the anomalous transparency of the Universe for VHE gamma rays. Interestingly, a significant portion of previously unexplored, but phenomenologically very interesting and theoretically very well motivated axion and ALP parameter space can be tackled in the foreseeable future by a number of terrestrial experiments searching for axion/ALP DM, for solar axions/ALPs, and for light apparently shining through a wall.

# 92. Searches for Quark and Lepton Compositeness

Revised 2019 by K. Hikasa (Tohoku University), M. Tanabashi (Nagoya University), K. Terashi (ICEPP, University of Tokyo), and N. Varelas (University of Illinois at Chicago)

## 92.1. Limits on contact interactions

If quarks and leptons are made of constituents, then at the scale of constituent binding energies (compositeness scale) there should appear new interactions among them. At energies much below the compositeness scale ($\Lambda$), these interactions are suppressed by inverse powers of $\Lambda$. The dominant effect of the compositeness of fermion $\psi$ should come from the lowest dimensional interactions with four fermions (contact terms), whose most general flavor-diagonal color-singlet chirally invariant form reads [1,2]

$$\mathcal{L} = \mathcal{L}_{LL} + \mathcal{L}_{RR} + \mathcal{L}_{LR} + \mathcal{L}_{RL},$$

with

$$\mathcal{L}_{LL} = \frac{g^2_{\rm contact}}{2\Lambda^2} \sum_{i,j} \eta^{ij}_{LL} (\bar\psi^i_L \gamma_\mu \psi^i_L)(\bar\psi^j_L \gamma^\mu \psi^j_L),$$

$$\mathcal{L}_{RR} = \frac{g^2_{\rm contact}}{2\Lambda^2} \sum_{i,j} \eta^{ij}_{RR} (\bar\psi^i_R \gamma_\mu \psi^i_R)(\bar\psi^j_R \gamma^\mu \psi^j_R),$$

$$\mathcal{L}_{LR} = \frac{g^2_{\rm contact}}{2\Lambda^2} \sum_{i,j} \eta^{ij}_{LR} (\bar\psi^i_L \gamma_\mu \psi^i_L)(\bar\psi^j_R \gamma^\mu \psi^j_R),$$

$$\mathcal{L}_{RL} = \frac{g^2_{\rm contact}}{2\Lambda^2} \sum_{i,j} \eta^{ij}_{RL} (\bar\psi^i_R \gamma_\mu \psi^i_R)(\bar\psi^j_L \gamma^\mu \psi^j_L), \qquad (92.1)$$

where $i, j$ are the indices of fermion species. Color and other indices are suppressed in Eq. (92.1). Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size $\Lambda$. Note $\eta^{ij}_{\alpha\beta} = \eta^{ji}_{\beta\alpha}$, therefore, in order to specify the contact interaction among the same fermion species $i = j$, it is enough to use $\eta_{LL}$, $\eta_{RR}$ and $\eta_{LR}$. We will suppress the indices of fermion species hereafter. We may determine the scale $\Lambda$ unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting $g^2_{\rm contact}/4\pi = g^2_{\rm contact}(\Lambda)/4\pi = 1$ for the new strong interaction coupling and by setting the largest magnitude of the coefficients $\eta_{\alpha\beta}$ to be unity. In the following, we denote

$$\Lambda = \Lambda^\pm_{LL} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, 0, 0)\ ,$$

$$\Lambda = \Lambda^\pm_{RR} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0, \pm 1, 0)\ ,$$

$$\Lambda = \Lambda^\pm_{VV} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, \pm 1, \pm 1)\ ,$$

$$\Lambda = \Lambda^\pm_{AA} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, \pm 1, \mp 1)\ ,$$

$$\Lambda = \Lambda^\pm_{V-A} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0, 0, \pm 1)\ . \qquad (92.2)$$

Such interactions can arise by interchanging constituents (when the fermions have common constituents), and/or by exchanging the binding quanta (whenever binding quanta couple to constituents of both particles).

Fermion scattering amplitude induced from the contact interaction in Eq. (92.1) interferes with the Standard Model (SM) amplitude destructively or constructively [2]. The sign of interference depends on the sign of $\eta_{\alpha\beta}$ $(\alpha, \beta = L, R)$. For instance, in the parton level $qq \to qq$ scattering cross section in the $\Lambda^\pm_{LL}$ model, the contact interaction amplitude and the SM gluon exchange amplitude interfere destructively for $\eta_{LL} = +1$, while they interfere constructively for $\eta_{LL} = -1$. In models of quark compositeness, the quark scattering cross sections induced from the contact interactions receive sizable QCD radiative corrections. Ref. 3 provides the exact next-to-leading order (NLO) QCD corrections to the contact interaction induced quark scattering cross sections.

Over the last three decades experiments at the CERN Sp$\bar{\rm p}$S [4,5], the Fermilab Tevatron [6,7], and the CERN LHC [8–12] have searched for quark contact interactions, characterized by the four-fermion effective Lagrangian in Eq. (92.1), using jet final states. These searches have been performed primarily by studying the angular distribution of the two highest transverse momentum, $p_{\rm T}$, jets (dijets), and the inclusive jet $p_{\rm T}$ spectrum. The variable $\chi = \exp(|(y_1 - y_2)|)$ is used to measure the dijet angular distribution, where $y_1$ and $y_2$ are the rapidities of the two jets with the highest transverse momenta. For collinear massless parton scattering, $\chi$ is related to the polar scattering angle $\theta^*$ in the partonic center-of-mass frame by $\chi = (1 + |\cos\theta^*|)/(1 - |\cos\theta^*|)$. The choice of $\chi$ is motivated by the fact that the angular distribution for Rutherford scattering, which is proportional to $1/(1 - \cos\theta^*)^2$, is independent of $\chi$. In perturbative QCD the $\chi$ distributions are relatively uniform and only mildly modified by higher-order QCD or electroweak corrections. Signatures of quark contact interactions exhibit more isotropic angular distribution than QCD and they can be identified as an excess at low values of $\chi$. In the inclusive jet cross section measurement, quark contact interaction effects are searched for as deviations from the predictions of perturbative QCD in the tails of the high-$p_{\rm T}$ jet spectrum [11].

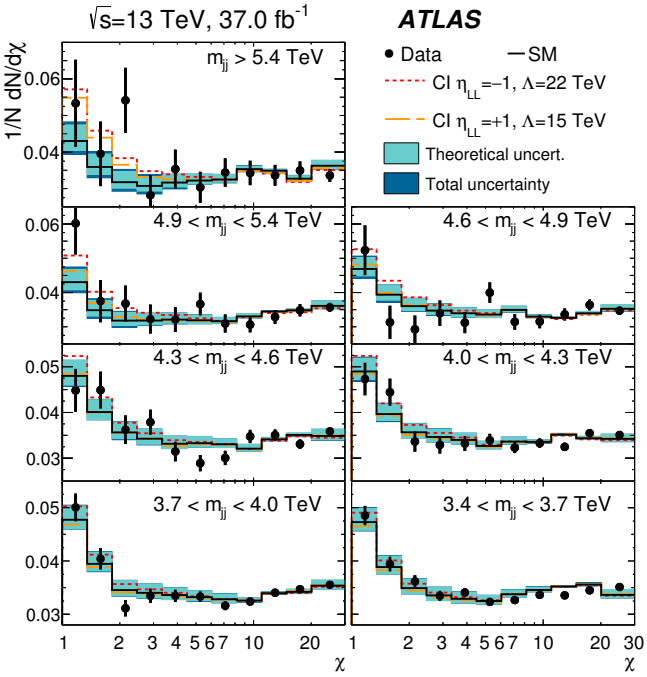

**Figure 92.1:** Normalized dijet angular distributions in several dijet mass ($m_{jj}$) ranges. The data distributions are compared to PYTHIA8 predictions with NLO and electroweak corrections applied (solid line) and with the predictions including a contact interaction (CI) term in which only left-handed quarks participate of compositeness scale $\Lambda^+_{LL} = 15$ TeV (dashed line) and $\Lambda^-_{LL} = 22$ TeV (dotted line). The theoretical uncertainties and the total theoretical and experimental uncertainties in the predictions are displayed as shaded bands around the SM prediction. Figure adopted from Ref. 9.

Recent results from the LHC, using data collected at proton-proton center-of-mass energy of $\sqrt{s} = 13$ TeV, extend previous limits on quark contact interactions. Figure 92.1 shows the normalized dijet angular distributions for several dijet mass ranges measured in ATLAS [9] at $\sqrt{s} = 13$ TeV. The data distributions are compared with SM predictions, estimated using PYTHIA8 [13] with GEANT4-based [14] ATLAS detector simulation and corrected to NLO QCD calculation provided by NLO Jet++ [15] including electroweak corrections [16], and with predictions including a contact interaction term in which only

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

left-handed quarks participate at compositeness scale $\Lambda^+_{LL} = 15$ TeV ($\Lambda^-_{LL} = 22$ TeV) with destructive (constructive) interference. Over a wide range of $\chi$ and dijet mass the data are well described by the SM predictions. Using the dijet angular distributions measured at high dijet masses and $\sqrt{s} = 13$ TeV, the ATLAS [9] and CMS [12] Collaborations have set 95% confidence level (C.L.) lower limits on the contact interaction scale $\Lambda$, ranging from 9.2 to 29.5 TeV for different quark contact interaction models that correspond to various combinations of ($\eta_{LL}$, $\eta_{RR}$, $\eta_{LR}$), as summarized in Figure 92.2. The contact interaction scale limits extracted using the dijet angular distributions include the exact NLO QCD corrections to dijet production induced by contact interactions [3]. In proton-proton collisions, the $\Lambda^{\pm}_{LL}$ and $\Lambda^{\pm}_{RR}$ contact interaction models result in identical tree-level cross sections and NLO QCD corrections and yield the same exclusion limits. For $\Lambda^{\pm}_{VV}$ and $\Lambda^{\pm}_{AA}$, the contact interaction predictions are identical at tree level, but exhibit different NLO QCD corrections and yield different exclusion limits.

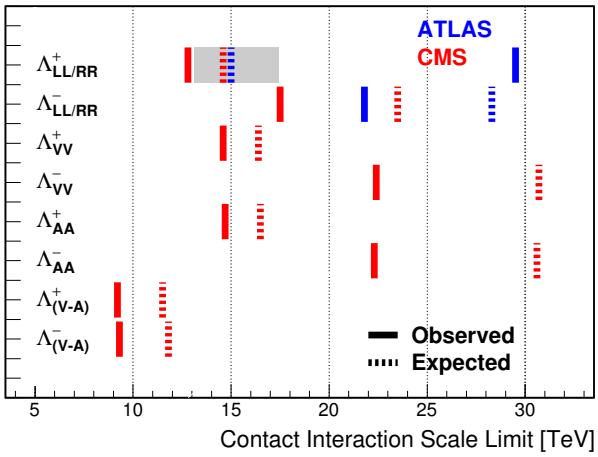

**Figure 92.2:** Observed (solid lines) and expected (dashed lines) 95% C.L. lower limits on the contact interaction scale $\Lambda$ for different contact interaction models from ATLAS [9] and CMS [12] using the dijet angular distributions. The contact interaction models used for the dijet angular distributions include the exact NLO QCD corrections to dijet production. The shaded band for the $\Lambda^+_{LL/RR}$ model indicates the range of contact interaction scale that was not excluded in ATLAS [9] due to statistical fluctuation of observed data.

If leptons ($l$) and quarks ($q$) are composite with common constituents, the interaction of these constituents will manifest itself in the form of a $llqq$-type four-fermion contact interaction Lagrangian at energies below the compositeness scale $\Lambda$. The $llqq$ terms in the contact interaction Lagrangian can be expressed as

$$\mathcal{L}_{LL} = \frac{g^2_{\rm contact}}{\Lambda^2} \sum_{i,j} \eta^{ij}_{LL} (\bar{q}^i_L \gamma_\mu q^i_L)(\bar{l}^j_L \gamma^\mu l^j_L),$$

$$\mathcal{L}_{RR} = \frac{g^2_{\rm contact}}{\Lambda^2} \sum_{i,j} \eta^{ij}_{RR} (\bar{q}^i_R \gamma_\mu q^i_R)(\bar{l}^j_R \gamma^\mu l^j_R),$$

$$\mathcal{L}_{LR} = \frac{g^2_{\rm contact}}{\Lambda^2} \sum_{i,j} \eta^{ij}_{LR} (\bar{q}^i_L \gamma_\mu q^i_L)(\bar{l}^j_R \gamma^\mu l^j_R),$$

$$\mathcal{L}_{RL} = \frac{g^2_{\rm contact}}{\Lambda^2} \sum_{i,j} \eta^{ij}_{RL} (\bar{q}^i_R \gamma_\mu q^i_R)(\bar{l}^j_L \gamma^\mu l^j_L). \qquad (92.3)$$

Searches on quark-lepton compositeness have been reported from experiments at LEP [17–20], HERA [21,22], the Tevatron [23,24], and recently from the ATLAS [25,26] and CMS [27–29] experiments at the LHC. The most stringent searches for $llqq$ contact interactions are performed by the LHC experiments using high-mass oppositely-charged lepton pairs produced through the $q\bar{q} \to l^+l^-$ Drell-Yan process. The contact interaction amplitude of the $u\bar{u} \to l^+l^-$ process ($l = e$ or $\mu$) interferes with the corresponding SM amplitude constructively (destructively) for $\eta^{ul}_{\alpha\beta} = -1$ ($\eta^{ul}_{\alpha\beta} = +1$). The ATLAS Collaboration has extracted limits on the $llqq$ contact interaction at $\sqrt{s} = 13$ TeV for the right-right ($\eta_{RR} = \pm 1$, $\eta_{LL} = \eta_{LR} = \eta_{RL} = 0$), left-left ($\eta_{LL} = \pm 1$, $\eta_{RR} = \eta_{LR} = \eta_{RL} = 0$), and left-right ($\eta_{LR} = \eta_{RL} = \pm 1$, $\eta_{RR} = \eta_{LL} = 0$) models. Combining the dielectron and dimuon channels, the 95% C.L. lower limits on the $llqq$ contact interaction scale $\Lambda$ are 35 TeV (28 TeV) for the right-right model, 40 TeV (25 TeV) for the left-left model, and 36 TeV (28 TeV) for the left-right model, each with constructive (destructive) interference [26]. The CMS Collaboration, using a 36 fb$^{-1}$ dataset at 13 TeV, has set 95% C.L. exclusion limits on the $llqq$ contact interaction scale that range from $\Lambda_{LL} > 20$ TeV for the destructive interference to $\Lambda_{RR} > 32$ TeV for the constructive interference, for the left-left and the right-right models, respectively [29].

Note that the contact interactions arising from the compositeness of quarks and leptons in Eq. (92.1) can also be regarded as a part of more general dimension six operators in the context of low energy standard model effective theory. For a complete list of these dimension six operators, see [30,31].

Interactions of hypothetical dark matter candidate particles with SM particles through mediators can also be described as contact interactions at low energy. See *"Searches for WIMPs and Other Particles"* in this volume for limits on the interactions involving dark matter candidate particles.

## 92.2. Limits on excited fermions

Another typical consequence of compositeness is the appearance of excited leptons and quarks ($l^*$ and $q^*$). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares a leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron $e^*$ is characterized by a nonzero transition-magnetic coupling with electrons. Smallness of the lepton mass and the success of QED prediction for $g - 2$ suggest chirality conservation, *i.e.,* an excited lepton should not couple to both left- and right-handed components of the corresponding lepton [32–34].

Excited leptons may be classified by $SU(2) \times U(1)$ quantum numbers. Typical examples are:

1. Sequential type

$$\begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_L, \qquad [\nu^*_R], \qquad l^*_R.$$

   $\nu^*_R$ is necessary unless $\nu^*$ has a Majorana mass.

2. Mirror type

$$[\nu^*_L], \qquad l^*_L, \qquad \begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_R.$$

3. Homodoublet type

$$\begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_L, \qquad \begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_R.$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their minimal gauge couplings. The couplings of excited leptons with $Z$ are given by

$$\frac{e}{2\sin\theta_W \cos\theta_W}(-1 + 2\sin^2\theta_W)\bar{l^*}\gamma^\mu l^* Z_\mu$$

$$+ \frac{e}{2\sin\theta_W \cos\theta_W}\bar{\nu^*}\gamma^\mu \nu^* Z_\mu$$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

in the homodoublet model. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at $q^2 \neq 0$, they are usually neglected.

Excited fermions may also be produced via the contact interactions with ordinary quarks and leptons [35]

$$\mathcal{L} = \frac{g^2_{\rm contact}}{\Lambda^2}\left[\eta'_{LL}(\bar{\psi}_L\gamma_\mu\psi_L)(\bar{\psi}^*_L\gamma^\mu\psi^*_L) + (\eta''_{LL}(\bar{\psi}_L\gamma_\mu\psi_L)(\bar{\psi}^*_L\gamma^\mu\psi_L) + \text{h.c.}) + \cdots\right]. \quad (92.4)$$

Again, the coefficient is conventionally taken $g^2_{\rm contact} = 4\pi$. It is widely assumed $\eta'_{LL} = \eta''_{LL} = 1$, $\eta'_{LR} = \eta''_{LR} = \eta'_{RL} = \eta''_{RL} = \eta'_{RR} = \eta''_{RR} = 0$ in experimental analyses for simplicity.

In addition, transition-magnetic type couplings with a gauge boson are expected. These couplings can be generally parameterized as follows:

$$\begin{aligned}\mathcal{L} =& \frac{\lambda^{(\psi^*)}_\gamma e}{2m_{\psi^*}}\bar{\psi}^*\sigma^{\mu\nu}(\eta_L\frac{1-\gamma_5}{2} + \eta_R\frac{1+\gamma_5}{2})\psi F_{\mu\nu} \\ &+ \frac{\lambda^{(\psi^*)}_Z e}{2m_{\psi^*}}\bar{\psi}^*\sigma^{\mu\nu}(\eta_L\frac{1-\gamma_5}{2} + \eta_R\frac{1+\gamma_5}{2})\psi Z_{\mu\nu} \\ &+ \frac{\lambda^{(l^*)}_W g}{2m_{l^*}}\bar{l}^*\sigma^{\mu\nu}\frac{1-\gamma_5}{2}\nu W_{\mu\nu} \\ &+ \frac{\lambda^{(\nu^*)}_W g}{2m_{\nu^*}}\bar{\nu}^*\sigma^{\mu\nu}(\eta_L\frac{1-\gamma_5}{2} + \eta_R\frac{1+\gamma_5}{2})l W^\dagger_{\mu\nu} \\ &+ \text{h.c.}, \end{aligned} \quad (92.5)$$

where $g = e/\sin\theta_W$, $\psi = \nu$ or $l$, $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ is the photon field strength, $Z_{\mu\nu} = \partial_\mu Z_\nu - \partial_\nu Z_\mu$, *etc.*. The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1.$$

Chirality conservation requires

$$\eta_L\eta_R = 0. \quad (92.6)$$

These couplings in Eq. (92.5) can arise from $SU(2) \times U(1)$-invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type $l^*$ with the Lagrangian (see [36,37])

$$\mathcal{L} = \frac{1}{2\Lambda}\bar{L}^*\sigma^{\mu\nu}(gf\frac{\tau^a}{2}W^a_{\mu\nu} + g'f'YB_{\mu\nu})\frac{1-\gamma_5}{2}L + \text{h.c.}, \quad (92.7)$$

where $L$ denotes the lepton doublet $(\nu, l)$, $\Lambda$ is the compositeness scale, $g$, $g'$ are $SU(2)$ and $U(1)_Y$ gauge couplings, and $W^a_{\mu\nu}$ and $B_{\mu\nu}$ are the field strengths for $SU(2)$ and $U(1)_Y$ gauge fields. These couplings satisfy the relation

$$\lambda_W = -\sqrt{2}\sin^2\theta_W(\lambda_Z\cot\theta_W + \lambda_\gamma), \quad (92.8)$$

with $\lambda_{W,Z,\gamma}$ being defined in Eq. (92.5) with $\lambda_{W,Z,\gamma} = \lambda^{(\ell^*)}_{W,Z,\gamma}$ or $\lambda_{W,Z,\gamma} = \lambda^{(\nu^*)}_{W,Z,\gamma}$. Here $(\eta_L, \eta_R) = (1, 0)$ is assumed. It should be noted that the electromagnetic radiative decay of $l^*$ ($\nu^*$) is forbidden if $f = -f'$ ($f = f'$).

Additional coupling with gluons is possible for excited quarks:

$$\mathcal{L} = \frac{1}{2\Lambda}\bar{Q}^*\sigma^{\mu\nu}\left(g_s f_s\frac{\lambda^a}{2}G^a_{\mu\nu} + gf\frac{\tau^a}{2}W^a_{\mu\nu} + g'f'YB_{\mu\nu}\right) \times \frac{1-\gamma_5}{2}Q + \text{h.c.}, \quad (92.9)$$

where $Q$ denotes a quark doublet, $g_s$ is the QCD gauge coupling, and $G^a_{\mu\nu}$ the gluon field strength.

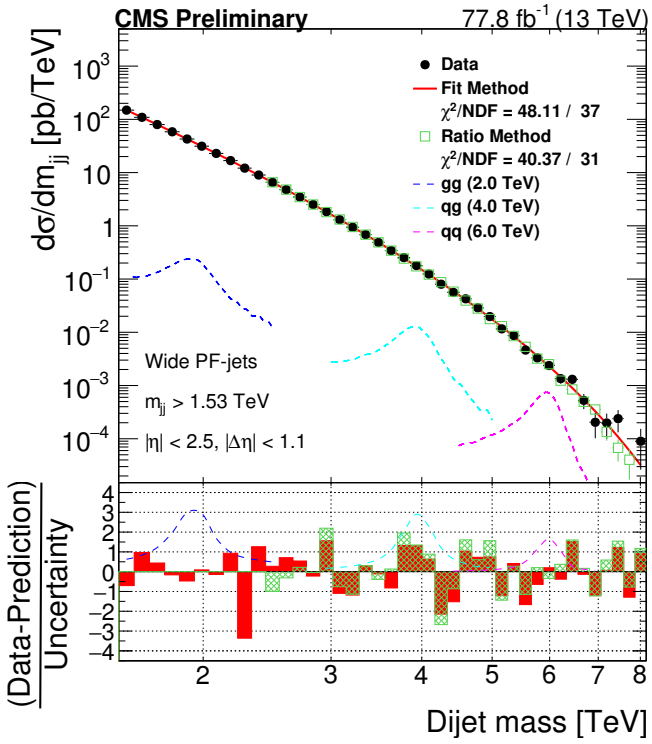

**Figure 92.3:** Dijet mass distribution measured by CMS using wide jets reconstructed from two highest transverse momentum jets by adding nearby jets within $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2} < 1.1$. The data distribution is compared to a fit representing a smooth background spectrum (solid curve). The excited quark signal with mass of 4.0 TeV (labeled as $qg$) is shown together with other benchmark signals. Shown at the bottom panel is the difference between the data and the fitted parametrization divided by the statistical uncertainty of the data. Figure adopted from Ref. 62.

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons ($l_8$) and the ordinary lepton ($l$) may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda}\sum_l\{\bar{l}^\alpha_8 g_S F^\alpha_{\mu\nu}\sigma^{\mu\nu}(\eta_L l_L + \eta_R l_R) + \text{h.c.}\} \quad (92.10)$$

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies $\eta_L\eta_R = 0$ as before.

Searches for the excited quarks and leptons have been performed over the last decades in experiments at the LEP [38–41], HERA [42,43], Tevatron [44,45], and LHC [46–71]. Most stringent constraints, which are described below at 95% confidence level, come from the LHC experiments.

The signature of excited quarks $q^*$ at hadron colliders is characterized by a narrow resonant peak in the reconstructed invariant mass distribution of the $q^*$ decay products. The decays via the transition-magnetic type operator in Eq. (92.9) are considered for excited quarks in LHC searches, and the final states to search for are dijet ($qg$) [46, 47, 59–62] or a jet in association with a photon ($q\gamma$) [48, 49, 63, 64] or a weak gauge boson ($qW$, $qZ$) [65, 66]. All analyses consider only spin-1/2 excited states of first generation quarks ($u^*$, $d^*$) with degenerate masses, expected to be predominantly produced in proton-proton collisions except for the excited $b$ quark searches described below. Only the minimal gauge interactions and the transition-magnetic couplings with the form given in Eq. (92.9) are considered in the production process, and hence the contact interactions in Eq. (92.4) are not considered. The compositeness scale $\Lambda$ is taken to be the same as the excited quark mass $m_{q^*}$. The transition-magnetic coupling coefficients $f_s$, $f$ and $f'$ are assumed to be equal to 1 (denoted by $f$).

With proton-proton collision data recorded at $\sqrt{s} = 13$ TeV at the LHC, the excited quark masses are excluded in dijet resonance searches up to 6.7 TeV in ATLAS using 140 fb$^{-1}$ [47] and 6.0 TeV in CMS using 77.8 fb$^{-1}$ [62]. Figure 92.3 shows the dijet mass distribution measured in CMS [62] by using the two highest $p_{\mathrm{T}}$ jets reconstructed with the anti-$k_{\mathrm{T}}$ algorithm [72] of a distance parameter of 0.4, and by combining nearby jets within $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2} < 1.1$ around the leading two jets. The measured dijet mass spectrum is compared to a fit with smoothly falling background shape (solid curve) to look for a narrow resonance; an excited quark signal with mass of 4.0 TeV is shown in the figure (denoted by $qg$) as one of the benchmark signals considered in the analysis.

The photon + jet resonance searches, targeting excited quarks decaying into a quark and a photon ($q^* \to q + \gamma$), have excluded $q^*$ masses up to 5.3 TeV in ATLAS [49] and 5.5 TeV in CMS [64] using collision data at $\sqrt{s} = 13$ TeV. The $W/Z$ boson + jet final states are examined to look for the $q^* \to q + W$ and $q + Z$ signal in CMS [66], exploiting jet substructure technique designed to provide sensitivity for highly-boosted hadronically decaying $W$ and $Z$ bosons. The lower mass limit of 5.0 (4.8) TeV is obtained from the $W$ + jet ($Z$ + jet) search using dataset recorded at $\sqrt{s} = 13$ TeV.

The excited $b$ quarks ($b^*$) are also considered in the present searches at the LHC. Assuming the similar production processes to the first-generation excited quarks, the $b^*$ has been searched for in final states containing at least one jet identified as originating from a $b$ quark ($b$-tagging). The searches using two jets including at least one $b$-tagged jet have been performed at 8 and 13 TeV [50, 51, 60], resulting in $b^*$ lower mass limits of 2.6 TeV in ATLAS using 36.1 fb$^{-1}$ at $\sqrt{s} = 13$ TeV [50] and 1.6 TeV in CMS using 19.7 fb$^{-1}$ at $\sqrt{s} = 8$ TeV [60]. The CMS Collaboration also performed a search for $b^* \to b + \gamma$ in events with a $b$-tagged jet in association with a photon using data at $\sqrt{s} = 13$ TeV [64], and excluded $b^*$ masses up to 1.8 TeV. Excited $b$ quarks with charged-current decay into a $W$-boson and a top quark ($b^* \to t + W$) were looked for in both ATLAS and CMS using the full 8 TeV data [52, 67]. ATLAS excluded $b^*$ masses below 1.5 TeV for the $b^*$ with left- and right-handed couplings [52] while CMS excluded the masses below 1.39(1.43) TeV for the left(right)-handed couplings [67].

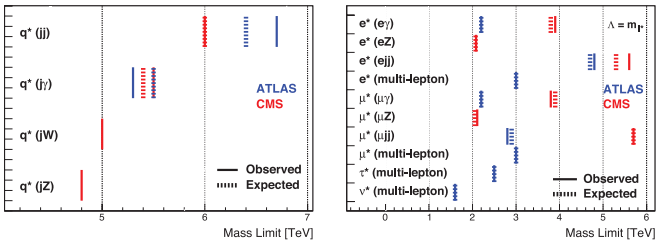

**Figure 92.4:** 95% C.L. lower mass limits for the excited quarks (left) and excited leptons (right) at ATLAS [47,49,55–57] and CMS [62,64,66] [69–71] experiments. Shown are the most stringent limits for each final state (denoted in parentheses) of the excited fermions from both experiments. Only first generation quarks ($u$, $d$) with transition-magnetic type interactions with $f_s = f = f' = 1$ are considered for the excited quarks. The excited lepton limits are given for the production via contact interactions with $\Lambda = m_{l^*}$.

Searches for excited leptons $l^*$ are also performed at the LHC using proton-proton collision data recorded at $\sqrt{s} = 7$ and 8 TeV [54–58, 68, 69] as well as at 13 TeV [70]. Considering single $l^*$ production in contact interactions (Eq. (92.4)) and electromagnetic radiative decay to a SM lepton and a photon ($l^* \to l + \gamma$ where $l = e, \mu$), the excited electron and muon masses are excluded for $\Lambda = m_{l^*}$ up to 3.9 and 3.8 TeV, respectively, using 35.9 fb$^{-1}$ at $\sqrt{s} = 13$ TeV in CMS [70] and 2.2 TeV using 13 fb$^{-1}$ at $\sqrt{s} = 8$ TeV in ATLAS [55].

With the full 20.3 fb$^{-1}$ data at $\sqrt{s} = 8$ TeV, the inclusive search on multi-lepton signatures with 3 or more charged leptons in ATLAS [56] further constrains the excited charged leptons and neutrinos. Considering both the transition-magnetic (Eq. (92.7)) and contact interaction (Eq. (92.4)) processes, the lower mass limits for the $e^*$, $\mu^*$, $\tau^*$ and $\nu^*$ (for every excited neutrino flavor) are obtained to be 3.0, 3.0, 2.5 and 1.6 TeV, respectively, for $\Lambda = m_{e^*}$, $m_{\mu^*}$, $m_{\tau^*}$ and $m_{\nu^*}$. The rate of pair-produced excited leptons is independent of $\Lambda$ for the minimal gauge interaction processes, and it allows to improve search sensitivity with multi-lepton signatures at high $\Lambda$, especially for excited neutrinos because the predominant $\nu_l^* \to l + W$ decays result in a higher acceptance for $\geq 3$ charged lepton final states.

Both ATLAS and CMS Collaborations performed searches for singly produced excited leptons. The single excited leptons, both produced and decayed in contact interaction processes (Eq. (92.4)), were searched for in CMS using 77.4 fb$^{-1}$ at 13 TeV [71] and in ATLAS using 20.3 fb$^{-1}$ at 8 TeV [57] using the final states with two leptons and two jets ($q\bar{q} \to l l^* \to l l q\bar{q}$). The CMS search [71] considered both excited electrons and excited muons, using the invariant mass of the combination of the two leptons and two jets as a discriminating variable to separate signal from background. The ATLAS search [57] considered only excited muons. The single excited electrons, produced in contact interactions and decayed either in contact interaction or charged-current processes, were considered in ATLAS using 36.1 fb$^{-1}$ at 13 TeV [58] in the final states with two electrons and two jets ($q\bar{q} \to ee^* \to eeq\bar{q}$) or an electron, missing transverse momentum and a hadronically decaying $W$-boson candidate ($q\bar{q} \to ee^* \to e\nu W$). The excited electron (muon) mass was excluded up to 5.6 (5.7) TeV in CMS [71] at $\Lambda = m_{e^*}$ ($\Lambda = m_{\mu^*}$), which is the best limit to date on the excited electrons (muons).

The CMS Collaboration also performed an excited lepton search in the final states containing a $Z$ boson [69], probing the excited leptons produced in contact interactions and decayed in neutral-current processes ($l^* \to l + Z$) with $f = f' = 1$ or $f = -f' = 1$. The leptonic and hadronic decays of $Z$ bosons have been considered in the search, and the most stringent limits are obtained from the hadronic $Z$ decay to be 2.08 (2.34) TeV and 2.11 (2.37) TeV for the $e^*$ and $\mu^*$, respectively, with $f = f' = 1$ ($f = -f' = 1$) at $\Lambda = m_{l^*}$.

Figure 92.4 summarizes the most stringent 95% C.L. lower mass limits for excited quarks and leptons obtained from the LHC experiments.

# 93. Dynamical Electroweak Symmetry Breaking: Implications of the $H^0$

Revised August 2019 by K.M. Black (Wisconsin U.), R.Sekhar Chivukula (UC San Diego) and M. Narain (Brown U.).

## 93.1 Introduction and Phenomenology

In theories of dynamical electroweak symmetry breaking, the electroweak interactions are broken to electromagnetism by the vacuum expectation value of a composite operator, typically a fermion bilinear. In these theories, the longitudinal components of the massive weak bosons are identified with composite Nambu-Goldstone bosons arising from dynamical symmetry breaking in a strongly-coupled extension of the standard model. Viable theories of dynamical electroweak symmetry breaking must also explain (or at least accommodate) the presence of an additional composite scalar state to be identified with the $H^0$ scalar boson [1,2] – a state unlike any other observed previously.

Theories of dynamical electroweak symmetry breaking can be classified by the nature of the composite singlet state to be associated with the $H^0$ and the corresponding dimensional scales $f$, the analog of the pion decay-constant in QCD, and $\Lambda$, the scale of the underlying strong dynamics.[1] Of particular importance is the ratio $v/f$, where $v^2 = 1/(\sqrt{2}G_F) \approx (246\,\text{GeV})^2$, since this ratio measures the expected size of the deviations of the couplings of a composite Higgs boson from those expected in the standard model. The basic possibilities, and the additional states that they predict, are described below.

### 93.1.1 *Technicolor, $v/f \simeq 1$, $\Lambda \simeq 1$ TeV*

Technicolor models [7–9] provided the first examples of theories of dynamical electroweak symmetry breaking. These theories incorporate a new asymptotically free gauge theory ("technicolor") and additional massless fermions ("technifermions" transforming under a vectorial representation of the gauge group). The global chiral symmetry of the fermions is spontaneously broken by the formation of a technifermion condensate, just as the approximate chiral symmetry in QCD is broken down to isospin by the formation of a quark condensate. The $SU(2)_W \times U(1)_Y$ interactions are embedded in the global technifermion chiral symmetries in such a way that the only unbroken gauge symmetry after chiral symmetry breaking is $U(1)_{em}$.[2] The theories naturally provide the Nambu-Goldstone bosons "eaten" by the $W$ and $Z$ boson. There would also typically be additional heavy states (e.g. vector mesons, analogous to the $\rho$ and $\omega$ mesons in QCD) with TeV masses [13,14], and the $WW$ and $ZZ$ scattering amplitudes would be expected to be strong at energies of order 1 TeV.

There are various possibilities for the scalar $H^0$ in technicolor models. First, the $H^0$ could be identified as a singlet scalar resonance, analogous to the $\sigma$ particle expected in pion-scattering in QCD [15, 16]. Alternatively, the $H^0$ could be identified as a dilaton, a (pseudo-)Goldstone boson of scale invariance in theories of "walking technicolor" [17–21].[3] Finally, the $H^0$ could be identified as an additional isosinglet state if the chiral symmetry breaking pattern of the technicolor theory provides for such a state.[4] In all of these cases, however, one expects large deviations in the couplings of this particle from those of the standard model Higgs boson. Since the couplings observed for the $H^0$ approximate those of the Higgs boson to the 10% level, models of this kind are very highly constrained.

### 93.1.2 *The Higgs doublet as a pseudo-Nambu-Goldstone Boson, $v/f < 1$, $\Lambda > 1$ TeV*

In technicolor models, the symmetry-breaking properties of the underlying strong dynamics necessarily breaks the electroweak gauge symmetries. An alternative possibility is that the underlying strong dynamics itself does not break the electroweak interactions, and that the entire quartet of bosons in the Higgs doublet (including the state associated with the $H^0$) are composite (pseudo-) Nambu-Goldstone particles [23, 24], In this case, the underlying dynamics can occur at energies exceeding 1 TeV and additional interactions with the top-quark mass generating sector (and possibly with additional weakly-coupled gauge bosons) cause the vacuum energy to be minimized when the composite Higgs doublet gains a vacuum expectation value [25, 26]. In these theories, the couplings of the remaining singlet scalar state would naturally be equal to that of the standard model Higgs boson up to corrections of order $(v/f)^2$ and, therefore, constraints on the size of deviations of the $H^0$ couplings from that of the standard model Higgs [27] give rise to lower bounds on the scales $f$ and $\Lambda$.[5]

The electroweak gauge interactions, as well as the interactions responsible for the top-quark mass, explicitly break the chiral symmetries of the composite Higgs model and lead generically to sizable corrections to the mass-squared of the Higgs-doublet – the so-called "Little Hierarchy Problem" [28]. "Little Higgs" theories [29–32] are examples of composite Higgs models in which the (collective) symmetry-breaking structure is selected so as to suppress these contributions to the Higgs mass-squared.

Composite Higgs models typically require a larger global symmetry of the underlying theory, and hence additional relatively light (compared to $\Lambda$) scalar particles, extra electroweak vector bosons (e.g. an additional $SU(2)\times U(1)$ gauge group), and vector-like partners of the top-quark of charge $+2/3$ and possibly also $+5/3$ [33]. In addition to these states, one would expect the underlying dynamics to yield additional scalar and vector resonances with masses of order $\Lambda$. If the theory respects a custodial symmetry [34], the couplings of these additional states to the electroweak and Higgs boson will be related – and, for example, one might expect a charged vector resonance to have similar branching ratios to $WZ$ and $WH$. Different composite Higgs models utilize different mechanisms for arranging for the hierarchy of scales $v < f$ and arranging for a scalar Higgs self-coupling small enough to produce an $H^0$ of mass of order 125 GeV, for a review see [35] . If the additional states in these models carry color, they can provide additional contributions to Higgs production via gluon fusion [36]. The extent to which Higgs production at the LHC conforms with standard model predictions provides additional constraints (typically lower bounds on the masses of the additional colored states of order 0.7 TeV) on these models.

In addition, if the larger symmetry of the underlying composite Higgs theory does not commute with the standard model gauge group, then the additional states found in those models – especially those related to the top-quark, which tend to have the largest couplings to the electroweak sector – may be *colorless*. For example, in twin Higgs models [37], the top-partners carry no standard model charges. The phenomenology of the additional states in twin Higgs theories is rather different, since lacking color the production of these particles at the LHC will be suppressed – and, their decays may occur only via the electroweak symmetry breaking sector, leading to their being long-lived.

### 93.1.3 *Top-Condensate, Top-Color, Top-Seesaw and related theories, $v/f < 1$, $\Lambda > 1$ TeV*

A final alternative is to consider a strongly interacting theory with a high (compared to a TeV) underlying dynamical scale that *would* naturally break the electroweak interactions, but whose

[1] In a strongly interacting theory "Naive Dimensional Analysis" [3, 4] implies that, in the absence of fine-tuning, $\Lambda \simeq g^* f$ where $g^* \simeq 4\pi$ is the typical size of a strong coupling in the low-energy theory [5, 6]. This estimate is modified in the presence of multiple flavors or colors [7] .

[2] For a review of technicolor models, see [10–12].

[3] If both the electroweak symmetry and the approximate scale symmetry are broken only by electroweak doublet condensate(s), then the decay-constants for scale and electroweak symmetry breaking may be approximately equal – differing only by terms formally proportional to the amount of explicit scale-symmetry breaking.

[4] In this case, however, the coupling strength of the singlet state to $WW$ and $ZZ$ pairs would be comparable to the couplings to gluon and photon pairs, and these would all arise from loop-level couplings in the underlying technicolor theory [22].

[5] In these models $v/f$ is an adjustable parameter, and in the limit $v/f \to 1$ they reduce, essentially, to the technicolor models discussed in the previous subsection. Our discussion here is consistent with that given there, since we expect corrections to the SM Higgs couplings to be large for $v/f \simeq 1$. Current measurements constrain the couplings of the $H^0$ to equal those predicted for the Higgs in the standard model to about the 10% level [27], suggesting that $f$ must have values of order a TeV or higher and, therefore, a dynamical scale $\Lambda$ of at least several TeV.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

strength is adjusted ("fine-tuned") to produce electroweak symmetry breaking at 1 TeV. This alternative is possible if the electroweak (quantum) phase transition is continuous (second order) in the strength of the strong dynamics [38]. If the fine tuning can be achieved, the underlying strong interactions will produce a light composite Higgs bound state with couplings equal to that of the standard model Higgs boson up to corrections of order $(1\ \text{TeV}/\Lambda)^2$. As in theories in which electroweak symmetry breaking occurs through vacuum alignment, therefore, constraints on the size of deviations of the $H^0$ couplings from that of the standard model Higgs give rise to lower bounds on the scale $\Lambda$. Formally, in the limit $\Lambda \to \infty$ (a limit which requires arbitrarily fine adjustment of the strength of the high-energy interactions), these theories are equivalent to a theory with a fundamental Higgs boson – and the fine adjustment of the coupling strength is a manifestation of the hierarchy problem of theories with a fundamental scalar particle.

In many of these theories the top-quark itself interacts strongly (at high energies), potentially through an extended color gauge sector [39, 39–43]. In these theories, top-quark condensation (or the condensation of an admixture of the top with additional vector-like quarks) is responsible for electroweak symmetry breaking, and the $H^0$ is identified with a bound state involving the third generation of quarks. These theories typically include an extra set of massive color-octet vector bosons (top-gluons), and an extra $U(1)$ interaction (giving rise to a top-color $\text{Z}'$) which couple preferentially to the third generation and whose masses define the scale $\Lambda$ of the underlying physics.

#### 93.1.4 *Flavor*

In addition to the electroweak symmetry breaking dynamics described above, which gives rise to the masses of the $W$ and $Z$ particles, additional interactions must be introduced to produce the masses of the standard model fermions. Two general avenues have been suggested for these new interactions. In "extended technicolor" (ETC) theories [44, 45], the gauge interactions in the underlying strongly interacting theory are extended to incorporate flavor. This extended gauge symmetry is broken down (possibly sequentially, at several different mass scales) to the residual strong interaction responsible for electroweak symmetry breaking. The massive gauge-bosons corresponding to the broken symmetries then mediate interactions between mass operators for the quarks/leptons and the corresponding bilinears of the strongly-interacting fermions, giving rise to the masses of the ordinary fermions after electroweak symmetry breaking.

In the case of "partial compositeness" [46], the additional flavor-dependent interactions arise from mixing between the ordinary quarks and leptons and massive composite fermions in the strongly-interacting underlying theory. Theories incorporating partial compositeness include additional vector-like partners of the ordinary quarks and leptons, typically with masses of order a TeV or less.

In both cases, the effects of flavor interactions on the electroweak properties of the ordinary quarks and leptons are likely to be most pronounced in the third generation of fermions.[6] The additional particles present in these theories, especially the additional scalars, often couple more strongly to heavier fermions.

Moreover, since the flavor interactions must give rise to quark mixing, we expect that a generic theory of this kind could give rise to large flavor-changing neutral-currents [45]. In ETC theories, these constraints are typically somewhat relaxed if the theory incorporates approximate generational flavor symmetries [47], the theory has a slowly running coupling constant or "walks" [17–21], or if $\Lambda > 1$ TeV [48]. In theories of partial compositeness, the masses of the ordinary fermions depend on the scaling-dimension of the operators corresponding to the composite fermions with which they mix. This leads to a new mechanism for generating the mass-hierarchy of the observed quarks and leptons that, potentially, ameliorates flavor-changing neutral current problems and can provide new contributions to the composite Higgs potential which allow for $v/f < 1$ [49–53].

Alternatively, one can assume that the underlying flavor dynamics respect flavor symmetries ("minimal" [54, 55] or "next-to-minimal" [56] flavor violation) that suppress flavor-changing neutral currents in the two light generations. Additional considerations apply when extending these arguments to potential explanation of neutrino masses (see, for example, [57, 58]).

Since the underlying high-energy dynamics in these theories are strongly coupled, there are no reliable calculation techniques that can be applied to analyze their properties. Instead, most phenomenological studies depend on the construction of a "low-energy" effective theory describing additional scalar, fermion, or vector boson degrees of freedom, which incorporates the relevant symmetries and, when available, dynamical principles. In some cases, motivated by the AdS/CFT correspondence [59], the strongly-interacting theories described above have been investigated by analyzing a dual compactified five-dimensional gauge theory. In these cases, the AdS/CFT "dictionary" is used to map the features of the underlying strongly coupled high-energy dynamics onto the low-energy weakly coupled dual theory [60].

More recently, progress has been made in investigating strongly-coupled models using lattice gauge theory [61]. These calculations offer the prospect of establishing which strongly coupled theories of electroweak symmetry breaking have a particle with properties consistent with those observed for the $H^0$ – and for establishing concrete predictions for these theories at the LHC [62].

## 93.2 Experimental Searches

As discussed above, the extent to which the couplings of the $H^0$ conform to the expectations for a standard model Higgs boson constrains the viability of each of these models. Measurements of the $H^0$ couplings, and their interpretation in terms of effective field theory, are summarized in the $H^0$ review in this volume. In what follows, we will focus on searches for the additional particles that might be expected to accompany the singlet scalar: extra scalars, fermions, and vector bosons. In some cases, detailed model-specific searches have been made for the particles described above (though generally not yet taking account of the demonstrated existence of the $H^0$ boson).

In most cases, however, generic searches (e.g. for extra $W'$ or $Z'$ particles, extra scalars in the context of multi-Higgs models, or for fourth-generation quarks) are quoted that can be used – when appropriately translated – to derive bounds on a specific model of interest.

The mass scale of the new particles implied by the interpretations of the low mass of $H^0$ discussed above, and existing studies from the Tevatron and lower-energy colliders, suggests that only the Large Hadron Collider has any real sensitivity. A number of analyses already carried out by ATLAS and CMS use relevant final states and might have been expected to observe a deviation from standard model expectations – in no case so far has any such deviation been reported. The detailed implications of these searches in various model frameworks are described below.

Except where otherwise noted, all limits in this section are quoted at a confidence level of 95%. The searches at $\sqrt{s} = 8$ TeV (Run 1) are based on 20.3 $\text{fb}^{-1}$ of data recorded by ATLAS, and an integrated luminosity of 19.7 $\text{fb}^{-1}$ analyzed by CMS. The datasets collected at $\sqrt{s} = 13$ TeV during Run 2 of the LHC since 2015 are based on analyses with varied integrated luminosities ranging from ∼2-140 $\text{fb}^{-1}$.

#### 93.2.1 *Searches for $Z'$ or $W'$ Bosons*

Massive vector bosons or particles with similar decay channels would be expected to arise in Little Higgs theories, in theories of Technicolor, or models involving a dilaton, adjusted to produce a light Higgs boson, consistent with the observed $H^0$. These particles would be expected to decay to pairs of vector bosons, or to third generation quarks, or to leptons. The generic searches for $W'$ and $Z'$ vector bosons listed below can, therefore, be used to constrain models incorporating a composite Higgs-like boson.

A general review of searches for $Z'$ and $W'$ bosons is also included in this volume [63, 64]. In the context of the dynamical electroweak symmetry breaking models, we emphasize their decays to third generation fermions by including a detailed overview,

[6] Indeed, from this point of view, the vector-like partners of the top-quark in top-seesaw and little Higgs models can be viewed as incorporating partial compositeness to explain the origin of the top quark's large mass.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

while also briefly summarizing the other searches.

$Z' \to \ell\ell$:

ATLAS [65] and CMS [66] have both searched for $Z'$ production with $Z' \to ee$ or $\mu\mu$. No deviation from the standard model prediction was seen in the dielectron and dimuon invariant mass spectra, by either the ATLAS or the CMS analysis, and lower limits on possible $Z'$ boson masses were set. A $Z'_{\rm SSM}$ with couplings equal to the standard model $Z'$ (a "sequential standard model" $Z'$) and a mass below 5.1 TeV was excluded by ATLAS, while CMS set a lower mass limit of 5.15 TeV. The experiments also place limits on the parameters of extra dimension models and in the case of ATLAS on the parameters of a minimal walking technicolor model [17–21], consistent with a 125 GeV Higgs boson [67]. For a general review of searches in these channels see the PDG review of Z prime in this volume [63].

In addition, both experiments have also searched for $Z'$ decaying to a ditau final state [68, 69]. An excess in $\tau^+\tau^-$ could have interesting implications for models in which lepton universality is not a requirement and enhanced couplings to the third generation are allowed. This analysis led to lower limits on the mass of a $Z'_{\rm SSM}$ of 2.4 and 2.1 TeV from ATLAS and CMS respectively.

$Z' \to q\bar{q}$:

The ability to relatively cleanly select $t\bar{t}$ pairs at the LHC together with the existence of enhanced couplings to the third generation in many models makes it worthwhile to search for new particles decaying in this channel. Both ATLAS [70] and CMS [71] have carried out searches for new particles decaying into $t\bar{t}$.

Both the ATLAS and CMS collaborations searched for $t\bar{t}$ in the all hadronic mode [72] [73] in both the resolved and boosted regions. No evidence of resonance production were seen and limits were produced for various models including the Z' boson in topcolor-assisted technicolor which excludes masses less than 3.1 to 3.6 TeV (ATLAS) depending on the details of the model and 3.3, 5.25, and 6.65 TeV for widths of 1, 10 and 30 percent relative to the mass of the resonance .

ATLAS also presented results on the lepton plus jets final state, where the top quark pair decays as $t\bar{t} \to WbWb$ with one W boson decaying leptonically and the other hadronically; CMS used final states where both, one or neither $W$ decays leptonically and then combined the results. The $t\bar{t}$ invariant mass spectrum was analyzed for any excess, and no evidence for any resonance was seen. ATLAS excluded a narrow ($\Gamma/m = 1.2\%$) leptophobic topcolor $Z'$ boson with masses between 0.7 and 2.1 TeV and with $\Gamma/m = 3\%$ between 0.7 and 3.2 TeV. CMS set limits on leptophobic $Z'$ bosons for three different assumed widths $\Gamma/m = 1.0\%$ , $\Gamma/m = 10.0\%$, and $\Gamma/m = 30.0\%$ of 3.9 TeV to 4.0 TeV and exclude RS KK gluons up to 3.3 TeV.

Both ATLAS [74] and CMS [75] have also searched for resonances decaying into $q\bar{q}$, $qg$ or $gg$ using the dijet invariant mass spectrum. Excited quarks are excluded up to masses of 6.7 TeV and model-independent upper limits on cross sections with a gaussian signal shape were set. CMS excluded string resonances with masses below 7.9 TeV, scalar diquarks below 7.5 TeV, axigluons and colorons below 6.6 TeV, excited quarks below 6.3 TeV, coloroctet scalars below 3.7 TeV, W' bosons below 3.6 TeV, Z' bosons with SM-like couplings below 2.9 TeV and between 3.1 TeV and 3.3 TeV, Randall–Sundrum Gravitons below 2.6 TeV.

$W' \to \ell\nu$:

Both LHC experiments have also searched for massive charged vector bosons. In this section we include a summary of the results, with emphasis on final states with third generation fermions, while the details on other decays are discussed in the mini-review of $W'$ [64]. ATLAS searched for a heavy $W'$ decaying to $e\nu$ or $\mu\nu$ and find no excess over the standard model expectation. A sequential standard model (SSM) $W'$ boson (assuming zero branching ratio to $WZ$) with mass less than 7 TeV was excluded [76] using 139 fb$^{-1}$ dataset at $\sqrt{s} = 13$ TeV, as well as setting model independent cross-section limits as a function of mass. Based on a smaller dataset, the CMS experiment excluded a SSM $W'$ boson with mass up to 4.1 TeV [77] and presented the upper limits on the production of generic $W'$ bosons decaying into this final state using a model-independent approach.

CMS [78] has carried out a complementary search in the $\tau\nu$ final state. As noted above, such searches place limits on models with enhanced couplings to the third generation. No excess was observed and limits between 2.0 and 2.7 TeV were set on the mass of a $W'$ decaying preferentially to the third generation; a $W'$ with universal fermion couplings was also excluded for masses less than 2.7 TeV.

$W' \to t\bar{b}$:

Heavy new gauge bosons can couple to left-handed fermions like the SM $W$ boson or to right-handed fermions. $W'$ bosons that couple only to right-handed fermions ($W'_R$) may not have leptonic decay modes, depending on the mass of the right-handed neutrino. For these $W'$ bosons, the tb ($t\bar{b} + \bar{t}b$) decay mode is especially important because in many models the $W'$ boson is expected to have enhanced couplings to the third generation of quarks relative to those in the first and second generations. It is also the hadronic decay mode with the best signal-to-background. ATLAS and CMS have performed searches for $W'$ bosons via the $W' \to$ tb decay channel in the lepton+jets and all-hadronic final state.

The CMS lepton+jets search [79–82], $W' \to$ tb $\to$ Wbb $\to \ell\nu$bb, proceeded via selecting events with an isolated lepton (electron or muon), and at least two jets, one of which is identified to originate from a b-quark. The mass of the $W'$ boson ($M_{\rm tb}$) was reconstructed using the four-momentum vectors of the final state objects (bb$\ell\nu$). The distribution of $M_{\rm tb}$ is used as the search discriminant. A search [82] using 35.9 fb$^{-1}$ of data, collected at $\sqrt{s}$ = 13 TeV, led to an exclusion of $W'_R$ bosons with masses below 3.4 TeV (3.6 TeV) if $M_{W'_R} >> M_{\nu_R}$ ($M_{W'_R} < M_{\nu_R}$), where $M_{\nu_R}$ is the mass of the right-handed neutrino.

The CMS search for $W' \to$tb decays using the all-hadronic final state focused on $W'$ masses above 1 TeV [81]. In this region, the top quark gets a large Lorentz boost and hence the three hadronic products from its decay merge into a single large-radius jet. Techniques which rely on substructure information of the jets [83] are employed to identify boosted all hadronic W boson and top quark jets and compute the mass of the jet. $W'$ candidate mass was computed from back-to-back boosted top-tagged jet and a low mass b-tagged jet. From this all-hadronic search, $W'$ bosons were excluded for masses up to 2.02 TeV.

ATLAS has searched for $W'_R$ bosons in the $t\bar{b}$ final state both for lepton+jets [84] and all-hadronic [85] decays of the top. No significant deviations from the standard model were seen in either analysis and limits were set on the $W' \to t\bar{b}$ cross section times branching ratio and $W'$ bosons with purely right-handed couplings to fermions were excluded for masses below 3.15 TeV when the two channels are combined.

In addition, the above studies also provided upper limits on the $W'$ effective couplings to right- and left-handed fermions. In Fig. 93.1 (bottom) the upper limits on $W'$ couplings normalized to the SM W boson couplings derived by ATLAS [86] are shown. The top panel of Fig. 93.1 shows the upper limits for arbitrary combinations of left- and right-handed couplings of the $W'$ boson to fermions set using a model independent approach by CMS [82].

### 93.2.2 *Searches for Resonances decaying to Vector Bosons and/or Higgs Bosons*

Both the ATLAS and CMS experiments have used the data collected at $\sqrt{s} = 13$ TeV to search for resonances decaying to pairs of bosons. Overall no significant excesses were seen in the full datasets that were analyzed and the results are interpreted in models with heavy vector triplets (HVT) [87], models with strong gravity and extra spatial dimensions, as well as setting model independent limits as a function of mass. For a full review of models including extra spatial dimensions including the interpretation of many of these results in that context please see the review of extra dimensions in this volume [60].

Utilizing data collected at $\sqrt{s} = 13$ TeV, ATLAS [88] and CMS [89], have both looked for a resonant state decaying into VV (with V = W or Z) , VH ( with H representing the SM Higgs boson), and HH. Both collaborations have analyzed bosonic decay modes. ATLAS searches in the $qqqq$, $\nu\nu qq$, $l\nu qq$ , $llqq$ , $l\nu l\nu$, $ll\nu\nu$, $l\nu ll$, $llll$, $qqbb$ $\nu\nu bb$, $l\nu bb$, and $llbb$ final states and combined the results

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

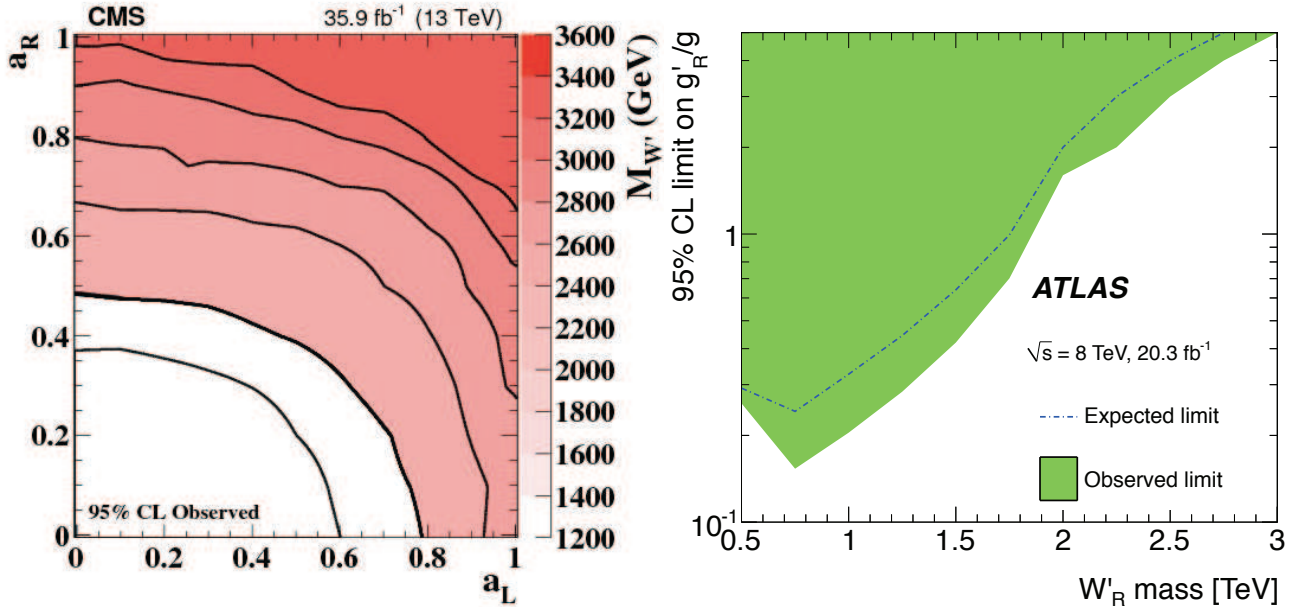

Figure 93.1: Left panel: Observed limits on the $W'$ boson mass as function of the left-handed ($a_{\rm L}$) and right-handed ($a_{\rm R}$) couplings. Black lines represent contours of equal $W'$ boson mass [82]. Right panel: Observed and expected regions, on the g′/g vs mass of the $W'$ boson plane, that are excluded at 95% CL, for right-handed $W'$ bosons [86].

(separately within each experiment) . While CMS analyzes the $qqqq$, $\nu\nu qq$, $l\nu qq$ , $llqq$ , $ll\nu\nu$, $\nu\nu bb$, $l\nu bb$, $llbb$ , $bbbb$, $\tau\tau bb$ , and $qq\tau\tau$ final states.

The combined limits are expressed both as limits on the cross-section as a function resonance mass as well as constraints on the coupling of the heavy boson triplet to quarks, leptons, and the Higgs boson.

$X \to WZ$:

ATLAS searches for new heavy resonances decaying into $WZ$ in the channels $WZ \to qqqq$ [90] , $l\nu qq$ [91], and $l\nu ll$ [92]. In the fully leptonic channel , the invariant mass of the W Z pair is obtained by considering all possible four lepton permutations in each event. The dominant background is Standard Model continuum WZ production, ZZ production where one lepton is not identified or falls outside the detector acceptance, and top quark plus vector boson production. No resonant production is seen in data and lower limits on the mass of a HVT decaying into WZ are set at 2260 (2460) GeV assuming a coupling constant of $g_V = 1$ ($g_V = 3$). In the $WZ \to l\nu qq$ mode, ATLAS searches in both the cases that the quarks are observed as individual jets (resolved) and where they merge into one jet in the detector (boosted) which probe the low and high $p_T$ regime of the Z boson. No significant excess is seen in either channel and combined lower mass limits are placed at 2900 (3000) GeV for $g_V = 1$ ($g_V = 3$) in the HVT model. In the all hadronic decay mode, ATLAS searches for two high $p_T$ hadronically decaying vector bosons looking for a resonant structure. No excess is seen and limits are placed excluding 1200-3000 (1200-3300) GeV for $g_V = 1$ ($g_V = 3$) in the HVT model.

The CMS collaboration searches for $VV \to qqqq$ [93] in the large R dijet search. The W and Z boson are identified through the mass of the large R jet and substructure variables. No excess is seen and limits are set for charged HVT bosons with masses lower than 3200 (3800) GeV for $g_V = 1$ ($g_V = 3$). Cross-section limits as function of mass are reported for the charged spin-1 resonance interpretation and are placed at 44.4 fb at 1.4 TeV to 0.7 pb at 4 TeV. In the $\nu\nu qq$ final state [94], the CMS collaboration searches for a charged spin 1 resonance decaying into a $VZ$ final state with a Z boson decaying into a pair of neutrinos and the other boson decaying into two collimated quarks reconstructed as a large R-jet. The transverse mass of the $VZ$ candidate is reconstructed and utilized to search for evidence of resonant $VZ$ production. No excess is seen and lower mass limits are placed on the charged resonance at 3100 (3400) GeV for $g_V = 1$ ($g_V = 3$) .

In the $2l2q$ final state, the CMS collaboration searches for a heavy resonance decaying into $ZV$ [95] looking for events with one large R-jet consistent with the hadronic decay of a vector boson and a Z boson reconstructed in the charged lepton decay channel (e or $\mu$). Limits are set for a HVT W' with a lower mass of 2270 (2330) for $g_V = 1$ ($g_V = 3$) .

$X \to WW$:

The ATLAS collaboration searches for a new heavy resonance decaying into $WW$ in the channels $WW \to qqqq$ [90] , $l\nu qq$ [91], and $l\nu\nu$ [96]. In the case where both $W$s decay leptonically, ATLAS utilizes the transverse of the two lepton and two neutrino final state and searches for an excess in this distribution between 200 GeV and 5 TeV. No excess is seen and the mass of a HVT is excluded below 1300 GeV. Further vector boson fusion is also considered and cross-section limits as a function of mass are placed ranging from 1.3 pb to 0.006 pb at 200 GeV to 3 TeV, respectively. In the $l\nu qq$ mode , ATLAS completed a companion analysis to the $WZ \to$ analysis discussed above and places lower mass limits of 2850 (3150) GeV for $g_V = 1$ ($g_V = 3$) in the HVT model. ATLAS also interprets the all hadronic mode analysis in the hypothesis that $WW \to qqqq$ and places limits on a HVT boson decaying into WW in the all hadronic mode between 1200 to 2200 (1200 to 2800) GeV for $g_V = 1$ ($g_V = 3$).

The CMS collaboration searches for $VV \to qqqq$ [93] in the large R dijet search. The W and Z boson are identified through the mass of the large R jet and substructure variables. No excess is seen and limits are set for charged HVT bosons with masses lower than 2700 (2800) GeV for $g_V = 1$ ($g_V = 3$). Cross-section limits as function of mass are reported for the uncharged spin-1 resonance interpretation and are placed at 41.6 fb at 1.4 TeV to 0.6 pb at 4 TeV.

$X \to VH$:

The ATLAS Collaboration searches for a new heavy resonance decaying into $WH$ and $ZH$ in the $qqbb$ ($WH$ and $ZH$) [97], $l\nu bb$ ($WH$), $\nu\nu bb$ ($ZH$), $llbb$($ZH$) [98]. In the all hadronic mode, ATLAS searches for boosted $VH$ production looking for two large R jets where the larger invariant mast large R jet is interpreted as the Higgs boson decay products while the lesser the hadronically decaying vector boson requiring b tagging on the Higgs boson subjets. The invariant mass is reconstructed a and a search is done for resonant production of $ZH$. None is found and limits from

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

1100 to 2500 (1300 to 3800 GeV) are placed for $g_V = 1$ ($g_V = 3$). ATLAS also searches for $ZH$ where the W or Z boson decays into $\nu\nu$, $l\nu$, and $ll$ . The analysis searches for both resolved and merged (boosted) b jets from the decay of the Higgs boson as well as defining signal regions based on the number of reconstructed charged leptons (0,1,or 2). In the dilepton channel the invariant mass is explicitly reconstructed of the entire diboson system, the single lepton channel reconstructs the diboson final state constraining the lepton and missing transverse momentum utilizing the known W boson mass, while the 0 charged lepton channel reconstructs the transverse mass of the diboson system. No excess is seen in any channel and limits on the production of a HVT are placed at 2800 GeV (2930) GeV for $g_V = 1$ ($g_V = 3$).

The CMS Collaboration searches for a heavy resonance decaying into $VH$ [99] searching for resonances decaying into a Higgs boson and either a hadronically decaying W or Z boson. The search identifies events with two large-R jets using substructure variables and requires one large-R jets is tagged with a pair of b-hadrons clustered in a single jet. The invariant mass of the $VH$ bosons is reconstructed and evidence for resonance production is sought. No excess is seen and limits are placed. With $g_V = 1$ (3) a narrow W' resonance with $m_{W'} < 2470(3150)$ GeV and $m_{Z'} < 1150(1190)$.

Summary of Searches with Diboson Final States:

Both ATLAS [88] and CMS [89] provide plots summarizing the various searches results and limits combining . The results are shown in the context of HVT models and models of strong gravity with extra spatial dimensions. No excess is seen in any search and limits on the 4.3 (4.5) TeV (ATLAS) and (CMS). Inclusion of decays directly to fermions increase these limits to 5.3 (5.5) TeV and 5.0 (5.2) TeV from the ATLAS and CMS combinations, respectively. Both collaborations also place varying limits on the coupling strength as a function of HVT boson mass as well.

### 93.2.3 *Vector-like third generation quarks*

Vector-like quarks (VLQ) have non-chiral couplings to W bosons, i.e. their left- and right-handed components couple in the same way. They therefore have vectorial couplings to W bosons. Vector-like quarks arise in Little Higgs theories, top-coloron-models, and theories of a composite Higgs boson with partial compositeness. In the following, the notation $T$ quark refers to a vector-like quark with charge 2/3 and the notation $B$ quark refers to a vector-like quark with charge $-1/3$, the same charges as the SM top and b quarks respectively. The exotic vector-like quarks $X_{5/3}$ and $Y_{-4/3}$ have charges 5/3, and $-4/3$ respectively. Vector-like quarks couple with SM quarks with Yukawa interactions and may exist as SU(2) singlets ($T$, and $B$), doublets $[(X_{5/3}, T),(T, B),(B, Y_{-4/3})]$, or triplets $[(X_{5/3}, T, B), (T, B, Y_{-4/3})]$. At the LHC, VLQs can be pair produced via the dominant gluon-gluon fusion. VLQs can also be produced singly by their electroweak effective couplings to a weak boson and a standard model quark. Single production rate is expected to dominate over the rate of pair production at large VLQ masses. $T$ quarks can decay to $bW$, $tZ$, or $tH^0$. Weak isospin singlets are expected to decay to all three final states with (asymptotic) branching fractions of 50%, 25%, 25%, respectively. Weak isospin doublets are expected to decay exclusively to $tZ$ and to $tH^0$ [100] with equal branching ratios. Analogously, $B$ quarks can decay to $tW$, $bZ$, or $bH^0$. The $Y_{-4/3}$ and $X_{5/3}$ quarks decay exclusively to $bW$ and to $tW$. While these are taken as the benchmark scenarios, other representations are possible and hence the final results are interpreted for many allowed branching fraction combinations.

Given the multiple decay modes of the VLQs, the final state signatures of both pair produced and the singly produced VLQs are fairly rich with leptons, jets, b jets, and missing energy. Depending on the mass of the VLQ, the top quarks and $W/Z/H^0$ bosons may be Lorentz boosted and identified using jet substructure techniques. Thus the searches are performed using lepton+jets signatures, multi-lepton and all-hadronic decays. In addition, $T$ or $B$ quarks with their antiparticles can result in events with same-sign leptons, for example if the decay $T \to tH \to bWW^+W^-$ is present, followed by leptonic decays of two same-sign $W$ bosons. In the following subsections, while we describe the searches for each of the decay modes of the VLQs, the same analysis can be re-interpreted to obtain the sensitivity to a combination with varied branching fractions to the different decay modes.

In the following sections, the results obtained for $T$ ($B$) quarks assuming 100% branching ratio to $Wb$ ($Wt$) are also applicable to heavy vector-like $Y_{-4/3}$ ($X_{5/3}$) with charge 4/3 (5/3).

#### 93.2.3.1 *Searches for* $T$ *quarks that decay to* $W$, $Z$ *and* $H^0$ *bosons*

$T/Y \to bW$:

CMS has searched for pair production of heavy $T$ quarks that decay exclusively to $bW$ [101–103]. The analysis selected events with exactly one charged lepton, assuming that the $W$ boson from the second $T$ quark decays hadronically. Under this hypothesis, a 2-constraint kinematic fit can be performed to reconstruct the mass of the $T$ quark as a narrow mass peak with a mass resolution of around 7%. In Refs. [102] and [103], the two-dimensional distribution of reconstructed mass vs $S_T$ was used to test for the signal, where $S_T$ is the scalar sum of the missing $p_T$ and the transverse momenta of the lepton and the leading four jets. This analysis, when combined with the search in the fully hadronic final state [104] excluded new quarks that decay 100% to $bW$ for masses below 0.89 TeV [103]. At times the hadronically-decaying $W$ boson is produced with a large Lorentz boost, leading to the $W$ decay products merged into a large-radius jet. Algorithms such as jet pruning [105] were used to remove contributions from soft, wide angle radiation, from large-radius jets, leading to better discrimination between QCD jets and those arising from decays of the heavy particles. If the mass of the boosted jet was compatible with the W boson mass, then the W boson candidate jet and its subjets were used in the kinematic reconstruction of the $T$ quark. No excess over standard model backgrounds was observed. Upper limits on the production cross section as a function of the mass of $T$ quarks were measured. By comparing them with the predicted cross section for vector like quark pair production, the strong pair production of $T$ quarks was excluded for masses below 1.30 TeV (1.28 TeV expected) [101].

Another "cut-based" search for pair produced $T$ quarks in the all-hadronic final state targeting the $Wb$ decay mode [106], relies on mass reconstruction of two highest $p_T$ $Wb$ combinations using boosted $W$ boson candidates with $p_T > 200$ GeV and b-tagged jets. $H_T$ is used as the signal discriminator, with selected events divided into nine categories based on the multiplicity of $W$ and $b$ jets in the event. From this search $T$ quarks with pure $Wb$ decays are excluded for masses below 1.04 TeV (1.07 TeV expected).

An analogous search has been carried out by ATLAS [107,108] for the pair production of heavy $T$ quarks. It used the lepton+jets final state with an isolated electron or muon and at least four jets, including a b jet and required reconstruction of the $T$ quark mass. Given the mass range of the $T$ quark being explored was from a 0.4 TeV to a couple of TeV, the $W$ boson from the $T$ quark may fall in two categories: those with a high boost leading to merged decay products, and others where the two jets from the $W$ boson were resolved. In addition, the selection was optimized to require large angular separation between the high $p_T$ $W$ bosons and the b jets.

The $T \to Wb$ candidates were constructed from both the leptonically and hadronically decaying $W$ bosons by pairing them with the two highest $p_T$ b-tagged jets in the event. The pairing of b jets with $W$ bosons which minimizes the difference between the masses of leptonically decaying $T$ ($m_{lep}(T)$) and the hadronic $T$ ($m_{had}(T)$) was chosen. Finally, $m_{lep}(T)$ was used as the discriminating variable in a signal region defined by high $S'_T$ (here $S'_T$ is defined as the scalar sum of the missing $p_T$, the $p_T$ of the lepton and jets), and the opening angle between the lepton and the neutrino ($\Delta R(e, \nu)$). With the 36.1 fb$^{-1}$ data collected during Run 2 at $\sqrt{s} = 13$ TeV, assuming 100% branching ratio to the $Wb$ decay, the observed lower limit on the $T$ mass was 1.35 TeV, and in the SU(2) singlet scenario, the lower mass limit was obtained to be 1.17 TeV [107].

A targeted search for a $T$ quark, produced singly in association with a light flavor quark and a b quark and decaying into $bW$, was carried out by CMS at $\sqrt{s}$=13 teV and a dataset corresponding to 2.3 fb$^{-1}$ [109]. The analysis used lepton+jets events, with at least

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

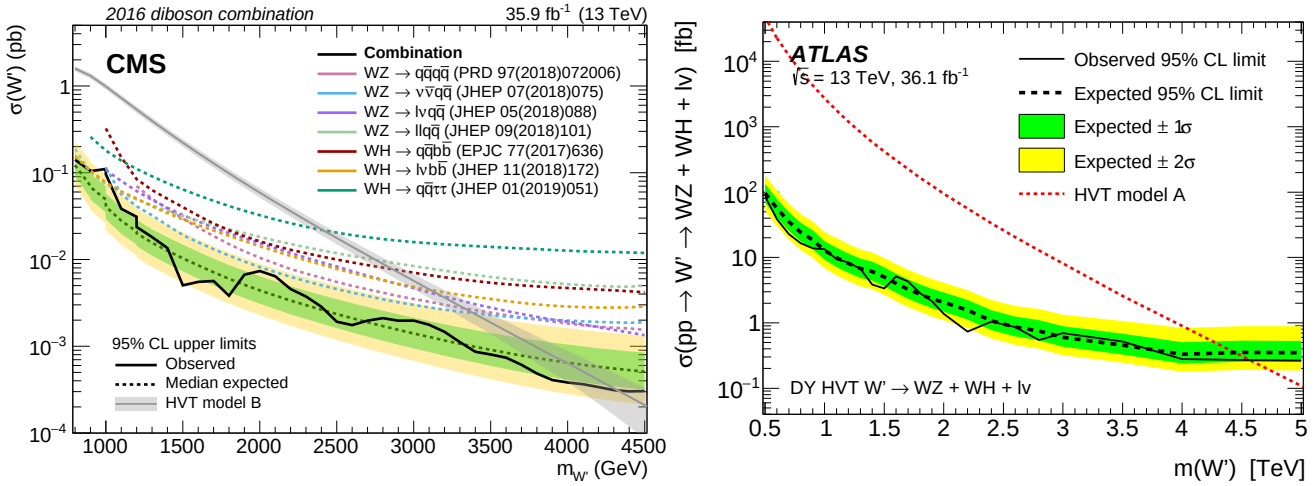

Figure 93.2: Left panel:Observed limits from $W'$ to diboson from CMS [89]. Right panel: Observed limits from $W'$ to diboson decays from ATLAS [88].

one b-tagged jet with large transverse momentum, and a jet in the forward $\eta$ region. Selected events were required to have $S''_T > 500$ GeV, where $S''_T$ is defined as the scalar sum of the transverse momenta of the lepton, the leading central jet, and the missing transverse momentum. The invariant mass of the $T$ candidate was used as the discriminating variable and was reconstructed using the four-vectors of the leptonically decaying $W$ boson and the leading central jet. No excess over the standard model prediction was observed. As the VLQ width is proportional to the square of the coupling, upper limits were set on the production cross section assuming a narrow width VLQ with coupling greater than 0.5. For $Y/T$ quarks with a coupling of 0.5 and a 100% branching fraction for the decay to $bW$ the excluded masses were in the range from 0.85 to 1.40 TeV [109]. A similar search [110, 111] performed by ATLAS singly produced $T$ or $Y_{-4/3}$ quark decaying to $Wb$ using a dataset corresponding to 36.1 fb$^{-1}$. The search was performed using lepton+jets events with a high $p_T$ b-tagged jet, and at least one forward jet. The reconstructed mass of the $T/Y_{-4/3}$ quark, was used as the discriminating variable and showed no excess above the expectation from SM. Interference effects with the SM background are included in the study. This search led to 95% CL upper limits on the mixing angle $|sin(\theta_L)|$ ($C_L^{Wb}$) in the range of 0.18–0.35 (0.25–0.49) for singlet $T$ quark mass between 0.8–1.2 TeV. This search also provided limits as a function of the $Y_{-4/3}$ quark mass, on the coupling of the $Y_{-4/3}$ quark to $bW$, and the mixing parameter $|sin\theta_R|$ ($C_R^{Wb}$) for a ($B$,$Y_{-4/3}$) doublet model [110]. For VLQ masses between 0.08–1.8 TeV, the limits on $|sin(\theta_R)|$ ($C_R^{Wb}$) is in the range 0.17–0.55 (0.24–0.77), where limits on $|sin\theta_R|$ ar around 0.18–0.19 and below the constraints from electroweak precision observables for $Y_{-4/3}$ quark mass between 0.9–1.25 TeV. For $Y_{-4/3}$ quark in the triplets ($T$,$B$,$Y_{-4/3}$), limits on $|sin(\theta_L)|$ ($C_L^{Wb}$) are between 0.16–0.39 (0.31–0.78) for masses between 0.8 GeV–1.6 TeV [110].

$T \to tH^0$:

ATLAS has performed a search for $T\overline{T}$ production with $T \to tH^0$ [108, 112]. Given the dominant decay mode $H^0 \to b\bar{b}$, these events are characterized by a large number of jets, many of which are b jets. Thus the event selection required one isolated electron or muon and high jet multiplicity (including b-tagged jets). The sample is categorized by the jet multiplicity (5 and $\geq$6 jets in the 1-lepton channel; 6 and $\geq$7 jets in the 0-lepton channel), b tag multiplicity (2, 3 and $\geq$4) and mass-tagged jet multiplicity (0, 1 and $\geq$2). The distribution of $m_{\rm eff}$, defined as the scalar sum of the lepton and jet $p_T$ and the missing $E_T$, for each category were used as the discriminant for the final signal and background separation. No excess of events were found. Weak isospin doublet $T$ quarks were excluded below 1.16 TeV.

A search by ATLAS for pair produced VLQs with an all-hadronic final state signature yields an exclusion of pure decays $T \to tH^0$ upto a $T$ quark mass of 1.01 TeV [113]. This analysis used a deep neural network technique to identify jets originating from boosted bosons and top-quarks and described further in subsection 93.2.3.2.

The CMS search for $T\overline{T}$ production, with $T \to tH^0$ decays has been performed in both lepton+jets, multilepton and all-hadronic final states. The lepton+jets analysis [114] emphasizes the presence of large number of b-tagged jets, and combined with other kinematic variables in a Boosted Decision Tree (BDT) for enhancing signal to background discrimination. The multilepton analysis [114] was optimized for the presence of b jets and the large hadronic activity. For $\mathcal{B}(T \to Wb) = 1$, the combined lepton+jets and multilepton analyses led to a lower limit on $T$ quark masses of 0.71 TeV. A search for $T \to tH^0$ in all-hadronic decays [115], optimized for a high mass $T$ quark, and based on identifying boosted top quark jets has been carried out by CMS. This search aimed to resolve subjets within the jets arising from boosted top quark decays, including b tagging of the subjets. A likelihood discriminator was defined based on the distributions of $H_T$, and the invariant mass of the two b jets in the events for signal and background. No excess above background expectations was observed. Assuming 100% branching ratio for $T \to tH^0$, this analysis led to a lower limit of 0.75 TeV on the mass of the $T$ quark.

Searches for $T$ quarks at $\sqrt{s}$=13 TeV, based on a 2.6 fb$^{-1}$ dataset [116] have been performed by CMS using the lepton+jets final state. This search has been optimized for high mass $T$ quarks by exploiting techniques to identify $W$ or Higgs bosons decaying hadronically with large transverse momenta. The boosted W channel excluded $T$ quarks decaying only to $bW$ with masses below 0.91 TeV, and the boosted tH channel excluded $T$ quarks decaying only to $tH$ for masses below 0.89 TeV.

A CMS search for $T \to tH^0$ with $H^0 \to \gamma\gamma$ decays has been performed [117] in pair production of $T$ quarks. To identify the Higgs boson produced in the decay of the heavy $T$ quark, and the subsequent $H^0 \to \gamma\gamma$ decay, the analysis focused on identification of two photons in events with one or more high $p_T$ lepton+jets or events with no leptons and large hadronic activity. A search for a resonance in the invariant mass distribution of the two photons in events with large hadronic activity defined by the $H_T$ variable showed no excess above the prediction from standard model processes. The analysis resulted in exclusion of $T$ quark masses below 0.54 TeV.

A search for electroweak single production of $T$ quark decaying to $tH^0$ using boosted topologies in fully hadronic [118] and lepton+jets [119] in the final states has been performed by CMS. The electroweak couplings of the $T$ quarks to the SM third generation quarks are highly model dependent and hence these couplings determine the rates of the single $T$ quark production. In both analyses, $T$ quark candidate invariant mass was reconstructed using the

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

boosted Higgs boson jets and the top quark. Higgs boson jets were identified using jet substructure techniques and subjet b tagging. For the lepton+jets analysis the top quark was reconstructed from the leptonically decaying W and the b jet, while in the all-hadronic analysis the top quark jet was tagged using substructure analysis. There was no excess of events observed above background. Exclusion limits on the product of the production cross section and the branching fraction ($\sigma(pp \to Tqt/b) \times \mathcal{B}(T \to tH^0)$) were derived for the $T$ quark masses in the range 0.70-1.8 TeV. From the lepton+jets analysis, for a mass of 1.0 TeV, values of ($\sigma(pp \to Tqt/b) \times \mathcal{B}(T \to tH^0)$ greater than 0.8 and 0.7 pb were excluded assuming left- and right-handed coupling of the T quark to standard model fermions, respectively [119]. For the all-hadronic analysis, upper limits between 0.31 and 0.93 pb were obtained on ($\sigma(pp \to Tqt/b) \times \mathcal{B}(T \to tH^0)$ for $T$ quark masses in the range 1.0-1.8 TeV [118].

$T \to tZ$:

Both ATLAS and CMS searched for $T$ quarks that decay exclusively into $tZ$ in pp collisions at $\sqrt{s} = 13$ TeV. No excesses were found in either search.

ATLAS performed a search [120] for optimized pair production of vector-like top quarks decaying into $tZ$ where the Z boson subsequently decays into neutrino pairs utilizing 36.1 fb$^{-1}$ of data. The search selected events with one lepton, multiple jets, and significant missing transverse momentum. No significant excesses were found and lower limits on the mass of a vector like top quark were placed, excluding masses below 0.87 TeV (weak-isopsin singlet), 1.05 TeV (weak-isospin doublet), and 1.16 TeV ( pure $tZ$ mode).

Another search by ATLAS for pair produced $T$ decaying to $tZ$ has been carried out by reconstructing the high transverse momentum $Z$ boson from a pair of opposite-sign same-flavor lepton, using events with two or three charged leptons [121]. The final analysis is based on three final signatures. In the trilepton events, at least one b-tagged jet is required and $S_T$ is used as the discriminating variable. In events with two leptons, at least 2 b jets are requested and those with zero or one high $p_T$ top-tagged jet, use $H_T$ as the discriminator. The second dilepton analysis with two top-tagged high $p_T$ jets focuses on hadronically decaying heavy resonances and the invariant mass of the Z boson and the highest $p_T$ b-tagged jet if found to be a good discriminating variable. No excess was observed over the background expectations. The combined analysis yields a lower limit on $T$ quark mass of 1.03 TeV (1.21 TeV) in the singlet (doublet) model or 100% branching ratio for $T \to tZ$ a lower limit on the $T$ quark mass of 1.34 TeV is obtained.

ATLAS has subsequently carried out a search [122] for singly produced $T$ quark decaying to $tZ$ where the Z boson decays into neutrino pairs. The search is carried out using 36.1 fb$^{-1}$ of data in events with two different final state signatures: one with jets, and significant missing $p_T$ (0L) and the other with single lepton, jets and missing $p_T$ (1L). Events are divided into signal and dedicated $W$+jets and $t\bar{t}$ background control regions. The sensitivity to $T$ quark signal is extracted using distributions of missing $p_T$ for 1L and the distributions of transverse mass $T$ quark constructed from missing $p_T$ and the high $p_T$ large-radius top-tagged jet for 0L analysis. The is no excess found over the expected background and lower limits on the production of $T$ singlets is obtained as a function of the left- and right-handed couplings $c_{L,W}$ and $c_{R,W}$ to top quarks and $W$ bosons, where $c_W$ above 0.7 are excluded for $T$ quark mass of 1.4 TeV. The limits on $c_W$ are also recasted into expected and observed 95% CL upper limits for the mixing angle ($\theta_L$) of a singlet $T$ with the top quark.

CMS searched [123] for single production of $T$ quarks decaying into $tZ$ with the $Z$ boson decaying to pairs of charged leptons (electrons and muons) and the top quark decaying hadronically using 35.9 fb$^{-1}$ of data. Limits were placed on $T$ quarks with masses between 0.7 and 1.7 TeV excluding the product of cross section and branching fraction above values of 0.27 to 0.04 pb. Additionally, limits on the product of cross section and branching fractions for a $Z'$ boson decaying into $tZ$ were set between 0.13 and 0.06 pb for $Z'$ boson masses in the range from 1.5 to 2.5 TeV.

Similar searches by ATLAS for singly produced $T$ decaying to $Zt$ have been performed in final state signatures with two or three charged leptons [121]. The analysis relies on tagging b jets and high $p_T$ large-radius jets originating from top-quarks. Additional selections are devised to reduce the contributions from pair production of $T$ quarks. For events with dilepton analysis, the discriminating variable is the mass of the $T$ quark formed using the invariant mass of the $Z$ boson candidate and the highest $p_T$ top-tagged jet, while for the trilepton analysis, the variable $S_T$ is used to search for an excess of data over the expected SM background. No excess above the SM expectations is observed. The two final states (dilepton and trileptons) are combined to obtain the final results. For the coupling parameter $\kappa_T$ between 0.1–1.6, the 95% CL upper limits on the production cross section times branching fraction into $Zt$ is between 0.16–0.18 (0.03–0.05) pb at $T$ quark mass of 0.7 (2) TeV.

Combination of $T \to bW/tZ/tH^0$:

Most of the analyses described above targeted an individual decay mode of the $T$ quark, with 100% branching ratio to either $bW$, $tZ$ or $tH^0$ and were optimized accordingly. However, they have varied sensitivity to all three decay modes and the results can be interpreted as a function of branching ratios to each of the three decay modes, with the total adding up to unity ($\mathcal{B}(tH) + \mathcal{B}(tZ) + \mathcal{B}(Wb) = 1$).

Combinations of analyses have been performed by both ATLAS and CMS. The limits set by ATLAS searches in $W(\ell\nu)b = X, H(bb)b + X, Z(\nu\bar{\nu}), Z(\ell\ell)t/b + X$, dileptons with same-sign charge, trileptons, all-hadronic final states have been combined and the results obtained for various sets of branching fractions for $T$ quark decays to $bW$, $tH^0$ and $tZ$ are shown in Fig. 93.3 (left). In the combined analysis, ATLAS sets lower $T$ quarks mass limit of 1.31 TeV for all possible values of the branching fractions to the three decay modes [107,120,124]. In Fig. 93.3, exclusion is shown in the plane of $\mathcal{B}(T \to Ht)$ versus $\mathcal{B}(T \to Wb)$, for different values of the $T$ quark mass. The default branching ratio values for the weak-isospin singlet and doublet cases are also shown in Fig. 93.3 as yellow circle and star symbols respectively. Assuming a weak isospin ($T$,$B$) doublet and $|V_{Tb}| << |V_{tB}|$, $T$ quark mass below 1.37 TeV is excluded.

CMS analysis for pair production of $T$, combined three channels with lepton final states: single lepton, two leptons with the same sign of the electric charge (SS), or at least three leptons (trilepton) [125]. For various combinations of branching fractions for $T$ quark decays to $bW$, $tH^0$ and $tZ$, the combined results exclude $T$ quarks with masses below 1.14–1.3 TeV and are shown in Figure 93.3 (right). Single lepton events are classified into 16 signal categories and 6 background control regions based on multiplicity of b-tagged, high $p_T$ $H^0$ and $W$-tagged jets. The discriminating variables are $H_T$ for $H^0$-tagged and the minimum invariant mass constructed from the lepton and the b jet, min[$M_{lb}$], for zero $H^0$-tagged events. For the same-sign dilepton and trilepton analyses, the non-prompt backgrounds due to misidentified jets and leptons are derived from data control regions. In the trilepton analysis the $S_T$ variable is used as the signal discriminator binned in four categories based on the lepton flavor combinations ($eee$, $ee\mu$, $e\mu\mu$, $\mu\mu\mu$). The single lepton analysis is most sensitive for $tHbW$ and $WbWb$ decay modes, within the the SS dilepton analysis $tHtH$ and $tHtZ$ have the best efficiency and for trileptons the $tZtZ$ and $tHtZ$ decays modes have the highest efficiency. CMS excludes singlet (doublet) $T$ quark masses below 1.2 (1.28) TeV. Masses below 800 GeV were excluded in previous searches. For $T$ quark masses in the range 0.8–1.8 TeV, cross sections smaller than 30.4–9.4 fb (21.2–6.1 fb) are excluded for the singlet (doublet) scenario.

Another inclusive search for pair produced $T$ in all-hadronic final state [106] has been performed by CMS using the boosted event shape tagger (BEST) neural network technique to classify jets in six categories $W$, $Z$, $H^0$, $t$, $b$, and light. This search does not focus on a given VLQ mode, but on various combinations of the boson and quark jets in the final state. Anti-$k_T$ jets with a distance parameter of 0.8 are used. The BEST NN algorithm simultaneously classifies jets according to heavy object type. For each of the six particle hypothesis, it boosts each jet constituent into corresponding frame along jet momentum direction, and cal-

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

culates event shape and angular variables in the boosted frame, with the expectation that when boosting to the correct rest frame, jet constituents will be isotropic and show the expected N-prong structure of the decaying object in its rest frame. A neural network is trained using the event shape and angular variables in the boosted frame to classify jets according to one of those six possibilities (W, Z, H, t, b, or light). The analysis bins the events into 126 categories depending on the number of W, Z, H, t, b, or light jets in the final state with a maximum of four such objects. For each category $H_T^{\rm AK8}$, the scalar sum of $p_T$ of all AK8 jets, is used as the signal discriminator. A scan over a combination of various branching fractions is also performed. This search excludes $T$ quark masses in the range 0.74–1.37 TeV for the $tH$ decay mode in the NN analysis.

An inclusive search for VLQs has been carried out by CMS targeted at heavy $T$ quarks decaying to any combination of $bW$, $tZ$, or $tH^0$ is described in [114]. Selected events have at least one isolated charged lepton. Events were categorized according to number and flavour of the leptons, the number of jets, and the presence of hadronic vector boson and top quark decays that are merged into a single jet. The use of jet substructure to identify hadronic decays significantly increases the acceptance for high $T$ quark masses. No excess above standard model backgrounds was observed. Limits on the pair production cross section of the new quarks are set, combining all event categories, for all combinations of branching fractions into the three final states. For $T$ quarks that exclusively decay to $bW/tZ/tH^0$, masses below 0.70/0.78/0.71 TeV are excluded.

93.2.3.2 *Searches for* $\boldsymbol{B}$ *quarks that decay to* $\boldsymbol{W}$, $\boldsymbol{Z}$ *and* $\boldsymbol{H^0}$ *bosons*

ATLAS and CMS have performed searches for pair production of heavy $B$ quarks which subsequently decay to $Wt$, $bZ$ or $bH^0$. The searches have been carried out in final states with single leptons, dileptons (with same charge or opposite charge), multileptons, as well as in fully hadronic final states.

$B \to bH^0X$:

Using 36.1 fb$^{-1}$ of data, ATLAS has performed a search for pair produced VLQs with all-hadronic final state signature [113]. While this analysis provides exclusion limits for all third generation VLQs, it provides the strongest results for $B \to bH^0$ decay mode and excludes pure $B \to bH^0$ decays for $B$ masses upto 1.01 TeV. The limits are also casted as a two-dimensional plane of branching ratio values of $B \to bH^0$ vs. $B \to Wb$. This analysis required the presence of high $p_T$ jets and multiple b tags. It used a multi-class DNN to classify jets arising from $W$, $Z$, $H^0$ bosons and top-quarks. In addition, the matrix element method is used to compute the likelihood for the event to arise from a particular VLQ final state and used to construct the final discriminator. To increase the performance sensitivity, processes with the same number of top quarks, $W/Z$ bosons, and $H^0$ Higgs bosons are combined into a single hypothesis.

$B \to WtX$:

A search for $B \to tW$ in $B$ pair produced events has been performed by the ATLAS experiment [107] using lepton+jets events with one hadronically decaying W and one leptonically decaying W utilizing 36.1 fb$^{-1}$ of data at $\sqrt{s} = 13$ TeV. The search was optimized for $T$ production decaying into $Wb$. Since the analysis was optimized for $T \to Wb$ rather than $Wt$ decays the analysis does not reconstruct the full $B$ mass. As discussed earlier, the hadronically and leptonically decaying heavy quarks were required to have similar reconstructed masses (within 300 GeV). The interpretation of the $T \to Wb$ in the context of $B \to tW$ production led to the exclusion of heavy B like VLQs for masses less than 1.25 TeV and 1.08 TeV, assuming a 100% branching fraction to $tW$ or SU(2) singlet B scenario, respectively.

A similar search by CMS [126], using 19.8 fb$^{-1}$ of $\sqrt{s} = 8$ TeV data, selected events with one lepton and four or more jets, with at least one b-tagged jet, significant missing $p_T$, and further categorizes them based on the number of jets tagged as arising from the decay of boosted $W$, $Z$ or $H^0$ bosons. The $S_T$ distributions of the events in different categories showed no excess of events above the expected background and yielded a lower limit on the $B$ quark mass of 0.73 TeV for $BR(B \to Wt) = 1$.

CMS [116] also searched for pair production of both $TT$ and $BB$ with collisions from 2.5 fb$^{-1}$ of $\sqrt{s} = 13$ TeV data. The analysis searches for events with one high $p_T$ lepton , multiple jets, and highly boosted W or Higgs bosons decaying hadronically. The analysis focuses on pair production and selects events with either a boosted W or Higgs candidate and then proceeds to search for anomalous production in excess of standard model production. Seeing no significant excesses CMS then proceeded to set limits in many different interpretations. The strongest was from the the $B \to Wt$ interpretation leading to excluding heavy vector-like $B$ quark less than 0.73 TeV.

The all-hadronic inclusive analysis [106] performed by CMS using the BEST NN technique to classify $W/Z/H^0/t/b$/light jets also gives exclusion limits on $B$ quark production for various combinations of branching fractions for decays to $tW$, $bZ$, $bH^0$. By considering categories based on various combinations of the boson and quark jets in the final state it excludes $B$ quarks with masses up to 1230 GeV, for $B$ decays to $tW$ with a 100% branching fraction.

Electroweak production of single heavy $B$+$b$ productions has been studied by CMS in the decay to $tW$ with lepton+jets final state [127]. Single lepton events with hadronic jets, including a forward jet, missing $p_T$ are selected and divided into 10 different categories based on lepton flavor (e/$\mu$), top-tagged, $W$-tagged, and 0/1/2 $b$-tagged jets. $B$ quark mass $m_{reco}$ is fully reconstructed from lepton, jets, and missing $p_T$, where the neutrino four-momentum is computed using the missing $p_T$ and the $W$ mass constraint (assuming massless $\nu$). For events within top-tagged category, the high $p_T$ top-tagged hadronic jet and the leptonically decaying $W$ boson is used to compute $m_{reco}$. The $m_{reco}$ distribution is used as the signal discriminator. In the absence of a excess over the expected SM background, the exclusion limits on the production cross section is for $B$ quark masses between 0.7-2 TeV varies between 0.3 to 0.03 pb. In addition, $B$ quarks with left-handed couplings and a relative width of 10, 20, and 30% are excluded for masses below 1.49, 1.59, and 1.66 TeV respectively.

$B \to bZX$:

A search by CMS [128] for the pair-production of a heavy $B$ quark and its antiparticle has been performed, where one the heavy $B$ quark decays to $bZ$. Events with a $Z$ boson decaying to $e^+e^-$ or $\mu^+\mu^-$ and at least one b jet are selected. The signal from $B \to bZ$ decays are expected to appear as a local enhancement in the $bZ$ mass distribution. No such enhancement was found and $B$ quarks that decay 100% into $bZ$ are excluded below 0.70 TeV. This analysis also set upper limits on the branching fraction for $B \to bZ$ decays of 30-100% in the $B$ quark mass range 0.45-0.70 TeV. A complementary search has been carried out by ATLAS for new heavy quarks decaying into a $Z$ boson and a b-quark [129]. Selected dilepton events contain a high transverse momentum $Z$ boson that decays leptonically, together with two b jets. If the dilepton events have an extra lepton in addition to those from the $Z$ boson, then only one $b$-jet is required. No significant excess of events above the standard model expectation was observed, and mass limits were set depending on the assumed branching ratios, as shown in Fig. 93.4. In a weak-isospin singlet scenario, a $B$ quark with mass lower than 0.65 TeV was excluded, while for a particular weak-isospin doublet scenario, a $B$ quark with mass lower than 0.73 TeV was ruled out.

ATLAS has searched for the electroweak production of single $B$ quarks, which is accompanied by a b jet and a light jet [129]. The dilepton selection for double $B$ production was modified for the single $B$ production study by requiring the presence of an additional energetic jet in the forward region. An upper limit of 200 fb was obtained for the process $\sigma(pp \to B\bar{b}q) \times B(B \to Zb)$ with a heavy $B$ quark mass at 0.70 TeV. This search indicated that the electroweak mixing parameter $X_{Bb}$ below 0.5 is neither expected or observed to be excluded for any values of $B$ quark mass.

Combination of $B \to tW/bZ/bH^0$:

The ATLAS experiment has combined the various analyses tar-

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

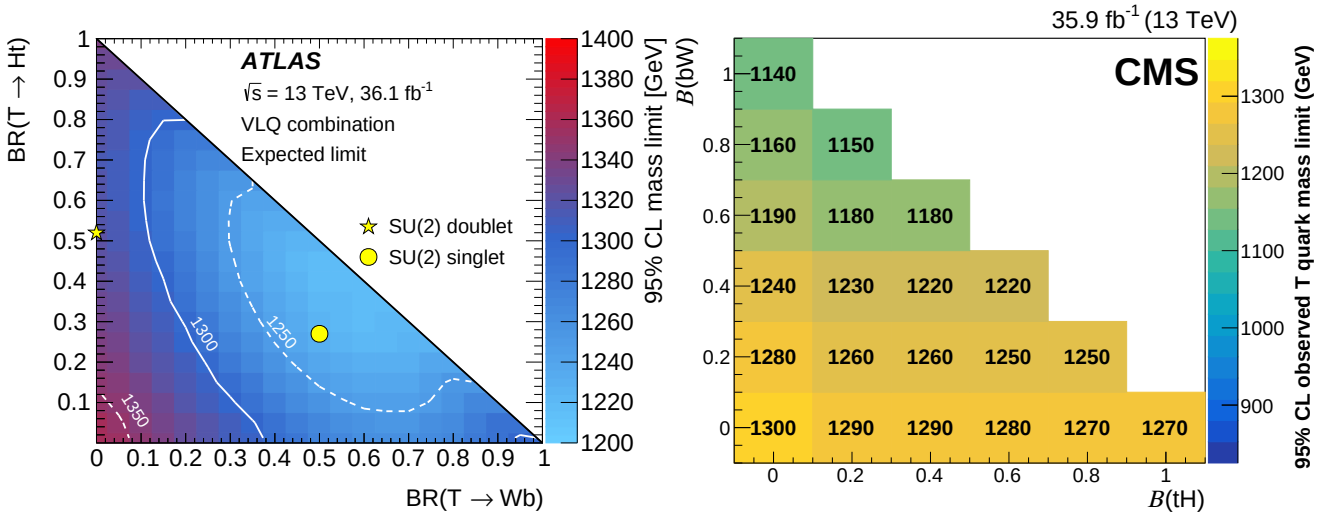

Figure 93.3: Left panel: observed limits on the mass of the $T$ quark in the plane of $\mathcal{B}(T \to tH^0)$ versus $\mathcal{B}(T \to bW)$ from a combination [124] of all ATLAS searches for $TT$ production. The markers indicate the default branching ratios for the SU(2) singlet and doublet scenarios. Right panel: the observed lower limits on the $T$ quark mass (in GeV), from CMS searches after combining all lepton channels [125], for various branching fraction scenarios. $\mathcal{B}(T \to Wb) + \mathcal{B}(T \to tZ) + \mathcal{B}(T \to tH^0) = 1$ is assumed.

geted for specific decay modes to obtain the most sensitive limits on the pair production of $B$ quarks [107, 108, 124]. Various searches ($W(\ell\nu)t + X, Z(\ell\ell)t/b + X$, same sign charge dilepton events, trilepton events, and all-hadronic) are combined to obtain lower limits on the mass of the $B$ quark in the plane of $BR(B \to Wt)$ vs $BR(B \to bH)$. The searches were optimized for 100% branching fractions and hence are most sensitive at large $BR(B \to Wt)$, and also at large $BR(B \to bH^0)$. For all possible values of branching ratios in the three decay modes $tW$, $bZ$, or $bH^0$, the lower limits on the $B$ quark mass was found to be 1.03 TeV and shown in Fig. 93.4 (left) as a function of both $B$ mass and branching ratio.

CMS combined three channels with lepton final states: single lepton, two leptons with the same sign of the electric charge (SS), or at least three leptons (trilepton) [125]. For various combinations of branching fractions for $B$ quark decays to $tW$, $bH^0$ and $bZ$, the combined results exclude $b$ quarks with masses below 0.91–1.24 TeV and are shown in Figure 93.4 (right) the details are provided earlier in subsection 93.2.3.1. The single lepton analysis is most sensitive for $tHbW$ and $WbWb$ decay modes, within the the SS dilepton analysis $tHtH$ and $tHtZ$ have the best efficiency and for trileptons the $tZtZ$ and $tHtZ$ decays modes have the highest efficiency. CMS excludes singlet (doublet) $B$ quark masses below 1.17 (0.94) TeV. Masses below 800 GeV were excluded in previous searches. For $B$ quark masses in the range 0.8–1.8 TeV, cross sections smaller than 40.6-–9.4 fb (101-–49.0 fb) are excluded for the singlet (doublet) scenario.

#### 93.2.3.3 *Searches for top-partner quark* $X_{5/3}$

Searches for a heavy top vector-like quark $X_{5/3}$, with exotic charge $\pm 5/3$, such as that proposed in Refs. [131, 132], have been performed by both ATLAS and CMS [107, 133].

The analyses assumed pair-production or single-production of $X_{5/3}$ with $X_{5/3}$ decaying with 100% branching fraction to to $tW$. Searches for $X_{5/3}$ have been performed using two final state signatures: same-sign leptons and lepton+jets.

The analysis based on searching for same-sign leptons, from the two $W$ bosons from one of the $X_{5/3}$, has smaller backgrounds compared to the lepton+jets signature. Requiring same-sign leptons eliminates most of the standard model background processes, leaving those with smaller cross sections: $t\bar{t}$, $W$, $t\bar{t}Z$, $WWW$, and same-sign $WW$. In addition, backgrounds from instrumental effects due to charge misidentification were considered. Assuming pair production of $X_{5/3}$, the analyses by CMS using $H_T$ as the discriminating variable restrict the $X_{5/3}$ mass to be higher than 1.16 (1.10) TeV for a right (left) handed chirality particle [133–135]. The limits obtained by ATLAS, by classifying the signal region by number of b jets, $H_T$, and missing $p_T$ in the event, corresponded to a lower mass limit on $X_{5/3}$ of 1.19 TeV [136, 137].

Searches for $X_{5/3}$ using leptons+jets final state signatures are based on either full or partial reconstruction of the $T$ mass from the lepton, jets (including b jets) and missing $p_T$. The CMS search [133, 138] also utilized jet substructure techniques to identify boosted $X_{5/3}$ topologies. The discriminating variable used was the mass constructed from the lepton and b-tagged jet, $M_{(\ell,b)}$, which corresponds to the visible mass of leptonically decaying top quark. To optimize the search sensitivity, the events were further separated into categories based on lepton flavor (e, $\mu$), the number of b-tagged jets, the number of W-tagged jets, and the number of t-tagged jets. In the absence of a signal, the CMS analysis excluded $X_{5/3}$ quark masses with right-handed (left-handed) couplings below 1.32 (1.30) TeV [138]. Combining the lepton+jets with the same-sign leptons analyses leads to a slight improvement and excludes $X_{5/3}$ quark masses with right-handed (left-handed) couplings below 1.33 (1.30) TeV.

The ATLAS lepton+jets search for $X_{5/3}$ utilized events with high $p_T$ W bosons and b jets. The search described earlier for $T$ pair production, with $T \to Wb$ decays, can be reinterpreted as a search for $X \to tW$. This analysis excluded $X_{5/3}$ with masses below 1.25 TeV [107].

The single $X_{5/3}$ production cross section depends on the coupling constant $\lambda$ of the $tWX$ vertex. ATLAS has performed an analysis of same-sign dileptons which includes both the single and pair production. This analysis led to a lower limit on the mass of the $X_{5/3}$ of 0.75 TeV for both values of $\lambda = 0.5$ and 1.0 [139].

Single heavy $X_{5/3}$+$t$ production has been studied by CMS in the decay to $tW$ with lepton+jets final state [127]. The description of the analysis is provided earlier in the discussion of $B \to WtX$ decays, where the reconstructed mass of $X_{5/3}$, $m_{reco}$ distribution is used as the signal discriminator. In the absence of a excess over the expected SM background, the exclusion limits on the production cross section is for $X_{5/3}$ quark masses between 0.7–2 TeV varies between 0.3 to 0.03 pb, depending on the width of $X_{5/3}$ between 1–10%. In addition, $X_{5/3}$ quarks with left-handed couplings and a relative width of 10, 20, and 30% are excluded for masses below 0.92, 1.3, and 1.45 TeV respectively.

### 93.2.4 *Heavy resonances decaying to VLQ*

CMS has performed search for VLQ production in the decay of massive resonances such as $Z'$ and $W'$ bosons.

$\underline{Z' \to tT}$: Specifically searches are presented by CMS in Refs. [140] and [141] for massive spin-1 $Z'$ resonances decaying to a top quark and heavy VLQ top quark partner $T$. The results of this search for a heavy spin-1 resonance are interpreted in the

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

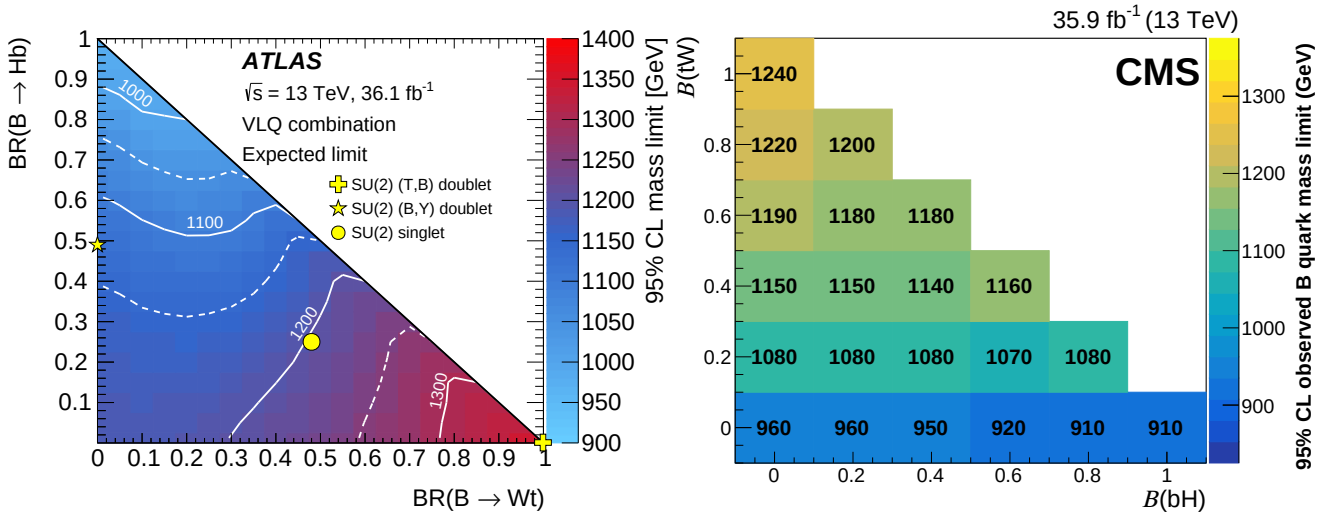

Figure 93.4: Observed limits on the mass of the $B$ quark in the plane of $BR(B \to bH^0)$ versus $BR(B \to tW)$ from ATLAS searches [124] on the left panel, and CMS searches [125] on the right panel, for $BB$ production. $\mathcal{B}(\mathcal{B} \to \mathcal{H}\rfloor) + \mathcal{B}(\mathcal{B} \to \lfloor\mathcal{Z}) + \mathcal{B}(\mathcal{B} \to \mathcal{W}\sqcup) = 1$ is assumed. The yellow markers indicate the branching ratios for the SU(2) singlet and doublet scenarios.

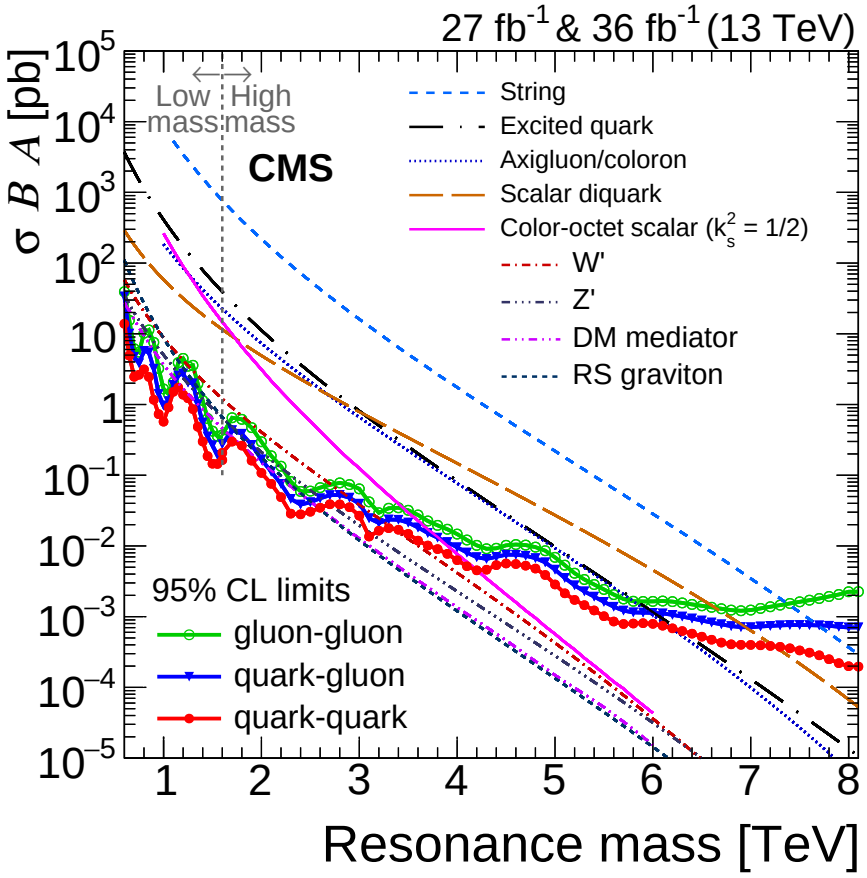

Figure 93.5: Observed 95% C.L. limits on $\sigma \times B \times A$ for string resonances, excited quarks, axigluons, colorons, E6 diquarks, s8 resonances, $W'$ and $Z'$ bosons, and Randall-Sundrum Gravitons $g_{KK}$ from [130].

context of two different models. In the $G^\star$ model which predicts ten VLQs ($T$, $B, \tilde{T}, \tilde{B}, T_{5/3}, T_{2/3}, T', B', B_{-1/3}, B_{-4/3}$) with the mass relationship $M(T_{5/3}) = M(T_{2/3}) = M(T)\cos(\phi_L)$. For the benchmark scenario [142], $\cos(\phi_L)$=0.84 and the branching fractions $T \to tH^0, tZ, Wb$ are 0.25, 0.25 and 0.5 respectively. The $\rho^0$ model predicts a multiple of four new VLQs $T, B, X_{2/3}, X_{5/3}$, and in the benchmark scenario [143], the branching fractions $T \to tH^0, tZ, Wb$ are 0.5, 0.5 and 0 respectively.

Two of the three different decays of the $Z' \to tT$ with $T \to tH^0, tZ, Wb$ are characterized by the presence of two top quark decays and a boson ($H^0/Z$). A search [141] by CMS, optimized for $T \to tH/Zt$ decays is carried out in the lepton+jets final state using a dataset corresponding to an integrated luminosity of 35.9 fb$^{-1}$. Jet substructure techniques are used to identify (or tag) the high $p_T$ large-radius jets originating from $H^0$, $Z$ bosons and merged top quarks. The mass of the $Z'$ boson is used as the signal discriminator and constructed using $H^0$ or $Z$-tagged dijet, the hadronic and leptonic top quark four vectors. For the

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

leptonic top quark reconstruction ($t \to b\ell\nu_\ell$), the neutrino four vector is obtained from the event missing $p_T$ using the $W$ boson mass constraint. While the high $p_T$ hadronic top quark jets from decays of massive $Z'$ bosons are mostly merged and identified by top tagging techniques, those from $T$ decays maybe resolved. The reconstructed $Z'$ candidate events are classified into six different categories requiring the presence of either $H^0$-tagged jet with 2 b-tagged subjets or one b-tagged subjet or a $Z$-tagged boson, each with either zero or one top-tagged jet. This search does not observe any significant deviation in data over the expectation from standard model backgrounds. Within the context of the $G^\star$ model, for a $T$ mass of 1.2 (1.5), this search excludes $G^\star$ [142] resonances with masses between 1.5–2.3 (2.0–2.4) TeV.

The search in the all-hadronic final state is based on a 2.6 fb$^{-1}$ dataset [140], and optimized for $T \to Wb$ decays. Jet substructure techniques are deployed for tagging jets from high $p_T$ $W$ boson and top quarks. Events are categorized into two groups based on the presence of b-tagged subjet in the top-tagged jet. Multijet background estimation is challenging and determined using sidebands defined by inverting the b tagging requirement. Upper limits on cross section for $Z' \to tT$ are obtained in the range of 0.13–10 pb. With additional data, this search has the potential to exclude scenarios in composite Higgs and extra dimension models.

$W' \to Tb/Bt$: $W'$ bosons are predicted to decay to VLQ third generation partners $T$, $B$ quarks within composite Higgs and warped extra dimensional models [144]. In the benchmark scenarios of this framework, $W'$ decays to $Tb$ or $Bt$ are equally distributed and the subsequent VLQ decays $T \to tH$ and $B \to bH^0$ each are assumed to have a branching fraction of 0.5. The search for $W' \to Tb/bH^0 \to tbH^0$ is performed using a sample of 35.9 fb$^{-1}$ by CMS [145] in the final state with all-hadronic decays of both the Higgs boson ($H^0 \to b\bar{b}$) and the top quark. Both the $H^0$ boson and the top quark are expected to be boosted in the decay of a heavy $W'$, and hence jet substructure techniques, including subjet b-tagging and double b-tagging are deployed to identify the $H^0$-tagged and the top-tagged jets. The three particle mass $m_{tbH^0}$, is used as the signal discriminant to observe the $W'$ resonance. There is no excess observed in data above the expected SM background. This search excludes $W'$ production cross section above 0.01–0.43 pb for masses between 1.5–4.0 TeV.

#### 93.2.5 *Colorons and Colored Scalars*

These particles are associated with top-condensate and top-seesaw models, which involve an enlarged color gauge group. The new particles decay to dijets, $t\bar{t}$, and $b\bar{b}$.

Direct searches for colorons, color-octect scalars and other heavy objects decaying to $q\bar{q}$, $qg$, $qq$, or $gg$ has been performed using LHC data from pp collisions at $\sqrt{s}$ =7, 8 and 13 TeV. Based on the analysis of dijet events from a data sample corresponding to a luminosity of 19.6 fb$^{-1}$, at $\sqrt{s} = 8$ TeV the CMS experiment excluded pair production of colorons with mass between $1.20 - 3.60$ and $3.90 - 4.08$ TeV [146]. Analyses of inclusive 8- and 10-jet final states with low missing transverse momentum by CMS [147], set limits in several benchmark models. Colorons (axigluons) with masses between 0.6 and 0.75 (up to 1.15) TeV were excluded, and gluinos in R-parity violating supersymmetric scenarios were ruled out from 0.6 up to 1.1 TeV.

A search for pair-produced colorons based on an integrated luminosity of 5.0 fb$^{-1}$ at $\sqrt{s} = 7$ TeV by CMS excluded colorons with masses between 0.25 TeV and 0.74 TeV, assuming colorons decay 100% into $q\bar{q}$ [148]. This analysis was based on events with at least four jets and two dijet combinations with similar dijet mass. Color-octet scalars (s8) with masses between 1.20−2.79 TeV were excluded by CMS [146], and below 2.7 TeV by ATLAS [149].

These studies have now been extended to take advantage of the increased center-of-mass energy during Run 2 of the LHC. Using the 35.9 fb$^{-1}$ of data collected at $\sqrt{s}$ =13 TeV, searches for narrow resonances have been performed by CMS. An analysis of the dijet invariant mass spectrum formed using wide jets [130, 150, 151], separated by $\Delta\eta_{jj} \leq 1.3$, led to limits on new particles decaying to parton pairs ($qq$, $qg$, $gg$). Specific exclusions on the masses of colorons and color-octet scalars were obtained and are shown in Fig. 93.5. Exclusions have been obtained for axigluons and colorons below 6.1 TeV, and color-octet scalars below 3.4 TeV.

## 93.3 Conclusions

As the above analyses have demonstrated, there is already substantial sensitivity to possible new particles predicted to accompany the $H^0$ in dynamical frameworks of electroweak symmetry breaking. No significant hints of any deviations from the standard model have been observed, and limits typically at the scale of a few hundred GeV to a few TeV are set.

Given the need to better understand the $H^0$ and to determine in detail how it behaves, such analyses continue to be a major theme of Run 2 the LHC, and we look forward to increased sensitivity as a result of the higher luminosity at the increased center of mass energy of collisions.

# 94. Grand Unified Theories

Revised August 2019 by A. Hebecker (Heidelberg U.) and J. Hisano (KMI, Nagoya U.).

## 94.1 The standard model

The Standard Model (SM) may be defined as the renormalizable field theory with gauge group $G_{SM} = SU(3)_C \times SU(2)_L \times U(1)_Y$, with 3 generations of fermions in the representation

$$(\mathbf{3},\mathbf{2})_{1/3} + (\overline{\mathbf{3}},\mathbf{1})_{-4/3} + (\overline{\mathbf{3}},\mathbf{1})_{2/3} + (\mathbf{1},\mathbf{2})_{-1} + (\mathbf{1},\mathbf{1})_{2}\ , \quad (94.1)$$

and a scalar Higgs doublet $H$ transforming as $(\mathbf{1},\mathbf{2})_1$. Here and below we use boldface numbers to specify the dimension of representations of non-Abelian groups (in this case fundamental and antifundamental) and lower indices for $U(1)$ charges. The fields of Eq. (94.1) should also be familiar as $[Q, u^c, d^c, L, e^c]$, with $Q = (u, d)$ and $L = (\nu, e)$ being the quark and lepton $SU(2)$-doublets and $u^c$, $d^c$, $e^c$ charge conjugate $SU(2)$-singlets.[1] Especially after the discovery of the Higgs, this model is remarkably complete and consistent with almost all experimental data.

A notable exception are neutrino masses, which are known to be non-zero but are absent in the SM even after the Higgs acquires its vacuum expectation value (VEV). The minimalist attitude is to allow for the dimension-five operator $(HL)^2$ [1], which induces (Majorana) neutrino masses. In the seesaw mechanism [2–4] this operator is generated by integrating out heavy singlet fermions (right-handed (r.h.) neutrinos). Alternatively, neutrinos can have Dirac masses if light singlet neutrinos are added to the SM spectrum.

Conceptual problems of the SM include the absence of a Dark Matter candidate, of a mechanism for generating the baryon asymmetry of the universe, and of any reason for the observed smallness of the $\theta$ parameter of QCD ($\theta_{QCD}$). In addition, the apparently rather complex group-theoretic data of Eq. (94.1) remains unexplained. Together with the abundance of seemingly arbitrary coupling constants, this disfavors the SM as a candidate fundamental theory, even before quantum gravity problems arise at energies near the Planck mass $M_P$.

To be precise, there are 19 SM parameters which have to be fitted to data: Three gauge couplings[2] $g_3$, $g_2$ and $g_1$, 13 parameters associated with the Yukawa couplings (9 charged fermion masses, three mixing angles and one CP phase in the CKM matrix.), the Higgs mass and quartic coupling, and $\theta_{QCD}$. In addition, Majorana neutrinos introduce 3 more masses and 6 mixing angles and phases. As we will see, the paradigm of grand unification addresses mainly the group theoretic data of Eq. (94.1) and the values of the three gauge couplings. In many concrete realizations, it then impacts also the other mentioned issues of the SM, such as the family structure and fermion mass hierarchy.

More specifically, after precision measurements of the Weinberg angle $\theta_W$ in the LEP experiments, supersymmetric GUTs (SUSY GUTs) have become the leading candidates in the search for 'Physics beyond the SM'. Supersymmetry (SUSY) is a symmetry between bosons and fermions which requires the addition of superpartners to the SM spectrum. If SUSY is motivated as a solution to the gauge hierarchy problem (i.e. to the naturalness or fine-tuning problem of the electroweak scale) [5], superpartners have to be present near the weak scale. SUSY GUTs [6] then lead to the prediction of $\theta_W$, in good agreement with subsequent observations [7]. However, the non-discovery of new particles at the LHC puts into question the presence of new physics at the TeV scale in general and in particular of low-scale supersymmetry. Still, SUSY may be present just outside the presently explored energy domain.

The measured Higgs mass (125 GeV) is in principle consistent with this picture, assuming superpartners in the region of roughly 10 TeV. Such heavy superpartners then induce radiative corrections raising the Higgs mass above the $Z$ boson mass $m_Z$ [8, 9]. However, from the vantage point of the hierarchy problem, heavy superpartners are problematic: They also contribute to SUSY-breaking Higgs mass parameters and thereby to the Higgs potential, tending to raise the $Z$ mass. As a result, the incarnation of SUSY in terms of the minimal supersymmetric SM (MSSM) is becoming questionable. Turning the logic around, one may say that compared to expectations based on the MSSM with superpartner masses below about 1 TeV, the measured Higgs mass value of 125 GeV is somewhat too high [10]. Independently, the LHC has disfavored light colored superpartners (which does not imply that *all* superpartners are heavy). These facts represent new hints for future work on SUSY GUTs or on GUTs without TeV-scale supersymmetry.

## 94.2 Basic group theory and charge quantization

### 94.2.1 $SU(4)_C \times SU(2)_L \times SU(2)_R$

Historically, the first attempt at unification was the Pati-Salam model with gauge group $G_{PS} = SU(4)_C \times SU(2)_L \times SU(2)_R$ [11]. It unifies SM fermions in the sense that one generation (plus an extra SM singlet) now comes from the $(\mathbf{4},\mathbf{2},\mathbf{1}) + (\overline{\mathbf{4}},\mathbf{1},\mathbf{2})$ of $G_{PS}$. This is easy to verify from the breaking pattern $SU(4)_C \to SU(3)_C \times U(1)_{B-L}$ together with the identification of SM hypercharge as a linear combination between $B - L$ (baryon minus lepton number) and the $T_3$ generator of $SU(2)_R$. This model explains charge quantization, that is, why all electric charges are integer multiples of some smallest charge in the SM. Concretely, the $\mathbf{4}$ and $\overline{\mathbf{4}}$ of $SU(4)_C$ identify lepton number as the 4th colour and the tracelessness of the diagonal generator implies that quark charges are expressed in terms of $1/N_c$ fractions of lepton charges. However, $G_{PS}$ is not simple (containing three simple factors), and thus it does not predict gauge coupling unification.

### 94.2.2 $SU(5)$

Since $G_{SM}$ has rank four (two for $SU(3)_C$ and one for $SU(2)_L$ and $U(1)_Y$, respectively), the rank-four group $SU(5)$ is the minimal choice for unification in a simple group [12]. The three SM gauge coupling constants derive from a universal coupling $\alpha_G$ at the GUT scale $M_G$. Explicitly embedding $G_{SM}$ in $SU(5)$ is straightforward, with $SU(3)_C$ and $SU(2)_L$ corresponding e.g. to the upper-left $3\times3$ and lower-right $2\times2$ blocks, respectively, in traceless $5\times5$ matrices for $SU(5)$ generators of the fundamental representation. The $U(1)_Y$ corresponds to matrices generated by $\mathrm{diag}(-2/3, -2/3, -2/3, 1, 1)$ and hence commutes with $SU(3)_C \times SU(2)_L \subset SU(5)$. It is then easy to derive how one SM generation precisely comes from the $\mathbf{10} + \overline{\mathbf{5}}$ of $SU(5)$ (where $\mathbf{10}$ is the antisymmetric rank-2 tensor):

$$\mathbf{10}: \begin{pmatrix} 0 & u_b^c & -u_g^c & u_r & d_r \\ -u_b^c & 0 & u_r^c & u_g & d_g \\ u_g^c & -u_r^c & 0 & u_b & d_b \\ -u_r & -u_g & -u_b & 0 & e^c \\ -d_r & -d_g & -d_b & -e^c & 0 \end{pmatrix} \quad \text{and} \quad \overline{\mathbf{5}}: \begin{pmatrix} d_r^c \\ d_g^c \\ d_b^c \\ e \\ -\nu_e \end{pmatrix}. \quad (94.2)$$

In addition to charge quantisation this structure explains why the l.h. quark and lepton states fall in $SU(2)_L$ doublets while the r.h. states are singlets.

Since $SU(5)$ has 24 generators, $SU(5)$ GUTs have 12 new gauge bosons known as $X$ bosons (or $X/Y$ bosons) in addition to the SM. $X$ bosons form an $SU(3)_C$-triplet and $SU(2)_L$-doublet. Their interaction connects quarks and leptons such that baryon and lepton numbers are not conserved and nucleon decay is predicted. Furthermore, $U(1)_Y$ hypercharge is automatically quantized since it is embedded in $SU(5)$.

In order to break the electroweak symmetry at the weak scale and give mass to quarks and leptons, Higgs doublets are needed. In the minimal $SU(5)$ model, they can sit in either a $\mathbf{5}_H$ or $\overline{\mathbf{5}}_H$. The three additional states are referred to as color-triplet Higgs scalars. Their couplings also violate baryon and lepton numbers, inducing nucleon decay. In order not to violently disagree with the non-observation of nucleon decay, the triplet mass must be greater than $\sim 10^{11}$ GeV [13]. Moreover, in SUSY GUTs [6], in order to cancel anomalies as well as give mass to both up and down quarks, both Higgs multiplets $\mathbf{5}_H$ and $\overline{\mathbf{5}}_H$ are required. As we shall discuss later, nucleon decay now constrains the Higgs triplets to have

[1] In our convention the electric charge is $Q = T_3 + Y/2$ and all our spinor fields are left-handed (l.h.).

[2] Equivalently, the $SU(2)_L$ and $U(1)_Y$ couplings are denoted as $g = g_2$ and $g' = \sqrt{3/5}\ g_1$. One also uses $\alpha_s = \alpha_3 = (g_3^2/4\pi)$, $\alpha_{\rm EM} = (e^2/4\pi)$ with $e = g\ \sin\theta_W$ and $\sin^2\theta_W = (g')^2/(g^2 + (g')^2)$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

mass significantly greater than $M_G$ in the minimal SUSY $SU(5)$ GUT since integrating out the Higgs triplets generates dimension-five baryon-number-violating operators [14]. The mass splitting between doublet and triplet in the $\mathbf{5}_H$ (and $\overline{\mathbf{5}}_H$) comes from their interaction with the $SU(5)$ breaking sector.

### 94.2.3 $SO(10)$

While $SU(5)$ allows for the minimal GUT models, unification is not complete: Two independent representations, **10** and $\overline{\mathbf{5}}$, are required for one SM generation. A further representation, an SU(5) singlet, has to be added to serve as r.h. neutrino in the seesaw mechanism. In this case, the r.h. neutrino masses are not necessarily related to the GUT scale. By contrast, a single **16**-dimensional spinor representation of $SO(10)$ accommodates a full SM generation together with an extra singlet, potentially providing a r.h. neutrino [15]. This is most easily understood from the breaking pattern $SO(10) \to SU(5) \times U(1)_X$ and the associated branching rule[3] $\mathbf{16} = \mathbf{10}_{-1} + \overline{\mathbf{5}}_3 + \mathbf{1}_{-4}$. Here the indices refer to charges under the $U(1)_X$ subgroup, which is orthogonal to $SU(5)$ and reflects the fact that $SO(10)$ has rank five. From the above, it is easy to see that $U(1)_X$ charges can be given as $2Y - 5(B-L)$. Intriguingly, all representations of $SO(10)$ are anomaly free in four dimensions (4d). Thus, the absence of anomalies in an $SU(5)$-GUT or a SM generation can be viewed as deriving from this feature.

We now describe in more detail how one family of quarks and leptons appears in the **16**. To understand this, recall that the $\Gamma$-matrices of the 10d Clifford algebra give rise to five independent, anticommuting 'creation-annihilation' operators $\Gamma^{a\pm} = (\Gamma^{2a-1} \pm i\Gamma^{2a})/2$ with $a = 1, ..., 5$. These correspond to five fermionic harmonic oscillators or "spin" 1/2 systems. The 32-dimensional tensor product of those is reducible since the 10d rotation generators $M_{mn} = -i[\Gamma^m, \Gamma^n]/4$ $(m, n = 1, ..., 10)$ always flip an even number of "spins". This gives rise to the **16** as displayed in Table 94.1. Next, one also recalls that the natural embedding of $SU(5)$ in $SO(10)$ relies on 'pairing up' the 10 real dimensions to produce 5 complex dimensions, $\mathbb{R}^{10} \equiv \mathbb{C}^5$, similarly to the paring up of $\Gamma^m$s used above. This makes it clear how to associate one $|\pm>$ system to each complex dimension of $SU(5)$, which explains the labeling of the "spin" columns in Table 94.1: The first three and last two "spins" correspond to $SU(3)_C$ and $SU(2)_L$, respectively. In fact, an $SU(3)_C$ rotation just raises one color index and lowers another, changing colors $\{r, g, b\}$, or changes relative phases between the three spin states. Similarly, an $SU(2)_L$ rotation raises one weak index and lowers another, thereby flipping the weak isospin from up to down or vice versa, or changes the relative phase between the two spin states. In this representation $U(1)_Y$ hypercharge is simply given by $Y = -2/3(\sum \text{ color spins}) + (\sum \text{ weak spins})$. $SU(5)$ rotations corresponding to $X$ bosons then raise (or lower) a color index, while at the same time lowering (or raising) a weak index. It is easy to see that such rotations can mix the states $\{Q,\ u^c,\ e^c\}$ and $\{d^c, L\}$ among themselves and $\nu^c$ is a singlet. Since $SO(10)$ has 45 generators, additional 21 gauge bosons are introduced including the $U(1)_X$ above. The 20 new $SO(10)$ rotations not in $SU(5)$ are then given by either raising any two spins or lowering them. With these rotations, **1** and **5** are connected with **10**. The last $SO(10)$ rotation changes phases of states with weight $2(\sum \text{ color spins}) + 2(\sum \text{ weak spins})$, which corresponds to $U(1)_X$.

$SO(10)$ has two inequivalent maximal subgroups and hence breaking patterns, $SO(10) \to SU(5) \times U(1)_X$ and $SO(10) \to SU(4)_C \times SU(2)_L \times SU(2)_R$. In the first case, one can carry on breaking to $G_{SM} \subset SU(5)$ precisely as in the minimal $SU(5)$ case above. Alternatively, one can identify $U(1)_Y$ as an appropriate linear combination of $U(1)_X$ and the $U(1)$ factor from $SU(5)$, leading to the so-called flipped $SU(5)$ [17] as an intermediate step in breaking $SO(10)$ to $G_{SM}$. In the second case, we have an intermediate Pati-Salam model thanks to the branching rule $\mathbf{16} = (\mathbf{4}, \mathbf{2}, \mathbf{1}) + (\overline{\mathbf{4}}, \mathbf{1}, \mathbf{2})$. Finally, $SO(10)$ can break directly to the SM at $M_G$. Gauge coupling unification remains intact in the case of this 'direct' breaking and for the breaking pattern $SO(10) \to SU(5) \to G_{SM}$ (with $SU(5)$ broken at $M_G$). In the case of intermediate-scale Pati-Salam or flipped $SU(5)$ models, gauge coupling predictions are modified. The Higgs multiplets in the minimal $SO(10)$ come from the fundamental representation, $\mathbf{10}_H = \mathbf{5}_H + \overline{\mathbf{5}}_H$. Note, only in $SO(10)$ does the representation type distinguish SM matter from Higgs fields.

[3] Useful references on group theory in the present context include [16] and refs. therein.

**Table 94.1:** Quantum numbers of **16**-dimensional representation of $SO(10)$.

| state | $Y$ | Color | Weak | $SU(5)$ | $SO(10)$ |

### 94.2.4 *Beyond* $SO(10)$

Finally, larger symmetry groups can be considered. For example, the exceptional group $E_6$ has maximal subgroup $SO(10) \times U(1)$ [18]. Its fundamental representation branches as $\mathbf{27} = \mathbf{16}_1 + \mathbf{10}_{-2} + \mathbf{1}_4$. Another maximal subgroup is $SU(3)_C \times SU(3)_L \times SU(3)_R \subset E_6$ with branching rule $\mathbf{27} = (\mathbf{3}, \mathbf{3}, \mathbf{1}) + (\overline{\mathbf{3}}, \mathbf{1}, \overline{\mathbf{3}}) + (\mathbf{1}, \overline{\mathbf{3}}, \mathbf{3})$. Independently of any underlying $E_6$, the group $[SU(3)]^3$ with additional permutation symmetry $Z_3$ interchanging the three factors can be considered. This is known as "trinification" [19]. The $E_6 \to [SU(3)]^3$ breaking pattern has been used in phenomenological analyses of the heterotic string [20]. However, in larger symmetry groups, such as $E_6$, $SU(6)$, etc., there are now many more states which have not been observed and must be removed from the effective low-energy theory.

Intriguingly, the logic by which $G_{SM}$ is a maximal subgroup of $SU(5)$, which together with $U(1)_X$ is a maximal subgroup of $SO(10)$, continues in a very elegant and systematic way up to the largest exceptional group. The resulting famous breaking chain $E_8 \to E_7 \to E_6 \to SO(10) \to SU(5) \to G_{SM}$ together with the special role played by $E_8$ in group and in string theory is a tantalizing hint at deeper structures. However, since all representations of $E_8$ and $E_7$ are real and can not lead to 4d chiral fermions, this is necessarily outside the 4d GUT framework.

## 94.3 GUT breaking and doublet-triplet splitting

In the standard, 4d field-theoretic approach to GUTs, the unified gauge group is broken spontaneously by an appropriate GUT Higgs sector. Scalar potentials (or superpotentials in SUSY GUTs) exist whose vacua spontaneously break $SU(5)$ or $SO(10)$. While these potentials are ad hoc (just like the Higgs potential in the SM), the most naive expectation is that all their dimensionful parameters are $O(M_G)$. In the simplest case of $SU(5)$, the **24** (adjoint) GUT Higgs develops a VEV along the $G_{SM}$-singlet direction as $\langle \Phi \rangle \propto \text{diag}(-2/3, -2/3, -2/3, 1, 1)$. In order for $SO(10)$ to break to $SU(5)$, the **16** or **126**, which have a $G_{SM}$-singlet with non-zero $U(1)_X$ charge, get a VEV.

The masses of doublet and triplet in the $\mathbf{5}_H$ (and $\overline{\mathbf{5}}_H$) generically split due to their coupling to the GUT Higgs. In addition, both the doublet and the triplet masses also get an equal contribution from an $SU(5)$-invariant GUT-scale mass term. Without any further structure, an extreme fine-tuning between two large effects is then necessary to keep the doublet mass at the electroweak scale. Supersymmetry plays an important role in for-

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

bidding large radiative correction to the doublet mass due to the non-renormalization theorem [5]. However, even in this case we have to fine tune parameters at tree level. This is the doublet-triplet splitting problem which, in the SUSY context, is clearly related the $\mu$-term problem of the MSSM (the smallness of the coefficient of $\mu H_u\ H_d$).

Several mechanisms for natural doublet-triplet splitting have been suggested under the assumption of supersymmetry, such as the sliding singlet [21], missing partner [22], missing VEV [23], and pseudo-Nambu-Goldstone boson mechanisms [24]. Particular examples of the missing partner mechanism for $SU(5)$ [25], the missing VEV mechanism for $SO(10)$ [26, 27] and the pseudo-Nambu-Goldstone boson mechanism for $SU(6)$ [28] have been shown to be consistent with gauge coupling unification and nucleon decay. From the GUT-scale perspective, one is satisfied if the triplets are naturally heavy and the doublets are massless ($\mu \simeq 0$). There are also several mechanisms for resolving the subsequent issue of why $\mu$ is of order the SUSY breaking scale [29].[4] For a review of the $\mu$ problem and some suggested solutions in SUSY GUTs and string theory, see [30–33] and references therein.

In general, GUT-breaking sectors successfully resolving the doublet-triplet splitting problem, dynamically stabilizing all GUT-scale VEVs and allowing for realistic neutrino masses and Yukawa couplings (including the GUT-symmetry violation in the latter) require a number of ingredients. However, for validity of the effective theory, introduction of higher or many representations is limited, otherwise a Landau pole may appear below the Planck scale. In addition, GUTs are only effective theories below the Planck scale in the 4d field-theoretic approach. Since $M_G$ is close to this scale, the effects of higher-dimension operators are not obviously negligible. In particular, operators including the GUT-breaking Higgs may affect low-energy predictions, such as quark and lepton masses.

Thus, especially in the context of GUT breaking and doublet-triplet splitting, models beyond 4d field theory appear attractive. While this is mainly the subject of the next section, some advantages can already be noted: In models with extra dimensions, in particular string constructions, GUT breaking may occur due to boundary conditions in the compactified dimensions [34–37]. No complicated GUT breaking sector is then required. Moreover, boundary conditions can give mass only to the triplet, leaving the doublet massless. This is similar to the 'missing partner mechanism' since the effective mass term does not 'pair up' the triplets from $\mathbf{5}_H$ and $\overline{\mathbf{5}}_H$ but rather each of them with further fields which are automatically present in the higher-dimensional theory. This can eliminate dimension-five nucleon decay (cf. Sec. 94.6).

## 94.4 String-theoretic and higher-dimensional unified models

As noted earlier, the GUT scale is dangerously close to the scale of quantum gravity. It may hence be necessary to discuss unified models of particle physics in the latter, more ambitious context. Among the models of quantum gravity, superstring or M-theory stands out as the best-studied and technically most developed proposal, possessing in particular a high level of internal, mathematical consistency. For our purposes, it is sufficient to know that five 10d and one 11d low-energy effective supergravity theories arise in this setting (cf. [38] and refs. therein).

Grand unification is realized most naturally in the context of the two 'heterotic' theories with gauge groups $\mathrm{E}_8\times\mathrm{E}_8$ and $SO(32)$, respectively [36, 39] (see [40] for some of the more recent results). Justified in part by the intriguing breaking path $\mathrm{E}_8 \to \cdots \to G_{SM}$ mentioned above, the focus has historically largely been on $\mathrm{E}_8\times\mathrm{E}_8$. To describe particle physics, solutions of the 10d theory with geometry $\mathbb{R}^{1,3} \times M_6$ are considered, where $M_6$ is a Calabi-Yau (CY) 3-fold (with 6 real dimensions) [36]. The background solution involves expectation values of higher-dimensional components of the $\mathrm{E}_8\times\mathrm{E}_8$ gauge fields. This includes both Wilson lines [34] and non-vanishing field-strength and leads, in general, to a reduced gauge symmetry and to chirality in the resulting 4d effective theory. The 4d fermions arise from 10d gauginos.

Given an appropriate embedding[5] of $G_{SM}$ in $\mathrm{E}_8\times\mathrm{E}_8$, gauge coupling unification is automatic at leading order. Corrections arise mainly through (string)-loop effects and are similar to the familiar field-theory thresholds of 4d GUTs[6] [41]. Thus, one may say that coupling unification is a generic prediction in spite of the complete absence[7] of a 4d GUT at any energy scale. This absence is both an advantage and a weakness. On the up side, GUT breaking and doublet-triplet splitting [43] are more naturally realized and dimension-five nucleon decay is relatively easy to avoid. On the down side, there is no reason to expect full GUT representations in the matter sector and flavor model building is much less tied to the GUT structure than in 4d.

Let us pause to explain the beautiful idea behind the advertised solution of the doublet-triplet splitting problem: One starts with a simply connected CY $X$ and mods out the action of a discrete group $G$ (say $\mathbb{Z}_2$). In the absence of fixed points, $X/G$ is smooth and has a non-contractible 1-cycle. Furthermore, let $G$ also act on the gauge bundle, according to an embedding $G \to \mathrm{E}_8$. Now the parallel transport around the 1-cycle is tied to a gauge rotation (one says a non-trivial Wilson-line is present). Moreover, this Wilson line can not be continuously turned off since, e.g. in the case of $\mathbb{Z}_2$, its square is the unit element of the group. The induced 'Wilson-line breaking', which comes on top of the breaking by non-zero field strengths, may remove certain sub-representations (e.g. the triplet of $SU(5) \to G_{SM}$) while keeping others exactly massless. A simpler and, due to fixed points, singular version of this will appear below in the context of orbifold GUTs.

One technical problem of heterotic constructions is the dependence on the numerous size and shape parameters of $M_6$ (the so-called moduli), the stabilization of which is poorly understood (see [44] for recent developments). Another is the sheer mathematical complexity of the analysis, involving in particular the study of (non-Abelian) gauge-bundles on CY spaces [45] (see however [46]).

An interesting aspect of heterotic string constructions is represented by orbifold models [35]. Here the internal space is given by a six-torus, modded out by a discrete symmetry group (e.g. $T^6/\mathbb{Z}_n$). More recent progress is reported in [47, 48], including in particular the systematic exploration of the phenomenological advantages of so-called 'non-prime' (referring to $n$) orbifolds. The symmetry breaking to $G_{SM}$ as well as the survival of Higgs doublets without triplet partners is ensured by the appropriate embedding of the discrete orbifold group in $\mathrm{E}_8\times\mathrm{E}_8$. String theory on such spaces, which are locally flat but include singularities, is much more calculable than in the CY case. The orbifold geometries can be viewed as singular limits of CYs.

An even simpler approach to unified models, which includes many of the advantages of full-fledged string constructions, is provided by Orbifold GUTs [37]. These are (mostly) 5d or 6d SUSY field theories with unified gauge group (e.g. $SU(5)$ or $SO(10)$), broken in the process of compactifying to 4d. To give a particularly simple example, consider $SU(5)$ on $\mathbb{R}^{1,3} \times S^1/(\mathbb{Z}_2 \times \mathbb{Z}_2')$. Here the compact space is an interval of length $\pi R/2$ and the embedding of $\mathbb{Z}_2'$ in the hypercharge direction of $SU(5)$ realizes the breaking to $G_{SM}$. Concretely, 5d $X$ bosons are given Dirichlet BCs at one endpoint of the interval and thus have no Kaluza-Klein (KK) zero mode. Their lightest modes have mass $\sim 1/R$, making the KK-scale the effective GUT scale. As an implication, the boundary theory has no $SU(5)$ invariance. Nevertheless, since the $SU(5)$-symmetric 5d bulk dominates 4d gauge couplings, unification remains a prediction. Many other features but also problems

[4] The solution of [29] relies on the absence of the fundamental superpotential term $\mu H_u\ H_d$ (or $\mu\, \mathbf{5}_H \overline{\mathbf{5}}_H$). This can be ensured either by a discrete $R$ symmetry or by a $U(1)_R$. The latter clashes with typical superpotentials for the GUT breaking sector. However, higher-dimensional or stringy GUTs, where the triplet Higgs is simply projected out, can be consistent with the $U(1)_R$ symmetry.

[5] All embeddings of $G_{SM}$ in one $\mathrm{E}_8$ factor which are consistent with a breaking-pattern $\mathrm{E}_8 \to SU(5) \to G_{SM}$ are suitable (cf. for example the natural breaking chain from $\mathrm{E}_8$ to $G_{SM}$ through maximal subgroups mentioned at the end of Sect. 94.3). Other embeddings can change the ratios between the three resulting $G_{SM}$ couplings at the GUT scale by group-theoretic factors. Crucially, due to the single 10d gauge coupling, no continuous tuning is possible.

[6] Field-theory thresholds of 4d GUTs are discussed in 94.5.

[7] See however [42].

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

of 4d GUTs can be circumvented, especially doublet-triplet splitting is easily realized.

With the advent of the string-theory 'flux landscape' [49], which is best understood in 10d type-IIB supergravity, the focus in string model building has shifted to this framework. While type II string theories have no gauge group in 10d, brane-stacks support gauge dynamics. A particularly appealing setting (see e.g. [50]) is provided by type IIB models with D7 branes (defining 8d submanifolds). However, in the $SO(10)$ context the **16** is not available and, for $SU(5)$, the top-Yukawa coupling vanishes at leading order [51]. As a crucial insight, this can be overcome on the non-perturbative branch of type IIB, also known as F-theory [52, 53]. This setting allows for more general branes, thus avoiding constraints of the D$p$-brane framework. GUT breaking can be realized using hypercharge flux (the VEV of the $\mathrm{U}(1)_Y$ field strength), an option not available in heterotic models. The whole framework combines the advantages of the heterotic or higher-dimensional unification approach with the more recent progress in understanding moduli stabilization. It thus represents at this moment the most active and promising branch of theory-driven GUT model building (see e.g. [54] and refs. therein).

As a result of the flux-breaking, a characteristic 'type IIB' or 'F-theoretic' tree-level correction to gauge unification arises [55]. The fact that this correction can be rather significant numerically is occasionally held against the framework of F-theory GUTs. However, at a parametric level, this correction nevertheless behaves like a 4d threshold, i.e., it provides $\mathcal{O}(1)$ additive contributions to the inverse 4d gauge couplings $\alpha_i^{-1}(M_G)$.

A final important issue in string GUTs is the so-called string-scale/GUT-scale problem [56]. It arises since, in heterotic compactifications, the Planck scale and the high-scale value of the gauge coupling unambiguously fix the string-scale to about $10^{18}$ GeV. As the compactification radius $R$ is raised above the string length, the GUT scale (identified with $1/R$) goes down and the string coupling goes up. Within the domain of perturbative string theory, a gap of about a factor $\sim 20$ remains between the lowest GUT scale achievable in this way and the phenomenological goal of $2\times 10^{16}$ GeV. The situation can be improved by venturing into the non-perturbative regime [56], by considering 'anisotropic' geometries with hierarchically different radii $R$ [56, 57] or by including GUT scale threshold corrections [58, 59].

In F-theory GUTs, the situation is dramatically improved since the gauge theory lives only in four out of the six compact dimensions. This allows for models with a 'decoupling limit', where the GUT scale is parametrically below the Planck scale [53]. However, moduli stabilization may not be without problems in such constructions, in part due to a tension between the required large volume and the desirable low SUSY breaking scale.

## 94.5 Gauge coupling unification

The quantitative unification of the three SM gauge couplings at the energy scale $M_G$ is one of the cornerstones of the GUT paradigm. It is obviously of direct phenomenological relevance. Gauge coupling unification is well understood in the framework of effective field theory (EFT) [60]. In the simplest case, the relevant EFT at energies $\mu \gg M_G$ has a unified gauge symmetry (say $SU(5)$ for definiteness) and a single running gauge coupling $\alpha_G(\mu)$. At energies $\mu \ll M_G$, states with mass $\sim M_G$ (such as $X$ bosons, GUT Higgs, color-triplet Higgs) have to be integrated out. The EFT now has three independent couplings and SM (or SUSY SM) matter content. One-loop renormalization group equations readily allow for an extrapolation to the weak scale,

$$\alpha_i^{-1}(m_Z) = \alpha_G^{-1}(M_G) + \frac{b_i}{2\pi}\log\left(\frac{M_G}{m_Z}\right) + \delta_i\,, \qquad (94.3)$$

($i = 1, 2, 3$). Here we defined $\delta_i$ to absorb all sub-leading effects, such as threshold corrections at or near the weak scale (e.g. from superpartners and the additional Higgs bosons in the case of the MSSM) and at the GUT scale, and also higher-order corrections. We will discuss them momentarily.

It is apparent from Eq. (94.3) that the three low-scale couplings can be very different. This is due to the large energy range $m_Z \ll \mu \ll M_G$ and the non-universal $\beta$-function coefficients ($b_i^{\mathrm{SM}} = \{41/10, -19/6, -7\}$ or $b_i^{\mathrm{MSSM}} = \{33/5, 1, -3\}$). Incomplete GUT multiplets, such as gauge and Higgs bosons in the SM and also their superpartners and the additional Higgs bosons in the MSSM, contribute to the differences between the $\beta$ functions. Inverting the argument, one expects that extrapolating the measured couplings to the high scale, we find quantitative unification at $\mu \sim M_G$. While this fails in the SM, it works intriguingly well in the MSSM (cf. Fig. 94.1).

The three equations contained in Eq. (94.3) can be used to determine the three 'unknowns' $\alpha_3(m_Z)$, $\alpha_G(M_G)$ and $M_G$, assuming that all other parameters entering the equations are given. Focusing on the SUSY case and using the $\overline{\mathrm{MS}}$ coupling constants $\alpha_{\mathrm{EM}}^{-1}(m_Z)$ and $\sin^2\theta_W(m_Z)$ from [62],

$$\alpha_{\mathrm{EM}}^{-1}(m_Z) = 127.955 \pm 0.010\,, \qquad (94.4)$$

$$\sin^2\theta_W(m_Z) = 0.23122 \pm 0.00003\,, \qquad (94.5)$$

as input, one determines $\alpha_{1,2}^{-1}(m_Z)$, which then gives

$$\alpha_G^{-1}(M_G) \simeq 24.3 \qquad \text{and} \qquad M_G \simeq 2\times 10^{16}\ \mathrm{GeV}\,. \qquad (94.6)$$

Here we have set $\delta_i = 0$ for simplicity. Crucially, one in addition obtains a prediction for the low-energy observable $\alpha_3$,

$$\alpha_3^{-1}(m_Z) = -\frac{5}{7}\alpha_1^{-1}(m_Z) + \frac{12}{7}\alpha_2^{-1}(m_Z) + \Delta_3\,, \qquad (94.7)$$

where

$$\Delta_3 = \frac{5}{7}\delta_1 - \frac{12}{7}\delta_2 + \delta_3\,. \qquad (94.8)$$

Here we followed the elegant formulation in Ref. [63] of the classical analyses of [7]. Of course, it is a matter of convention which of the three low-energy gauge coupling parameters one 'predicts' and indeed, early works on the subject discussed the prediction of $\sin^2\theta_W$ in terms of $\alpha_{\mathrm{EM}}$ and $\alpha_3$ [64, 65].

Remarkably, the leading order result (i.e. Eq. (94.7) with $\delta_i = 0$) is in excellent agreement with experiments [62]:

$$\alpha_3^{\mathrm{LO}}(m_Z) = 0.117 \qquad \text{vs.} \qquad \alpha_3^{\mathrm{EXP}}(m_Z) = 0.1181 \pm 0.0011\,. \qquad (94.9)$$

However, this near perfection is to some extent accidental. To see this, we now discuss the various contributions to the $\delta_i$ (and hence to $\Delta_3$).

The two-loop running correction from the gauge sector $\Delta_3^{(2)}$ and the low-scale threshold correction $\Delta_3^{(l)}$ from superpartners can be summarized as [63]

$$\Delta_3^{(2)} \simeq -0.82 \qquad \text{and} \qquad \Delta_3^{(l)} \simeq \frac{19}{28\pi}\log\left(\frac{m_{\mathrm{SUSY}}}{m_Z}\right)\,. \qquad (94.10)$$

The relevant scale $m_{\mathrm{SUSY}}$ can be estimated as [66]

$$m_{\mathrm{SUSY}} \;\to\; m_H^{3/19} m_{\widetilde{H}}^{12/19} m_{\widetilde{W}}^{4/19} \times \left(\frac{m_{\widetilde{W}}}{m_{\widetilde{g}}}\right)^{28/19} \left(\frac{m_{\widetilde{l}}}{m_{\widetilde{q}}}\right)^{3/19}\,, \qquad (94.11)$$

where $m_H$ stands for the masses of non-SM Higgs states and superpartner masses are given in self-evident notation. Detailed analyses including the above effects are best done using appropriate software packages, such as SOFTSUSY [61] (or alternatively SuSpect [67] or SPheno [68]). See also [61] for references to the underlying theoretical two-loop analyses.

To get a very rough feeling for these effects, let us assume that all superpartners are degenerate at $m_{\mathrm{SUSY}} = 1$ TeV, except for heavier gluinos: $m_{\widetilde{W}}/m_{\widetilde{g}} \simeq 1/3$. This gives $\Delta_3^{(l)} \simeq -0.35 + 0.22\ln(m_{\mathrm{SUSY}}/m_Z) \simeq 0.18$. The resulting prediction of $\alpha_3(m_Z) \simeq 0.126$ significantly upsets the perfect one-loop agreement found earlier. Before discussing this issue further, it is useful to introduce yet another important type of correction, the high or GUT scale thresholds.

To discuss high scale thresholds, let us set all other corrections to zero for the moment and write down a version of Eq. (94.3)

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

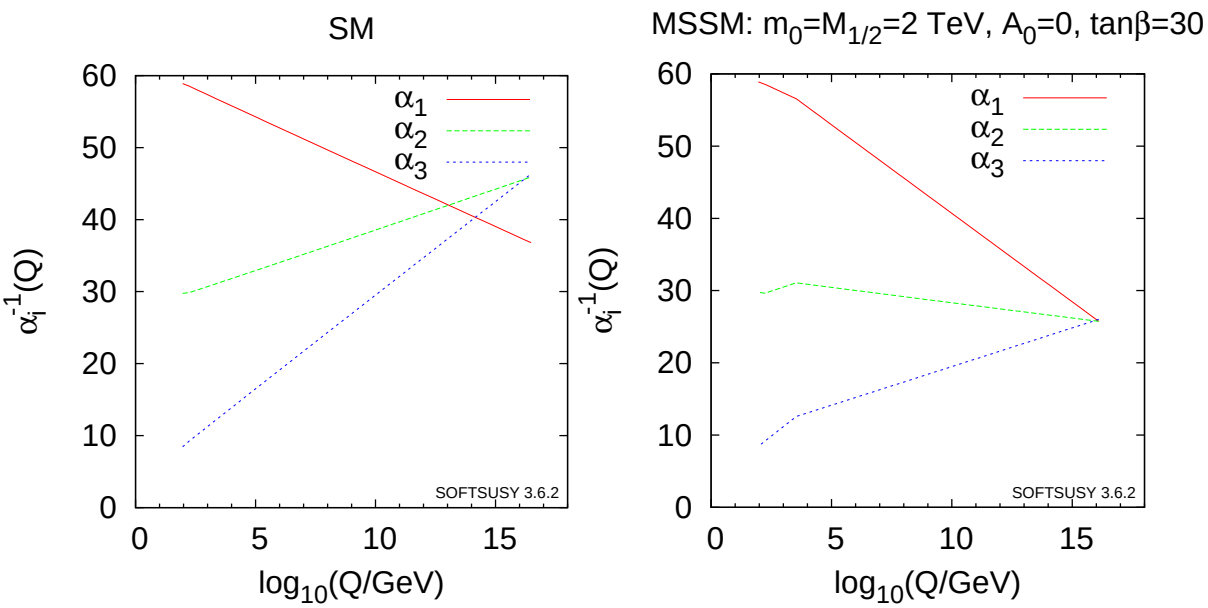

Figure 94.1: Running couplings in SM and MSSM using two-loop RG evolution. The SUSY threshold at 2 TeV is clearly visible on the MSSM side. (We thank Ben Allanach for providing the plots created using SOFTSUSY [61].)

that captures the running near and above the GUT scale more correctly. The threshold correction at one-loop level can be evaluated accurately by the simple step-function approximation for the $\beta$ functions in the $\overline{\rm DR}$ scheme[8] [72],

$$\alpha_i^{-1}(m_Z) = \alpha_G^{-1}(\mu) + \frac{1}{2\pi}\left[b_i \ln\frac{\mu}{m_Z} + b_i^C \ln\frac{\mu}{M_C} + b_i^X \ln\frac{\mu}{M_X} + b_i^\Phi \ln\frac{\mu}{M_\Phi}\right] . \quad (94.12)$$

Here we started the running at some scale $\mu \gg M_G$, including the contribution of the minimal set of states relevant for the transition from the high-scale $SU(5)$ model to the MSSM. These are the color-triplet Higgs multiplets with mass $M_C$, massive vector multiplets of $X$-bosons with mass $M_X$ (including GUT Higgs degrees of freedom), and the remaining GUT-Higgs fields and superpartners with mass $M_\Phi$. The coefficients $b_i^{C,X,\Phi}$ can be found in Ref. [73]. Crucially, the $b_i$ in Eq. (94.12) conspire to make the running GUT-universal at high scales, such that the resulting prediction for $\alpha_3$ does not depend on the value of $\mu$.

To relate this to our previous discussion, we can, for example, define $M_G \equiv M_X$ and then choose $\mu = M_G$ in Eq. (94.12). This gives the high-scale threshold corrections

$$\delta_i^{(h)} = \frac{1}{2\pi}\left[b_i^C \ln\frac{M_G}{M_C} + b_i^\Phi \ln\frac{M_G}{M_\Phi}\right] , \quad (94.13)$$

and a corresponding correction $\Delta_3^{(h)}$. To get some intuition for the magnitude, one can furthermore assume $M_\Phi = M_G$, finding (with $b_i^C = \{2/5, 0, 1\}$)

$$\Delta_3^{(h)} = \frac{9}{14\pi}\ln\left(\frac{M_G}{M_C}\right) . \quad (94.14)$$

To obtain the desired effect of $-\Delta_3^{(2)} - \Delta_3^{(l)} \simeq +0.64$, the triplet Higgs would have to be by about a factor 20 lighter than the GUT scale. While this is ruled out by nucleon decay in the minimal model [74] as will be discussed Sec. 94.6, it is also clear that threshold corrections of this order of magnitude can, in general, be realized with a certain amount of GUT-scale model building, e.g. in specific $SU(5)$ [25] or $SO(10)$ [26,27] constructions. Corrections can also be much larger or of different sign if, as is required in many fully realistic 4d GUT models, many additional (and in particular higher) representations are introduced. Thus, there is considerable model building freedom. Nevertheless, a significant constraint from getting the right GUT threshold corrections while keeping the triplet Higgs heavy remains.

The above analysis implicitly assumes universal soft SUSY breaking masses at the GUT scale, which directly affect the spectrum of SUSY particles at the weak scale. In the simplest case we have a universal gaugino mass $M_{1/2}$, a universal mass for squarks and sleptons $m_{16}$ and a universal Higgs mass $m_{10}$, as motivated by $SO(10)$. In some cases, threshold corrections to gauge coupling unification can be exchanged for threshold corrections to soft SUSY parameters (see [75] and refs. therein). For example, if gaugino masses were not unified at $M_G$ and, in particular, gluinos were lighter than winos at the weak scale (cf. Eq. (94.11)), then it is possible that, due to weak scale threshold corrections, a much smaller or even slightly negative threshold correction at the GUT scale would be consistent with gauge coupling unification [76].

It is also noteworthy that perfect unification can be realized without significant GUT-scale corrections, simply by slightly raising the (universal) SUSY breaking scale. In this case the dark matter abundance produced by thermal processes in the early universe (if the lightest neutralino is the dark matter particle) is too high. However, even if the gaugino mass in the MSSM is about 1 TeV to explain the dark matter abundance, if the Higgsino and the non-SM Higgs boson masses are about 10-100 TeV, the effective SUSY scale can be raised [77]. This setup is realized in split SUSY [78] or the pure gravity mediation model [79] based on anomaly mediation [80]. Since the squarks and sleptons are much heavier than the gaugino masses in those setups, a gauge hierarchy problem is reintroduced. The facts that no superpartners have so far been seen at the LHC and that the observed Higgs mass favors heavier stop masses than about 1 TeV force one to accept a certain amount of fine-tuning anyway.

For non-SUSY GUTs or GUTs with a very high SUSY breaking scale to fit the data, new light states in incomplete GUT multiplets or multiple GUT breaking scales are required. For example, non-SUSY models $SO(10) \to SU(4)_C \times SU(2)_L \times SU(2)_R \to$ SM, with the second breaking scale of order an intermediate scale, determined by light neutrino masses using the see-saw mechanism, can fit the low-energy data for gauge couplings [81] and at the same time survive nucleon decay bounds [82]. Alternatively, one can appeal to string-theoretic corrections discussed in Sec. 94.4 to compensate for a high SUSY breaking scale. This has, for ex-

[8] The $\overline{\rm DR}$ scheme is frequently used in a supersymmetric regularization [69]. The renormalization transformation of the gauge coupling constants from $\overline{\rm MS}$ to $\overline{\rm DR}$ scheme is given in Ref. [70]. For an alternative treatment using holomorphic gauge couplings and NSVZ $\beta$-functions see e.g. [71].

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

ample, been concretely analyzed in the context of F-theory GUTs in [83]. Similarly, one may even wonder whether particularly large GUT threshold corrections could be sufficient to ensure non-SUSY precision unification. Notice here that the gauge coupling unification predicts just one parameter. When introducing new states, typically one can fit the data by choice of their masses. This is not the case in SUSY GUTs with low-scale SUSY breaking scale where the masses are constrained by fine tuning.

In 5d or 6d orbifold GUTs, certain "GUT scale" threshold corrections come from the Kaluza-Klein modes between the compactification scale, $M_c \sim 1/R$, and the effective cutoff scale $M_*$. In string theory, this cutoff scale is the string scale. Gauge coupling unification at two loops then constrains the values of $M_c$ and $M_*$.[9] Often, one finds $M_c$ to be lower than the 4d GUT scale. Since the $X$-bosons, responsible for nucleon decay, get mass at the compactification scale, this has significant consequences for nucleon decay.

Finally, it has been shown that non-supersymmetric GUTs in warped 5d orbifolds can be consistent with gauge coupling unification. This assumes (in 4d language) that the r.h. top quark and the Higgs doublets are composite-like objects with a compositeness scale in the TeV range [85].

## 94.6 Nucleon decay

Quarks and leptons are indistinguishable in any 4d GUT, and both the baryon ($B$) and lepton number ($L$) are not conserved. This leads to baryon-number-violating nucleon decay. In addition to baryon-number violation, lepton-number violation is also required for nucleon decay since, in the SM, leptons are the only free fermions which are lighter than nucleons. The lowest-dimension operators relevant for nucleon decay are ($B$+$L$) violating dimension-six four-fermion-terms in the SM, and all baryon-violating operators with dimension less than seven preserve ($B$–$L$) [1, 86].

In $SU(5)$ GUTs, the dimension-six operators are induced by $X$ boson exchange. These operators are suppressed by $(1/M_X^2)$ ($M_X$ is the $X$ boson mass), and the nucleon lifetime is given by $\tau_N \propto M_X^4/(\alpha_G^2\, m_p^5)$ ($m_p$ is proton mass). The dominant decay mode of the proton (and the baryon-violating decay mode of the neutron), via $X$ boson exchange, is $p \to e^+\, \pi^0$ ($n \to e^+\, \pi^-$). In any simple gauge symmetry, with one universal GUT coupling $\alpha_G$ and scale $M_X$, the nucleon lifetime from gauge boson exchange is calculable. Hence, the GUT scale may be directly observed via the extremely rare decay of the nucleon. Experimental searches for nucleon decay began with the Kolar Gold Mine, Homestake, Soudan, NUSEX, Frejus, HPW, IMB, and Kamiokande detectors [64]. The present experimental bounds on the modes come from Super-Kamiokande. With 306 kton-years of data they find $\tau_p/\mathrm{Br}(p \to e^+\pi^0) > 1.67 \times 10^{34}$ years at 90% CL [87]. In addition, Hyper-Kamiokande [88] is planned to reach to $\tau_p/\mathrm{Br}(p \to e^+\pi^0) \sim 10^{35}$ years. The hadronic matrix elements for baryon-number-violating operators are evaluated with lattice QCD simulations [89]. In SUSY $SU(5)$ GUTs, the lower bound on the $X$ boson mass from null results in nucleon decay searches is approaching $10^{16}$ GeV [90], which is close to the GUT scale suggested by gauge coupling unification. On the other hand, the prediction for nucleon decay in non-SUSY GUTs is hard to quantify. The reason is that gauge couplings do not unify with just the SM particle content. Once extra states or large thresholds are included to ensure precision unification, a certain range of unification scales is allowed.

In SUSY GUTs there are additional sources for baryon and/or lepton-number violation – dimension-four and five operators [14]. These arise since, in the SUSY SM, quarks and leptons have scalar partners (squarks and sleptons). Although our notation does not change, when discussing SUSY models our fields are chiral superfields and both fermionic and bosonic matter is implicitly represented by those. In this language, baryon- and/or lepton-number-violating dimension-four and five operators are given as so-called $F$ terms of products of chiral superfields, which contain two fermionic components and the rest scalars or products of scalars. Within the context of $SU(5)$ the dimension-four and five operators have the form

$$(\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}) \supset (u^c\ d^c\ d^c) + (Q\ L\ d^c) + (e^c\ L\ L),$$

$$(\mathbf{10}\ \mathbf{10}\ \mathbf{10}\ \bar{\mathbf{5}}) \supset (Q\ Q\ Q\ L) + (u^c\ u^c\ d^c\ e^c) + B\text{- and } L\text{-conserving terms},$$

respectively.

The dimension-four operators in ($\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}$) violate either baryon number or lepton number. The nucleon lifetime is extremely short if both types of dimension-four operators are present in the SUSY SM since squark or slepton exchange induces the dangerous dimension-six SM operators. Even in the case that they violate baryon number or lepton number only but not both, they are constrained by various phenomena [91]. For example, the primordial baryon number in the universe is washed out unless the dimensionless coupling constants are less than $10^{-7}$. Both types of operators can be eliminated by requiring $R$ parity, which distinguishes Higgs from ordinary matter multiplets. $R$ parity [92] or its cousin, matter parity [6, 93], act as $F \to -F$, $H \to H$ with $F = \{\mathbf{10}, \bar{\mathbf{5}}\}$, $H = \{\bar{\mathbf{5}}_H, \mathbf{5}_H\}$ in $SU(5)$.[10] In $SU(5)$, the Higgs multiplet $\bar{\mathbf{5}}_H$ and the matter multiplets $\bar{\mathbf{5}}$ have identical gauge quantum numbers. In $E_6$, Higgs and matter multiplets could be unified within the fundamental **27** representation. Only in $SO(10)$ are Higgs and matter multiplets distinguished by their gauge quantum numbers. The $Z_4$ center of $SO(10)$ distinguishes **10**s from **16**s and can be associated with $R$ parity [94].

The baryon-number violating dimension-five operators have a dimensionful coupling. They are generated by integrating out the color-triplet Higgs with GUT-scale mass in SUSY GUTs such that the coefficient is suppressed by $1/M_G$. Note that both triplet Higgsinos (due to their fermionic nature) and Higgs scalars (due to their mass-enhanced trilinear coupling with matter) contribute to the operators. The dimension-five operators include squarks and/or sleptons. To allow for nucleon decay, these must be converted to light quarks or leptons by exchange of a gaugino or Higgsino in the SUSY SM. The nucleon lifetime is proportional to $M_G^2\, m_{\mathrm{SUSY}}^2/m_p^5$, where $m_{\mathrm{SUSY}}$ is the SUSY breaking scale. Thus, dimension-five operators may predict a shorter nucleon lifetime than dimension-six operators. Unless accidental cancellations are present, the dominant decay modes from dimension-five operators include a $K$ meson, such as $p \to K^+\, \bar{\nu}$ ($n \to K^0\, \bar{\nu}$). This is due to a simple symmetry argument: The operators are given as $(Q_i\ Q_j\ Q_k\ L_l)$ and $(u_i^c\ u_j^c\ d_k^c\ e_l^c)$, where $i, j, k, l\,(= 1, 2, 3)$ are family indices and color and weak indices are implicit. They must be invariant under $SU(3)_C$ and $SU(2)_L$ so that their color and weak doublet indices must be anti-symmetrized. Since these operators are given by bosonic superfields, they must be totally symmetric under interchange of all indices. Thus the first operator vanishes for $i = j = k$ and the second vanishes for $i = j$. Hence a second or third generation member exists in the dominant modes of nucleon decay unless these modes are accidentally suppressed [93].

The Super-Kamiokande bounds on the proton lifetime severely constrain the dimension-five operators. With 306 kton-years of data they find $\tau_p/\mathrm{Br}(p \to K^+\bar{\nu}) > 6.61 \times 10^{33}$ years at 90% CL [87]. In the minimal SUSY $SU(5)$, $\tau_p/\mathrm{Br}(p \to K^+\bar{\nu})$ is smaller than about $10^{31}$ years if the triplet Higgs mass is $10^{16}$ GeV and $m_{\mathrm{SUSY}} = 1$ TeV [95]. The triplet Higgs mass bound from nucleon decay is then in conflict with gauge coupling unification so that this model is considered to be ruled out [74].

Since nucleon decay induced by the triplet Higgs is a severe problem in SUSY GUTs, various proposals for its suppression have been made. First, some accidental symmetry or accidental structure in non-minimal Higgs sectors in $SU(5)$ or $SO(10)$ theories may suppress the dimension-five operators [22, 26, 27, 96].

[9] It is interesting to note that a ratio $M_*/M_c \sim 100$, needed for gauge coupling unification to work in orbifold GUTs, is typically the maximum value for this ratio consistent with perturbativity [84].

[10] This forbids the dimension-four operator ($\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}$), but allows the Yukawa couplings for quark and lepton masses of the form ($\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}_H$) and ($\mathbf{10}\ \mathbf{10}\ \mathbf{5}_H$). It also forbids the dimension-three, lepton-number-violating operator ($\bar{\mathbf{5}}\ \mathbf{5}_H$) $\supset$ ($L\ H_u$) as well as the dimension-five, baryon-number-violating operator ($\mathbf{10}\ \mathbf{10}\ \mathbf{10}\ \bar{\mathbf{5}}_H$) $\supset$ ($Q\ Q\ Q\ H_d$) + ···.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

Symmetries to suppress the dimension-five operators are typically broken by the VEVs responsible for the color-triplet Higgs masses. Consequently the dimension-five operators are generically generated via the triplet Higgs exchange in SUSY $SU(5)$ GUTs, as mentioned above. In other words, the nucleon decay is suppressed if the Higgs triplets in $\bar{\mathbf{5}}_H$ and $\mathbf{5}_H$ do not have a common mass term but, instead, their mass terms involve partners from other $SU(5)$ multiplets. Second, the SUSY breaking scale may be around $\mathcal{O}$(10–100) TeV in order to explain the observed Higgs boson mass at the LHC. In this case, nucleon decay is automatically suppressed [78, 97, 98]. Third, accidental cancellations among diagrams due to a fine-tuned structure of squark and slepton flavor mixing might suppress nucleon decay [99]. Last, we have also implicitly assumed a hierarchical structure for Yukawa matrices in the analysis. It is however possible to fine-tune a hierarchical structure for quarks and leptons which baffles the family structure so that the nucleon decay is suppressed [100]. The upper bound on the proton lifetime from some of these theories is approximately a factor of 10 above the experimental bounds. Future experiments with larger neutrino detectors, such as JUNO [101], Hyper-Kamiokande [88] and DUNE [102], are planned and will have higher sensitivities to nucleon decay.

Are there ways to avoid the stringent predictions for proton decay discussed above? Orbifold GUTs and string theories, see Sec. 94.4, contain grand unified symmetries realized in higher dimensions. In the process of compactification and GUT symmetry breaking, the triplet Higgs states may be removed (projected out of the massless sector of the theory). In such models, the nucleon decay due to dimension-five operators can be severely suppressed or eliminated completely. However, nucleon decay due to dimension-six operators may be enhanced, since the gauge-bosons mediating proton decay obtain mass at the compactification scale, $M_c$, which is typically less than the 4d GUT scale (cf. Sec. 94.5). Alternatively, the same projections which eliminate the triplet Higgs may rearrange the quark and lepton states such that the massless states of one family come from different higher-dimensional GUT multiplets. This can suppress or completely eliminate even dimension-six proton decay. Thus, enhancement or suppression of dimension-six proton decay is model-dependent. In some complete 5d orbifold GUT models [63, 103] the lifetime for the decay $\tau_p/\mathrm{Br}(p \to e^+\pi^0)$ can be near the bound of $1 \times 10^{34}$ years with, however, large model-dependence and/or theoretical uncertainties. In other cases, the modes $p \to K^+\bar{\nu}$ and $p \to K^0\mu^+$ may be dominant [63]. Thus, interestingly, the observation of nucleon decay may distinguish string or higher-dimensional GUTs from 4d ones.

In orbifold GUTs or string theory, new discrete symmetries consistent with SUSY GUTs can forbid all dimension-three and four baryon- and lepton-number-violating operators. Even the $\mu$ term and dimension-five baryon- and lepton-number-violating operators can be forbidden to all orders in perturbation theory [33]. The $\mu$ term and dimension-five baryon- and lepton-number-violating operators may then be generated, albeit sufficiently suppressed, via non-perturbative effects. The simplest example of this is a $Z_4^R$ symmetry which is the unique discrete $R$ symmetry consistent with $SO(10)$ [33]. Even though it forbids the dimension-five proton decay operator to the desired level, it allows the required dimension-five neutrino mass term. In this case, proton decay is dominated by dimension-six operators, leading to decays such as $p \to e^+\pi^0$.

## 94.7 Yukawa coupling unification

In the SM, masses and mixings for quarks and leptons come from the Yukawa couplings with the Higgs doublet, but the values of these couplings remain a mystery. GUTs provide at least a partial understanding since each generation is embedded in unified multiplet(s). Specifically, since quarks and leptons are two sides of the same coin, the GUT symmetry relates the Yukawa couplings (and hence the masses) of quarks and leptons.

In $SU(5)$, there are two types of independent renormalizable Yukawa interactions given by $\lambda_{ij}$ $(\mathbf{10}_i \ \mathbf{10}_j \ \mathbf{5}_H)$ + $\lambda'_{ij}$ $(\mathbf{10}_i \ \bar{\mathbf{5}}_j \ \bar{\mathbf{5}}_H)$. These contain the SM interactions $\lambda_{ij}\ (Q_i\ u^c_j\ H_u) + \lambda'_{ij}\ (Q_i\ d^c_j\ H_d + e^c_i\ L_j\ H_d)$. Here $i, j\ (=1,2,3)$ are, as before, family indices. Hence, at the GUT scale we have tree-level relations between Yukawa coupling constants for charged lepton and down quark masses, such as $\lambda_b = \lambda_\tau$ in which $\lambda_{b/\tau}$ are the bottom quark /$\tau$ lepton Yukawa coupling constants [104,105]. In $SO(10)$, there is only one type of independent renormalizable Yukawa interaction given by $\lambda_{ij}$ $(\mathbf{16}_i\ \mathbf{16}_j\ \mathbf{10}_H)$, leading to relations among all Yukawa coupling constants and quark and lepton masses within one generation [106,107] (such as $\lambda_t = \lambda_b = \lambda_\tau$, with $\lambda_t$ the top quark Yukawa coupling constant).

In addition to gauge coupling unification, the ratio of bottom quark and $\tau$ lepton mass has been a central target in the study of GUTs since it was found that this ratio was almost consistent with observations after including the QCD correction [104]. Today the quark masses and the gauge coupling constants are known precisely such that, as discussed below, the ratio of bottom quark and $\tau$ lepton mass has become a target of precision analyses in the GUT context.

### 94.7.1 *The third generation, $b$–$\tau$ or $t$–$b$–$\tau$ unification*

Third generation Yukawa couplings are larger than those of the first two generations. Hence, the fermion mass relations predicted from renormalizable GUT interactions which we introduced above are expected to be more reliable. In order to compare them with data, we have to include the radiative correction to these relations from the RG evolution between GUT and fermion mass scale, from integrating out heavy particles at the GUT scale, and from weak scale thresholds.

Since testing Yukawa coupling unification is only possible in models with successful gauge coupling unification, we here focus on SUSY GUTs. In the MSSM, top and bottom quark and $\tau$ lepton masses are related to the Yukawa coupling constants at the scale $m_Z$ as

$$m_t(m_Z) = \lambda_t(m_Z)\ v_u(1 + \delta m_t/m_t),$$
$$m_{b/\tau}(m_Z) = \lambda_{b/\tau}(m_Z)\ v_d(1 + \delta m_{b/\tau}/m_{b/\tau}),$$

where $\langle H_u^0\rangle \equiv v_u = \sin\beta\ v/\sqrt{2}$, $\langle H_d^0\rangle \equiv v_d = \cos\beta\ v/\sqrt{2}$, $v_u/v_d \equiv \tan\beta$ and $v \sim 246$ GeV is fixed by the Fermi constant, $G_\mu$. Here, $\delta m_f/m_f$ $(f = t, b, \tau)$ represents the threshold correction due to integrating out SUSY partners. For the bottom quark mass, it is found [108] that the dominant corrections come from the gluino-sbottom and from the Higgsino-stop loops,

$$\left(\frac{\delta m_b}{m_b}\right)_{g3} \sim \frac{g_3^2}{6\pi^2}\frac{m_{\tilde{g}}\mu}{m^2_{\mathrm{SUSY}}}\tan\beta \qquad \text{and}$$
$$\left(\frac{\delta m_b}{m_b}\right)_{\lambda_t} \sim \frac{\lambda_t^2}{16\pi^2}\frac{A_t\mu}{m^2_{\mathrm{SUSY}}}\tan\beta\,, \tag{94.16}$$

where $m_{\tilde{g}}$, $\mu$, and $A_t$ stand for gluino and Higgsino masses and trilinear stop coupling, respectively. Note that Eq. (94.16) only illustrates the structure of the corrections – non-trivial functional dependences on several soft parameters $\sim m_{\mathrm{SUSY}}$ have been suppressed. For the full one-loop correction to the bottom quark mass see, for example, Ref. [109].

Note also that the corrections do not go to zero as SUSY particles become much heavier than $m_Z$. They may change the bottom quark mass at the $\mathcal{O}(10)$% level for $\tan\beta = \mathcal{O}(10)$. The total effect is sensitive to the relative phase between gluino and Higgsino masses since $A_t \sim -m_{\tilde{g}}$ due to the infrared fixed point nature of the RG equation for $A_t$ [110] in settings where SUSY breaking terms come from Planck scale dynamics, such as gravity mediation. The $\tau$ lepton mass also receives a similar correction, though only at the few % level. The top quark mass correction, not being proportional to $\tan\beta$, is at most 10% [111].

Including one loop threshold corrections at $m_Z$ and additional RG running, one finds the top, bottom and $\tau$ pole masses. In SUSY GUTs, $b$–$\tau$ unification has two possible solutions with $\tan\beta \sim 1$ or $\mathcal{O}(10)$. The small $\tan\beta$ solution may be realized in the MSSM if superpartner masses are $\mathcal{O}(10)$ TeV, as suggested by the observed Higgs mass [97]. The large $\tan\beta$ limit such as $\tan\beta \sim$ 40–50 overlaps the $SO(10)$ symmetry relation [111, 112]. When $\tan\beta$ is large, there are significant threshold corrections to

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

down quark masses as mentioned above, and Yukawa unification is only consistent with low-energy data in a restricted region of SUSY parameter space, with important consequences for SUSY searches [111, 113]. More recent analyses of Yukawa unification after LHC Run-I are found in Ref. [114].

Gauge coupling unification is also successful in the scenario of split supersymmetry [78], in which squarks and sleptons have mass at a scale $\tilde{m} \gg m_Z$, while gauginos and/or Higgsinos have masses of order the weak scale. Unification of $b$–$\tau$ Yukawa couplings requires $\tan\beta$ to be fine-tuned close to 1 [97]. If by contrast, $\tan\beta \gtrsim 1.5$, $b$–$\tau$ Yukawa unification only works for $\tilde{m} \lesssim 10^4$ GeV. This is because the effective theory between the gaugino mass scale and $\tilde{m}$ includes only one Higgs doublet, as in the standard model. As a result, the large top quark Yukawa coupling tends to increase the ratio $\lambda_b/\lambda_\tau$ due to the vertex correction, which is absent in supersymmetric theories, as one runs down in energy below $\tilde{m}$. This is opposite to what happens in the MSSM where the large top quark Yukawa coupling lowers the ratio $\lambda_b/\lambda_\tau$ [105].

#### 94.7.2 *Beyond leading order: three-family models*

Simple Yukawa unification is not possible for the first two generations. Indeed, the simplest implementation of $SU(5)$ implies $\lambda_s = \lambda_\mu$, $\lambda_d = \lambda_e$ and hence $\lambda_s/\lambda_d = \lambda_\mu/\lambda_e$. This is an RG-invariant relation which extrapolates to $m_s/m_d = m_\mu/m_e$ at the weak scale, in serious disagreement with data ($m_s/m_d \sim 20$ and $m_\mu/m_e \sim 200$). An elegant solution to this problem was given by Georgi and Jarlskog [115] (for a recent analysis in the SUSY context see [116]).

More generally, we have to recall that in all of the previous discussion of Yukawa couplings, we assumed renormalizable interactions as well as the minimal matter and Higgs content. Since the GUT scale is close to the Planck scale, higher-dimension operators involving the GUT-breaking Higgs may modify the predictions, especially for lower generations. An example is provided by the operators $\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}_H\ \mathbf{24}_H$ with $\mathbf{24}_H$ the GUT-breaking Higgs of $SU(5)$. We can fit parameters to the observed fermion masses with these operators, though some fine-tuning is introduced in doing so. The SM Higgs doublet may come in part from higher representations of the GUT group. For example, the **45** of $SU(5)$ includes an $SU(2)_L$ doublet with appropriate $U(1)_Y$ charge [115]. This **45** can, in turn, come from the **120** or **126** of $SO(10)$ after its breaking to $SU(5)$ [117, 118]. These fields may also have renormalizable couplings with quarks and leptons. The relations among the Yukawa coupling constants in the SM are modified if the SM Higgs doublet is a linear combination of several such doublets from different $SU(5)$ multiplets. Finally, the SM fermions may not be embedded in GUT multiplets in the minimal way. Indeed, if all quarks and leptons are embedded in **16**s of $SO(10)$, the renormalizable interactions with $\mathbf{10}_H$ cannot explain the observed CKM mixing angles. This situation improves when extra matter multiplets, such as **10**, are introduced: After $U(1)_X$, which distinguishes the $\bar{\mathbf{5}}$s coming from the **16** and the **10** of $SO(10)$, is broken (e.g. by a VEV of $\mathbf{16}_H$ or $\mathbf{126}_H$), the r.h. down quarks and l.h. leptons in the SM can be linear combinations of components in **16**s and **10**s. As a result, $\lambda \neq \lambda'$ in $SU(5)$ [119].

To construct realistic three-family models, some or all of the above effects can be used. Even so, to achieve significant predictions for fermion masses and mixing angles grand unification alone is not sufficient. Other ingredients, for example additional global family symmetries are needed (in particular, non-Abelian symmetries can strongly reduce the number of free parameters). These family symmetries constrain the set of effective higher-dimensional fermion mass operators discussed above. In addition, sequential breaking of the family symmetry can be correlated with the hierarchy of fermion masses [120]. One simple, widely known idea in this context is to ensure that each $\mathbf{10}_i$ enters Yukawa interactions together with a suppression factor $\epsilon^{3-i}$ ($\epsilon$ being a small parameter). This way one automatically generates a stronger hierarchy in up-type quark Yukawas as compared to down-type quark and lepton Yukawas and no hierarchy for neutrinos, which agrees with observations at the $\mathcal{O}(1)$-level. Three-family models exist which fit all the data, including neutrino masses and mixing [27, 121].

Finally, a particularly ambitious variant of unification is to require that the fermions of all three generations come from a single representation of a large gauge group. A somewhat weaker assumption is that the flavor group (e.g. $SU(3)$) unifies with the SM gauge group in a simple gauge group at some energy scale $M \geq M_G$. Early work on such 'flavor-unified GUTs', see e.g. [119, 122], has been reviewed in [123, 124]. For a selection of more recent papers see [125]. In such settings, Yukawa couplings are generally determined by gauge couplings together with symmetry breaking VEVs. This is reminiscent of heterotic string GUTs, where all couplings come from the 10d gauge coupling. However, while the $\mathrm{E}_8 \to SU(3)\times\mathrm{E}_6$ branching rule $\mathbf{248} = (\mathbf{8},\mathbf{1}) + (\mathbf{1},\mathbf{78}) + (\mathbf{3},\mathbf{27}) + (\bar{\mathbf{3}},\bar{\mathbf{27}})$ looks very suggestive in this context, the way in which most modern heterotic models arrive at three generations is actually more complicated.

## 94.8 Neutrino masses

We see from atmospheric and solar neutrino oscillation observations, along with long baseline accelerator and reactor experiments, that neutrinos have finite masses. By adding three "sterile" neutrinos $\nu_i^c$ with Yukawa couplings $\lambda_{\nu,ij}$ $(\nu_i^c\ L_j\ H_u)$ $(i,j = 1,2,3)$, one easily obtains three massive Dirac neutrinos with mass $m_\nu = \lambda_\nu\ v_u$, analogously to quark and charged lepton masses. However, in order to obtain a $\tau$ neutrino with mass of order 0.1 eV, one requires the exceedingly small coupling ratio $\lambda_{\nu_\tau}/\lambda_\tau \lesssim 10^{-10}$. By contrast, in GUTs the seesaw mechanism *naturally* explains such tiny neutrino masses as follows [2–4]: The sterile neutrinos have no SM gauge quantum numbers so that there is no symmetry other than global lepton number which forbids the Majorana mass term $\frac{1}{2}M_{ij}\ \nu_i^c\ \nu_j^c$. Note also that sterile neutrinos can be identified with the r.h. neutrinos necessarily contained in complete families of $SO(10)$ or Pati-Salam models. Since the Majorana mass term violates $U(1)_X$ in $SO(10)$, one might expect $M_{ij} \sim M_G$. The heavy sterile neutrinos can be integrated out, defining an effective low-energy theory with only three light active Majorana neutrinos with the effective dimension-five operator

$$-\mathcal{L}_{eff} = \frac{1}{2}c_{ij}\ (L_i\ H_u)\ (L_j\ H_u)\,, \qquad (94.17)$$

where $c = \lambda_\nu^T\ M^{-1}\ \lambda_\nu$. This then leads to a $3\times 3$ Majorana neutrino mass matrix $m = m_\nu^T\ M^{-1}\ m_\nu$.

The seesaw mechanism implemented by r.h. neutrinos is sometimes called the type-I seesaw model. There are variant models in which the dimension-five operator for neutrino masses is induced in different ways: In the type-II model, an $SU(2)_L$ triplet Higgs boson $\Sigma$ is introduced to have couplings $\Sigma L^2$ and also $\Sigma H_u^2$ [117, 126]. In the type-III model, an $SU(2)_L$ triplet of fermions $\tilde{\Sigma}$ with a Yukawa coupling $\tilde{\Sigma}LH_u$ is introduced [127]. In these models, the dimension-five operator is induced by integrating out the triplet Higgs boson or fermions. Such models can also be implemented in GUTs by introducing Higgs bosons in the **15** or fermions in the **24** in $SU(5)$ GUTs or the **126** in $SO(10)$ GUTs. Notice that the gauge non-singlet fields in the type-II and III models have masses at the intermediate scale. Thus, gauge coupling unification is not automatic if these variant mechanisms are implemented in SUSY GUTs.

Atmospheric neutrino oscillations discovered by Super-Kamiokande [128] require neutrino masses with $\Delta m_\nu^2 \sim 2.5\times 10^{-3}$ eV$^2$ with maximal mixing [62], in the simplest scenario of two neutrino dominance. With hierarchical neutrino masses this implies $m_{\nu_\tau} = \sqrt{\Delta m_\nu^2} \sim 0.05$ eV. Next, we can try to relate the neutrino Yukawa coupling to the top quark Yukawa coupling, $\lambda_{\nu_\tau} = \lambda_t$ at the GUT scale, as in $SO(10)$ or $SU(4)\times SU(2)_L \times SU(2)_R$ models. This gives $M \sim 10^{14}$ GeV, which is remarkably close to the GUT scale.

Neutrinos pose a special problem for GUTs. The question is why the quark mixing angles in the CKM matrix are small while there are two large lepton mixing angles in the PMNS matrix. Global fits of neutrino masses and mixing angles can, for example, be found in Refs. [129] and [130]. For SUSY GUT models which fit quark and lepton masses, see Ref. [131] for reviews. Finally, for a compilation of the range of SUSY GUT predictions for neutrino mixing, see [132].

## 94.9 Selected topics

### 94.9.1 *Global symmetries*

As we discussed, global symmetries are frequently introduced to control higher-dimension operators in GUT models. This is particularly important in the context of nucleon decay but also plays a role in GUT-based flavor model building and cosmological applications, such as baryogenesis and inflation. However, we should note that appealing to global symmetries to suppress specific interactions may not be as straightforward as it naively seems. Indeed, there are two possibilities: On the one hand, the relevant symmetry might be gauged at a higher scale. Effects of the VEVs responsible for the spontaneous breaking are then in principle dangerous and need to be quantified. On the other hand, the symmetry might be truly only global. This must e.g. be the case for anomalous symmetries, which are then also violated by field-theoretic non-perturbative effects. The latter can in principle be exponentially small. It is, however, widely believed that global symmetries are always broken in quantum gravity (see e.g. [133]). One then needs to understand which power or functional form the Planck scale suppression of the relevant interaction has. For example, dimension-five baryon number violating operators suppressed by just one unit of the Planck or string scale are completely excluded.

In view of the above, it is also useful to recall that in string models 4d global symmetries generally originate in higher-dimensional gauge symmetries [38, 134]. Here 'global' implies that the gauge boson has acquired a Stückelberg-mass. This is a necessity in the anomalous case (Green-Schwarz mechanism [135]) but can also happen to non-anomalous symmetries. One expects no symmetry violation beyond the well-understood non-perturbative effects. Discrete symmetries arise as subgroups of continuous gauge symmetries, such as $\mathbb{Z}_N \subset U(1)$. In particular, non-anomalous subgroups of Stückelberg-massive $U(1)$s represent unbroken discrete gauge symmetries and as such are non-perturbatively exact (see e.g. [136]). Of course, such discrete gauge symmetries may also arise as remnants of continuous gauge symmetries after conventional 4d spontaneous breaking.

### 94.9.2 *Anomaly constraints vs. GUT paradigm*

As emphasized at the very beginning, the fact that the SM fermions of one generation fill out the $\mathbf{10}+\overline{\mathbf{5}}$ of $SU(5)$ appears to provide overwhelming evidence for some form of GUT embedding. However, one should be aware that a counterargument can be made which is related to the issue of 'charge quantization by anomaly cancellation' (see [137,138] for some early papers and [139] for a more detailed reference list): Imagine we only knew that the low-energy gauge group were $G_{SM}$ and the matter content included the $(\mathbf{3},\mathbf{2})_Y$, i.e. a 'quark doublet' with $U(1)$-charge $Y$. One can then ask which possibilities exist of adding further matter to ensure the cancellation of all triangle anomalies. It turns out that this problem has only three different, minimal[11] solutions [138]. One of those is precisely a single SM generation, with the apparent '$SU(5)$-ness' emerging accidentally. Thus, if one randomly picks models from the set of consistent gauge theories, preconditioning on $G_{SM}$ and $(\mathbf{3},\mathbf{2})_Y$, one may easily end up with '$\mathbf{10}+\overline{\mathbf{5}}$' of an $SU(5)$ that is in no way dynamically present. This is precisely what happens in the context of non-GUT string model building [140].

### 94.9.3 *Magnetic monopoles*

In the broken phase of a GUT there are typically localized classical solutions carrying magnetic charge under an unbroken $U(1)$ symmetry [141]. These magnetic monopoles with mass of order $M_G/\alpha_G$ can be produced during a possible GUT phase transition in the early universe. The flux of magnetic monopoles is experimentally found to be less than $\sim 10^{-16}$ cm$^{-2}$ s$^{-1}$ sr$^{-1}$ [142]. Many more are however predicted, hence the GUT monopole problem. In fact, one of the original motivations for inflation was to solve the monopole problem by exponential expansion after the GUT phase transition [143] and hence dilution of the monopole density. Other possible solutions to the monopole problem include: sweeping them away by domain walls [144], $U(1)$ electromagnetic symmetry breaking at high temperature [145] or GUT symmetry non-restoration [146]. Parenthetically, it was also shown that GUT monopoles can catalyze nucleon decay [147]. A significantly stronger bound on the monopole flux can then be obtained by considering X-ray emission from radio pulsars due to monopole capture and the subsequent nucleon decay catalysis [148].

Note that the present upper bound on the inflationary vacuum energy density is very close to the GUT scale, $V_{inf}^{1/4} = (1.88\times10^{16}\,\text{GeV})\times(r/0.10)^{1/4}$, with the scalar-to-tensor ratio constrained to $r < 0.07$ [149]. This guarantees that reheating does not lead to temperatures above $M_G$ and hence the monopole problem is solved by inflation (unless $M_G$ is unexpectedly low).

### 94.9.4 *Flavor violation*

Yukawa interactions of GUT-scale particles with quarks and leptons may leave imprints on the flavor violation induced by SUSY breaking parameters [150]. To understand this, focus first on the MSSM with universal Planck-scale boundary conditions (as e.g. in gravity mediation). Working in a basis where up-quark and lepton Yukawas are diagonal, one finds that the large top-quark Yukawa coupling reduces the l.h. squark mass squareds in the third generation radiatively. It turns out that only the l.h. down-type squark mass matrix has sizable off-diagonal terms in the flavor basis after CKM-rotation. However, in GUTs the color-triplet Higgs has flavor violating interactions from the Yukawa coupling $\lambda_{ij}$ $(\mathbf{10}_i\,\mathbf{10}_j\,\mathbf{5}_H)$, such that flavor-violating r.h. slepton mass terms are radiatively generated in addition [151]. In $SU(5)$ extension of the type-I seesaw model, where r.h. neutrinos are introduced as $SU(5)$ singlets with interactions $\lambda''_{ij}$ $(\mathbf{1}_i\,\bar{\mathbf{5}}_j\,\mathbf{5}_H)$, the doublet and color-triplet Higgses acquire another type of Yukawa coupling, respectively. They then radiatively generate flavor-violating l.h. slepton [152] and r.h. down squark masses [153]. These flavor-violating SUSY breaking terms induce new contributions to FCNC processes in quark and lepton sectors, such as $\mu\to e\gamma$ and $K^0$–$\bar{K}^0$ and $B^0$–$\bar{B}^0$ mixing. Note that even if the SUSY breaking terms are generated at $M_G$, the r.h. neutrino Yukawa coupling may induce sizable flavor violation in l.h. slepton masses due to the running between $M_G$ and the right-handed-neutrino mass scale.

EDMs are also induced when both l.h. and r.h. squarks/sleptons have flavor-violating mass terms with relative phases, as discussed for $SO(10)$ in [154] or for $SU(5)$ with r.h. neutrinos in [155]. Thus, such low-energy observables constrain GUT-scale interactions.

### 94.9.5 *From GUT baryogenesis to leptogenesis and B/L-violating transitions*

During inflation, any conserved quantum number is extremely diluted. Thus, one expects the observed baryon asymmetry of the universe to originate at reheating or in the subsequent cosmological evolution. In detail, the situation is slightly more involved: Both baryon number $B$ and lepton number $L$ are global symmetries of the SM. However, $(B+L)$ is anomalous and violated by thermal fluctuations in the early universe, via so-called sphaleron processes. Moreover, it is violated in GUT models, as is most apparent in proton decay. By contrast, $(B-L)$ is anomaly free and preserved by both the SM as well as $SU(5)$ or $SO(10)$ gauge interactions.

Now, the old idea of GUT baryogenesis [156,157] is to generate a $(B+L)$ and hence a baryon asymmetry by the out-of-equilibrium decay of the color-triplet Higgs. However such an asymmetry, generated at GUT temperatures, is washed out by sphalerons[12]. This can be overcome [159] using lepton-number violating interaction of neutrinos to create a $(B-L)$ from the $(B+L)$ asymmetry, before sphaleron processes become sufficiently fast at $T < 10^{12}$ GeV. This $(B-L)$ asymmetry can then survive the subsequent sphaleron dominated phase. Note that this does not work in the minimal SUSY GUT setting, with the triplet Higgs above the

[11] Adding extra vector-like sets of fields, e.g. two fermions which only transform under $U(1)$ and have charges $Y$ and $-Y$, is considered to violate minimality.

[12] To be precise, if lepton flavor numbers $L_i$ $(i=1$–$3)$ are nonzero and $(L_i-L_j)\neq 0$ $(i\neq j)$, one may obtain nonzero values for $B$ and $L$ even if $(B-L)=0$ [158].

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

GUT scale. The reason is that a correspondingly high reheating temperature would be required which, as explained above, is ruled out by Planck data.

However, the most widely accepted simple way out of the dilemma is to directly generate a net $(B-L)$ asymmetry dynamically in the early universe, also using r.h. neutrinos. Indeed, we have seen that neutrino oscillations suggest a new scale of physics of order $10^{14}$ GeV. This scale is associated with heavy Majorana neutrinos in the seesaw mechanism. If in the early universe, the decay of the heavy neutrinos is out of equilibrium and violates both lepton number and CP, then a net lepton number may be generated. This lepton number will then be partially converted into baryon number via electroweak processes [160]. This mechanism is called leptogenesis.

If the three heavy Majorana neutrino masses are hierarchical, the net lepton number is produced by decay of the lightest one, and it is proportional to the CP asymmetry in the decay. The CP asymmetry is bounded from above, and the lightest neutrino mass is required to be larger than $10^9$ GeV in order to explain the observed baryon asymmetry [161]. This implies that the reheating temperature after inflation should be larger than $10^9$ GeV so that the heavy neutrinos are thermally produced[13]. In supersymmetric models, there is a tension between leptogenesis and Big Bang Nucleosynthesis (BBN) if gravitinos decay in the BBN era. The gravitino problem gives a constraint on the reheating temperature $\lesssim 10^{6-10}$ GeV though the precise value depends on the SUSY breaking parameters [163]. Recent reviews of leptogenesis can be found in Ref. [164].

One of the important tests of leptogenesis are searches for neutrinoless double-$\beta$ ($0\nu\beta\beta$) decays[14]. In a $0\nu\beta\beta$ decay, only two electrons but no (anti-)neutrinos are emitted by the decaying nucleus. This is in contrast to ordinary double-$\beta$ decay. Thus, $0\nu\beta\beta$ decays are lepton-number-violating with $\Delta L = 2$. At the nucleon level, this is described by dimension-nine effective operators for $nn \to ppee$. These operators may in turn come from SM operators of with dimension less than nine, in combination with SM weak interactions. The lowest one is the dimension-five operator generating the Majorana neutrino mass terms (Eq. (94.17)). Thus, if the lepton-number violating effective interactions come from physics at energies much above the weak scale, the $0\nu\beta\beta$ decay rates are proportional to the Majorana neutrino masses. The latest experimental results are reviewed in [62]. For recent studies of the $0\nu\beta\beta$ decay including SM operators up to mass dimension nine, see [165] and refs. therein.

In addition to $L$-violation, one can consider $(B-L)$ and $B$ violating phenomena. They are interesting in their own right and may also be relevant to baryogenesis. The relevant operators have higher mass dimension than the familiar dimension-six $(B+L)$-violating operators (cf. Sec. 94.6). They may be predicted in SO(10) GUTs with an intermediate scale, at which baryogenesis is realized, such as in [166]. First, one may have nucleon decays with $\Delta(B-L) = 2$, such as $n \to e^-\pi^+$. This is induced by dimension-seven effective operators in the SM, which are suppressed by the SM Higgs VEV or derivatives. Second, there are neutron-antineutron ($n$–$\bar{n}$) oscillations, which are induced by $\Delta B = 2$ dimension-nine effective operators in the SM. The upper bound on the mean time for $n$–$\bar{n}$ transitions is directly derived using free neutrons [167]. It is also constrained from the lower limit on the lifetime for neutrons bound in $^{16}O$, derived by Super-Kamiokande [168]. Their results are very similar. Super-Kamiokande also searches for dinucleon decays with $\Delta B = 2$, such as $pp \to \pi^+\pi^+$ and $nn \to \pi^\pm\pi^\mp$ [169].

## 94.10 Conclusion

Most conservatively, grand unification means that (some of) the SM gauge interactions of $U(1)_Y$, $SU(2)_L$ and $SU(3)_C$ become part of a larger, unifying gauge symmetry at a high energy scale. In most models, especially in the simplest and most appealing variants of $SU(5)$ and $SO(10)$ unification, the statement is much stronger: One expects the three gauge couplings to unify (up to small threshold corrections) at a unique scale, $M_G$, and the proton to be unstable due to exchange of gauge bosons of the larger symmetry group. Supersymmetric grand unified theories provide, by far, the most predictive and economical framework allowing for perturbative unification. Many more details than could be discussed in the present article can be found in some of the classic reviews [123,170] and the two books [171] (see also [172] for two recent overviews).

Thus, the three classical pillars of GUTs are gauge coupling unification at $M_G \sim 2 \times 10^{16}$ GeV, low-energy supersymmetry (with a large SUSY desert), and nucleon decay. The first of these may be viewed as predicting the value of the strong coupling – a prediction which has already been verified (see Fig. 94.1). Numerically, this prediction remains intact even if SUSY partner masses are somewhat above the weak scale. However, at the conceptual level a continuously increasing lower bound on the SUSY scale is nevertheless problematic for the GUT paradigm: Indeed, if the independent, gauge-hierarchy-based motivation for SUSY is completely abandoned, the SUSY scale and hence $\alpha_3$ become simply free parameters and the first two pillars crumble. Thus, it is important to keep pushing bounds on proton decay which, although again not completely universal in all GUT constructions, is arguably a more generic part of the GUT paradigm than low-energy SUSY.

Whether or not Yukawa couplings unify is more model dependent. However, irrespective of possible (partial) Yukawa unification, there certainly exists a very interesting and potentially fruitful interplay between flavor model building and grand unification. Especially in the neutrino sector this is strongly influenced by the developing experimental situation.

Another phenomenological signature of grand unification is the strength of the direct coupling of the QCD axion to photons, relative to its coupling to gluons. It is quantified by the predicted anomaly ratio $E/N = 8/3$ (see [173, 174]). This arises in field-theoretic axion models consistent with GUT symmetry (such as DFSZ [175]) and in string-theoretic GUTs [174,176]. In the latter, the axion does not come from the phase of a complex scalar but is a fundamental shift-symmetric real field, coupling through a higher-dimension operator directly to the product of the GUT field-strength and its dual.

It is probably fair to say that, due to limitations of the 4d approach, including especially remaining ambiguities (free parameters or ad hoc assumptions) in models of flavor and GUT breaking, the string theoretic approach has become more important in GUT model building. In this framework, challenges include learning how to deal with the many vacua of the 'landscape' as well as, for each vacuum, developing the tools for reliably calculating detailed, phenomenological observables. Finally, due to limitations of space, the present article has barely touched on the interesting cosmological implications of GUTs. They may become more important in the future, especially in the case that a high inflationary energy scale is established observationally.

[13] This constraint may be avoided in resonant leptogenesis [162], in which the right-handed neutrinos are required to be almost degenerate in mass.

[14] Another important test of leptogenesis would be the observation of CP violation in neutrino oscillations. Strictly speaking, the CP phase in the PMNS matrix does not contribute to $\epsilon_1$ in the seesaw model. Nevertheless, the observation of CP violation in neutrino oscillations would suggest that the seesaw mechanism is associated with a large CP violation, similarly to the quark sector.

# 95. Leptoquarks

Updated August 2019 by S. Rolli (US Department of Energy) and M. Tanabashi (Nagoya U.)

Leptoquarks are hypothetical particles carrying both baryon number (B) and lepton number (L). The possible quantum numbers of leptoquark states can be restricted by assuming that their direct interactions with the ordinary standard model (SM) fermions are dimensionless and invariant under the SM gauge group. Table 95.1 shows the list of all possible quantum numbers with this assumption [1]. The columns of $SU(3)_C$, $SU(2)_W$, and $U(1)_Y$ in Table 95.1 indicate the QCD representation, the weak isospin representation, and the weak hypercharge, respectively. The spin of a leptoquark state is taken to be 1 (vector leptoquark) or 0 (scalar leptoquark).

**Table 95.1:** Possible leptoquarks and their quantum numbers.

| Spin | $3B+L$ | $SU(3)_c$ | $SU(2)_W$ | $U(1)_Y$ | Allowed coupling |
|---|---|---|---|---|---|
| 0 | $-2$ | $\bar{3}$ | 1 | 1/3 | $\bar{q}_L^c \ell_L$ or $\bar{u}_R^c e_R$ |
| 0 | $-2$ | $\bar{3}$ | 1 | 4/3 | $\bar{d}_R^c e_R$ |
| 0 | $-2$ | $\bar{3}$ | 3 | 1/3 | $\bar{q}_L^c \ell_L$ |
| 1 | $-2$ | $\bar{3}$ | 2 | 5/6 | $\bar{q}_L^c \gamma^\mu e_R$ or $\bar{d}_R^c \gamma^\mu \ell_L$ |
| 1 | $-2$ | $\bar{3}$ | 2 | $-1/6$ | $\bar{u}_R^c \gamma^\mu \ell_L$ |
| 0 | 0 | 3 | 2 | 7/6 | $\bar{q}_L e_R$ or $\bar{u}_R \ell_L$ |
| 0 | 0 | 3 | 2 | 1/6 | $\bar{d}_R \ell_L$ |
| 1 | 0 | 3 | 1 | 2/3 | $\bar{q}_L \gamma^\mu \ell_L$ or $\bar{d}_R \gamma^\mu e_R$ |
| 1 | 0 | 3 | 1 | 5/3 | $\bar{u}_R \gamma^\mu e_R$ |
| 1 | 0 | 3 | 3 | 2/3 | $\bar{q}_L \gamma^\mu \ell_L$ |

If we do not require leptoquark states to couple directly with SM fermions, different assignments of quantum numbers become possible [2,3].

Leptoquark states are expected to exist in various extensions of the SM. The Pati-Salam model [4] is an example predicting the existence of a leptoquark state. Leptoquark states also exist in grand unification theories based on $SU(5)$ [5], $SO(10)$ [6], which includes Pati-Salam color $SU(4)$, and larger gauge groups. Scalar quarks in supersymmetric models with R-parity violation may also have leptoquark-type Yukawa couplings. The bounds on the leptoquark states can therefore be applied to constrain R-parity-violating supersymmetric models. Scalar leptoquarks are expected to exist at the TeV scale in extended technicolor models [7,8] where leptoquark states appear as the bound states of techni-fermions. Compositeness of quarks and leptons also provides examples of models which may have light leptoquark states [9].

Bounds on leptoquark states are obtained both directly and indirectly. Direct limits are from their production cross sections at colliders, while indirect limits are calculated from bounds on leptoquark-induced four-fermion interactions, which are obtained from low-energy experiments, or from collider experiments below threshold. These four-fermion interactions often cause lepton-flavor non-universalities in heavy quark decays. Anomalies observed recently in the $R_K$ and $R_D$ ratios [10,11] in the semi-leptonic $B$ decays may be explained in models with TeV scale leptoquarks.

If a leptoquark couples to quarks (leptons) belonging to more than a single generation in the mass eigenbasis, it can induce four-fermion interactions causing flavor-changing neutral currents (lepton-family-number violations). The quantum number assignment of Table 1 allows several leptoquark states to couple to both left- and right-handed quarks simultaneously. Such leptoquark states are called non-chiral and may cause four-fermion interactions affecting the $(\pi \to e\nu)/(\pi \to \mu\nu)$ ratio [12]. Non-chiral scalar leptoquarks also contribute to the muon anomalous magnetic moment [13,14]. Since indirect limits provide more stringent constraints on these types of leptoquarks, it is often assumed that a leptoquark state couples only to a single generation of quarks and a single generation of leptons in a chiral interaction, for which indirect limits become much weaker. Additionally, this assumption gives strong constraints on models of leptoquarks.

Refs. [15,16,17] give extensive lists of the bounds on the leptoquark-induced four-fermion interactions. For the isoscalar scalar and vector leptoquarks $S_0$ and $V_0$, for example, which couple with the first- (second-) generation left-handed quark, and the first-generation left-handed lepton, the bounds $\lambda^2 < 0.07 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for $S_0$, and $\lambda^2 < 0.4 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for $V_0$ ($\lambda^2 < 0.7 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for $S_0$, and $\lambda^2 < 0.5 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for $V_0$) with $\lambda$ being the leptoquark coupling strength, can be derived from the limits listed in Ref. [17]. The $e^+e^-$ experiments are sensitive to the indirect effects coming from $t$- and $u$-channel exchanges of leptoquarks in the $e^+e^- \to q\bar{q}$ process. The HERA experiments give bounds on the leptoquark-induced four-fermion interaction. For detailed bounds obtained in this way, see the Boson Particle Listings for "Indirect Limits for Leptoquarks" and its references.

Collider experiments provide direct limits on the leptoquark states through limits on the pair- and single-production cross sections. The leading-order cross sections of the parton processes

$$\begin{aligned} &q + \bar{q} \to {\rm LQ} + \overline{\rm LQ} \\ &g + g \to {\rm LQ} + \overline{\rm LQ} \\ &e + q \to {\rm LQ} \end{aligned} \tag{95.1}$$

may be written as [21]

$$\begin{aligned} \hat{\sigma}_{\rm LO}\Big[q\bar{q} \to {\rm LQ} + \overline{\rm LQ}\Big] &= \frac{2\alpha_s^2 \pi}{27\hat{s}}\beta^3, \\ \hat{\sigma}_{\rm LO}\Big[gg \to {\rm LQ} + \overline{\rm LQ}\Big] &= \frac{\alpha_s^2 \pi}{96\hat{s}} \\ &\quad \times \Big[\beta(41 - 31\beta^2) + (18\beta^2 - \beta^4 - 17)\log\frac{1+\beta}{1-\beta}\Big], \\ \hat{\sigma}_{\rm LO}\Big[eq \to {\rm LQ}\Big] &= \frac{\pi\lambda^2}{4}\delta(\hat{s} - M_{\rm LQ}^2) \end{aligned} \tag{95.2}$$

for a scalar leptoquark. Here $\sqrt{\hat{s}}$ is the invariant energy of the parton subprocess, and $\beta \equiv \sqrt{1 - 4M_{\rm LQ}^2/\hat{s}}$. The leptoquark Yukawa coupling is given by $\lambda$. Leptoquarks are also produced singly at hadron colliders through $g + q \to {\rm LQ} + \ell$ [22], which allows extending to higher masses the collider reach in the leptoquark search [23], depending on the leptoquark Yukawa coupling. See also Ref. [24] for a comprehensive review on the leptoquark phenomenology in precision experiments and particle colliders.

Leptoquark states which couple only to left- or right-handed quarks are called chiral leptoquarks. Leptoquark states which couple only to the first (second, third) generation are referred as the first- (second-, third-) generation leptoquarks.

The LHC, Tevatron and LEP experiments have been searching for pair production of the leptoquark states, which arises from the leptoquark gauge interaction. Due to the typical decay of the leptoquark into charged and neutral leptons and quarks, the searches are carried on in signatures including high $P_T$ charged leptons, high $E_T$ jets and large missing transverse energy. Additionally searches for pair produced LQs are often organized by the decay mode of the pair of LQs, via the decay parameter $\beta$, which represents the branching fraction into a charge lepton vs a neutrino: $beta = 1$ for both LQs decaying into a charged letpon, $beta = 0.5$ for one LQ decaying into a charged lepton and one into a neutrino. The gauge couplings of a scalar leptoquark are determined uniquely according to its quantum numbers in Table 95.1. Since all of the leptoquark states belong to color-triplet representation, the scalar leptoquark pair-production cross section at the Tevatron and LHC can be determined solely as a function of the leptoquark mass without making further assumptions. This is in contrast to the indirect or single-production limits, which give constraints in the leptoquark mass-coupling plane.

Older results from the Tevatron run can be found here: [26], [27], [28] and [29].

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

Since the previous version of this review, both ATLAS and CMS have updated their results concerning searches for first, second, and third generation LQs and leptoquark states which couple only with the $i$-th generation quarks and the $j$-th generation leptons ($i \neq j$) without causing conflicts with severe indirect constraints. The datasets were almost all collected at center of mass energy of 13 TeV and corresponding to the latest integrated luminosity collected before the shutdown of the LHC occuring in 2019 and 2020.

It is worthy to note that organizing LQs by flavor quantum number first before organizing them by gauge quantum number is becoming more common and advantageous because it relates more closely to some of the experimental searches being performed. The traditional nomenclature for 1st, 2nd, and 3rd generation LQ encourages only looking for the diagonal elements in a flavor matrix of possibilities, which has been the traditional experimental search strategy.

Current results extend previous mass limits for scalar leptoquarks to $>$ 1435 GeV (first generation, CMS, $\beta$ =1, $\sqrt{s}$ = 13 TeV) and $>$ 1270 GeV(first generation, CMS, $\beta$ =0.5,$\sqrt{s}$ = 13 TeV) [30]; $>$ 1400 GeV (first generation, ATLAS, $\beta$ =1, $\sqrt{s}$ = 13 TeV) and $>$ 1290 GeV (first generation, ATLAS, $\beta$ =0.5, $\sqrt{s}$ = 13 TeV ) [31]; $>$ 1530 GeV (second generation, CMS, $\beta$ =1, $\sqrt{s}$ = 13 TeV) and $>$ 1285 GeV (second generation, CMS, $\beta$ =0.5, $\sqrt{s}$ = 13 TeV) [32]; and $>$ 1560 GeV (second generation, ATLAS, $\beta$ =1,$\sqrt{s}$ = 13 TeV) and $>$ 1230 GeV (second generation, ATLAS, $\beta$ =0.5,$\sqrt{s}$ = 13 TeV) [31]. All limits are presented at 95% C.L.

As for third generation leptoquarks, CMS results are the following: 1) assuming that all leptoquarks decay to a top quark and a $\tau$ lepton, the existence of pair produced, third-generation leptoquark up to a mass of 900 GeV ($\beta$ =1, 13 TeV) is excluded at 95% confidence level [33]; 2) assuming that all leptoquarks decay to a bottom quark and a $\tau$ lepton, the existence of pair produced, third-generation leptoquark up to a mass of 1020 GeV ($\beta$ =1, 13 TeV) is excluded at 95% confidence level [34]; 3)assuming that all leptoquarks decay to a bottom quark and a $\tau$ neutrino, the existence of pair produced, third-generation leptoquark up to a mass of 450 GeV ($\beta$ =0, 7 TeV)is excluded at 95% confidence level [35]. In a recent paper [36], the ATLAS collaboration has limits on pair production of third generation scalar leptoquarks where all possible decays of the leptoquark into a quark ($t$, $b$) and a lepton ($\tau$, $\nu$) of the third generation are considered. The limits are presented as a function of the leptoquark mass and the branching ratio into charged leptons for leptoquark of up-type ($LQ_3^{up} \rightarrow \tau\nu/b\tau$) and down-type ($LQ_3^d \rightarrow b\nu/t\tau$); many results are re-interpretation of previously published ATLAS searches. The collaboration finds that masses below 800 GeV are excluded for both $LQ_3^u$ and $LQ_3^d$ independently of the branching ratio, with masses below about 1 TeV being excluded for the limiting cases of branching ratios equal to zero or unity.

It is also possible to consider leptoquark states which couple only with the $i$-th generation quarks and the $j$-th generation leptons ($i \neq j$) without causing conflicts with severe indirect constraints. Such couplings have received renewed attention because they may provide an explanation to anomalies in rare $B - meson$ decays and the anomalous magnetic moment of the muon. See Ref. [37], [38] and [39] and references therein for collider search strategies and limits on the pair production cross sections of this class of leptoquark states. In this framework, a novel CMS result [40] presents a non-traditional search for pair production of LQs coupled to a top quark and a muon. As no deviation from the standard model prediction was observed, scalar LQs decaying exclusively into $top - \mu$ are excluded up to masses of 1420 GeV.

The magnetic-dipole-type and the electric-quadrupole-type interactions of a vector leptoquark are not determined even if we fix its gauge quantum numbers as listed in the Table 95.1 [41]. The production of vector leptoquarks depends in general on additional assumptions, where the leptoquark couplings and their pair production cross sections are enhanced relative to the scalar leptoquark contributions. The most stringent limits on vector LQ production are now from CMS [42] where previous searches for squarks and gluinos have been reinterpreted to constrain models of leptoquark production. LQ masses below 1530 GeV are excluded assuming the Yang-Mills case with coupling $\kappa$ = 1, or 1115 GeV in the minimal coupling case where $\kappa$ = 0, placing the most stringent constraint to date from pair production of vector LQs.

The leptoquark pair-production cross sections in $e^+e^-$ collisions depend on the leptoquark $SU(2) \times U(1)$ quantum numbers and Yukawa coupling with electron [43].

Searches for first generation leptoquark singly produced were performed by the HERA experiments. Since the leptoquark single-production cross section depends on its Yukawa coupling, the leptoquark mass limits from HERA are usually displayed in the mass-coupling plane. For leptoquark Yukawa coupling $\lambda$ = 0.1, early ZEUS Collaboration bounds on the first-generation leptoquarks range from 248 to 290 GeV, depending on the leptoquark species [45]. The ZEUS Collaboration has recently released a new paper [46] where data corresponding to a luminosity of around 1 $fb^1$ have been used in the framework of *eeqq* contact interactions (CI) to set limits on possible high-energy contributions beyond the Standard Model to electron-quark scattering. The analysis of the *ep* data has been based on simultaneous fits of parton distribution functions including contributions of Contact Interaction (CI) couplings to *ep* scattering. Several general CI models and scenarios with heavy leptoquarks were considered. As unambiguous deviations from the SM cannot be established, limits for CI compositeness scales and LQ mass scales were set that are in the TeV range. The H1 Collaboration has a comprehensive summary of searches for first generation leptoquarks using the full data sample collected in *ep* collisions at HERA (446 $pb^{-1}$). No evidence of production of leptoquarks was observed in final states with a large transverse momentum electron or large missing transverse momentum. For a coupling strength $\lambda$ = 0.3, first generation leptoquarks with masses up to 800 GeV are excluded at 95% C.L. [48].

At the LHC, the CMS collaboration performed searches for single production of first and second generation leptoquarks [49], which is complementary to the HERA searches in the high $\lambda$ region (for coupling strength $\lambda$ = 1.0, first generation leptoquarks are excluded for masses up to 1.73 TeV and second generation leptoquark are excluded up to masses of 530 GeV). CMS also recently searched for third generation LQ decaying into $\tau$ and *bottom* in [50]. Assuming unit Yukawa coupling ($\lambda$), a third generation scalar leptoquark is excluded for masses below 740 GeV. Limits are also set on $\lambda$ of the hypothesized leptoquark as a function of its mass. Above $\lambda$ = 1.4, the results provide the best upper limit on the mass of a third-generation scalar leptoquark decaying to a $\tau$ lepton and a bottom quark.

Searches for LQ will continue with more LHC data, particularly in light of the renewed interest in this type of particle to explain violation of letpon flavor universality and other anomalies, which point to explanations laying outside the Standard Model.

# 96. Magnetic Monopoles

Revised August 2019 by D. Milstead (Stockholm U.) and E.J. Weinberg (Columbia U.).

## 96.1 Theory of magnetic monopoles

The symmetry between electric and magnetic fields in the source-free Maxwell's equations naturally suggests that electric charges might have magnetic counterparts, known as magnetic monopoles. Although the greatest interest has been in the supermassive monopoles that are a firm prediction of all grand unified theories, one cannot exclude the possibility of lighter monopoles.

In either case, the magnetic charge is constrained by a quantization condition first found by Dirac [1]. Consider a monopole with magnetic charge $Q_M$ and a Coulomb magnetic field

$$\mathbf{B} = \frac{Q_M}{4\pi}\frac{\hat{\mathbf{r}}}{r^2}\,. \tag{96.1}$$

Any vector potential $\mathbf{A}$ whose curl is equal to $\mathbf{B}$ must be singular along some line running from the origin to spatial infinity. This Dirac string singularity could potentially be detected through the extra phase that the wavefunction of a particle with electric charge $Q_E$ would acquire if it moved along a loop encircling the string. For the string to be unobservable, this phase must be a multiple of $2\pi$. Requiring that this be the case for any pair of electric and magnetic charges gives the condition that all charges be integer multiples of minimum charges $Q_E^{\rm min}$ and $Q_M^{\rm min}$ obeying

$$Q_E^{\rm min}Q_M^{\rm min} = 2\pi\,. \tag{96.2}$$

(For monopoles which also carry an electric charge, called dyons [2], the quantization conditions on their electric charges can be modified. However, the constraints on magnetic charges, as well as those on all purely electric particles, will be unchanged.)

Another way to understand this result is to note that the conserved orbital angular momentum of a point electric charge moving in the field of a magnetic monopole has an additional component, with

$$\mathbf{L} = m\mathbf{r}\times\mathbf{v} - 4\pi Q_E Q_M\hat{\mathbf{r}} \tag{96.3}$$

Requiring the radial component of $\mathbf{L}$ to be quantized in half-integer units yields Eq. 96.1.

If there are unbroken gauge symmetries in addition to the U(1) of electromagnetism, the above analysis must be modified [3] [4]. For example, a monopole could have both a U(1) magnetic charge and a color magnetic charge. The latter could combine with the color charge of a quark to give an additional contribution to the phase factor associated with a loop around the Dirac string, so that the U(1) charge could be the Dirac charge $Q_M^D \equiv 2\pi/e$, the result that would be obtained by substituting the electron charge into Eq. (96.1). On the other hand, for monopoles without color-magnetic charge, one would simply insert the quark electric charges into Eq. 96.1 and conclude that $Q_M$ must be a multiple of $6\pi/e$.

The prediction of GUT monopoles arises from the work of 't Hooft [5] and Polyakov [6], who showed that certain spontaneously broken gauge theories have nonsingular classical solutions that lead to magnetic monopoles in the quantum theory. The simplest example occurs in a theory where the vacuum expectation value of a triplet Higgs field $\boldsymbol{\Phi}$ breaks an SU(2) gauge symmetry down to the U(1) of electromagnetism and gives a mass $M_V$ to two of the gauge bosons. In order to have finite energy, $\boldsymbol{\Phi}$ must approach a vacuum value at infinity. However, there is a continuous family of possible vacua, since the scalar field potential determines only the magnitude $v$ of $\langle\boldsymbol{\Phi}\rangle$, but not its orientation in the internal SU(2) space. In the monopole solution, the direction of $\boldsymbol{\Phi}$ in internal space is correlated with the position in physical space; *i.e.*, $\phi^a \sim v\hat{r}^a$. The stability of the solution follows from the fact that this twisting Higgs field cannot be smoothly deformed to a spatially uniform vacuum configuration. Reducing the energetic cost of the spatial variation of $\boldsymbol{\Phi}$ requires a nonzero gauge potential, which turns out to yield the magnetic field corresponding to a charge $Q_M = 4\pi/e$. Numerical solution of the classical field equations shows that the mass of this monopole is

$$M_{\rm mon} \sim \frac{4\pi M_V}{e^2}\,. \tag{96.4}$$

The essential ingredient here was the fact that the Higgs fields at spatial infinity could be arranged in a topologically nontrivial configuration. A discussion of the general conditions under which this is possible is beyond the scope of this review, so we restrict ourselves to the two phenomenologically most important cases.

The first is the standard electroweak theory, with $\mathrm{SU}(2)\times\mathrm{U}(1)$ broken to U(1). There are no topologically nontrivial configurations of the Higgs field, and hence no topologically stable monopole solutions.

The second is when any simple Lie group is broken to a subgroup with a U(1) factor, a case that includes all grand unified theories. The monopole mass is determined by the mass scale of the symmetry breaking that allows nontrivial topology. For example, an SU(5) model with

$$\mathrm{SU}(5) \xrightarrow{M_X} \mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1) \xrightarrow{M_W} \mathrm{SU}(3)\times\mathrm{U}(1) \tag{96.5}$$

has a monopole [7] with $Q_M = 2\pi/e$ and mass

$$M_{\rm mon} \sim \frac{4\pi M_{\rm X}}{g^2}\,, \tag{96.6}$$

where $g$ is the SU(5) gauge coupling. For a unification scale of $10^{16}$ GeV, these monopoles would have a mass $M_{\rm mon} \sim 10^{17}$ – $10^{18}$ GeV.

In theories with several stages of symmetry breaking, monopoles of different mass scales can arise. In an SO(10) theory with

$$\mathrm{SO}(10) \xrightarrow{M_1} \mathrm{SU}(4)\times\mathrm{SU}(2)\times\mathrm{SU}(2) \xrightarrow{M_2} \mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1) \tag{96.7}$$

there is monopole with $Q_M = 2\pi/e$ and mass $\sim 4\pi M_1/g^2$ and a much lighter monopole with $Q_M = 4\pi/e$ and mass $\sim 4\pi M_2/g^2$ [8].

The central core of a GUT monopole contains the fields of the superheavy gauge bosons that mediate baryon number violation, so one might expect that baryon number conservation could be violated in baryon–monopole scattering. The surprising feature, pointed out by Callan [9] and Rubakov [10], is that these processes are not suppressed by powers of the gauge boson mass. Instead, the cross-sections for catalysis processes such as $p$ + monopole $\to e^+ + \pi^0$ + monopole are essentially geometric; *i.e.*, $\sigma_{\Delta B}\beta \sim 10^{-27}$ cm$^2$, where $\beta = v/c$. Note, however, that this catalysis is model-dependent and is not even a universal property of all GUT monopoles.

## 96.2 Production and Annihilation

GUT monopoles are far too massive to be produced in any foreseeable accelerator. However, they could have been produced in the early universe as topological defects arising via the Kibble mechanism [11] in a symmetry-breaking phase transition. Estimates of the initial monopole abundance, and of the degree to which it can be reduced by monopole-antimonopole annihilation, predict a present-day monopole abundance that exceeds by many orders of magnitude the astrophysical and experimental bounds described below [12]. Cosmological inflation and other proposed solutions to this primordial monopole problem generically lead to present-day abundances exponentially smaller than could be plausibly detected, although potentially observable abundances can be obtained in scenarios with carefully tuned parameters.

If monopoles light enough to be produced at colliders exist, one would expect that these could be produced by analogs of the electromagnetic processes that produce pairs of electrically charged particles. Because of the large size of the magnetic charge, this is a strong coupling problem for which perturbation theory cannot be trusted. Indeed, the problem of obtaining reliable quantitative estimates of the production cross-sections remains an open one, on which there is no clear consensus.

## 96.3 Astrophysical and Cosmological Bounds

If there were no galactic magnetic field, one would expect monopoles in the galaxy to have typical velocities of the order of $10^{-3}c$, comparable to the virial velocity in the galaxy (relevant if the monopoles cluster with the galaxy) and the peculiar velocity of the galaxy with respect to the CMB rest frame (relevant

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

if the monopoles are not bound to the galaxy). This situation is modified by the existence of a galactic magnetic field $B \sim 3\mu$G. A monopole with the Dirac charge and mass $M$ would be accelerated by this field to a velocity

$$v_{\rm mag} \sim \begin{cases} c, & M \lesssim 10^{11}{\rm GeV}\,, \\ 10^{-3}c\left(\frac{10^{17}\,{\rm GeV}}{M}\right)^{1/2}, & M \gtrsim 10^{11}{\rm GeV}\,. \end{cases} \quad (96.8)$$

Accelerating these monopoles drains energy from the magnetic field. Parker [13] obtained an upper bound on the flux of monopoles in the galaxy by requiring that the rate of this energy loss be small compared to the time scale on which the galactic field can be regenerated. With reasonable choices for the astrophysical parameters (see Ref. [14] for details), this Parker bound is

$$F < \begin{cases} 10^{-15}\,{\rm cm}^{-2}\,{\rm sr}^{-1}\,{\rm sec}^{-1}\,, & M \lesssim 10^{17}\,{\rm GeV}\,, \\ 10^{-15}\left(\frac{M}{10^{17}\,{\rm GeV}}\right){\rm cm}^{-2}\,{\rm sr}^{-1}\,{\rm sec}^{-1}\,, & M \gtrsim 10^{17}\,{\rm GeV}\,. \end{cases} \quad (96.9)$$

Applying similar arguments to an earlier seed field that was the progenitor of the current galactic field leads to a tighter bound [15],

$$F < \left[\frac{M}{10^{17}{\rm GeV}} + (3\times 10^{-6})\right] 10^{-16}\,{\rm cm}^{-2}{\rm sr}^{-1}{\rm sec}^{-1}. \quad (96.10)$$

Considering magnetic fields in galactic clusters gives a bound [16] which, although less secure, is about three orders of magnitude lower than the Parker bound.

A flux bound can also be inferred from the total mass of monopoles in the universe. If the monopole mass density is a fraction $\Omega_M$ of the critical density, and the monopoles were uniformly distributed throughout the universe, there would be a monopole flux

$$F_{\rm uniform} = 1.3{\times}10^{-16}\Omega_M \left(\frac{10^{17}\,{\rm GeV}}{M}\right)\left(\frac{v}{10^{-3}c}\right){\rm cm}^{-2}{\rm sr}^{-1}{\rm sec}^{-1}. \quad (96.11)$$

If we assume that $\Omega_M \sim 0.1$, this gives a stronger constraint than the Parker bound for $M \sim 10^{15}$ GeV. However, monopoles with masses $\sim 10^{17}$ GeV are not ejected by the galactic field and can be gravitationally bound to the galaxy. In this case their flux within the galaxy is increased by about five orders of magnitude for a given value of $\Omega_M$, and the mass density bound only becomes stronger than the Parker bound for $M \sim 10^{18}$ GeV.

A much more stringent flux bound applies to GUT monopoles that catalyze baryon number violation. The essential idea is that compact astrophysical objects would capture monopoles at a rate proportional to the galactic flux. These monopoles would then catalyze proton decay, with the energy released in the decay leading to an observable increase in the luminosity of the object. A variety of bounds, based on neutron stars [17–21] , white dwarfs [22], and Jovian planets [23] have been obtained. These depend in the obvious manner on the catalysis cross section, but also on the details of the astrophysical scenarios; *e.g.*, on how much the accumulated density is reduced by monopole-antimonopole annihilation, and on whether monopoles accumulated in the progenitor star survive its collapse to a white dwarf or neutron star. The bounds obtained in this manner lie in the range

$$F\left(\frac{\sigma_{\Delta B}\beta}{10^{-27}{\rm cm}^2}\right) \sim (10^{-18} - 10^{-29}){\rm cm}^{-2}{\rm sr}^{-1}{\rm sec}^{-1}. \quad (96.12)$$

It is important to remember that not all GUT monopoles catalyze baryon number nonconservation. In particular, the intermediate mass monopoles that arise in some GUTs at later stages of symmetry-breaking are examples of theoretically motivated monopoles that are exempt from the bound of the above equation.

## 96.4 Searches for Magnetic Monopoles

To date there have been no confirmed observations of exotic particles possessing magnetic charge. Precision measurements of the properties of known particles have led to tight limits on the values of magnetic charge they may possess. Using the induction method (see below), the electron's magnetic charge has been found to be $Q_e^m < 10^{-24}Q_M^D$ [24] (where $Q_M^D$ is the Dirac charge). Furthermore, measurements of the anomalous magnetic moment of the muon have been used to place a model dependent lower limit of 120 GeV on the monopole mass [1] [25]. Nevertheless, guided mainly by Dirac's argument and the predicted existence of monopoles from spontaneous symmetry breaking mechanisms, searches have been routinely made for monopoles produced at accelerators, in cosmic rays, and bound in matter [26]. Although the resultant limits from such searches are usually made under the assumption of a particle possessing only magnetic charge, most of the searches are also sensitive to dyons.

## 96.5 Search Techniques

Search strategies are determined by the expected interactions of monopoles as they pass through matter. These would give rise to a number of striking characteristic signatures. Since a complete description of monopole search techniques falls outside of the scope of this minireview, only the most common methods are described below. More comprehensive descriptions of search techniques can be found in Refs. [27] [28].

The induction method exploits the long-ranged electromagnetic interaction of the monopole with the quantum state of a superconducting ring which would lead to a monopole which passes through such a ring inducing a permanent current. The induction technique typically uses Superconducting Quantum Interference Devices (SQUID) technology for detection and is employed for searches for monopoles in cosmic rays and matter. Another approach is to exploit the electromagnetic energy loss of monopoles. Monopoles with Dirac charge would typically lose energy at a rate which is several thousand times larger than that expected from particles possessing the elementary electric charge. Consequently, scintillators, gas chambers and nuclear track detectors (NTDs) have been used in cosmic ray and collider experiments. A further approach, which has been used at colliders, is to search for particles describing a non-helical path in a uniform magnetic field.

### 96.5.1 *Searches for Monopoles Bound in Matter*

Monopoles have been sought in a range of bulk materials which it is assumed would have absorbed incident cosmic ray monopoles over a long exposure time of order million years. Materials which have been studied include moon rock, meteorites, manganese modules, and sea water [29, 30]. A stringent upper limit on the monopoles per nucleon ratio of $\sim 10^{-29}$ has been obtained [30].

### 96.5.2 *Searches in Cosmic Rays*

Direct searches for monopoles in cosmic rays refer to those experiments in which the passage of the monopole is measured by an active detector. Searches made assuming a catalysis processes in which GUT monopoles could induce nucleon decay are discussed in the next section. To interpret the results of the non-catalysis searches, the cross section for the catalysis process is typically either set to zero [31] or assigned a modest value (1mb) [32].

Although early cosmic ray searches using the induction technique [33] and NTDs [34] observed monopole candidates, none of these apparent observations have been confirmed. Recent experiments have typically employed large scale detectors. The MACRO experiment at the Gran Sasso underground laboratory comprised three different types of detector: liquid scintillator, limited stream tubes, and NTDs, which provided a total acceptance of $\sim$ 10000m$^2$ for an isotropic flux. As shown in Fig. 96.1, this experiment has so far provided the most extensive $\beta$-dependent flux limits for GUT monopoles with Dirac charge [32]. Also shown are limits from an experiment at the OHYA mine in Japan [31], which used a 2000m$^2$ array of NTDs.

In Fig. 96.1, upper flux limits are also shown as a function of mass for monopole speed $\beta > 0.05$. In addition to MACRO

[1] Where no ambiguity is likely to arise, a reference to a monopole implies a particle possessing Dirac charge.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

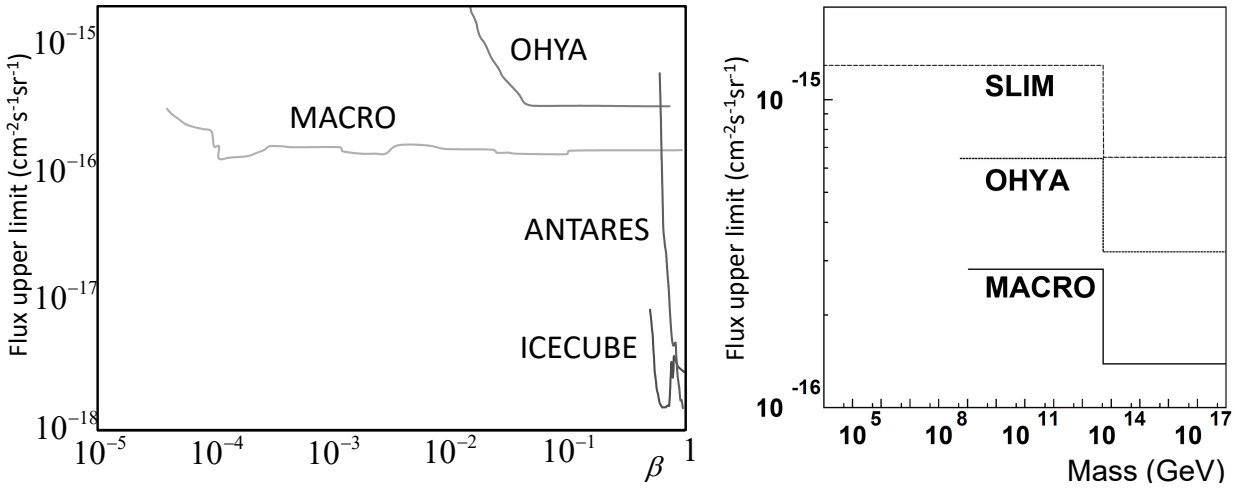

Figure 96.1: Upper flux limits for (left) GUT monopoles as a function of $\beta$ (right) Monopoles as a function of mass for $\beta > 0.05$.

and OYHA flux limits, results from the SLIM [35] high-altitude experiment are shown. The SLIM experiment provided a good sensitivity to intermediate mass monopoles ($10^5 \lesssim M \lesssim 10^{12}$ GeV). In addition to the results shown in Fig. 96.1, limits as low as $\sim 1.5 \times 10^{-18}$ cm$^{-2}$s$^{-1}$sr$^{-1}$ were obtained for monopoles with $\beta > 0.51$ and $\beta > 0.6$ by the IceCube [36] and Antares [37] experiments, respectively. Stringent constraints on the flux of ultra-relativistic monopoles have been obtained at the Pierre Auger Observatory [38] which was sensitive to monopoles with $\gamma$ values ranging from $10^9$ to $10^{12}$, leading to flux limits in the range $10^{-15} - 2.5 \times 10^{-21}$ cm$^{-2}$s$^{-1}$sr$^{-1}$. The RICE [39] and ANITA-II experiments [40] at the South Pole have also sought ultra-relativistic monopoles with $\gamma$ values of $10^7 \lesssim \gamma \lesssim 10^{12}$ and $10^9 \lesssim \gamma \lesssim 10^{13}$, respectively, and which produced flux limits as low as $2.5 \times 10^{-21}$ cm$^{-2}$s$^{-1}$sr$^{-1}$.

### 96.5.3 *Searches via the Catalysis of Nucleon-Decay*

Searches have been performed for evidence of the catalysed decay of a nucleon by a monopole, as predicted by the Callan-Rubakov mechanism. The searches are thus sensitive to the assumed value of the catalysis decay cross section. Searches have been made with the Soudan [41] and Macro [42] experiments, using tracking detectors. Searches at IMB [43], the underwater Lake Baikal experiment [44] and the The IceCube experiment [45] which exploit the Cerenkov effect have also been made. The resulting $\beta$-dependent flux limits from these experiments typically vary between $\sim 10^{-18}$ and $\sim 10^{-14}$cm$^{-2}$sr$^{-1}$s$^{-1}$. A recent search for low energy neutrinos (assumed to be produced from induced proton decay in the sun) was made at Super-Kamiokande [46]. A model- and $\beta$-dependent of limit of $6.3 \times 10^{-24}(\frac{\beta}{10^{-3}})^2$cm$^{-2}$sr$^{-1}$s$^{-1}$ was obtained.

### 96.5.4 *Searches at Colliders*

Searches have been performed at hadron-hadron, electron-positron and lepton-hadron experiments. Collider searches can be broadly classed as being direct or indirect. In a direct search, evidence of the passage of a monopole through material, such as a charged particle track, is sought. In indirect searches, virtual monopole processes are assumed to influence the production rates of certain final states.

#### 96.5.4.1 *Direct Searches at Colliders*

Collider experiments typically express their results in terms of upper limits on a production cross section and/or monopole mass. To calculate these limits, ansatzes are used to model the kinematics of monopole-antimonopole pair production processes since perturbative field theory cannot be used to calculate the rate and kinematic properties of produced monopoles. Limits therefore suffer from a degree of model-dependence, implying that a comparison between the results of different experiments can be problematic, in particular when this concerns excluded mass regions. A conservative approach with as little model-dependence as possible is thus to present representative values of the upper cross-section limits as a function of one half the centre-of-mass energy of the collisions, as shown in Fig. 96.2 for recent results from high energy colliders.

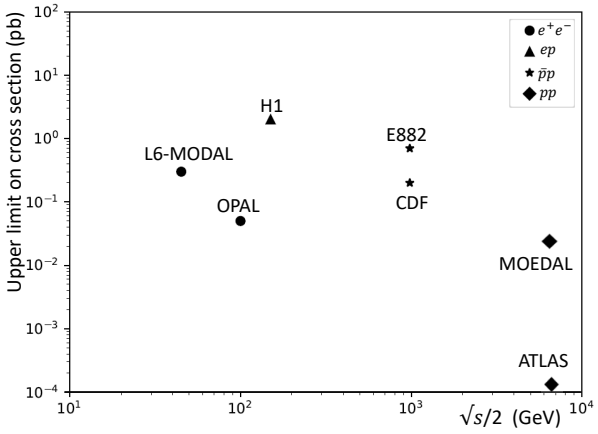

Figure 96.2: Upper limits on the production cross sections of monopoles from various collider-based experiments.

Searches for monopoles produced at the highest available energies in hadron-hadron collisions were made in $pp$ collisions at the LHC by the ATLAS [47, 48] and MoEDAL [49, 50] experiments. The experiments looked for highly ionising particles leaving characteristic energy deposition profiles and stopped monopoles with the induction method, respectively. The charge-dependent mass limits extend up to around 4 TeV. The ATLAS work considers monopoles with $0.5Q_M^D$ and $2Q_M^D$ while MoEDAL quotes limits for monopoles with charges from $Q_M^D$ to $5Q_M^D$. MoEDAL considered monopole-pair production via photon fusion along with, as is commonly used in hadron-hadron collisions, Drell-Yan processes [51]. Tevatron searches have also been carried out by the CDF [52] and E882 [53] experiments. The CDF experiment used a dedicated time-of-flight system whereas the E882 experiment employed the induction technique to search for stopped monopoles in discarded detector material which had been part of the CDF and D0 detectors using periods of luminosity. Earlier searches at the Tevatron, such as [54], used NTDs and were based on comparatively modest amounts of integrated luminosity. Lower energy hadron-hadron experiments have employed a variety of search techniques including plastic track detectors [55] and searches for trapped monopoles [56].

The only LEP-2 search was made by OPAL [57] which quoted

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

cross section limits for the production of monopoles possessing masses up to around 103 GeV. At LEP-1, searches were made with NTDs deployed around an interaction region. This allowed a range of charges to be sought for masses up to $\sim 45$ GeV. The L6-MODAL experiment [58] gave limits for monopoles with charges in the range $0.9Q_M^D$ and $3.6Q_M^D$, whilst an earlier search by the MODAL experiment was sensitive to monopoles with charges as low as $0.1Q_M^D$ [59]. The deployment of NTDs around the beam interaction point was also used at earlier $e^+e^-$ colliders such as KEK [60] and PETRA [61]. Searches at $e^+e^-$ facilities have also been made for particles following non-helical trajectories [62] [63].

There has so far been one search for monopole production in lepton-hadron scattering. Using the induction method, monopoles were sought which could have stopped in the aluminium beampipe which had been used by the H1 experiment at HERA [64]. Cross section limits were set for monopoles with charges in the range $Q_M^D - 6Q_M^D$ for masses up to around 140 GeV.

96.5.4.2 *Indirect Searches at Colliders*

It has been proposed that virtual monopoles can mediate processes which give rise to multi-photon final-states [65] [66]. Photon-based searches were made by the D0 [67] and L3 [68] experiments. The D0 work led to spin-dependent lower mass limits of between 610 and 1580 GeV, while L3 reported a lower mass limit of 510 GeV. However, it should be stressed that uncertainties on the theoretical calculations which were used to derive these limits are difficult to estimate.

# VOLUME II: TABLE OF CONTENTS

**PARTICLE LISTINGS***

**Illustrative key and abbreviations** 999

**Gauge and Higgs bosons**
($\gamma$, gluon, graviton, $W$, $Z$, Higgs, Axions) 1013

**Leptons**
($e$, $\mu$, $\tau$, Heavy-charged lepton searches, Neutrino properties, Number of neutrino types Double-$\beta$ decay, Neutrino mixing, Heavy-neutral lepton searches) 1101

**Quarks**
($u$, $d$, $s$, $c$, $b$, $t$, $b'$, $t'$ ($4^{th}$ gen.), Free quarks) 1173

**Mesons**
Light unflavored ($\pi$, $\rho$, $a$, $b$) ($\eta$, $\omega$, $f$, $\phi$, $h$) 1209
Other light unflavored 1332
Strange ($K, K^*$) 1337
Charmed ($D, D^*$) 1391
Charmed, strange ($D_s$, $D_s^*$, $D_{sJ}$) 1448
Bottom ($B$, $V_{cb}/V_{ub}$, $B^*$, $B_J^*$) 1465
Bottom, strange ($B_s$, $B_s^*$, $B_{sJ}^*$) 1640
Bottom, charmed ($B_c$) 1664
$c\overline{c}$ ($\eta_c$, $J/\psi(1S)$, $\chi_c$, $h_c$, $\psi$) 1668
$b\overline{b}$ ($\eta_b$, $\Upsilon$, $\chi_b$, $h_b$) 1782

**Baryons**
$N$ 1825
$\Delta$ 1878
$\Lambda$ 1902
$\Sigma$ 1927
$\Xi$ 1959
$\Omega$ 1971
Charmed ($\Lambda_c$, $\Sigma_c$, $\Xi_c$, $\Omega_c$) 1974
Doubly charmed ($\Xi_{cc}$) 1996
Bottom ($\Lambda_b$, $\Sigma_b$, $\Xi_b$, $\Omega_b$, $b$-baryon admixture) 1997
Exotic baryons ($P_c$ pentaquarks) 2014

**Searches not in Other Sections**
Magnetic monopole searches 2017
Supersymmetric particle searches 2019
Technicolor 2062
Searches for quark and lepton compositeness 2063
Extra dimensions 2067
WIMP and dark matter searches 2073
Other particle searches 2085

*The divider sheets give more detailed indices for each main section of the Particle Listings.

# Illustrative Key to the Particle Listings

Name of particle. "Old" name used before 1986 renaming scheme also given if different. See the section "Naming Scheme for Hadrons" for details.

## $a_0(1200)$

$I^G(J^{PC}) = 1^-(0^{++})$ — Particle quantum numbers (where known).

OMITTED FROM SUMMARY TABLE — Indicates particle omitted from Particle Physics Summary Table, implying particle's existence is not confirmed.

Evidence not compelling, may be a kinematic effect.

General comments on particle.

Quantity tabulated below.

### $a_0(1200)$ MASS

Top line gives our best value (and error) of quantity tabulated here, based on weighted average of measurements used. Could also be from fit, best limit, estimate, or other evaluation. See next page for details.

| VALUE (MeV) | EVTS | DOCUMENT ID | | TECN | CHG | COMMENT |
|---|---|---|---|---|---|---|
| **1206± 7 OUR AVERAGE** | | | | | | |
| 1210± 8±9 | 3000 | FENNER | 87 | MMS | − | 3.5 $\pi^- p$ |
| 1198±10 | | PIERCE | 83 | ASPK | + | 2.1 $K^- p$ |
| 1216±11±9 | 1500 | [1] MERRILL | 81 | HBC | 0 | 3.2 $K^- p$ |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | | |
| 1192±16 | 200 | LYNCH | 81 | HBC | ± | 2.7 $\pi^- p$ |

"Document id" for this result; full reference given below.

Footnote number linking measurement to text of footnote.

[1] Systematic error was added quadratically by us in our 1986 edition.

Measurement technique. (See abbreviations on next page.)

### $a_0(1200)$ WIDTH

Number of events *above background*.

| VALUE (MeV) | EVTS | DOCUMENT ID | | TECN | CHG | COMMENT |
|---|---|---|---|---|---|---|
| **41±11 OUR AVERAGE** Error includes scale factor of 1.8. See the ideogram below. | | | | | | |
| 50± 8 | | PIERCE | 83 | ASPK | + | 2.1 $K^- p$ |
| $70^{+30}_{-20}$ | 200 | LYNCH | 81 | HBC | ± | 2.7 $\pi^- p$ |
| 25± 5±7 | | MERRILL | 81 | HBC | 0 | 3.2 $K^- p$ |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | | |
| <60 | | FENNER | 87 | MMS | − | 3.5 $\pi^- p$ |

Measured value used in averages, fits, limits, etc.

Scale factor > 1 indicates possibly inconsistent data.

Reaction producing particle, or general comments.

Error in measured value (often statistical only; followed by systematic if separately known; the two are combined in quadrature for averaging and fitting.)

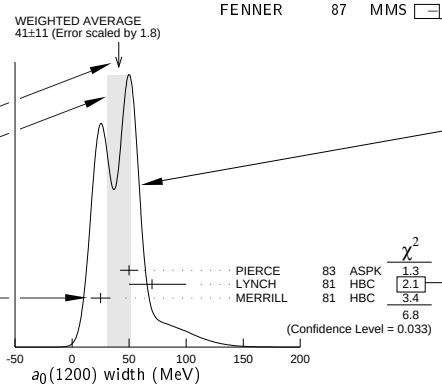
"Change bar" indicates result added or changed since previous edition.

Measured value *not used* in averages, fits, limits, etc. See the Introductory Text for explanations.

Charge(s) of particle(s) detected.

Arrow points to weighted average.

Shaded pattern extends $\pm 1\sigma$ (scaled by "scale factor" S) from weighted average.



Ideogram to display possibly inconsistent data. Curve is sum of Gaussians, one for each experiment (area of Gaussian = 1/error; width of Gaussian = ±error). See Introductory Text for discussion.

Value and error for each experiment.

Contribution of experiment to $\chi^2$ (if no entry present, experiment not used in calculating $\chi^2$ or scale factor because of very large error).

### $a_0(1200)$ DECAY MODES

| Mode | Fraction ($\Gamma_i/\Gamma$) | Scale factor/ Confidence level |
|---|---|---|
| $\Gamma_1$ $3\pi$ | (65.2±1.3) % | S=1.7 |
| $\Gamma_2$ $K\overline{K}$ | (34.8±1.3) % | S=1.7 |
| $\Gamma_3$ $\eta\pi^\pm$ | < 5 $\times 10^{-4}$ | CL=95% |

Partial decay mode (labeled by $\Gamma_i$).

Our best value for branching fraction as determined from data averaging, fitting, evaluating, limit selection, etc. This list is basically a compact summary of results in the Branching Ratio section below.

### $a_0(1200)$ BRANCHING RATIOS

Branching ratio.

**$\Gamma(3\pi)/\Gamma_{total}$** — $\Gamma_1/\Gamma$

| VALUE | DOCUMENT ID | | TECN | CHG | COMMENT |
|---|---|---|---|---|---|
| **0.652±0.013 OUR FIT** Error includes scale factor of 1.7. | | | | | |
| **0.643±0.010 OUR AVERAGE** | | | | | |
| 0.64 ±0.01 | PIERCE | 83 | ASPK | + | 2.1 $K^- p$ |
| 0.74 ±0.06 | MERRILL | 81 | HBC | 0 | 3.2 $K^- p$ |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| 0.48 ±0.15 | [2] LYNCH | 81 | HBC | ± | 2.7 $\pi^- p$ |

Our best value (and error) of quantity tabulated, as determined from constrained fit (using *all significant* measured branching ratios for this particle).

Weighted average of measurements of this ratio only.

[2] Data has questionable background subtraction.

Footnote (referring to LYNCH 81).

**$\Gamma(K\overline{K})/\Gamma_{total}$** — $\Gamma_2/\Gamma$

| VALUE | DOCUMENT ID | | TECN | CHG | COMMENT |
|---|---|---|---|---|---|
| **0.348±0.013 OUR FIT** Error includes scale factor of 1.7. | | | | | |
| **0.35 ±0.05** | PIERCE | 83 | ASPK | + | 2.1 $K^- p$ |

Branching ratio in terms of partial decay mode(s) $\Gamma_i$ above.

**$\Gamma(K\overline{K})/\Gamma(3\pi)$** — $\Gamma_2/\Gamma_1$

| VALUE | DOCUMENT ID | | TECN | CHG | COMMENT |
|---|---|---|---|---|---|
| **0.535±0.030 OUR FIT** Error includes scale factor of 1.7. | | | | | |
| **0.50 ±0.03** | MERRILL | 81 | HBC | 0 | 3.2 $K^- p$ |

**$\Gamma(\eta(\text{neutral decay})\pi^\pm)/\Gamma_{total}$** — $0.71\Gamma_3/\Gamma$

| VALUE (units $10^{-4}$) | CL% | DOCUMENT ID | | TECN | CHG | COMMENT |
|---|---|---|---|---|---|---|
| **<3.5** | 95 | PIERCE | 83 | ASPK | + | 2.1 $K^- p$ |

Confidence level for measured upper limit.

### $a_0(1200)$ REFERENCES

References, ordered inversely by year, then author.

| | | | | |
|---|---|---|---|---|
| FENNER | 87 | PRL 55 14 | H. Fenner *et al.* | (SLAC) (FNAL) UP |
| PIERCE | 83 | PL 123B 230 | J.H. Pierce | |
| LYNCH | 81 | PR D24 610 | G.R. Lynch *et al.* | (CLEO Collab.) |
| MERRILL | 81 | PRL 47 143 | D.W. Merrill *et al.* | (SACL, CERN) |

"Document id" used on data entries above.

Partial list of author(s) in addition to first author.

Quantum number determinations in this reference.

Journal, report, preprint, etc. (See abbreviations on next page.)

Institution(s) of author(s). (See abbreviations on next page.)

# Abbreviations Used in the Particle Listings

### Indicator of Procedure Used to Obtain Our Result

| | |
|---|---|
| OUR AVERAGE | From a weighted average of selected data. |
| OUR FIT | From a constrained or overdetermined multiparameter fit of selected data. |
| OUR EVALUATION | Not from a direct measurement, but evaluated from measurements of other quantities. |
| OUR ESTIMATE | Based on the observed range of the data. Not from a formal statistical procedure. |
| OUR LIMIT | For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement. |

### Measurement Techniques (i.e., Detectors and Methods of Analysis)

| | |
|---|---|
| A1 | A1 Collaboration at MAMI |
| A2MM | A2 spectrometer at the Mainz Microtron, MAMI |
| ABRA | ABRACADABRA QCD axion dark matter search |
| ACCM | ACCMOR Collaboration |
| ADMX | Axion Dark Matter Experiment |
| AEMS | Argonne effective mass spectrometer |
| ALEP | ALEPH – CERN LEP detector |
| ALPS | Photon regeneration experiment |
| AMND | AMANDA South Pole neutrino detector |
| AMY | AMY detector at KEK-TRISTAN |
| ANAI | Direct DM detection exp. with NaI at Canfranc Underground Lab, Spain |
| ANIT | Antarctic Impulsive Transient Antenna balloon mission |
| ANTR | ANTARES underwater neutrino telescope in the Western Mediterranean Sea |
| APEX | FNAL APEX Collab. |
| ARG | ARGUS detector at DORIS |
| ARGD | Fit to semicircular amplitude path on Argand diagram |
| ASP | Anomalous single-photon detector |
| ASPK | Automatic spark chambers |
| ASTE | ASTERIX detector at LEAR |
| ASTR | Astronomy |
| ATLS | ATLAS detector at CERN LHC |
| AUGE | Pierre Auger Observatory |
| AURG | Resonant-mass gravitational wave AURIGA detector |
| B787 | BNL experiment 787 detector |
| B791 | BNL experiment 791 detector |
| B845 | BNL experiment 845 detector |
| B852 | BNL E-852 |
| B865 | BNL E865 detector |
| B871 | BNL experiment 871 detector |
| B949 | BNL E949 detector at AGS |
| BABR | BaBar Collab. |
| BAIK | Lake Baikal neutrino telescope |
| BAKS | Baksan underground scintillation telescope |
| BC | Bubble chamber |
| BDMP | Beam dump |
| BEAT | CERN BEATRICE Collab. |
| BEBC | Big European bubble chamber at CERN |
| BELL | Belle Collab. |
| BES | BES Beijing Spectrometer at Beijing Electron-Positron Collider |
| BES2 | BES Beijing Spectrometer at Beijing Electron-Positron Collider |
| BES3 | BES Beijing Spectrometer at Beijing Electron-Positron Collider |
| BIS2 | BIS-2 spectrometer at Serpukhov |
| BKEI | BENKEI spectrometer system at KEK Proton Synchroton |
| BOLO | Bolometer, a cryogenic thermal detector |
| BONA | Bonanza nonmagnetic detector at DORIS |
| BORX | BOREXINO |
| BPWA | Barrelet-zero partial-wave analysis |
| C100 | COSINE-100 experiment in South Korea |
| CALO | Calorimeter |
| CAST | CAST experiment at CERN |
| CBAL | Crystal Ball detector at SLAC-SPEAR or DORIS |
| CBAR | Crystal Barrel detector at CERN-LEAR |
| CBOX | Crystal Box at LAMPF |
| CBTP | CBELSA/TAPS Collaboration |
| CC | Cloud chamber |
| CCFR | Columbia-Chicago-Fermilab-Rochester detector |
| CDEX | China Dark Matter Experiment |
| CDF | Collider detector at Fermilab |
| CDF2 | CDF-II Collab. |
| CDHS | CDHS neutrino detector at CERN |
| CDM2 | CDMS II, Cryogenic Dark Matter Search at Soudan Underground Lab. |
| CDMS | CDMS Collaboration |
| CELL | CELLO detector at DESY |
| CGNT | CoGeNT dark matter search experiment |
| CHER | Cherenkov detector |
| CHM2 | CHARM-II neutrino detector (glass) at CERN |
| CHOZ | Nuclear Power Station near Chooz, France |
| CHRM | CHARM neutrino detector (marble) at CERN |
| CHRS | CHORUS Collaboration – CERNS SPS |
| CIB | Cosmic Infrared Background |
| CIBS | CERN-IHEP boson spectrometer |
| CLAS | Jefferson CLAS Collab. |
| CLE2 | CLEO II detector at CESR |
| CLE3 | CLEO III detector at CESR |
| CLEC | CLEO-c detector at CESR |
| CLEO | Cornell magnetic detector at CESR |
| CMB | Cosmic Microwave Background |
| CMD | Cryogenic magnetic detector at VEPP-2M, Novosibirsk |
| CMD2 | Cryogenic magnetic detector 2 at VEPP-2M, Novosibirsk |
| CMD3 | Cryogenic magnetic detector 3 at VEPP-2000, Novosibirsk |
| CMS | CMS detector at CERN LHC |
| CNTR | Counters |
| COMB | Combined analysis of data from independent experiments. |
| COMP | COMPASS experiment at the CERN SPS |
| COSM | Cosmology and astrophysics |
| COSY | COSY-TOF Collaboration |
| COUP | COUPP (the Chicagoland Observatory for Underground Particle Physics) Collab. |
| CPLR | CPLEAR Collaboration |
| CRBT | Crystal Ball and TAPS detector at MAMI |
| CRES | CRESST cryogenic detector |
| CRYB | Crystal Ball at BNL |
| CRYM | Crystal Ball detector at Mainz Microtron MAMI |
| CSB2 | Columbia U. - Stony Brook BGO calorimeter inserted in NaI array |
| CSME | COSME Collaboration |
| CUOR | CUORICINO experiment at Gran Sasso Laboratory. |
| CUSB | Columbia U. - Stony Brook segmented NaI detector at CESR |
| D0 | D0 detector at Fermilab Tevatron Collider |
| DAMA | DAMA, dark matter detector at Gran Sasso National Lab. |
| DASP | DESY double-arm spectrometer |
| DAYA | Daya Bay Collaboration |
| DBC | Deuterium bubble chamber |
| DCHZ | Double Chooz Collaboration |
| DEAP | DEAP-3600 DM search with argon at SNOLAB |
| DISP | Graviton mass measurement based on dispersion measure |
| DLCO | DELCO detector at SLAC-SPEAR or SLAC-PEP |
| DLPH | DELPHI detector at LEP |
| DM1 | Magnetic detector no. 1 at Orsay DCI collider |
| DM2 | Magnetic detector no. 2 at Orsay DCI collider |
| DMIC | DAMIC Dark Matter in CCD experiment at Fermilab |
| DMTP | Dark Matter Time Projection Chamber (DMTPC) directional detection experiment |
| DONU | DONUT Collab. |
| DPWA | Energy-dependent partial-wave analysis |
| DRFT | Directional dark matter detector at Boulby Underground Science Facility |
| DS50 | DarkSide-50 Liquid Argon TPC at Gran Sasso National Laboratory |
| E137 | SLAC E137 beam-dump experiment |
| E621 | Fermilab E621 detector |
| E653 | Fermilab E653 detector |
| E665 | Fermilab E665 detector |
| E687 | Fermilab E687 detector |
| E691 | Fermilab E691 detector |
| E705 | Fermilab E705 Spectrometer-Calorimeter |
| E731 | Fermilab E731 Spectrometer-Calorimeter |
| E756 | Fermilab E756 detector |
| E760 | Fermilab E760 detector |
| E761 | Fermilab E761 detector |
| E771 | Fermilab E771 detector |
| E773 | Fermilab E773 Spectrometer-Calorimeter |
| E789 | Fermilab E789 detector |
| E791 | Fermilab E791 detector |
| E799 | Fermilab E799 Spectrometer-Calorimeter |
| E835 | Fermilab E835 detector |
| EDE2 | EDELWEISS II dark matter search Collaboration |
| EDE3 | EDELWEISS III dark matter search Collaboration |
| EDEL | EDELWEISS dark matter search Collaboration |
| EHS | Four-pi detector at CERN |

# Abbreviations Used in the Particle Listings

ELEC Electronic combination
EMC European muon collaboration detector at CERN
EMUL Emulsions
ESR Electron spin resonance spectroscopy
FAST Fiber Active Scintillator Target detector at PSI
FBC Freon bubble chamber
FENI FENICE (at the ADONE collider of Frascati)
FIT Fit to previously existing data
FLAT Large Area Telescope onboard the Fermi Gamma-Ray Space Telescope (Fermi-LAT)
FMPS Fermilab Multiparticle Spectrometer
FOCS FNAL E831 FOCUS Collab.
FRAB ADONE $B\overline{B}$ group detector
FRAG ADONE $\gamma\gamma$ group detector
FRAM ADONE MEA group detector
FREJ FREJUS Collaboration – modular flash chamber detector (calorimeter)
GA24 Hodoscope Cherenkov $\gamma$ calorimeter (IHEP GAMS-2000) (CERN GAMS-4000)
GALX GALLEX solar neutrino detector in the Gran Sasso Underground Lab.
GAM2 IHEP hodoscope Cherenkov $\gamma$ calorimeter GAMS-2000
GAM4 CERN hodoscope Cherenkov $\gamma$ calorimeter GAMS-4000
GAMS IHEP hodoscope Cherenkov $\gamma$ calorimeter GAMS-4$\pi$
GNO Gallium Neutrino Observatory in the Gran Sasso Underground Lab.
GOLI CERN Goliath spectrometer
GRAL GRAAL Collaboration
H1 H1 detector at DESY/HERA
HAWC High Altitude Water Cherenkov Observatory experiment at Sierra Negra, Mexico
HBC Hydrogen bubble chamber
HDBC Hydrogen and deuterium bubble chambers
HDES HADES Collaboration at GSI in Darmstadt
HDMO Heidelberg-Moscow Experiment
HDMS Heidelberg Dark Matter Search Experiment
HEBC Helium bubble chamber
HEPT Helium proportional tubes
HERA H1 and ZEUS Collaborations at DESY/HERA
HERB HERA-B detector at DESY/HERA
HERM HERMES detector at DESY/HERA
HESS High Energy Stereoscopic System gamma-ray instrument
HFS Hyperfine structure
HLBC Heavy-liquid bubble chamber
HOME Homestake underground scintillation detector
HPGE High-purity Germanium detector
HPS Heavy Photon Search experiment at JLAB
HPW Harvard-Pennsylvania-Wisconsin detector
HRS SLAC high-resolution spectrometer
HYBR Hybrid: bubble chamber + electronics
HYCP HyperCP Collab. (FNAL E-871)
HYST HAYSTAC axion search experiment
IACT Imaging Air Cherenkov Telescope
ICAR ICARUS experiment at Gran Sasso Laboratory.
ICCB IceCube neutrino detector at South Pole
IGEX IGEX Collab.
IMB Irvine-Michigan-Brookhaven underground Cherenkov detector
IMB3 Irvine-Michigan-Brookhaven underground Cherenkov detector
INDU Magnetic induction
IPWA Energy-independent partial-wave analysis
ISTR IHEP ISTRA+ spectrometer-calorimeter
JADE JADE detector at DESY
JPAC Joint Physics Analysis Center (JPAC) Collaboration
K246 KEK E246 detector with polarimeter
K2K KEK to Super-Kamiokande
K391 KEK E391a detector
K470 KEK-E470 Stopping K detector
KAM2 KAMIOKANDE-II underground Cherenkov detector
KAMI KAMIOKANDE underground Cherenkov detector
KAR2 KARMEN2 calorimeter at the ISIS neutron spallation source at Rutherford
KARM KARMEN calorimeter at the ISIS neutron spallation source at Rutherford
KEDR detector operating at VEPP-4M collider (Novosibirsk)
KIMS Korea Invisible Mass Search experiment at YangYang, Korea
KLND KamLand Collab. (Japan)
KLOE KLOE detector at DAFNE (the Frascati e+e- collider Italy)
KOLR Kolar Gold Field underground detector
KOTO KOTO experiment with $K_L^0$ beam at J-PARC
KTEV KTeV Collaboration
L3 L3 detector at LEP
LASR Laser
LASS Large-angle superconducting solenoid spectrometer at SLAC
LATT Lattice calculations
LEBC Little European bubble chamber at CERN
LEGS BNL LEGS Collab.
LENA Nonmagnetic lead-glass NaI detector at DORIS
LEP From combination of all 4 LEP experiments: ALEPH, DELPHI, L3, OPAL
LEPS Low-Energy Pion Spectrometer at the Paul Scherrer Institute
LGW Lead Glass Wall collaboration at SPEAR/SLAC
LHC Combined analysis of LHC experiments
LHCB LHCb detector at CERN LHC
L+P Multichannel L + P model fit
LSD Mont Blanc liquid scintillator detector
LSND Liquid Scintillator Neutrino Detector
LSW Light Shining through a Wall
LUX Large Underground Xenon experiment at SURF
MAC MAC detector at PEP/SLAC
MAJD Majorana Demonstrator experiment at SURF
MBNE Fermilab MiniBooNE neutrino experiment
MBR Molecular beam resonance technique
MCRO MACRO detector in Gran Sasso
MD1 Magnetic detector at VEPP-4, Novosibirsk
MDRP Millikan drop measurement
MEG Muon to electron conversion detector at PSI
MGFL MAGIC and Fermi-LAT Collaborations
MGIC MAGIC Telescopes gamma-ray observatory
MICA Underground mica deposits
MICR MICROSCOPE satellite test of weak equivalence principle
MINS Fermilab MINOS experiment
MIRA MIRABELLE Liquid-hydrogen bubble chamber
MLEV Magnetic levitation
MLS Modified Laurent Series
MMS Missing mass spectrometer
MOED MoEDAL magnetic monopoles search experiment at LHC
MPS Multiparticle spectrometer at BNL
MPS2 Multiparticle spectrometer upgrade at BNL
MPSF Multiparticle spectrometer at Fermilab
MPWA Model-dependent partial-wave analysis
MRK1 SLAC Mark-I detector
MRK2 SLAC Mark-II detector
MRK3 SLAC Mark-III detector
MRKJ Mark-J detector at DESY
MRS Magnetic resonance spectrometer
MUG2 Muon (g-2)
MWPC Multi-Wire Proportional Chamber
NA14 CERN NA14
NA31 CERN NA31 Spectrometer-Calorimeter
NA32 CERN NA32 Spectrometer
NA48 CERN NA48 Collaboration
NA49 CERN NA49 Collaboration
NA60 CERN NA60 Collaboration
NA62 CERN NA62 Experiment
NA64 CERN SPS NA64 Experiment
NAGE NEWAGE, New generation WIMP-search experiment with advanced gaseous tracking
NAIA NAIAD (NaI Advanced Detector) dark matter search experiment
ND NaI detector at VEPP-2M, Novosibirsk
NEOS NEOS Collaboration
NEWS NEWS-G direct dark matter search at LSM
NICE Serpukhov nonmagnetic precision spectrometer
NMR Nuclear magnetic resonance
NOMD NOMAD Collaboration, CERN SPS
NOVA NOvA experiment with Fermilab's NuMI neutrino beam
NTEV NuTeV Collab. at Fermilab
nTRV neutron Time-Reversal Violation
NUSX Mont Blanc NUSEX underground detector
OBLX OBELIX detector at LEAR
OKA OKA collaboration at U70 accelerator in Protvino, Russia
OLYA Detector at VEPP-2M and VEPP-4, Novosibirsk
OMEG CERN OMEGA spectrometer
OPAL OPAL detector at LEP
OPER OPERA experiment with emulsion tracking at Gran Sasso

| | |
|---|---|
| OSPK | Optical spark chamber |
| PIBE | The PIBETA detector at the Paul Scherrer Institute (PSI), Switzerland. |
| PICA | PICASSO dark matter search experiment |
| PICO | PICO bubble chamber experiment in SNOLAB underground laboratory |
| PIE3 | $\pi$E3 beam-line of Paul Scherrer Institute |
| PLAS | Plastic detector |
| PLUT | DESY PLUTO detector |
| PMLA | PAMELA space spectrometer on Resurs-DK1 satellite |
| PNDX | PandaX dual-phase liquid xenon dark matter experiment at Jin-Ping |
| PPTA | Parkes Pulsar Timing Array |
| PRMX | The PRIMEX detector in Hall B at TJNAF |
| PWA | Partial-wave analysis |
| QUAX | QUAX axion search experiment |
| RDK2 | NIST rare radioactive decay experiment |
| REDE | Resonance depolarization |
| RENO | RENO Collaboration |
| RICE | Radio Ice Cherenkov Experiment |
| RVUE | Review of previous data |
| SAGE | US - Russian Gallium Experiment |
| SCDM | SuperCDMS experiment at Soudan Underground Lab. |
| SELX | FNAL SELEX Collab. |
| SENS | Sub-Electron-Noise Skipper CCD Experimental Instrument (SENSEI) |
| SFM | CERN split-field magnet |
| SHF | SLAC Hybrid Facility Photon Collaboration |
| SHUK | SHUKET: search for U(1) dark matter with an electromagnetic telescope |
| SIGM | Serpukhov CERN-IHEP magnetic spectrometer (SIGMA) |
| SILI | Silicon detector |
| SIMP | SIMPLE, dark matter detector at Laboratori Nazionali del Sud |
| SKAM | Super-Kamiokande Collab. |
| SLAX | Solar Axion Experiment in Canfranc Underground Laboratory |
| SLD | SLC Large Detector for $e^+ e^-$ colliding beams at SLAC |
| SMPL | SIMPLE, Superheated Instrument for Massive ParticLe Experiments |
| SND | Novosibirisk Spherical neutral detector at VEPP-2M |
| SNDR | SINDRUM spectrometer at PSI |
| SNO | SNO Collaboration (Sudbury Neutrino Observatory) |
| SNO+ | SNO+ Collaboration (Sudbury Neutrino Observatory) |
| SOU2 | Soudan 2 underground detector |
| SOUD | Soudan underground detector |
| SPEC | Spectrometer |
| SPED | From maximum of speed plot or resonant amplitude |
| SPHR | Bonn SAPHIR Collab. |
| SPNX | SPHINX spectrometer at IHEP accelerator |
| SPRK | Spark chamber |
| SQID | SQUID device |
| STRC | Streamer chamber |
| SVD2 | SVD-2 experiment at IHEP, Protvino |
| T2K | T2K Collaboration |
| TASS | DESY TASSO detector |
| TEVA | Combined analysis of CDF and DØ experiments |
| TEXO | TEXONO Collab., ultra low energy Ge detector at Kuo-Sheng Laboratory |
| THEO | Theoretical or heavily model-dependent result |
| TNF | TNF-IHEP facility at 70 GeV IHEP accelerator |
| TOF | Time-of-flight |
| TOPZ | TOPAZ detector at KEK-TRISTAN |
| TPC | TPC detector at PEP/SLAC |
| TPS | Tagged photon spectrometer at Fermilab |
| TRAP | Penning trap |
| TWST | TWIST spectrometer at TRIUMF |
| UA1 | UA1 detector at CERN |
| UA2 | UA2 detector at CERN |
| UA5 | UA5 detector at CERN |
| UCNA | UCNA collaboration using polarizeed ultracold neutrons at LANSCE |
| UKDM | UK Dark Matter Collab. |
| VES | Vertex Spectrometer Facility at 70 GeV IHEP accelerator |
| VLBI | Very Long Baseline Interferometer |
| VNS | VENUS detector at KEK-TRISTAN |
| VRTS | Very Energetic Radiation Imaging Telescope Array System (VERITAS) |
| WA75 | CERN WA75 experiment |
| WA82 | CERN WA82 experiment |
| WA89 | CERN WA89 experiment |
| WARP | Liquid argon detector for CDM searches at Gran Sasso |
| WASA | WASA detector at CELSIUS, Uppsala and at COSY, Juelich |
| WDMX | WISP Dark Matter eXperiment (WISPDMX) for direct hidden photon search |
| WIRE | Wire chamber |
| X100 | XENON100 dark matter search experiment at Gran Sasso National Laboratory |
| XE10 | XENON10 experiment at Gran Sasso National Laboratory |
| XE1T | XENON1T dark matter search experiment at Gran Sasso National Laboratory |
| XEBC | Xenon bubble chamber |
| XMAS | XMASS, liquid xenon scintillation detector at Kamioka Observatory |
| YUKA | Graviton mass measurement based on Yukawa potential |
| ZEP2 | ZEPLIN-II dark matter detector |
| ZEP3 | ZEPLIN-III dark matter detector at Palmer Underground Lab. |
| ZEPL | ZEPLIN-I galactic dark matter detector |
| ZEUS | ZEUS detector at DESY/HERA |

### Conferences

Conferences are generally referred to by the location at which they were held (e.g., HAMBURG, TORONTO, CORNELL, BRIGHTON, etc.).

### Journals

| | |
|---|---|
| AA | Astronomy and Astrophysics |
| ADVP | Advances in Physics |
| AFIS | Anales de Fisica |
| AJP | American Journal of Physics |
| AL | Astronomy Letters |
| ANP | Annals of Physics |
| ANPL | Annals of Physics (Leipzig) |
| ANYAS | Annals of the New York Academy of Sciences |
| AP | Atomic Physics |
| APAH | Acta Physica Academiae Scientiarum Hungaricae |
| APJ | Astrophysical Journal |
| APJS | Astrophysical Journal Suppl. |
| APP | Acta Physica Polonica |
| APS | Acta Physica Slovaca |
| ARNPS | Annual Review of Nuclear and Particle Science |
| ARNS | Annual Review of Nuclear Science |
| ASP | Astroparticle Physics |
| AST | American Statistician |
| BAPS | Bulletin of the American Physical Society |
| BASUP | Bulletin of the Academy of Science, USSR (Physics) |
| CJNP | Chinese Journal of Nuclear Physics |
| CJP | Canadian Journal of Physics |
| CNPP | Comments on Nuclear and Particle Physics |
| CP | Chinese Physics |
| CPC | Chinese Physics C |
| CTP | Communications in Theoretical Physics |

# GAUGE AND HIGGS BOSONS

## $\gamma$ (photon)

$I(J^{PC}) = 0,1(1^{--})$

### $\gamma$ MASS

Results prior to 2008 are critiqued in GOLDHABER 10. All experimental results published prior to 2005 are summarized in detail by TU 05.

The following conversions are useful: 1 eV = $1.783 \times 10^{-33}$ g = $1.957 \times 10^{-6}$ $m_e$; $\lambda\!\!\!^{-}_C = (1.973 \times 10^{-7}$ m)$\times$(1 eV/$m_\gamma$).

| VALUE (eV) | CL% | DOCUMENT ID | | COMMENT |
|---|---|---|---|---|

| $<2.3 \times 10^{-15}$ | | GOLDHABER | 68 | Satellite data |

[1] RYUTOV 07 extends the method of RYUTOV 97 to the radius of Pluto's orbit.

[2] BONETTI 17 uses frequency-dependent time delays of repeating FRB with well-determined redshift, assuming the DM is caused by expected dispersion in IGM. There are several uncertainties, leading to mass limit $2.2 \times 10^{-14}$ eV.

[3] BONETTI 16 uses frequency-dependent time delays of FRB, assuming the DM is caused by expected dispersion in IGM. There are several uncertainties, leading to mass limit $1.8 \times 10^{-14}$ eV, if indeed the FRB is at the initially reported redshift.

[4] RETINO 16 looks for deviations from Ampere's law in the solar wind, using Cluster four spacecraft data. Authors quote a range of limits from $1.9 \times 10^{-15}$ eV to $7.9 \times 10^{-14}$ eV depending on the assumptions of the vector potential from the interplanetary magnetic field.

[5] EGOROV 14 studies chromatic dispersion of lensed quasar positions ("gravitational rainbows") that could be produced by any of several mechanisms, among them via photon mass. Limit not competitive but obtained on cosmological distance scales.

[6] ACCIOLY 10 limits come from possible alterations of anomalous magnetic moment of electron and gravitational deflection of electromagnetic radiation. Reported limits are not "claimed" by the authors and in any case are not competitive.

[7] When trying to measure $m$ one must distinguish between measurements performed on large and small scales. If the photon acquires mass by the Higgs mechanism, the large-scale behavior of the photon might be effectively Maxwellian. If, on the other hand, one postulates the Proca regime for all scales, the very existence of the galactic field implies $m < 10^{-26}$ eV, as correctly calculated by YAMAGUCHI 59 and CHIBISOV 76.

[8] TU 06 continues the work of LUO 03, with extended LAKES 98 method, reporting the improved limit $\mu^2 A = (0.7 \pm 1.7) \times 10^{-13}$ T/m if $A = 0.2$ $\mu$G out to $4 \times 10^{22}$ m. Reported result $\mu = (0.9 \pm 1.5) \times 10^{-52}$ g reduces to the frequentist mass limit $1.2 \times 10^{-19}$ eV (FELDMAN 98).

[9] FULLEKRUG 04 adopted KROLL 71A method with newer and better Schumann resonance data. Result questionable because assumed frequency shift with photon mass is assumed to be linear. It is quadratic according to theorem by GOLDHABER 71B, KROLL 71, and PARK 71.

[10] LUO 03 extends LAKES 98 technique to set a limit on $\mu^2 A$, where $\mu^{-1}$ is the Compton wavelength $\lambda\!\!\!^{-}_C$ of the massive photon and $A$ is the ambient vector potential. The important departure is that the apparatus rotates, removing sensitivity to the direction of $A$. They take $A = 10^{12}$ Tm, due to "cluster level fields." But see comment of GOLDHABER 03 and reply by LUO 03B.

[11] LAKES 98 reports limits on torque on a toroid Cavendish balance, obtaining a limit on $\mu^2 A < 2 \times 10^{-9}$ Tm/m$^2$ via the Maxwell-Proca equations, where $\mu^{-1}$ is the characteristic length associated with the photon mass and $A$ is the ambient vector potential in the Lorentz gauge. Assuming $A \approx 1 \times 10^{12}$ Tm due to cluster fields he obtains $\mu^{-1} > 2 \times 10^{10}$ m, corresponding to $\mu < 1 \times 10^{-17}$ eV. A more conservative limit, using $A \approx (1$ $\mu$G)$\times$(600 pc) based on the galactic field, is $\mu^{-1} > 1 \times 10^{9}$ m or $\mu < 2 \times 10^{-16}$ eV.

[12] RYUTOV 97 uses a magnetohydrodynamics argument concerning survival of the Sun's field to the radius of the Earth's orbit. "To reconcile observations to theory, one has to reduce [the photon mass] by approximately an order of magnitude compared with" per DAVIS 75. "Secure limit, best by this method" (per GOLDHABER 10).

[13] FISCHBACH 94 analysis is based on terrestrial magnetic fields; approach analogous to DAVIS 75. Similar result based on a much smaller planet probably follows from more precise $B$ field mapping. "Secure limit, best by this method" (per GOLDHABER 10).

[14] CHERNIKOV 92, motivated by possibility that photon exhibits mass only below some unknown critical temperature, searches for departure from Ampere's Law at 1.24 K. See also RYAN 85.

[15] RYAN 85, motivated by possibility that photon exhibits mass only below some unknown critical temperature, sets mass limit at $< (1.5 \pm 1.4) \times 10^{-42}$ g based on Coulomb's Law departure limit at 1.36 K. We report the result as frequentist 90% CL (FELDMAN 98).

[16] CHIBISOV 76 depends in critical way on assumptions such as applicability of virial theorem. Some of the arguments given only in unpublished references.

[17] DAVIS 75 analysis of Pioneer-10 data on Jupiter's magnetic field. "Secure limit, best by this method" (per GOLDHABER 10).

[18] FRANKEN 71 method is of dubious validity (KROLL 71A, JACKSON 99, GOLDHABER 10, and references therein).

[19] KROLL 71A used low frequency Schumann resonances in cavity between the conducting earth and resistive ionosphere, overcoming objections to resonant-cavity methods (JACKSON 99, GOLDHABER 10, and references therein). "Secure limit, best by this method" (per GOLDHABER 10).

[20] WILLIAMS 71 is landmark test of Coulomb's law. "Secure limit, best by this method" (per GOLDHABER 10).

### $\gamma$ CHARGE

OKUN 06 has argued that schemes in which all photons are charged are inconsistent. He says that if a neutral photon is also admitted to avoid this problem, then other problems emerge, such as those connected with the emission and absorption of charged photons by charged particles. He concludes that in the absence of a self-consistent phenomenological basis, interpretation of experimental data is at best difficult.

| VALUE (e) | CHARGE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **<1 $\times 10^{-46}$** | **mixed** | [1] ALTSCHUL | 07B | VLBI | Aharonov-Bohm effect |
| **<1 $\times 10^{-35}$** | **single** | [2] CAPRINI | 05 | CMB | Isotropy constraint |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| $<1 \times 10^{-32}$ | single | [1] ALTSCHUL | 07B | VLBI | Aharonov-Bohm effect |
| $<3 \times 10^{-33}$ | mixed | [3] KOBYCHEV | 05 | VLBI | Smear as function of B·$E_\gamma$ |
| $<4 \times 10^{-31}$ | single | [3] KOBYCHEV | 05 | VLBI | Deflection as function of B·$E_\gamma$ |
| $<8.5 \times 10^{-17}$ | | [4] SEMERTZIDIS | 03 | | Laser light deflection in B-field |
| $<3 \times 10^{-28}$ | single | [5] SIVARAM | 95 | CMB | For $\Omega_M = 0.3$, $h^2 = 0.5$ |
| $<5 \times 10^{-30}$ | | [6] RAFFELT | 94 | TOF | Pulsar $f_1 - f_2$ |
| $<2 \times 10^{-28}$ | | [7] COCCONI | 92 | | VLBA radio telescope resolution |
| $<2 \times 10^{-32}$ | | COCCONI | 88 | TOF | Pulsar $f_1 - f_2$ TOF |

[1] ALTSCHUL 07B looks for Aharonov-Bohm phase shift in addition to geometric phase shift in radio interference fringes (VSOP mission).

[2] CAPRINI 05 uses isotropy of the cosmic microwave background to place stringent limits on possible charge asymmetry of the Universe. Charge limits are set on the photon, neutrino, and dark matter particles. Valid if charge asymmetries produced by different particles are not anticorrelated.

[3] KOBYCHEV 05 considers a variety of observable effects of photon charge for extragalactic compact radio sources. Best limits if source observed through a foreground cluster of galaxies.

[4] SEMERTZIDIS 03 reports the first laboratory limit on the photon charge in the last 30 years. Straightforward improvements in the apparatus could attain a sensitivity of $10^{-20}$ e.

[5] SIVARAM 95 requires that CMB photon charge density not overwhelm gravity. Result scales as $\Omega_M h^2$.

[6] RAFFELT 94 notes that COCCONI 88 neglects the fact that the time delay due to dispersion by free electrons in the interstellar medium has the same photon energy dependence as that due to bending of a charged photon in the magnetic field. His limit is based on the assumption that the entire observed dispersion is due to photon charge. It is a factor of 200 less stringent than the COCCONI 88 limit.

[7] See COCCONI 92 for less stringent limits in other frequency ranges. Also see RAFFELT 94 note.

## graviton

$J = 2$

### graviton MASS

Van Dam and Veltman (VANDAM 70), Iwasaki (IWASAKI 70), and Zakharov (ZAKHAROV 70) almost simultanously showed that "... there is a discrete difference between the theory with zero-mass and a theory with finite mass, no matter how small as compared to all external momenta." The resolution of this "vDVZ discontinuity" has to do with whether the linear approximation is valid. De Rham *et al.* (DE-RHAM 11) have shown that nonlinear effects not captured in their linear treatment can give rise to a screening mechanism, allowing for massive gravity theories. See also GOLDHABER 10 and DE-RHAM 17 and references therein. Experimental limits have been set based on a Yukawa potential or signal dispersion. $h_0$ is the Hubble constant in units of 100 km s$^{-1}$ Mpc$^{-1}$.

The following conversions are useful: 1 eV = $1.783 \times 10^{-33}$ g = $1.957 \times 10^{-6}$ $m_e$; $\lambda_C = (1.973 \times 10^{-7}$ m$) \times (1$ eV$/m_g)$.

[1] CHOUDHURY 04 concludes from a study of weak-lensing data that masses heavier than about the inverse of 100 Mpc seem to be ruled out if the gravitation field has the Yukawa form.

[2] DESAI 18 limit based on dynamical mass models of galaxy cluster Abell 1689.

[3] GUPTA 18 obtains graviton mass limits using stacked clusters from 3 disparate surveys.

[4] RANA 18 limit, 68% CL, obtained using weak lensing mass profiles out to the radius at which the cluster density falls to 200 times the critical density of the Universe. Limit is based on the fractional change between Newtonian and Yukawa accelerations for the 50 most massive galaxy clusters in the Local Cluster Substructure Survey. Limits for other CL's and other density cuts are also given.

[5] RANA 18 limit, 68% CL, obtained using mass measurements via the SZ effect out to the radius at which the cluster density falls to 500 times the critical density of the Universe for 182 optically confirmed galaxy clusters in an Altacama Cosmology Telescope survey. Limits for other CL's and other density cuts are also given.

[6] ABBOTT 16 and ABBOTT 17 assumed a dispersion relation for gravitational waves modified relative to GR.

[7] ZAKHAROV 16 constrains range of Yukawa gravity interaction from S2 star orbit about black hole at Galactic center. The limit is $< 2.9 \times 10^{-21}$ eV for $\delta = 100$.

[8] BRITO 13 explore massive graviton (spin-2) fluctuations around rotating black holes.

[9] BASKARAN 08 consider fluctuations in pulsar timing due to photon interactions ("surfing") with background gravitational waves.

[10] GRUZINOV 05 uses the DGP model (DVALI 00) showing that non-perturbative effects restore continuity with Einstein's equations as the gravition mass approaches 0, then bases his limit on Solar System observations.

[11] GERSHTEIN 04 use non-Einstein field relativistic theory of gravity (RTG), with a massive graviton, to obtain the 95% CL mass limit implied by the value of $\Omega_{tot} = 1.02 \pm 0.02$ current at the time of publication.

[12] DVALI 03 suggest scale of horizon distance via DGP model (DVALI 00). For a horizon distance of $3 \times 10^{26}$ m (about age of Universe/$c$; GOLDHABER 10) this graviton mass limit is implied.

[13] FINN 02 analyze the orbital decay rates of PSR B1913+16 and PSR B1534+12 with a possible graviton mass as a parameter. The combined frequentist mass limit is at 90%CL.

[14] As of 2014, limits on dP/dt are now about 0.1% (see T. Damour, "Experimental tests of gravitational theory," in this *Review*).

[15] DAMOUR 91 is an analysis of the orbital period change in binary pulsar PSR 1913+16, and confirms the general relativity prediction to 0.8%. "The theoretical importance of the [rate of orbital period decay] measurement has long been recognized as a direct confirmation that the gravitational interaction propagates with velocity $c$ (which is the immediate cause of the appearance of a damping force in the binary pulsar system) and thereby as a test of the existence of gravitational radiation and of its quadrupolar nature." TAYLOR 93 adds that orbital parameter studies now agree with general relativity to 0.5%, and set limits on the level of scalar contribution in the context of a family of tensor [spin 2]-biscalar theories.

## $W$

$J = 1$

**See the related review(s):**
Mass and Width of the $W$ Boson

### $W$ MASS

The $W$-mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass-dependent width. To obtain the world average, common systematic uncertainties between experiments are properly taken into account. The LEP-2 average $W$ mass based on published results is 80.376 ± 0.033 GeV [SCHAEL 13A]. The combined Tevatron data yields an average $W$ mass of 80.387 ± 0.016 GeV [AALTONEN 13N]. A combination of the LEP average with this Tevatron average and the ATLAS value [AABOUD 18J], assuming a common systematic error of 7 MeV between the latter two [Jens Erler, 52nd Rencontres de Moriond

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

EW, March 2017], the world average $W$ mass of 80.379 ± 0.012 GeV is obtained. OUR FIT quotes this value for the $W$ mass.

[1] AABOUD 18J select 4.61M $W^+ \to \mu^+\nu_\mu$, 3.40M $W^+ \to e^+\nu_e$, 3.23M $W^- \to \mu^-\overline{\nu}_\mu$ and 2.49M $W^- \to e^-\overline{\nu}_e$ events in 4.6 fb$^{-1}$ $pp$ data at 7 TeV. The $W$ mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations. The systematic error includes 0.011 GeV experimental and 0.014 GeV modelling uncertainties.

[2] ABAZOV 14N is a combination of ABAZOV 09AB and ABAZOV 12F, also giving more details on the analysis.

[3] AALTONEN 12E select 470k $W \to e\nu$ decays and 625k $W \to \mu\nu$ decays in 2.2 fb$^{-1}$ of Run-II data. The mass is determined using the transverse mass, transverse lepton momentum and transverse missing energy distributions, accounting for correlations. This result supersedes AALTONEN 07F. AALTONEN 14D gives more details on the procedures followed by the authors.

[4] ABDALLAH 08A use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu$ and $W^+W^- \to q\overline{q}q\overline{q}$ events for energies 172 GeV and above. The $W$ mass was also extracted from the dependence of the $WW$ cross section close to the production threshold and combined appropriately to obtain the final result. The systematic error includes ±0.025 GeV due to final state interactions and ±0.009 GeV due to LEP energy uncertainty.

[5] ABBIENDI 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The result quoted here is obtained combining this mass value with the results using $W^+W^- \to \ell\nu_\ell\ell'\nu_{\ell'}$ events in the energy range 183–207 GeV (ABBIENDI 03C) and the dependence of the $WW$ production cross-section on $m_W$ at threshold. The systematic error includes ±0.009 GeV due to the uncertainty on the LEP beam energy.

[6] ACHARD 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events in the C.M. energy range 189–209 GeV. The result quoted here is obtained combining this mass value with the results obtained from a direct $W$ mass reconstruction at 172 and 183 GeV and with those from the dependence of the $WW$ production cross-section on $m_W$ at 161 and 172 GeV (ACCIARRI 99).

[7] SCHAEL 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events in the C.M. energy range 183–209 GeV. The result quoted here is obtained combining this mass value with those obtained from the dependence of the $W$ pair production cross-section on $m_W$ at 161 and 172 GeV (BARATE 97 and BARATE 97S respectively). The systematic error includes ±0.009 GeV due to possible effects of final state interactions in the $q\overline{q}q\overline{q}$ channel and ±0.009 GeV due to the uncertainty on the LEP beam energy.

[8] ABAZOV 02D improve the measurement of the $W$-boson mass including $W \to e\nu_e$ events in which the electron is close to a boundary of a central electromagnetic calorimeter module. Properly combining the results obtained by fitting $m_T(W)$, $p_T(e)$, and $p_T(\nu)$, this sample provides a mass value of 80.574 ± 0.405 GeV. The value reported here is a combination of this measurement with all previous DØ $W$-boson mass measurements.

[9] AFFOLDER 01E fit the transverse mass spectrum of 30115 $W \to e\nu_e$ events ($M_W$= 80.473 ± 0.065 ± 0.092 GeV) and of 14740 $W \to \mu\nu_\mu$ events ($M_W$= 80.465 ± 0.100 ± 0.103 GeV) obtained in the run IB (1994–95). Combining the electron and muon results, accounting for correlated uncertainties, yields $M_W$= 80.470 ± 0.089 GeV. They combine this value with their measurement of ABE 95P reported in run IA (1992–93) to obtain the quoted value.

[10] ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic $e^+p$ and $e^-p$ neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.

[11] ABAZOV 12F select 1677k $W \to e\nu$ decays in 4.3 fb$^{-1}$ of Run-II data. The mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations.

[12] ABAZOV 09AB study the transverse mass, transverse electron momentum, and transverse missing energy in a sample of 0.5 million $W \to e\nu$ decays selected in Run-II data. The quoted result combines all three methods, accounting for correlations.

[13] AALTONEN 07F obtain high purity $W \to e\nu_e$ and $W \to \mu\nu_\mu$ candidate samples totaling 63,964 and 51,128 events respectively. The $W$ mass value quoted above is derived by simultaneously fitting the transverse mass and the lepton, and neutrino $p_T$ distributions.

[14] AKTAS 06 fit the $Q^2$ dependence ($300 < Q^2 < 30{,}000$ GeV$^2$) of the charged-current differential cross section with a propagator mass. The first error is experimental and the second corresponds to uncertainties due to input parameters and model assumptions.

[15] CHEKANOV 02C fit the $Q^2$ dependence ($200 < Q^2 < 60000$ GeV$^2$) of the charged-current differential cross sections with a propagator mass fit. The last error is due to the uncertainty on the probability density functions.

[16] BREITWEG 00D fit the $Q^2$ dependence ($200 < Q^2 < 22500$ GeV$^2$) of the charged-current differential cross sections with a propagator mass fit. The last error is due to the uncertainty on the probability density functions.

[17] ALITTI 92B result has two contributions to the systematic error (±0.83); one (±0.81) cancels in $m_W/m_Z$ and one (±0.17) is noncancelling. These were added in quadrature. We choose the ALITTI 92B value without using the LEP $m_Z$ value, because we perform our own combined fit.

[18] There are two contributions to the systematic error (±0.84): one (±0.81) which cancels in $m_W/m_Z$ and one (±0.21) which is non-cancelling. These were added in quadrature.

[19] ABE 89I systematic error dominated by the uncertainty in the absolute energy scale.

[20] ALBAJAR 89 result is from a total sample of 299 $W \to e\nu$ events.

[21] ALBAJAR 89 result is from a total sample of 67 $W \to \mu\nu$ events.

[22] ALBAJAR 89 result is from $W \to \tau\nu$ events.

## $W/Z$ MASS RATIO

| −0.19 ±0.58 | 1722 | ABE | 90G | CDF | $E_{cm}^{p\overline{p}}$= 1.8 TeV |

[1] AABOUD 18J select 4.61M $W^+ \to \mu^+\nu_\mu$, 3.40M $W^+ \to e^+\nu_e$, 3.23M $W^- \to \mu^-\overline{\nu}_\mu$ and 2.49M $W^- \to e^-\overline{\nu}_e$ events in 4.6 fb$^{-1}$ $pp$ data at 7 TeV. The $W$ mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations. The systematic error includes 0.007 GeV experimental and 0.024 GeV modelling uncertainties.

## $W$ WIDTH

The $W$ width listed here corresponds to the width parameter in a Breit-Wigner distribution with mass-dependent width. To obtain the world average, common systematic uncertainties between experiments are properly taken into account. The LEP-2 average $W$ width based on published results is 2.195 ± 0.083 GeV [SCHAEL 13A]. The combined Tevatron data yields an average W width of 2.046±0.049 GeV [FERMILAB-TM-2460-E].

OUR FIT uses these average LEP and Tevatron width values and combines them assuming no correlations.

[1] ABAZOV 09AK obtain this result fitting the high-end tail (100-200 GeV) of the transverse mass spectrum in $W \to e\nu$ decays.

[2] AALTONEN 08B obtain this result fitting the high-end tail (90–200 GeV) of the transverse mass spectrum in semileptonic $W \to e\nu_e$ and $W \to \mu\nu_\mu$ decays.

[3] ABDALLAH 08A use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The systematic error includes ±0.065 GeV due to final state interactions.

[4] ABBIENDI 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The systematic error includes ±0.003 GeV due to the uncertainty on the LEP beam energy.

[5] ACHARD 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events in the C.M. energy range 189–209 GeV. The result quoted here is obtained combining this value of the width with the result obtained from a direct $W$ mass reconstruction at 172 and 183 GeV (ACCIARRI 99).

[6] SCHAEL 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The systematic error includes ±0.05 GeV due to possible effects of final state interactions in the $q\overline{q}q\overline{q}$ channel and ±0.01 GeV due to the uncertainty on the LEP beam energy.

[7] ABAZOV 02E obtain this result fitting the high-end tail (90–200 GeV) of the transverse-mass spectrum in semileptonic $W \to e\nu_e$ decays.

[8] AFFOLDER 00M fit the high transverse mass (100–200 GeV) $W \to e\nu_e$ and $W \to \mu\nu_\mu$ events to obtain $\Gamma(W) = 2.04 \pm 0.11(\text{stat}) \pm 0.09(\text{syst})$ GeV. This is combined with the earlier CDF measurement (ABE 95C) to obtain the quoted result.

[9] ABBOTT 00B measure $R = 10.43 \pm 0.27$ for the $W \to e\nu_e$ decay channel. They use the SM theoretical predictions for $\sigma(W)/\sigma(Z)$ and $\Gamma(W \to e\nu_e)$ and the world average for $B(Z \to ee)$. The value quoted here is obtained combining this result ($2.169 \pm 0.070$ GeV) with that of ABBOTT 99H.

[10] ABE 95W measured $R = 10.90 \pm 0.32 \pm 0.29$. They use $m_W$=80.23 ± 0.18 GeV, $\sigma(W)/\sigma(Z) = 3.35 \pm 0.03$, $\Gamma(W \to e\nu) = 225.9 \pm 0.9$ MeV, $\Gamma(Z \to e^+e^-) = 83.98 \pm 0.18$ MeV, and $\Gamma(Z) = 2.4969 \pm 0.0038$ GeV.

[11] ALITTI 92 measured $R = 10.4^{+0.7}_{-0.6} \pm 0.3$. The values of $\sigma(Z)$ and $\sigma(W)$ come from $O(\alpha_s^2)$ calculations using $m_W = 80.14 \pm 0.27$ GeV, and $m_Z = 91.175 \pm 0.021$ GeV along with the corresponding value of $\sin^2\theta_W = 0.2274$. They use $\sigma(W)/\sigma(Z) = 3.26 \pm 0.07 \pm 0.05$ and $\Gamma(Z) = 2.487 \pm 0.010$ GeV.

[12] ALBAJAR 91 measured $R = 9.5^{+1.1}_{-1.0}$ (stat. + syst.). $\sigma(W)/\sigma(Z)$ is calculated in QCD at the parton level using $m_W = 80.18 \pm 0.28$ GeV and $m_Z = 91.172 \pm 0.031$ GeV along with $\sin^2\theta_W = 0.2322 \pm 0.0014$. They use $\sigma(W)/\sigma(Z) = 3.23 \pm 0.05$ and $\Gamma(Z) = 2.498 \pm 0.020$ GeV. This measurement is obtained combining both the electron and muon channels.

## $W^+$ DECAY MODES

$W^-$ modes are charge conjugates of the modes below.

| | Mode | | Fraction ($\Gamma_i/\Gamma$) | | Confidence level |
|---|---|---|---|---|---|
| $\Gamma_1$ | $\ell^+\nu$ | [a] | (10.86± 0.09) % | | |
| $\Gamma_2$ | $e^+\nu$ | | (10.71± 0.16) % | | |
| $\Gamma_3$ | $\mu^+\nu$ | | (10.63± 0.15) % | | |
| $\Gamma_4$ | $\tau^+\nu$ | | (11.38± 0.21) % | | |
| $\Gamma_5$ | hadrons | | (67.41± 0.27) % | | |
| $\Gamma_6$ | $\pi^+\gamma$ | | < 7 | $\times 10^{-6}$ | 95% |
| $\Gamma_7$ | $D_s^+\gamma$ | | < 1.3 | $\times 10^{-3}$ | 95% |
| $\Gamma_8$ | $c$X | | (33.3 ± 2.6 ) % | | |
| $\Gamma_9$ | $c\overline{s}$ | | (31 $^{+13}_{-11}$ ) % | | |
| $\Gamma_{10}$ | invisible | [b] | ( 1.4 ± 2.9 ) % | | |
| $\Gamma_{11}$ | $\pi^+\pi^+\pi^-$ | | < 1.01 | $\times 10^{-6}$ | 95% |

[a] $\ell$ indicates each type of lepton ($e$, $\mu$, and $\tau$), not sum over them.

[b] This represents the width for the decay of the $W$ boson into a charged particle with momentum below detectability, p< 200 MeV.

## $W$ PARTIAL WIDTHS

### $\Gamma$(invisible) $\Gamma_{10}$

This represents the width for the decay of the $W$ boson into a charged particle with momentum below detectability, p< 200 MeV.

| VALUE (MeV) | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| **30 $^{+52}_{-48}$ ±33** | [1] BARATE | 99I | ALEP | $E^{ee}_{cm}$= 161+172+183 GeV |

• • • We do not use the following data for averages, fits, limits, etc. • • •

| | | | | |
|---|---|---|---|---|
| [2] BARATE | 99L | ALEP | $E^{ee}_{cm}$= 161+172+183 GeV |

[1] BARATE 99I measure this quantity using the dependence of the total cross section $\sigma_{WW}$ upon a change in the total width. The fit is performed to the $WW$ measured cross sections at 161, 172, and 183 GeV. This partial width is < 139 MeV at 95%CL.

[2] BARATE 99L use $W$-pair production to search for effectively invisible $W$ decays, tagging with the decay of the other $W$ boson to Standard Model particles. The partial width for effectively invisible decay is < 27 MeV at 95%CL.

## $W$ BRANCHING RATIOS

Overall fits are performed to determine the branching ratios of the $W$ boson. Averages on $W \to e\nu$, $W \to \mu\nu$, and $W \to \tau\nu$, and their correlations are obtained by combining results from the four LEP experiments properly taking into account the common systematic uncertainties and their correlations [SCHAEL 13A]. A first fit determines the three individual leptonic braching ratios $B(W \to e\nu)$, $B(W \to \mu\nu)$, and $B(W \to \tau\nu)$. This fit has a $\chi^2 = 6.3$ for 9 degrees of freedom. The correlation coefficients between the branching fractions are 0.14 $(e-\mu)$, −0.20 $(e-\tau)$, −0.12 $(\mu-\tau)$. A second fit assumes lepton universality and determines the leptonic branching ratio $B(W \to \ell\nu)$ and the hadronic branching ratio is derived as $B(W \to \text{hadrons}) = 1 - 3\,B(W \to \ell\nu)$. This fit has a $\chi^2 = 15.4$ for 11 degrees of freedom.

### $\Gamma(\ell^+\nu)/\Gamma_{total}$ $\Gamma_1/\Gamma$

$\ell$ indicates average over $e$, $\mu$, and $\tau$ modes, not sum over modes.

[1] AABOUD 17Q make a precise determination of $W \to e\nu$ and $W \to \mu\nu$ production in the follwoing fiducial phase space: lepton pseudo-rapidity range $|\eta| < 2.5$, lepton and neutrino transverse momenta larger than 25 GeV each, and $W$ transverse mass larger than 25 GeV. They determine the ratio of the $W$ branching fractions $B(W \to e\nu)/B(W \to \mu\nu) = 0.9967 \pm 0.0004 \pm 0.0101 = 0.997 \pm 0.010$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[2] AAIJ 16AJ make precise measurements of forward $W \to e\nu$ and $W \to \mu\nu$ production in proton-proton collisions at 8 TeV and determine the ratio of the $W$ branching fractions $B(W \to e\nu)/B(W \to \mu\nu) = 1.020 \pm 0.002 \pm 0.019$.

[3] ABACHI 95D obtain this result from the measured $\sigma_W B(W \to \mu\nu) = 2.09 \pm 0.23 \pm 0.11$ nb and $\sigma_W B(W \to e\nu) = 2.36 \pm 0.07 \pm 0.13$ nb in which the first error is the combined statistical and systematic uncertainty, the second reflects the uncertainty in the luminosity.

[4] ABE 92I obtain $\sigma_W B(W \to \mu\nu) = 2.21 \pm 0.07 \pm 0.21$ and combine with ABE 91C $\sigma_W B((W \to e\nu))$ to give a ratio of the couplings from which we derive this measurement.

[1] ABBOTT 00D measure $\sigma_W \times B(W \to \tau\nu_\tau) = 2.22 \pm 0.09 \pm 0.10 \pm 0.10$ nb. Using the ABBOTT 00B result $\sigma_W \times B(W \to e\nu_e) = 2.31 \pm 0.01 \pm 0.05 \pm 0.10$ nb, they quote the ratio of the couplings from which we derive this measurement.

[2] ABE 92E use two procedures for selecting $W \to \tau\nu_\tau$ events. The missing $E_T$ trigger leads to $132 \pm 14 \pm 8$ events and the $\tau$ trigger to $47 \pm 9 \pm 4$ events. Proper statistical and systematic correlations are taken into account to arrive at $\sigma B(W \to \tau\nu) = 2.05 \pm 0.27$ nb. Combined with ABE 91C result on $\sigma B(W \to e\nu)$, ABE 92E quote a ratio of the couplings from which we derive this measurement.

[3] This measurement is derived by us from the ratio of the couplings of ALITTI 92F.

[1] ABBIENDI 06A measure $\langle N_{charged} \rangle = 38.74 \pm 0.12 \pm 0.26$ when both $W$ bosons decay hadronically and $\langle N_{charged} \rangle = 19.39 \pm 0.11 \pm 0.09$ when one $W$ boson decays semileptonically. The value quoted here is obtained under the assumption that there is no color reconnection between $W$ bosons; the value is a weighted average taking into account correlations in the systematic uncertainties.

[2] ABREU,P 00F measure $\langle N_{charged} \rangle = 39.12 \pm 0.33 \pm 0.36$ and $38.11 \pm 0.57 \pm 0.44$ in the fully hadronic final states at 189 and 183 GeV respectively, and $\langle N_{charged} \rangle = 19.49 \pm 0.31 \pm 0.27$ and $19.78 \pm 0.49 \pm 0.43$ in the semileptonic final states. The value quoted is a weighted average without assuming any correlations.

[3] ABBIENDI 99N use the final states $W^+W^- \to q\overline{q}\ell\overline{\nu}_\ell$ to derive this value.

[4] ABREU 98C combine results from both the fully hadronic as well semileptonic $WW$ final states after demonstrating that the $W$ decay charged multiplicity is independent of the topology within errors.

## TRIPLE GAUGE COUPLINGS (TGC'S)

Revised April 2017 by M.W. Grünewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Fourteen independent couplings, seven each for $ZWW$ and $\gamma WW$, completely describe the $VWW$ vertices within the most general framework of the electroweak Standard Model (SM) consistent with Lorentz invariance and U(1) gauge invariance. Of each of the seven TGCs, three conserve $C$ and $P$ individually, three violate $CP$, and one violates $C$ and $P$ individually while conserving $CP$. Assumption of $C$ and $P$ conservation and electromagnetic gauge invariance reduces the number of independent $VWW$ couplings to five: one common set [1,2]

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

is $(\kappa_\gamma, \kappa_Z, \lambda_\gamma, \lambda_Z, g_1^Z)$, where $\kappa_\gamma = \kappa_Z = g_1^Z = 1$ and $\lambda_\gamma = \lambda_Z = 0$ in the Standard Model at tree level. The parameters $\kappa_Z$ and $\lambda_Z$ are related to the other three due to constraints of gauge invariance as follows: $\kappa_Z = g_1^Z - (\kappa_\gamma - 1)\tan^2\theta_W$ and $\lambda_Z = \lambda_\gamma$, where $\theta_W$ is the weak mixing angle. The $W$ magnetic dipole moment, $\mu_W$, and the $W$ electric quadrupole moment, $q_W$, are expressed as $\mu_W = e\,(1+\kappa_\gamma+\lambda_\gamma)/2M_W$ and $q_W = -e\,(\kappa_\gamma - \lambda_\gamma)/M_W^2$.

Precision measurements of suitable observables at LEP1 has already led to an exploration of much of the TGC parameter space. At LEP2, the $VWW$ coupling arises in $W$-pair production via $s$-channel exchange, or in single $W$ production via the radiation of a virtual photon off the incident $e^+$ or $e^-$. At the Tevatron and the LHC, hard-photon bremsstrahlung off a produced $W$ or $Z$ signals the presence of a triple-gauge vertex. In order to extract the value of one TGC, the others are generally kept fixed to their SM values. While most analyses use the above gauge constraints in the extraction of TGCs, one analysis of $W$-pair events also determines the real and imaginary parts of all 14 couplings using unconstrained single-parameter fits [3]. The results are consistent. Some experiments have determined limits on the couplings under various non-LEP scenarios and assuming different values of the form factor $\Lambda$, where the coupling parameters are scaled by $1/(1+s/\Lambda^2)^2$. For practical reasons it is not possible to quote all such determinations in the listings. For that the individual papers may be consulted. Recently, EFT-inspired sets of couplings [4,5], such as $c_{WWW}/\Lambda^2, c_W/\Lambda^2, c_B/\Lambda^2$ which are linearly related to the couplings discussed above, are also determined by the LHC experiments.

[1] ABDALLAH 10 use data on the final states $e^+e^- \to jj\ell\nu, jjjj, jjX, \ell X$, at center-of-mass energies between 189–209 GeV at LEP2, where $j$ = jet, $\ell$ = lepton, and $X$ represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

[2] SCHAEL 05A study single–photon, single–$W$, and $WW$–pair production from 183 to 209 GeV. The result quoted here is derived from the $WW$–pair production sample. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[3] ABBIENDI 04D combine results from $W^+W^-$ in all decay channels. Only *CP*-conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $0.923 < g_1^Z < 1.054$.

[4] ACHARD 04D study $WW$–pair production, single–$W$ production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained from the $WW$–pair production sample including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[5] SIRUNYAN 19CL study $WW$ and $WZ$ production in lepton + jet events, with one $W$ boson decaying leptonically (electron or muon), and another $W$ or $Z$ boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $0.9939 < g_1^Z < 1.0074$.

[6] SIRUNYAN 18BZ study $pp \to Z\,jet\,jet$ events at 13 TeV where $Z \to e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with $p_T$ of the leading/sub-leading lepton > 30/20 GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the $Z$ mass. The two highest $p_T$ jets are selected with $p_T$ of the leading/sub-leading jet > 50/30 GeV respectively and dijet invariant mass > 200 GeV. Templates in the transverse momentum of the $Z$ are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limit is obtained: $0.965 < g_1^Z < 1.042$.

[7] AABOUD 17S analyze electroweak production of a $W$ boson in association with two jets at high dijet invariant mass, with the $W$ boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with $39 \pm 4$ events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.87 < g_1^Z < 1.12$.

[8] AABOUD 17U analyze production of $WW$ or $WZ$ boson pairs with one $W$ boson decaying to electron or muon plus neutrino, and the other $W$ or $Z$ boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.979 < g_1^Z < 1.024$.

[9] KHACHATRYAN 17O analyse $WZ$ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the $Z$ boson mass. The $Z$ transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $0.982 < g_1^Z < 1.035$.

[10] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\overline{q}$ production at 8 TeV where $\ell$ is an electron or muon with $p_T$ > 30 or 25 GeV respectively. Suitable cuts are put on the $p_T$ of the dijet system and the missing $E_T$ of the event yielding a total of 285 and 204 $WV$ events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $0.9913 < g_1^Z < 1.024$.

[11] AAD 16AR study $WW$ production in $pp$ collisions and select 6636 $WW$ candidates in decay modes with electrons or muons with an expected background of $1546 \pm 157$ events. Assuming the LEP formulation and setting the form-factor $\Lambda$ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.984 < g_1^Z < 1.027$.

[12] AAD 16P study $WZ$ production in $pp$ collisions and select 2091 $WZ$ candidates in 4 decay modes with electrons and muons, with an expected background of $1825 \pm 7$ events. Analyzing the $WZ$ transverse momentum distribution, the resulting 95% C.L. limit is: $0.981 < g_1^Z < 1.029$.

[13] AAD 14Y determine the electroweak $Z$-dijet cross section in 8 TeV $pp$ collisions. $Z \to ee$ and $Z \to \mu\mu$ decays are selected with the di-lepton $p_T > 20$ GeV and mass in the 81–101 GeV range. Minimum two jets are required with $p_T > 55$ and 45 GeV and no additional jets with $p_T > 25$ GeV in the rapidity interval between them. The normalized $p_T$ balance between the $Z$ and the two jets is required to be < 0.15. This leads to a selection of 900 events with dijet mass > 1 TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit $0.5 < g_1^Z < 1.26$ for a form factor value $\Lambda = \infty$.

[14] AAD 13AL study $WW$ production in $pp$ collisions and select 1325 $WW$ candidates in decay modes with electrons or muons with an expected background of $369 \pm 61$ events. Assuming the LEP formulation and setting the form-factor $\Lambda$ = infinity, a fit to the

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.961 < g_1^Z < 1.052$. Supersedes AAD 12AC.

[15] CHATRCHYAN 13BF determine the $W^+W^-$ production cross section using unlike sign di-lepton ($e$ or $\mu$) events with high $\not{p}_T$. The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of $247 \pm 34$. The $p_T$ distribution of the leading lepton is fitted to obtain 95% C.L. limits of $0.905 \leq g_1^Z \leq 1.095$.

[16] AAD 12CD study $WZ$ production in $pp$ collisions and select 317 $WZ$ candidates in three $\ell\nu$ decay modes with an expected background of $68.0 \pm 10.0$ events. The resulting 95% C.L. range is: $0.943 < g_1^Z < 1.093$. Supersedes AAD 12V.

[17] AALTONEN 12AC study $WZ$ production in $p\overline{p}$ collisions and select 63 $WZ$ candidates in three $\ell\nu$ decay modes with an expected background of $7.9 \pm 1.0$ events. Based on the cross section and shape of the $Z$ transverse momentum spectrum, the following 95% C.L. range is reported: $0.92 < g_1^Z < 1.20$ for a form factor of $\Lambda = 2$ TeV.

[18] ABAZOV 12AG combine new results with already published results on $W\gamma$, $WW$ and $WZ$ production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $g_1^Z = 1.022^{+0.032}_{-0.030}$.

[19] ABAZOV 11 study the $p\overline{p} \rightarrow 3\ell\nu$ process arising in $WZ$ production. They observe 34 $WZ$ candidates with an estimated background of 6 events. An analysis of the $p_T$ spectrum of the $Z$ boson leads to a 95% C.L. limit of $0.944 < g_1^Z < 1.154$, for a form factor $\Lambda = 2$ TeV.

[20] AALTONEN 10K study $p\overline{p} \rightarrow W^+W^-$ with $W \rightarrow e/\mu\nu$. The $p_T$ of the leading (second) lepton is required to be $> 20$ (10) GeV. The final number of events selected is 654 of which $320 \pm 47$ are estimated to be background. The 95% C.L. interval is $0.76 < g_1^Z < 1.34$ for $\Lambda = 1.5$ TeV and $0.78 < g_1^Z < 1.30$ for $\Lambda = 2$ TeV.

[21] ABAZOV 09AD study the $p\overline{p} \rightarrow \ell\nu$ 2jet process arising in $WW$ and $WZ$ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the $p_T$ spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $0.88 < g_1^Z < 1.20$.

[22] ABAZOV 09AJ study the $p\overline{p} \rightarrow 2\ell 2\nu$ process arising in $WW$ production. They select 100 events with an expected $WW$ signal of 65 events. An analysis of the $p_T$ spectrum of the two charged leptons leads to 95% C.L. limits of $0.86 < g_1^Z < 1.3$, for a form factor $\Lambda = 2$ TeV.

[23] ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \rightarrow W^+W^- \rightarrow (qq)(\ell\nu)$, where $\ell = e$ or $\mu$. Values of all other couplings are fixed to their standard model values.

[24] ABAZOV 07Z set limits on anomalous TGCs using the measured cross section and $p_T(Z)$ distribution in $WZ$ production with both the $W$ and the $Z$ decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $0.86 < g_1^Z < 1.35$.

[25] ABAZOV 05S study $\overline{p}p \rightarrow WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\overline{\ell}'$ ($\ell$ and $\ell' = e$ or $\mu$). Three events (estimated background $0.71 \pm 0.08$ events) with $WZ$ decay characteristics are observed from which they derive limits on the anomalous $WWZ$ couplings. The 95% CL limit for a form factor scale $\Lambda = 1.5$ TeV is $0.51 < g_1^Z < 1.66$, fixing $\lambda_Z$ and $\kappa_Z$ to their Standard Model values.

[26] ABREU 01I combine results from $e^+e^-$ interactions at 189 GeV leading to $W^+W^-$ and $We\nu_e$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $0.84 < g_1^Z < 1.13$.

[27] ABBOTT 99I perform a simultaneous fit to the $W\gamma$, $WW \rightarrow$ dilepton, $WW/WZ \rightarrow e\nu jj$, $WW/WZ \rightarrow \mu\nu jj$, and $WZ \rightarrow$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95%CL limits are $0.63 < g_1^Z < 1.57$, fixing $\lambda_Z$ and $\kappa_Z$ to their Standard Model values, and assuming Standard Model values for the $WW\gamma$ couplings.

## $\kappa_\gamma$

[1] ABDALLAH 10 use data on the final states $e^+e^- \rightarrow jj\ell\nu$, $jjjj$, $jjX$, $\ell X$, at center-of-mass energies between 189–209 GeV at LEP2, where $j$ = jet, $\ell$ = lepton, and $X$ represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

[2] SCHAEL 05A study single–photon, single–$W$, and $WW$–pair production from 183 to 209 GeV. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[3] ABBIENDI 04D combine results from $W^+W^-$ in all decay channels. Only *CP*-conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $0.73 < \kappa_\gamma < 1.07$.

[4] ACHARD 04D study $WW$–pair production, single–$W$ production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[5] AABOUD 17U analyze production of $WW$ or $WZ$ boson pairs with one $W$ boson decaying to electron or muon plus neutrino, and the other $W$ or $Z$ boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \rightarrow \infty$: $0.939 < \kappa_\gamma < 1.064$.

[6] SIRUNYAN 17X study $pp \rightarrow WW/WZ \rightarrow \ell\nu q\overline{q}$ production at 8 TeV where $\ell$ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the $p_T$ of the dijet system and the missing $E_T$ of the event yielding a total of 285 and 204 $WV$ events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $0.956 < \kappa_\gamma < 1.063$.

[7] CHATRCHYAN 14AB measure $W\gamma$ production cross section for $p_T^\gamma > 15$ GeV and $R(\ell\gamma) > 0.7$, which is the separation between the $\gamma$ and the final state charged lepton ($e$ or $\mu$) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. After background subtraction the number of $e\nu\gamma$ and $\mu\nu\gamma$ events is determined to be $3200 \pm 325$ and $4970 \pm 543$ respectively, compatible with expectations from the SM. This leads to a 95% CL limit of $0.62 < \kappa_\gamma < 1.29$, assuming other parameters have SM values.

[8] AAD 13AN study $W\gamma$ production in $pp$ collisions. In events with no additional jet, 4449 (6578) W decays to electron (muon) are selected, with an expected background of $1662 \pm 262$ ($2538 \pm 362$) events. Analysing the photon $p_T$ spectrum above 100 GeV yields a 95% C.L. limit of $0.59 < \kappa_\gamma < 1.46$. Supersedes AAD 12BX.

[9] CHATRCHYAN 13BF determine the $W^+W^-$ production cross section using unlike sign di-lepton ($e$ or $\mu$) events with high $\not{p}_T$. The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of $247 \pm 34$. The $p_T$ distribution of the leading lepton is fitted to obtain 95% C.L. limits of $0.79 \leq k_\gamma \leq 1.22$.

[10] ABAZOV 12AG combine new results with already published results on $W\gamma$, $WW$ and $WZ$ production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $\kappa_\gamma = 1.048^{+0.106}_{-0.105}$.

[11] ABAZOV 11AC study $W\gamma$ production in $p\overline{p}$ collisions at 1.96 TeV, with the $W$ decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon $E_T$ spectrum above 15 GeV yields at 95% C.L. the result: $0.6 < \kappa_\gamma < 1.4$ for a formfactor $\Lambda = 2$ TeV.

[12] CHATRCHYAN 11M study $W\gamma$ production in $pp$ collisions at $\sqrt{s} = 7$ TeV using 36 pb$^{-1}$ $pp$ data with the $W$ decaying to electron and muon. The total cross section is measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$. The number of candidate (background) events is 452 ($228 \pm 21$) for the electron channel and 520 ($277 \pm 25$) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of $-0.11 < \kappa_\gamma < 2.04$.

[13] AALTONEN 10K study $p\overline{p} \rightarrow W^+W^-$ with $W \rightarrow e/\mu\nu$. The $p_T$ of the leading (second) lepton is required to be $> 20$ (10) GeV. The final number of events selected is 654 of which $320 \pm 47$ are estimated to be background. The 95% C.L. interval is $0.37 < \kappa_\gamma < 1.72$ for $\Lambda = 1.5$ TeV and $0.43 < \kappa_\gamma < 1.65$ for $\Lambda = 2$ TeV.

[14] AARON 09B study single-$W$ production in $ep$ collisions at 0.3 TeV C.M. energy. They select 53 $W \rightarrow e/\mu$ events with a standard model expectation of $54.1 \pm 7.4$ events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of $-3.7 < \kappa_\gamma < -1.5$ or $0.3 < \kappa_\gamma < 1.5$, where the ambiguity is due to the quadratic dependence of the cross section to the coupling parameter.

[15] ABAZOV 09AD study the $p\overline{p} \rightarrow \ell\nu$ 2jet process arising in $WW$ and $WZ$ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the $p_T$ spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $0.56 < \kappa_\gamma < 1.55$.

[16] ABAZOV 09AJ study the $p\overline{p} \rightarrow 2\ell 2\nu$ process arising in $WW$ production. They select 100 events with an expected $WW$ signal of 65 events. An analysis of the $p_T$ spectrum of the two charged leptons leads to 95% C.L. limits of $0.46 < \kappa_\gamma < 1.83$, for a form factor $\Lambda = 2$ TeV.

[17] ABAZOV 08R use 0.7 fb$^{-1}$ $p\overline{p}$ data at $\sqrt{s} = 1.96$ TeV to select 263 $W\gamma + X$ events, of which 187 constitute signal, with the $W$ decaying into an electron or a muon, which is required to be well separated from a photon with $E_T > 9$ GeV. A likelihood fit to the photon $E_T$ spectrum yields a 95% CL limit $0.49 < \kappa_\gamma < 1.51$ with other couplings fixed to their Standard Model values.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[18] ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \to W^+W^- \to (qq)(\ell\nu)$, where $\ell = e$ or $\mu$. Values of all other couplings are fixed to their standard model values.

[19] AALTONEN 07L set limits on anomalous TGCs using the $p_T(W)$ distribution in $WW$ and $WZ$ production with the $W$ decaying to an electron or muon and the $Z$ to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are $0.54 < \kappa_\gamma < 1.39$ for a form factor scale $\Lambda = 1.5$ TeV.

[20] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 1$ TeV is $-0.05 < \kappa_\gamma < 2.29$, fixing $\lambda_\gamma = 0$. With the assumption that the $WW\gamma$ and $WWZ$ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $0.68 < \kappa < 1.45$.

[21] ABAZOV 05J perform a likelihood fit to the photon $E_T$ spectrum of $W\gamma$ + X events, where the $W$ decays to an electron or muon which is required to be well separated from the photon. For $\Lambda = 2.0$ TeV the 95% CL limits are $0.12 < \kappa_\gamma < 1.96$. In the fit $\lambda_\gamma$ is kept fixed to its Standard Model value.

[22] ABREU 01I combine results from $e^+e^-$ interactions at 189 GeV leading to $W^+W^-$, $We\nu_e$, and $\nu\overline{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $0.87 < \kappa_\gamma < 1.68$.

[23] BREITWEG 00 search for $W$ production in events with large hadronic $p_T$. For $p_T > 20$ GeV, the upper limit on the cross section gives the 95%CL limit $-3.7 < \kappa_\gamma < 2.5$ (for $\lambda_\gamma = 0$).

[24] ABBOTT 99I perform a simultaneous fit to the $W\gamma$, $WW \to$ dilepton, $WW/WZ \to e\nu jj$, $WW/WZ \to \mu\nu jj$, and $WZ \to$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95%CL limits are $0.75 < \kappa_\gamma < 1.39$.

## $\lambda_\gamma$

[1] ABDALLAH 10 use data on the final states $e^+e^- \to jj\ell\nu$, $jjjj$, $jjX$, $\ell X$, at center-of-mass energies between 189–209 GeV at LEP2, where $j$ = jet, $\ell$ = lepton, and $X$ represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

[2] SCHAEL 05A study single–photon, single–$W$, and $WW$–pair production from 183 to 209 GeV. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[3] ABBIENDI 04D combine results from $W^+W^-$ in all decay channels. Only $CP$-conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $-0.13 < \lambda_\gamma < 0.01$.

[4] ACHARD 04D study $WW$–pair production, single–$W$ production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[5] CHATRCHYAN 14AB measure $W\gamma$ production cross section for $p_T^\gamma > 15$ GeV and $R(\ell\gamma) > 0.7$, which is the separation between the $\gamma$ and the final state charged lepton ($e$ or $\mu$) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. After background subtraction the number of $e\nu\gamma$ and $\mu\nu\gamma$ events is determined to be $3200 \pm 325$ and $4970 \pm 543$ respectively, compatible with expectations from the SM. This leads to a 95% CL limit of $-0.050 < \lambda_\gamma < 0.037$, assuming all other parameters have SM values.

[6] AAD 13AN study $W\gamma$ production in $pp$ collisions. In events with no additional jet, 4449 (6578) W decays to electron (muon) are selected, with an expected background of $1662 \pm 262$ ($2538 \pm 362$) events. Analysing the photon $p_T$ spectrum above 100 GeV yields a 95% C.L. limit of $-0.065 < \lambda_\gamma < 0.061$. Supersedes AAD 12BX.

[7] ABAZOV 12AG combine new results with already published results on $W\gamma$, $WW$ and $WZ$ production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $\lambda_\gamma = 0.007^{+0.021}_{-0.022}$.

[8] ABAZOV 11AC study $W\gamma$ production in $p\overline{p}$ collisions at 1.96 TeV, with the $W$ decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon $E_T$ spectrum above 15 GeV yields at 95% C.L. the result: $-0.08 < \lambda_\gamma < 0.07$ for a formfactor $\Lambda = 2$ TeV.

[9] CHATRCHYAN 11M study $W\gamma$ production in $pp$ collisions at $\sqrt{s} = 7$ TeV using 36 pb$^{-1}$ $pp$ data with the $W$ decaying to electron and muon. The total cross section is measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$. The number of candidate (background) events is 452 ($228 \pm 21$) for the electron channel and 520 ($277 \pm 25$) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of $-0.18 < \lambda_\gamma < 0.17$.

[10] AARON 09B study single–$W$ production in $ep$ collisions at 0.3 TeV C.M. energy. They select 53 $W \to e/\mu$ events with a standard model expectation of $54.1 \pm 7.4$ events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of $-2.5 < \lambda_\gamma < 2.5$.

[11] ABAZOV 09AD study the $p\overline{p} \to \ell\nu$ 2jet process arising in $WW$ and $WZ$ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the $p_T$ spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $-0.10 < \lambda_\gamma < 0.11$.

[12] ABAZOV 09AJ study the $p\overline{p} \to 2\ell 2\nu$ process arising in $WW$ production. They select 100 events with an expected $WW$ signal of 65 events. An analysis of the $p_T$ spectrum of the two charged leptons leads to 95% C.L. limits of $-0.14 < \lambda_\gamma < 0.18$, for a form factor $\Lambda = 2$ TeV.

[13] ABAZOV 08R use 0.7 fb$^{-1}$ $p\overline{p}$ data at $\sqrt{s} = 1.96$ TeV to select 263 $W\gamma + X$ events, of which 187 constitute signal, with the $W$ decaying into an electron or a muon, which is required to be well separated from a photon with $E_T > 9$ GeV. A likelihood fit to the photon $E_T$ spectrum yields a 95% CL limit $-0.12 < \lambda_\gamma < 0.13$ with other couplings fixed to their Standard Model values.

[14] ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \to W^+W^- \to (qq)(\ell\nu)$, where $\ell = e$ or $\mu$. Values of all other couplings are fixed to their standard model values.

[15] AALTONEN 07L set limits on anomalous TGCs using the $p_T(W)$ distribution in $WW$ and $WZ$ production with the $W$ decaying to an electron or muon and the $Z$ to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are $-0.18 < \lambda_\gamma < 0.17$ for a form factor scale $\Lambda = 1.5$ TeV.

[16] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 1$ TeV is $-0.97 < \lambda_\gamma < 1.04$, fixing $\kappa_\gamma = 1$. With the assumption that the $WW\gamma$ and $WWZ$ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $-0.29 < \lambda < 0.30$.

[17] ABAZOV 05J perform a likelihood fit to the photon $E_T$ spectrum of $W\gamma$ + X events, where the $W$ decays to an electron or muon which is required to be well separated from the photon. For $\Lambda = 2.0$ TeV the 95% CL limits are $-0.20 < \lambda_\gamma < 0.20$. In the fit $\kappa_\gamma$ is kept fixed to its Standard Model value.

[18] ABREU 01I combine results from $e^+e^-$ interactions at 189 GeV leading to $W^+W^-$, $We\nu_e$, and $\nu\overline{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $-0.11 < \lambda_\gamma < 0.23$.

[19] BREITWEG 00 search for $W$ production in events with large hadronic $p_T$. For $p_T > 20$ GeV, the upper limit on the cross section gives the 95%CL limit $-3.2 < \lambda_\gamma < 3.2$ for $\kappa_\gamma$ fixed to its Standard Model value.

[20] ABBOTT 99I perform a simultaneous fit to the $W\gamma$, $WW \to$ dilepton, $WW/WZ \to e\nu jj$, $WW/WZ \to \mu\nu jj$, and $WZ \to$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95%CL limits are $-0.18 < \lambda_\gamma < 0.19$.

## $\kappa_Z$

This coupling is $CP$-conserving ($C$- and $P$- separately conserving).

[1] ACHARD 04D study $WW$–pair production, single–$W$ production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the $WW$–pair production sample. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[2] SIRUNYAN 19CL study $WW$ and $WZ$ production in lepton + jet events, with one $W$ boson decaying leptonically (electron or muon), and another $W$ or $Z$ boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $0.9921 < \kappa_Z < 1.0082$.

[3] AABOUD 17S analyze electroweak production of a $W$ boson in association with two jets at high dijet invariant mass, with the $W$ boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

momentum larger than 600 GeV, 30 events are observed in the data with $39 \pm 4$ events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.85 < \kappa_Z < 1.16$.

[4] KHACHATRYAN 17O analyse $WZ$ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the $Z$ boson mass. The $Z$ transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $0.79 < \kappa_Z < 1.25$.

[5] AAD 16AR study $WW$ production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of $1546 \pm 157$ events. Assuming the LEP formulation and setting the form-factor $\Lambda$ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.975 < \kappa_Z < 1.020$.

[6] AAD 16P study $WZ$ production in $pp$ collisions and select 2091 $WZ$ candidates in 4 decay modes with electrons and muons, with an expected background of $1825 \pm 7$ events. Analyzing the $WZ$ transverse momentum distribution, the resulting 95% C.L. limit is: $0.81 < \kappa_Z < 1.30$.

[7] AAD 13AL study $WW$ production in $pp$ collisions and select 1325 $WW$ candidates in decay modes with electrons or muons with an expected background of $369 \pm 61$ events. Assuming the LEP formulation and setting the form-factor $\Lambda$ = infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.957 < \kappa_Z < 1.043$. Supersedes AAD 12AC.

[8] AAD 12CD study $WZ$ production in $pp$ collisions and select 317 $WZ$ candidates in three $\ell\nu$ decay modes with an expected background of $68.0 \pm 10.0$ events. The resulting 95% C.L. range is: $0.63 < \kappa_Z < 1.57$. Supersedes AAD 12V.

[9] AALTONEN 12AC study $WZ$ production in $p\overline{p}$ collisions and select 63 $WZ$ candidates in three $\ell\nu$ decay modes with an expected background of $7.9 \pm 1.0$ events. Based on the cross section and shape of the $Z$ transverse momentum spectrum, the following 95% C.L. range is reported: $0.61 < \kappa_Z < 1.90$ for a form factor of $\Lambda = 2$ TeV.

[10] ABAZOV 11 study the $p\overline{p} \to 3\ell\nu$ process arising in $WZ$ production. They observe 34 $WZ$ candidates with an estimated background of 6 events. An analysis of the $p_T$ spectrum of the $Z$ boson leads to a 95% C.L. limit of $0.600 < \kappa_Z < 1.675$, for a form factor $\Lambda = 2$ TeV.

[11] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $0.55 < \kappa_Z < 1.55$, fixing $\lambda_Z$=0. With the assumption that the $WW\gamma$ and $WWZ$ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $0.68 < \kappa < 1.45$.

[12] ABAZOV 05S study $\overline{p}p \to WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\overline{\ell}'$ ($\ell$ and $\ell' = e$ or $\mu$). Three events (estimated background $0.71 \pm 0.08$ events) with $WZ$ decay characteristics are observed from which they derive limits on the anomalous $WWZ$ couplings. The 95% CL limit for a form factor scale $\Lambda = 1$ TeV is $-1.0 < \kappa_Z < 3.4$, fixing $\lambda_Z$ and $g_1^Z$ to their Standard Model values.

## $\lambda_Z$

This coupling is *CP*-conserving (*C*- and *P*- separately conserving).

[1] ACHARD 04D study $WW$–pair production, single–$W$ production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the $WW$–pair production sample. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[2] SIRUNYAN 19CL study $WW$ and $WZ$ production in lepton + jet events, with one $W$ boson decaying leptonically (electron or muon), and another $W$ or $Z$ boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $-0.0065 < \lambda_Z < 0.0066$.

[3] SIRUNYAN 18BZ study $pp \to Z$ *jet jet* events at 13 TeV where $Z \to e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with $p_T$ of the leading/sub-leading lepton > 30/20 GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the $Z$ mass. The two highest $p_T$ jets are selected with $p_T$ of the leading/sub-leading jet > 50/30 GeV respectively and dijet invariant mass > 200 GeV. Templates in the transverse momentum of the $Z$ are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limit is obtained $-0.010 < \lambda_Z < 0.010$.

[4] AABOUD 17S analyze electroweak production of a $W$ boson in association with two jets at high dijet invariant mass, with the $W$ boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with $39 \pm 4$ events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-0.053 < \lambda_Z < 0.042$.

[5] AABOUD 17U analyze production of $WW$ or $WZ$ boson pairs with one $W$ boson decaying to electron or muon plus neutrino, and the other $W$ or $Z$ boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-0.013 < \lambda_Z < 0.013$.

[6] KHACHATRYAN 17O analyse $WZ$ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the $Z$ boson mass. The $Z$ transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $-0.018 < \lambda_Z < 0.016$.

[7] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\overline{q}$ production at 8 TeV where $\ell$ is an electron or muon with $p_T$ > 30 or 25 GeV respectively. Suitable cuts are put on the $p_T$ of the dijet system and the missing $E_T$ of the event yielding a total of 285 and 204 $WV$ events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $-0.011 < \lambda_Z < 0.011$.

[8] AAD 16AR study WW production in $pp$ collisions and select 6636 $WW$ candidates in decay modes with electrons or muons with an expected background of $1546 \pm 157$ events. Assuming the LEP formulation and setting the form-factor $\Lambda$ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $-0.019 < \lambda_Z < 0.019$.

[9] AAD 16P study $WZ$ production in $pp$ collisions and select 2091 $WZ$ candidates in 4 decay modes with electrons and muons, with an expected background of $1825 \pm 7$ events. Analyzing the $WZ$ transverse momentum distribution, the resulting 95% C.L. limit is: $-0.016 < \lambda_Z < 0.016$.

[10] AAD 14Y determine the electroweak $Z$-dijet cross section in 8 TeV $pp$ collisions. $Z \to ee$ and $Z \to \mu\mu$ decays are selected with the di-lepton $p_T > 20$ GeV and mass in the 81–101 GeV range. Minimum two jets are required with $p_T > 55$ and 45 GeV and no additional jets with $p_T > 25$ GeV in the rapidity interval between them. The normalized $p_T$ balance between the $Z$ and the two jets is required to be < 0.15. This leads to a selection of 900 events with dijet mass > 1 TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit $-0.15 < \lambda_Z < 0.13$ for a form factor value $\Lambda = \infty$.

[11] AAD 13AL study $WW$ production in $pp$ collisions and select 1325 $WW$ candidates in decay modes with electrons or muons with an expected background of $369 \pm 61$ events. Assuming the LEP formulation and setting the form-factor $\Lambda$ = infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $-0.062 < \lambda_Z < 0.059$. Supersedes AAD 12AC.

[12] CHATRCHYAN 13BF determine the $W^+W^-$ production cross section using unlike sign di-lepton ($e$ or $\mu$) events with high $\not{p}_T$. The leptons have $p_T > 20$ GeV/$c$ and are isolated. 1134 candidate events are observed with an expected SM background of $247 \pm 34$. The $p_T$ distribution of the leading lepton is fitted to obtain 95% C.L. limits of $-0.048 \leq \lambda_Z \leq 0.048$.

[13] AAD 12CD study $WZ$ production in $pp$ collisions and select 317 $WZ$ candidates in three $\ell\nu$ decay modes with an expected background of $68.0 \pm 10.0$ events. The resulting 95% C.L. range is: $-0.046 < \lambda_Z < 0.047$. Supersedes AAD 12V.

[14] AALTONEN 12AC study $WZ$ production in $p\overline{p}$ collisions and select 63 $WZ$ candidates in three $\ell\nu$ decay modes with an expected background of $7.9 \pm 1.0$ events. Based on the cross section and shape of the $Z$ transverse momentum spectrum, the following 95% C.L. range is reported: $-0.08 < \lambda_Z < 0.10$ for a form factor of $\Lambda = 2$ TeV.

[15] ABAZOV 11 study the $p\overline{p} \to 3\ell\nu$ process arising in $WZ$ production. They observe 34 $WZ$ candidates with an estimated background of 6 events. An analysis of the $p_T$ spectrum of the $Z$ boson leads to a 95% C.L. limit of $-0.077 < \lambda_Z < 0.093$, for a form factor $\Lambda = 2$ TeV.

[16] AALTONEN 10K study $p\overline{p} \to W^+W^-$ with $W \to e/\mu\nu$. The $p_T$ of the leading (second) lepton is required to be > 20 (10) GeV. The final number of events selected is 654 of which $320 \pm 47$ are estimated to be background. The 95% C.L. interval is $-0.16 < \lambda_Z < 0.16$ for $\Lambda = 1.5$ TeV and $-0.14 < \lambda_Z < 0.15$ for $\Lambda = 2$ TeV.

[17] ABAZOV 07Z set limits on anomalous TGCs using the measured cross section and $p_T(Z)$ distribution in $WZ$ production with both the $W$ and the $Z$ decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $-0.17 < \lambda_Z < 0.21$.

[18] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $-0.39 < \lambda_Z < 0.39$, fixing $\kappa_Z$=1. With the assumption that the $WW\gamma$ and $WWZ$ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $-0.29 < \lambda < 0.30$.

[19] ABAZOV 05S study $\overline{p}p \to WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\overline{\ell}'$ ($\ell$ and $\ell' = e$ or $\mu$). Three events (estimated background $0.71 \pm 0.08$ events) with $WZ$ decay characteristics are observed from which they derive limits on the anomalous $WWZ$ couplings. The 95% CL limit for a form factor scale $\Lambda = 1.5$ TeV is $-0.48 < \lambda_Z < 0.48$, fixing $g_1^Z$ and $\kappa_Z$ to their Standard Model values.

## $g_5^Z$

## *W* ANOMALOUS MAGNETIC MOMENT

The full magnetic moment is given by $\mu_W = e(1+\kappa+\lambda)/2m_W$. In the Standard Model, at tree level, $\kappa = 1$ and $\lambda = 0$. Some papers have defined $\Delta\kappa = 1-\kappa$ and assume that $\lambda = 0$. Note that the electric quadrupole moment is given by $-e(\kappa-\lambda)/m_W^2$. A description of the parameterization of these moments and additional references can be found in HAGIWARA 87 and BAUR 88. The parameter $\Lambda$ appearing in the theoretical limits below is a regularization cutoff which roughly corresponds to the energy scale where the structure of the *W* boson becomes manifest.

| | | [11] HERZOG | 84 | THEO | |

[1] ABREU 01I combine results from $e^+e^-$ interactions at 189 GeV leading to $W^+W^-$, $We\nu_e$, and $\nu\overline{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV to determine $\Delta g_1^Z$, $\Delta\kappa_\gamma$, and $\lambda_\gamma$. $\Delta\kappa_\gamma$ and $\lambda_\gamma$ are simultaneously floated in the fit to determine $\mu_W$.

[2] ABE 95G report $-1.3 < \kappa < 3.2$ for $\lambda$=0 and $-0.7 < \lambda < 0.7$ for $\kappa$=1 in $p\overline{p} \to e\nu_e\gamma$X and $\mu\nu_\mu\gamma$X at $\sqrt{s} = 1.8$ TeV.

[3] ALITTI 92C measure $\kappa = 1^{+2.6}_{-2.2}$ and $\lambda = 0^{+1.7}_{-1.8}$ in $p\overline{p} \to e\nu\gamma$+ X at $\sqrt{s} = 630$ GeV. At 95%CL they report $-3.5 < \kappa < 5.9$ and $-3.6 < \lambda < 3.5$.

[4] SAMUEL 92 use preliminary CDF and UA2 data and find $-2.4 < \kappa < 3.7$ at 96%CL and $-3.1 < \kappa < 4.2$ at 95%CL respectively. They use data for $W\gamma$ production and radiative *W* decay.

[5] SAMUEL 91 use preliminary CDF data for $p\overline{p} \to W\gamma$X to obtain $-11.3 \le \Delta\kappa \le 10.9$. Note that their $\kappa = 1-\Delta\kappa$.

[6] GRIFOLS 88 uses deviation from $\rho$ parameter to set limit $\Delta\kappa \lesssim 65\ (M_W^2/\Lambda^2)$.

[7] GROTCH 87 finds the limit $-37 < \Delta\kappa < 73.5$ (90% CL) from the experimental limits on $e^+e^- \to \nu\overline{\nu}\gamma$ assuming three neutrino generations and $-19.5 < \Delta\kappa < 56$ for four generations. Note their $\Delta\kappa$ has the opposite sign as our definition.

[8] VANDERBIJ 87 uses existing limits to the photon structure to obtain $|\Delta\kappa| < 33\ (m_W/\Lambda)$. In addition VANDERBIJ 87 discusses problems with using the $\rho$ parameter of the Standard Model to determine $\Delta\kappa$.

[9] GRAU 85 uses the muon anomaly to derive a coupled limit on the anomalous magnetic dipole and electric quadrupole ($\lambda$) moments $1.05 > \Delta\kappa\ \ln(\Lambda/m_W) + \lambda/2 > -2.77$. In the Standard Model $\lambda = 0$.

[10] SUZUKI 85 uses partial-wave unitarity at high energies to obtain $|\Delta\kappa| \lesssim 190\ (m_W/\Lambda)^2$. From the anomalous magnetic moment of the muon, SUZUKI 85 obtains $|\Delta\kappa| \lesssim 2.2/\ln(\Lambda/m_W)$. Finally SUZUKI 85 uses deviations from the $\rho$ parameter and obtains a very qualitative, order-of-magnitude limit $|\Delta\kappa| \lesssim 150\ (m_W/\Lambda)^4$ if $|\Delta\kappa| \ll 1$.

[11] HERZOG 84 consider the contribution of *W*-boson to muon magnetic moment including anomalous coupling of $WW\gamma$. Obtain a limit $-1 < \Delta\kappa < 3$ for $\Lambda \gtrsim 1$ TeV.

### $c_{WWW}/\Lambda^2$, $c_W/\Lambda^2$, $c_B/\Lambda^2$

These couplings are used in EFT-based approaches to anomalous couplings. They are linearly related to the couplings discussed above.

[1] AABOUD 19BA study $WW$ production in decay modes with an electron and a muon. The charged leptons are each required to have a transverse momentum larger than 27 GeV and rapidity less than 2.5. The electron-muon system is required to have a mass larger than 55 GeV and a transverse momentum larger than 30 GeV. The missing transverse energy must be larger than 20 GeV. Events containing a jet with transverse momentum exceeding 35 GeV and rapidity smaller than 4.5 are rejected. A total of 12,659 events are selected in the data, with an expected background of $4240 \pm 477$ events. Analysing the transverse momentum spectrum of the leading charged lepton, the following 95% C.L. limits are derived in units of TeV$^{-2}$: $-3.4 < c_{WWW}/\Lambda^2 < 3.3$, $-7.4 < c_W/\Lambda^2 < 4.1$, $-21 < c_B/\Lambda^2 < 18$, $-1.6 < c_{\overline{W}WW}/\Lambda^2 < 1.6$, $-76 < c_{\overline{W}}/\Lambda^2 < 76$.

[2] SIRUNYAN 19AD study inclusive $WZ$ production, with $W$ and $Z$ decaying to electrons or muons. The leading (subleading) charged lepton candidate from the $Z$ boson decay is required to have a transverse momentum larger than 25 GeV (10 GeV). The charged lepton candidate from the $W$ boson decay is required to have a transverse momentum larger than 25 GeV. The invariant mass of the two leptons from $Z$ decay is required to be within 15 GeV of the $Z$ mass, while the invariant mass of the tri-lepton system is required to exceed 100 GeV. A total of 3,831 tri-lepton events are observed, with a fitted SM $WZ$ signal of 3166 $\pm$ 62 events and a fitted background of 666 $\pm$ 45 events. The approximated $WZ$ invariant mass distribution is analyzed to set 95% C.L. limits as follows: $-4.1 < c_W/\Lambda^2 < 1.1$, $-2.0 < c_{WWW}/\Lambda^2 < 2.1$, $-100 < c_B/\Lambda^2 < 160$, in units of TeV$^{-2}$.

[3] SIRUNYAN 19CL study $WW$ and $WZ$ production in lepton + jet events, with one $W$ boson decaying leptonically (electron or muon), and another $W$ or $Z$ boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limits are obtained in units of TeV$^{-2}$: $-1.58 < c_{WWW}/\Lambda^2 < 1.59$, $-2.00 < c_W/\Lambda^2 < 2.65$, $-8.78 < c_B/\Lambda^2 < 8.54$.

[4] AABOUD 18Q study $pp \to ZZ$ events at $\sqrt{s} = 13$ TeV with $Z \to e^+e^-$ or $Z \to \mu^+\mu^-$. The number of events observed in the 4$e$, 2$e$ 2$\mu$, and 4$\mu$ channels is 249, 465, and 303 respectively. Analysing the $p_T$ spectrum of the leading $Z$ boson, the following the following 95% C.L. limits are derived in units of TeV$^{-4}$: $-5.9 < c_{\widetilde{B}W}/\Lambda^4 < 5.9$, $-3.0 < c_{WW}/\Lambda^4 < 3.0$, $-3.3 < c_{BW}/\Lambda^4 < 3.3$, $-2.7 < c_{BB}/\Lambda^4 < 2.8$.

[5] SIRUNYAN 18BZ study $pp \to Z$ *jet jet* events at 13 TeV where $Z \to e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with $p_T$ of the leading/sub-leading lepton > 30/20 GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the $Z$ mass. The two highest $p_T$ jets are selected with $p_T$ of the leading/sub-leading jet > 50/30 GeV respectively and dijet invariant mass > 200 GeV. Templates in the transverse momentum of the $Z$ are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limits are obtained in units of TeV$^{-2}$: $-2.6 < c_{WWW}/\Lambda^2 < 2.6$ and $-8.4 < c_W/\Lambda^2 < 10.1$.

[6] AABOUD 17S analyze electroweak production of a $W$ boson in association with two jets at high dijet invariant mass, with the $W$ boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 $\pm$ 4 events expected in the Standard Model, yielding the following limits at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-33 < c_W/\Lambda^2 < 30$, $-170 < c_B/\Lambda^2 < 160$, $-13 < c_{WWW}/\Lambda^2 < 9$, $-580 < c_{\widetilde{W}}/\Lambda^2 < 580$, $-11 < c_{\widetilde{W}WW}/\Lambda^2 < 11$, in units of TeV$^{-2}$.

[7] AABOUD 17U analyze production of $WW$ or $WZ$ boson pairs with one $W$ boson decaying to electron or muon plus neutrino, and the other $W$ or $Z$ boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limits at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-3.1 < c_{WWW}/\Lambda^2 < 3.1$, $-19 < c_B/\Lambda^2 < 20$, $-5.1 < c_W/\Lambda^2 < 5.8$, in units of TeV$^{-2}$.

[8] KHACHATRYAN 17O analyse $WZ$ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the $Z$ boson mass. The $Z$ transverse momentum spectrum is analyzed to set 95% C.L. limits of: $-260 < c_B/\Lambda^2 < 210$, $-4.2 < c_W/\Lambda^2 < 8.0$, $-4.6 < c_{WWW}/\Lambda^2 < 4.2$, in units of TeV$^{-2}$.

[9] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\overline{q}$ production at 8 TeV where $\ell$ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the $p_T$ of the dijet system and the missing $E_T$ of the event yielding a total of 285 and 204 $WV$ events observed in the electron and muon channels. The following 95% C.L. limits in units of TeV$^{-2}$ are obtained: $-2.7 < c_{WWW}/\Lambda^2 < 2.7$, $-14 < c_B/\Lambda^2 < 17$, $-2.0 < c_W/\Lambda^2 < 5.7$.

[10] AAD 16AR study $WW$ production in $pp$ collisions and select 6636 $WW$ candidates in decay modes with electrons or muons with an expected background of 1546 $\pm$ 157 events. Assuming an EFT formulation, a fit to the transverse momentum distribution of the leading charged lepton, leads to 95% C.L. ranges of: $-4.61 < c_{WWW}/\Lambda^2 < 4.60$, $-5.87 < c_W/\Lambda^2 < 10.54$ and $-20.9 < c_B/\Lambda^2 < 26.3$,in units of TeV$^{-2}$.

[11] AAD 16P study $WZ$ production in $pp$ collisions and select 2091 $WZ$ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 $\pm$ 7 events. Analyzing the $WZ$ transverse momentum distribution, the resulting 95% C.L. limits are: $-3.9 < c_{WWW}/\Lambda^2 < 4.0$, $-4.3 < c_W/\Lambda^2 < 6.8$, and $-320 < c_B/\Lambda^2 < 210$, in units of TeV$^{-2}$.

[12] KHACHATRYAN 16BI determine the $W^+W^-$ production cross section using unlike sign di-lepton ($e$ or $\mu$) events with high $p_T$. The leptons have $p_T > 20$ GeV/c and are isolated. Events are required to have no jets above $p_T$ of 30 GeV/c. 4847 (2233) events are selected with different (same) flavor leptons, with an expected total background of 1179 $\pm$ 123 (643 $\pm$ 73) events. Analysing the di-lepton invariant mass spectrum, the following values are obtained: $c_{WWW}/\Lambda^2 = 0.1 \pm 3.2$, $c_W/\Lambda^2 = -3.6^{+5.0}_{-4.5}$ and $c_B/\Lambda^2 = -3.2^{+15.0}_{-14.5}$, in units of TeV$^{-2}$. The limits at 95% C.L. are: $-5.7 < c_{WWW}/\Lambda^2 < 5.9$, $-11.4 < c_W/\Lambda^2 < 5.4$ and $-29.2 < c_B/\Lambda^2 < 23.9$, in units of TeV$^{-2}$.

## ANOMALOUS *W*/*Z* QUARTIC COUPLINGS

Revised November 2015 by M.W. Grünewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Quartic couplings, $WWZZ$, $WWZ\gamma$, $WW\gamma\gamma$, and $ZZ\gamma\gamma$, were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowers dimensional representation of operators (dimension 6) which presumes the SU(2)×U(1) gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. . In this representation possible quartic couplings, $a_0, a_c, a_n$, are expressed in terms of the following dimension-6 operators [1,2];

$$L_6^0 = -\frac{e^2}{16\Lambda^2}\, a_0\, F^{\mu\nu}\, F_{\mu\nu}\vec{W}^\alpha \cdot \vec{W}_\alpha$$
$$L_6^c = -\frac{e^2}{16\Lambda^2}\, a_c\, F^{\mu\alpha}\, F_{\mu\beta}\vec{W}^\beta \cdot \vec{W}_\alpha$$
$$L_6^n = -i\frac{e^2}{16\Lambda^2}\, a_n \epsilon_{ijk}\, W^{(i)}_{\mu\alpha}\, W^{(j)}_{\nu}\, W^{(k)\alpha} F^{\mu\nu}$$
$$\widetilde{L}_6^0 = -\frac{e^2}{16\Lambda^2}\, \widetilde{a}_0\, F^{\mu\nu}\, \widetilde{F}_{\mu\nu}\vec{W}^\alpha \cdot \vec{W}_\alpha$$
$$\widetilde{L}_6^n = -i\frac{e^2}{16\Lambda^2}\, \widetilde{a}_n \epsilon_{ijk}\, W^{(i)}_{\mu\alpha}\, W^{(j)}_{\nu}\, W^{(k)\alpha} \widetilde{F}^{\mu\nu}$$

where $F, W$ are photon and $W$ fields, $L_6^0$ and $L_6^c$ conserve $C$, $P$ separately ($\widetilde{L}_6^0$ conserves only $C$) and generate anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ couplings, $L_6^n$ violates $CP$ ($\widetilde{L}_6^n$ violates both $C$ and $P$) and generates an anomalous $W^+W^-Z\gamma$ coupling, and $\Lambda$ is an energy scale for new physics. For the $ZZ\gamma\gamma$ coupling the $CP$-violating term represented by $L_6^n$ does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the $WW\gamma\gamma$ and $ZZ\gamma\gamma$ couplings separately, leading to two sets parametrized as $a_0^V/\Lambda^2$ and $a_c^V/\Lambda^2$, where $V = W$ or $Z$.

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned}\mathcal{L}_{AQGC} = &-\frac{e^2}{8}\frac{a_0^W}{\Lambda^2}F_{\mu\nu}F^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2}{16}\frac{a_c^W}{\Lambda^2}F_{\mu\nu}F^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &-e^2g^2\frac{\kappa_0^W}{\Lambda^2}F_{\mu\nu}Z^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2g^2}{2}\frac{\kappa_c^W}{\Lambda^2}F_{\mu\nu}Z^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &+\frac{f_{T,0}}{\Lambda^4}Tr[\widehat{W}_{\mu\nu}\widehat{W}^{\mu\nu}] \times Tr[\widehat{W}_{\alpha\beta}\widehat{W}^{\alpha\beta}]\end{aligned}$$

The energy scale of possible new physics is $\Lambda$, and $g = e/sin(\theta_W)$, $e$ being the unit electric charge and $\theta_W$ the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators $a_0^W/\Lambda^2$ and $a_c^W/\Lambda^2$ are associated with the $WW\gamma\gamma$ vertex. Among dimension 8 operators, $\kappa_0^W/\Lambda^2$ and $\kappa_c^W/\Lambda^2$ are associated with the $WWZ\gamma$ vertex, whereas the parameter $f_{T,0}/\Lambda^4$ contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters $f_{M,i}/\Lambda^4$ as follows [3]:

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,2}}{\Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,3}}{\Lambda^4}$$

where $g' = e/cos(\theta_W)$ and $M_W$ is the invariant mass of the $W$ boson. This relation provides a translation between limits on dimension 6 operators $a_{0,c}^W$ and $f_{M,j}/\Lambda^4$. It is further required [4] that $f_{M,0} = 2f_{M,2}$ and $f_{M,1} = 2f_{M,3}$ which suppresses contributions to the $WWZ\gamma$ vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total – $f_{S,i},\ i = 1, 2$, $f_{M,i},\ i = 0, \ldots, 8$ and $f_{T,i}, i = 0, \ldots, 9$ – each scaled by $1/\Lambda^4$.

The ATLAS collaboration [6], on the other hand, follows a K-matrix driven approach of Ref. 7 in which the anomalous couplings can be expressed in terms of two parameters $\alpha_4$ and $\alpha_5$, which account for all BSM effects.

It is the early stages in the determination of quartic couplings by the LHC experiments. It is hoped that the two collaborations, ATLAS and CMS, will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison and allow for a possible LHC combination.

### $a_0/\Lambda^2$, $a_c/\Lambda^2$, $a_n/\Lambda^2$, $\kappa_0^W/\Lambda^2$, $\kappa_c^W/\Lambda^2$, $f_{T,0}/\Lambda^4$, $f_{M,i}/\Lambda^4$, $\alpha_4$, $\alpha_5$, $F_{S,i}/\Lambda^4$, $F_{M,i}/\Lambda^4$, $F_{T,i}/\Lambda^4$

Anomalous $W$ quartic couplings are measured by the experiments at LEP, the Tevatron, and the LHC. Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below). As discussed in the review on the "Anomalous $W/Z$ quartic couplings (QGCS)," the measurements are typically done using different operator expansions which then do not allow the results to be compared and averaged. At least one common framework should be agreed upon for the use in the future publications by the experiments.

Some publications from LHC experiments derive limits for various assumed values of the form-factor cutoff $\Lambda_{FF}$. The values quoted below are for $\Lambda_{FF} \to \infty$.

[1] SIRUNYAN 19BM search for the final state $W^+W^-W^\pm$ using $W$ decays to electrons or muons. Two event samples are considered, events with three leptons, or events with two oppositely charged leptons accompanied by two jets. In a kinematic region selected to enhance the effect of anomalous couplings, no events are selected in the data, and 95% C.L. upper limits are obtained as follows: $-1.2 < f_{T,0}/\Lambda^4 < 1.2$, $-3.3 < f_{T,1}/\Lambda^4 < 3.3$, $-2.7 < f_{T,2}/\Lambda^4 < 2.6$, in units of TeV$^{-4}$ and without application of a form factor.

[2] SIRUNYAN 19BP study $WZ$ plus 2 jets production, using $W$ and $Z$ decay channels with electrons or muons. In the data, 75 events are selected, with a fitted SM signal of $15.1 \pm 1.6$ events and a fitted background of $62.4 \pm 2.8$ events. The transverse mass distribution of the $WZ$ system is analyzed to set the following limits at 95% C.L., in units of TeV$^{-4}$: $-9.15 < f_{M,0}/\Lambda^4 < 9.15$, $-9.15 < f_{M,1}/\Lambda^4 < 9.45$, $-26.5 < f_{S,0}/\Lambda^4 < 27.5$, $-41.2 < f_{S,1}/\Lambda^4 < 42.8$, $-0.75 < f_{T,0}/\Lambda^4 < 0.81$, $-0.49 < f_{T,1}/\Lambda^4 < 0.55$, $-1.49 < f_{T,2}/\Lambda^4 < 1.85$.

[3] SIRUNYAN 19CQ search for anomalous electroweak production of vector boson pairs in association with two jets. Events are selected by requiring two jets with a large invariant mass and rapidity separation, one or two leptons (electrons or muons), and a $W$ or $Z$ boson decaying hadronically. In the $WV$ ($ZV$) channel, 347 (47) events are selected in the data, with a total expected background of $352 \pm 19$ ($50.3 \pm 5.8$) events. Analysing the mass distribution of the $WV$ or $ZV$ system, the following 95% C.L. limits are obtained: $-2.7 < f_{S,0}/\Lambda^4 < 2.7$, $-3.4 < f_{S,1}/\Lambda^4 < 3.4$, $-0.69 < f_{M,0}/\Lambda^4 < 0.70$, $-2.0 < f_{M,1}/\Lambda^4 < 2.1$, $-1.3 < f_{M,6}/\Lambda^4 < 1.3$, $-3.4 < f_{M,7}/\Lambda^4 < 3.4$, $-0.12 < f_{T,0}/\Lambda^4 < 0.11$, $-0.12 < f_{T,1}/\Lambda^4 < 0.13$, $-0.28 < f_{T,2}/\Lambda^4 < 0.28$, in units of TeV$^{-4}$.

[4] SIRUNYAN 18CC study $pp$ collisions at $\sqrt{s} = 13$ TeV leading to a pair of same-sign $W$ pairs decaying leptonically ($e$ or $\mu$) associated with a pair of jets. Isolated leptons with $p_T > 25$ (20) GeV for the leading (trailing) lepton, with $|\eta| < 2.5$ (2.4) for $e$ ($\mu$) and jets with $p_T > 30$ GeV, $|\eta| < 5.0$, $|\Delta\eta_{jj}| > 2.5$ and $m_{jj} > 500$ GeV is required. Further cuts are applied to minimize $Z \to e\,e$ events, non-prompt leptons and hadronically decaying taus. The number of selected events is 201, with an expected SM signal of $66.9 \pm 2.4$ and background of $138 \pm 13$ events. Analysing the dilepton invariant mass spectrum the following 95% C.L. limits are derived: $-7.7 < f_{S,0}/\Lambda^4 < 7.7$, $-21.6 < f_{S,1}/\Lambda^4 < 21.8$, $-6.0 < f_{M,0}/\Lambda^4 < 5.9$, $-8.7 < f_{M,1}/\Lambda^4 < 9.1$, $-11.9 < f_{M,6}/\Lambda^4 < 11.8$, $-13.3 < f_{M,7}/\Lambda^4 < 12.9$, $-0.62 < f_{T,0}/\Lambda^4 < 0.65$, $-0.28 < f_{T,1}/\Lambda^4 < 0.31$, $-0.89 < f_{T,2}/\Lambda^4 < 1.02$.

[5] AABOUD 17AA analyze $W^\pm W^\pm$ production in association with two jets and $W$ decay modes with electrons or muons. In the kinematic region of VBS the effect of anomalous QGCs is enhanced by requiring the transverse mass of the $WW$ system to be larger than 400 GeV. In the data, 8 events are selected with a total background expected from SM processes of $3.8 \pm 0.6$ events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% CL limits on the QGCs: $-0.14 < \alpha_4 < 0.15$ and $-0.22 < \alpha_5 < 0.22$. Supersedes AAD 14AM.

[6] AABOUD 17AG determine the $WW\gamma$ and $WZ\gamma$ cross sections in 8 TeV $pp$ interactions by studying the final states $e\nu\mu\nu\gamma$ and $e\nu jj\gamma$ or $\mu\nu jj\gamma$. Upper limits on the production cross sections are derived in a fiducial region optimized for BSM physics. These are used to derive the following 95% C.L. upper limits for quartic couplings assuming the form scale factor, $\Lambda_{FF} = \infty$ (all in units of $10^3$ TeV$^{-4}$): $-0.3 < f_{M,0}/\Lambda^4 < 0.3$, $-0.5 < f_{M,1}/\Lambda^4 < 0.5$, $-1.8 < f_{M,2}/\Lambda^4 < 1.8$, $-1.1 < f_{M,4}/\Lambda^4 < 1.1$, $-1.7 < f_{M,5}/\Lambda^4 < 1.7$, $-0.6 < f_{M,6}/\Lambda^4 < 0.6$, $-1.1 < f_{M,7}/\Lambda^4 < 1.1$, $-0.1 < f_{T,0}/\Lambda^4 < 0.1$, $-0.2 < f_{T,1}/\Lambda^4 < 0.2$, $-0.4 < f_{T,4}/\Lambda^4 < 0.4$, $-1.5 < f_{T,5}/\Lambda^4 < 1.6$, $-1.9 < f_{T,6}/\Lambda^4 < 1.9$, $-4.3 < f_{T,7}/\Lambda^4 < 4.3$.

[7] AABOUD 17D analyze electroweak diboson ($WV$, $V = W, Z$) production in association with a high-mass dijet system. In the data, 32 events are selected with an expected total background of $32 \pm 12$ events. Analysing the transverse mass distribution of the $WV$ system, the following limits are set at 95% C.L.: $-0.024 < \alpha_4 < 0.030$ and $-0.028 < \alpha_5 < 0.033$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[8] AABOUD 17J analyze the $Z\gamma$ production in association with a high-mass dijet system, with the $Z$ boson decaying into a pair of electrons, muons, or neutrinos. In the charged lepton (neutrino) channel, events are selected with a dijet mass larger than 500 (600) GeV and a transverse photon energy larger than 250 (150) GeV, with 2 (4) events selected in the data and $0.30 \pm 0.08$ ($1.6 \pm 0.5$) expected background events. The observed event yield is used to determine 95% CL limits as follows: $-4.1 \times 10^3 < f_{T,9}/\Lambda^4 < 4.2 \times 10^3$, $-1.9 \times 10^3 < f_{T,8}/\Lambda^4 < 2.1 \times 10^3$, $-1.9 \times 10^1 < f_{T,0}/\Lambda^4 < 1.6 \times 10^1$, $-1.6 \times 10^2 < f_{M,0}/\Lambda^4 < 1.8 \times 10^2$, $-3.5 \times 10^2 < f_{M,1}/\Lambda^4 < 3.4 \times 10^2$, $-8.9 \times 10^2 < f_{M,2}/\Lambda^4 < 8.9 \times 10^2$, $-1.7 \times 10^3 < f_{M,3}/\Lambda^4 < 1.7 \times 10^3$, in units of TeV$^{-4}$ and without application of a form factor.

[9] AABOUD 17M analyze tri-boson $W^\pm W^\pm W^\mp$ production in decay channels with three charged leptons or two like-sign charged leptons with two jets, where the lepton can be an electron or muon. In the data, 24 tri-lepton events and 21 di-lepton plus jets events are selected, compared to a total event yield expected in the SM of $30.8 \pm 3.0$ and $21.9 \pm 2.0$, respectively. Analysing the tri-lepton transverse mass or the transverse momentum sum of the two leptons, two jets and the missing transverse energy, the following limits at 95% CL are derived for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-0.13 < f_{S,0}/\Lambda^4 < 0.18$, $-0.21 < f_{S,1}/\Lambda^4 < 0.27$, in units of $10^4$ TeV$^{-4}$, which are converted into the following limits: $-0.49 < \alpha_4 < 0.75$ and $-0.48 < \alpha_5 < 0.62$.

[10] KHACHATRYAN 17AA analyse electroweak production of $Z\gamma$ in association with two hadronic jets, with the $Z$ boson decaying to electron or muon pairs. Events with photon transverse momentum larger than 60 GeV and di-jet invariant mass larger than 400 GeV are selected. The $Z\gamma$ inavariant mass spectrum is analysed to set 95% C.L. limits as follows: $-71 < f_{M,0}/\Lambda^4 < 75$, $-190 < f_{M,1}/\Lambda^4 < 182$, $-32 < f_{M,2}/\Lambda^4 < 31$, $-58 < f_{M,3}/\Lambda^4 < 59$, $-3.8 < f_{T,0}/\Lambda^4 < 3.4$, $-4.4 < f_{T,1}/\Lambda^4 < 4.4$, $-9.9 < f_{T,2}/\Lambda^4 < 9.0$, $-1.8 < f_{T,8}/\Lambda^4 < 1.8$, $-4.0 < f_{T,9}/\Lambda^4 < 4.0$, in units of TeV$^{-4}$ and without application of a form factor.

[11] KHACHATRYAN 17M analyse electroweak production of $W\gamma$ in association with two hadronic jets, with the $W$ boson decaying to electrons or muons. Events with photon transverse momentum larger than 200 GeV and di-jet invariant mass larger than 200 GeV are selected. The $W$ transverse momentum spectrum is analysed to set 95% C.L. limits as follows: $-77 < f_{M,0}/\Lambda^4 < 74$, $-125 < f_{M,1}/\Lambda^4 < 129$, $-26 < f_{M,2}/\Lambda^4 < 26$, $-43 < f_{M,3}/\Lambda^4 < 44$, $-40 < f_{M,4}/\Lambda^4 < 40$, $-65 < f_{M,5}/\Lambda^4 < 65$, $-129 < f_{M,6}/\Lambda^4 < 129$, $-164 < f_{M,7}/\Lambda^4 < 162$, $-5.4 < f_{T,0}/\Lambda^4 < 5.6$, $-3.7 < f_{T,1}/\Lambda^4 < 4.0$, $-11 < f_{T,2}/\Lambda^4 < 12$, $-3.8 < f_{T,5}/\Lambda^4 < 3.8$, $-2.8 < f_{T,6}/\Lambda^4 < 3.0$, $-7.3 < f_{T,7}/\Lambda^4 < 7.7$, in units of TeV$^{-4}$ and without application of a form factor.

[12] SIRUNYAN 17AD study $pp$ collisions at $\sqrt{s} = 13$ TeV to determine the cross section of $ZZjj$ with the $Z$ decaying to $ee$ or $\mu\mu$. The $ZZ$ mass distribution is used to set upper limits on the anomalous quartic couplings. The 95% upper limits for the relevant quartic couplings in units of TeV$^{-4}$ are: $-0.46 < f_{T,0}/\Lambda^4 < 0.44$, $-0.61 < f_{T,1}/\Lambda^4 < 0.61$, $-1.2 < f_{T,2}/\Lambda^4 < 1.2$, $-0.84 < f_{T,8}/\Lambda^4 < 0.84$, $-1.8 < f_{T,9}/\Lambda^4 < 1.8$.

[13] SIRUNYAN 17AR study $pp$ collisions at $\sqrt{s} = 8$ TeV to determine the cross section of $pp \to W\gamma\gamma$ and $pp \to Z\gamma\gamma$ where $W \to \ell\nu$ and $Z \to \ell^+\ell^-$, $\ell$ being an electron or a muon. The number of $W$ events in the $e$ and $\mu$ channels is 63 and 108 respectively, and the number of $Z$ events in the $e$ and $\mu$ channels is 117 and 141. To increase sensitivity, the transverse momentum of the leading photon is required to be larger than 70 GeV. The 95% C.L. upper limits in units of TeV$^{-4}$ are $-701 < f_{M,2}/\Lambda^4 < 683$, $-1170 < f_{M,3}/\Lambda^4 < 1220$, $-33.5 < f_{T,0}/\Lambda^4 < 34.0$, $-44.3 < f_{T,1}/\Lambda^4 < 44.8$, $-93.8 < f_{T,2}/\Lambda^4 < 93.2$.

[14] AABOUD 16E study $WW$ production in two-photon mediated $pp$ collisions at 8 TeV where the $W$ boson decays into an electron or muon, probing the $\gamma\gamma WW$ vertex for anomalous quartic gauge couplings. The lepton $p_T$ is required to be larger than 30 GeV. Limits on anomalous couplings are determined from events with $p_T$ larger than 120 GeV where the aQGC effect is enhanced and the SM background reduced; in the data corresponding to an integrated luminosity of 20.2fb$^{-1}$, 1 event is selected with an expected SM background of $0.37 \pm 0.13$ events. The 95% C.L. limits without a form-factor cutoff ($\Lambda_{\text{cutoff}} \to \infty$) are as follows: $-1.7 < a_0^W/\Lambda^2 < 1.7$ and $-6.4 < a_C^W/\Lambda^2 < 6.3$ in units of $10^{-6}$ GeV$^{-2}$. In terms of another set of variables: $-6.6 < f_{M,0}/\Lambda^4 < 6.6$ and $-24 < f_{M,1}/\Lambda^4 < 25$ in units of $10^{-11}$ GeV$^{-4}$.

[15] AAD 16Q study $Z\gamma\gamma$ production in $pp$ collisions. In events with no additional jets, 29 (22) $Z$ decays to electron (muon) pairs are selected, with an expected background of $3.3 \pm 1.1$ ($6.5 \pm 2.0$) events, as well as 19 $Z$ decays to netrino pairs with an expected background of $8.3 \pm 4.4$ events. Analysing the photon transverse momentum distribution for $m_{\gamma\gamma}$ above 200 GeV (300 GeV) for lepton (neutrino) events, yields the 95% C.L. limits: $-1.6 \times 10^4 < f_{M,2}/\Lambda^4 < 1.6 \times 10^4$, $-2.9 \times 10^4 < f_{M,3}/\Lambda^4 < 2.7 \times 10^4$, $-0.86 \times 10^2 < f_{T,0}/\Lambda^4 < 1.03 \times 10^2$, $-0.69 \times 10^3 < f_{T,5}/\Lambda^4 < 0.68 \times 10^3$, $-0.74 \times 10^4 < f_{T,9}/\Lambda^4 < 0.74 \times 10^4$ in units of TeV$^{-4}$ and without application of a form factor $\Lambda_{FF}$.

[16] KHACHATRYAN 16AX searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \to ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 13 events containing an $e^\pm\mu^\mp$ pair with $p_T(e, \mu) > 30$ GeV are selected in a total luminosity of 19.7 fb$^{-1}$, with an expected $\gamma\gamma \to WW$ signal of $5.3 \pm 0.1$ events and an expected background of $3.9 \pm 0.5$ events. When combining with the data collected at 7 TeV (CHATRCHYAN 13AA), and not assuming a form factor, the following 1-parameter limits at 95% C.L. are obtained from the $p_T(e, \mu)$ spectrum: $|a_0^W/\Lambda^2| < 1.1 \times 10^{-6}$ GeV$^{-2}$ ($a_C^W = 0$), and $|a_C^W/\Lambda^2| < 4.1 \times 10^{-6}$ GeV$^{-2}$ ($a_0^W = 0$). In terms of another set of variables: $|f_{M,0}/\Lambda^4| < 4.2 \times 10^{-12}$ GeV$^{-4}$, $|f_{M,1}/\Lambda^4| < 16 \times 10^{-12}$ GeV$^{-4}$, $|f_{M,2}/\Lambda^4| < 2.1 \times 10^{-12}$ GeV$^{-4}$, $|f_{M,3}/\Lambda^4| < 7.8 \times 10^{-12}$ GeV$^{-4}$.

[17] AAD 15N study $W\gamma\gamma$ events in 8 TeV $pp$ interactions, where the $W$ decays into an electron or a muon. The events are characterized by an isolated lepton, a missing transverse energy due to the decay neutrino, and two isolated photons, with the $p_T$ of the lepton and the photons being $> 20$ GeV. The number of candidate events observed in the electron channel for N(jet) $\geq$ 0 and N(jet) = 0 is 47 and 15, the corresponding numbers for the muon channel being 110 and 53. The backgrounds expected are $30.2 \pm 7.4$, $8.7 \pm 3.0$, $52.1 \pm 12.2$, and $24.4 \pm 8.3$ respectively. The 95% C.L. limits on the values of the parameters $f_{T,0}/\Lambda^4$, $f_{M,2}/\Lambda^4$ and $f_{M,3}/\Lambda^4$ are $-0.9$–$0.9 \times 10^2$, $-0.8$–$0.8 \times 10^4$, and $-1.5$–$1.4 \times 10^4$ respectively, without application of a form factor $\Lambda_{FF}$.

[18] KHACHATRYAN 15D study vector-boson-scattering tagged by two jets, requiring two same-sign charged leptons arising from $W^\pm W^\pm$ production and decay. The two jets must have a transverse momentum larger than 30 GeV, while the leptons, electrons or muons, must have a transverse momentum $> 20$ GeV. The dijet mass is required to be $> 500$ GeV, the dilepton mass $> 50$ GeV, with additional requirement of differing from the $Z$ mass by $> 15$ GeV. In the two categories $W^+W^+$ and $W^-W^-$, 10 and 2 data events are observed in a data sample corresponding to an integrated luminosity of 19.4 fb$^{-1}$, with an expected background of $3.1 \pm 0.6$ and $2.6 \pm 0.5$ events. Analysing the distribution of the dilepton invariant mass, the following limits at 95% C.L. are obtained, in units of TeV$^{-4}$: $-38 < f_{S,0}/\Lambda^4 < 40$, $-118 < f_{S,1}/\Lambda^4 < 120$, $-33 < f_{M,0}/\Lambda^4 < 32$, $-44 < f_{M,1}/\Lambda^4 < 47$, $-65 < f_{M,6}/\Lambda^4 < 63$, $-70 < f_{M,7}/\Lambda^4 < 66$, $-4.2 < f_{T,0}/\Lambda^4 < 4.6$, $-1.9 < f_{T,1}/\Lambda^4 < 2.2$, $-5.2 < f_{T,2}/\Lambda^4 < 6.4$.

[19] AAD 14AM analyze electroweak production of $WW$ jet jet same-charge diboson plus two jets production, with the $W$ bosons decaying to electron or muon, to study the quartic $WWWW$ coupling. In a kinematic region enhancing the electroweak production over the strong production, 34 events are observed in the data while $29.8 \pm 2.4$ events are expected with a backgound of $15.9 \pm 1.9$ events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% CL limits on the quartic gauge couplings: $-0.14 < \alpha_4 < 0.16$ and $-0.23 < \alpha_5 < 0.24$.

[20] CHATRCHYAN 14Q study $WV\gamma$ production in 8 TeV $pp$ collisions, in the single lepton final state, with $W \to \ell\nu$, $Z \to$ dijet or $W \to \ell\nu$, $W \to$ dijet, the dijet mass resolution precluding differentiation between the $W$ and $Z$. $p_T$ and pseudo-rapidity cuts are put on the lepton, the photon and the two jets to minimize backgrounds. The dijet mass is required to be between 70–100 GeV and $|\Delta\eta_{jj}| < 1.4$. The selected number of muon (electron) events are 183 (139), with SM expectation being $194.2 \pm 11.5$ ($147.9 \pm 10.7$) including signal and background. The photon $E_T$ distribution is used to set limits on the anomalous quartic couplings. The following 95% CL limits are deduced (all in units of TeV$^{-2}$ or TeV$^{-4}$): $-21 < a_0^W/\Lambda^2 < 20$, $-34 < a_C^W/\Lambda^2 < 32$, $-12 < \kappa_0^W/\Lambda^2 < 10$ and $-18 < \kappa_C^W/\Lambda^2 < 17$; and $-25 < f_{T,0}/\Lambda^4 < 24$ TeV$^{-4}$.

[21] ABAZOV 13D searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \to ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 946 events containing an $e^+e^-$ pair with missing energy are selected in a total luminosity of 9.7 fb$^{-1}$, with an expectation of $983 \pm 108$ events from Standard-Model processes. The following 1-parameter limits at 95% CL are otained: $|a_0^W/\Lambda^2| < 4.3 \times 10^{-4}$ GeV$^{-2}$ ($a_C^W = 0$), $|a_C^W/\Lambda^2| < 1.5 \times 10^{-3}$ GeV$^{-2}$ ($a_0^W = 0$).

[22] CHATRCHYAN 13AA searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \to ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 2 events containing an $e^\pm\mu^\mp$ pair with $p_T(e, \mu) > 30$ GeV are selected in a total luminosity of 5.05 fb$^{-1}$, with an expected $ppWW$ signal of $2.2 \pm 0.4$ events and an expected background of $0.84 \pm 0.15$ events. The following 1-parameter limits at 95% CL are otained from the $p_T(e, \mu)$ spectrum: $|a_0^W/\Lambda^2| < 4.0 \times 10^{-6}$ GeV$^{-2}$ ($a_C^W = 0$), $|a_C^W/\Lambda^2| < 1.5 \times 10^{-5}$ GeV$^{-2}$ ($a_0^W = 0$).

[23] ABBIENDI 04B select 187 $e^+e^- \to W^+W^-\gamma$ events in the C.M. energy range 180–209 GeV, where $E_\gamma > 2.5$ GeV, the photon has a polar angle $|\cos\theta_\gamma| < 0.975$ and is well isolated from the nearest jet and charged lepton, and the effective masses of both fermion-antifermion systems agree with the $W$ mass within $3\,\Gamma_W$. The measured differential cross section as a function of the photon energy and photon polar angle is used to extract the 95% CL limits: $-0.020$ GeV$^{-2} < a_0/\Lambda^2 < 0.020$ GeV$^{-2}$, $-0.053$ GeV$^{-2} < a_c/\Lambda^2 < 0.037$ GeV$^{-2}$ and $-0.16$ GeV$^{-2} < a_n/\Lambda^2 < 0.15$ GeV$^{-2}$.

[24] ABBIENDI 04L select 20 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ acoplanar events in the energy range 180–209 GeV and 176 $e^+e^- \to q\overline{q}\gamma\gamma$ events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ quartic couplings. Further combining with the $W^+W^-\gamma$ sample of ABBIENDI 04B the following one–parameter 95% CL limits are obtained: $-0.007 < a_0^Z/\Lambda^2 < 0.023$ GeV$^{-2}$, $-0.029 < a_C^Z/\Lambda^2 < 0.029$ GeV$^{-2}$, $-0.020 < a_0^W/\Lambda^2 < 0.020$ GeV$^{-2}$, $-0.052 < a_C^W/\Lambda^2 < 0.037$ GeV$^{-2}$.

[25] In the CM energy range 183 to 209 GeV HEISTER 04A select 30 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ events with two acoplanar, high energy and high transverse momentum photons. The photon–photon acoplanarity is required to be $> 5°$, $E_\gamma/\sqrt{s} > 0.025$ (the more energetic photon having energy $> 0.2\sqrt{s}$), $p_{T_\gamma}/E_{\text{beam}} > 0.05$ and $|\cos\theta_\gamma| < 0.94$. A likelihood fit to the photon energy and recoil missing mass yields the following one–parameter 95% CL limits: $-0.012 < a_0^Z/\Lambda^2 < 0.019$ GeV$^{-2}$, $-0.041 < a_C^Z/\Lambda^2 < 0.044$ GeV$^{-2}$, $-0.060 < a_0^W/\Lambda^2 < 0.055$ GeV$^{-2}$, $-0.099 < a_C^W/\Lambda^2 < 0.093$ GeV$^{-2}$.

[26] ABDALLAH 03I select 122 $e^+e^- \to W^+W^-\gamma$ events in the C.M. energy range 189–209 GeV, where $E_\gamma > 5$ GeV, the photon has a polar angle $|\cos\theta_\gamma| < 0.95$ and is well isolated from the nearest charged fermion. A fit to the photon energy spectra yields $a_c/\Lambda^2 = 0.000^{+0.019}_{-0.040}$ GeV$^{-2}$, $a_0/\Lambda^2 = -0.004^{+0.018}_{-0.010}$ GeV$^{-2}$, $\tilde{a}_0/\Lambda^2 = -0.007^{+0.019}_{-0.008}$ GeV$^{-2}$, $a_n/\Lambda^2 = -0.09^{+0.16}_{-0.05}$ GeV$^{-2}$, and $\tilde{a}_n/\Lambda^2 = +0.05^{+0.07}_{-0.15}$ GeV$^{-2}$, keeping the other parameters fixed to their Standard Model values (0). The 95% CL limits are: $-0.063$ GeV$^{-2} < a_c/\Lambda^2 < +0.032$ GeV$^{-2}$, $-0.020$ GeV$^{-2} < a_0/\Lambda^2 < +0.020$ GeV$^{-2}$, $-0.020$ GeV$^{-2} < \tilde{a}_0/\Lambda^2 < +0.020$ GeV$^{-2}$, $-0.18$ GeV$^{-2} < a_n/\Lambda^2 < +0.14$ GeV$^{-2}$, $-0.16$ GeV$^{-2} < \tilde{a}_n/\Lambda^2 < +0.17$ GeV$^{-2}$.

[27] ACHARD 02F select 86 $e^+e^- \to W^+W^-\gamma$ events at 192–207 GeV, where $E_\gamma > 5$ GeV and the photon is well isolated. They also select 43 acoplanar $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ events in this energy range, where the photon energies are $> 5$ GeV and $> 1$ GeV and the photon polar angles are between 14° and 166°. All these 43 events are in the recoil mass region corresponding to the $Z$ (75–110 GeV). Using the shape and normalization of the photon spectra in the $W^+W^-\gamma$ events, and combining with the 42 event sample from

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

189 GeV data (ACCIARRI 00T), they obtain: $a_0/\Lambda^2 = 0.000 \pm 0.010$ GeV$^{-2}$, $a_c/\Lambda^2 = -0.013 \pm 0.023$ GeV$^{-2}$, and $a_n/\Lambda^2 = -0.002 \pm 0.076$ GeV$^{-2}$. Further combining the analyses of $W^+W^-\gamma$ events with the low recoil mass region of $\nu\overline{\nu}\gamma\gamma$ events (including samples collected at 183 + 189 GeV), they obtain the following one-parameter 95% CL limits: $-0.015$ GeV$^{-2} < a_0/\Lambda^2 < 0.015$ GeV$^{-2}$, $-0.048$ GeV$^{-2} < a_c/\Lambda^2 < 0.026$ GeV$^{-2}$, and $-0.14$ GeV$^{-2} < a_n/\Lambda^2 < 0.13$ GeV$^{-2}$.

*Z* Boson

## Z MASS

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The $Z$ boson" and ref. LEP-SLC 06). The fit is performed using the $Z$ mass and width, the $Z$ hadronic pole cross section, the ratios of hadronic to leptonic partial widths, and the $Z$ pole forward-backward lepton asymmetries. This set is believed to be most free of correlations.

The $Z$-boson mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass dependent width. The value is 34 MeV greater than the real part of the position of the pole (in the energy-squared plane) in the $Z$-boson propagator. Also the LEP experiments have generally assumed a fixed value of the $\gamma - Z$ interferences term based on the standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted $Z$ mass. See ACCIARRI 00Q and ABBIENDI 04G for a detailed investigation of both these issues.

| 91.14 | ±0.12 | | 480 | [12] ABRAMS | 89B | MRK2 | $E_{cm}^{ee}$= 89–93 GeV |
| 93.1 | ±1.0 | ±3.0 | 24 | [13] ALBAJAR | 89 | UA1 | $E_{cm}^{p\overline{p}}$= 546,630 GeV |

[1] ABBIENDI 01A error includes approximately 2.3 MeV due to statistics and 1.8 MeV due to LEP energy uncertainty.
[2] The error includes 1.6 MeV due to LEP energy uncertainty.
[3] The error includes 1.8 MeV due to LEP energy uncertainty.
[4] BARATE 00C error includes approximately 2.4 MeV due to statistics, 0.2 MeV due to experimental systematics, and 1.7 MeV due to LEP energy uncertainty.
[5] ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic $e^+p$ and $e^-p$ neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.
[6] ABBIENDI 04G obtain this result using the S–matrix formalism for a combined fit to their cross section and asymmetry data at the $Z$ peak and their data at 130–209 GeV. The authors have corrected the measurement for the 34 MeV shift with respect to the Breit–Wigner fits.
[7] ACHARD 04C select $e^+e^- \to Z\gamma$ events with hard initial–state radiation. Z decays to $q\overline{q}$ and muon pairs are considered. The fit results obtained in the two samples are found consistent to each other and combined considering the uncertainty due to ISR modelling as fully correlated.
[8] ACCIARRI 00Q interpret the $s$-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to $Z$-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the $\gamma/Z$ interference term. The authors have corrected the measurement for the 34.1 MeV shift with respect to the Breit-Wigner fits. The error contains a contribution of ±2.3 MeV due to the uncertainty on the $\gamma Z$ interference.
[9] MIYABAYASHI 95 combine their low energy total hadronic cross-section measurement with the ACTON 93D data and perform a fit using an S-matrix formalism. As expected, this result is below the mass values obtained with the standard Breit-Wigner parametrization.
[10] Enters fit through $W/Z$ mass ratio given in the $W$ Particle Listings. The ALITTI 92B systematic error (±0.93) has two contributions: one (±0.92) cancels in $m_W/m_Z$ and one (±0.12) is noncancelling. These were added in quadrature.
[11] First error of ABE 89 is combination of statistical and systematic contributions; second is mass scale uncertainty.
[12] ABRAMS 89B uncertainty includes 35 MeV due to the absolute energy measurement.
[13] ALBAJAR 89 result is from a total sample of 33 $Z \to e^+e^-$ events.

## *Z* WIDTH

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The $Z$ boson" and ref. LEP-SLC 06).

| 2.7 | ±2.0 | ±1.0 | 25 | [10] ANSARI | 87 | UA2 | $E_{cm}^{p\overline{p}}$= 546,630 GeV |

[1] ABBIENDI 01A error includes approximately 3.6 MeV due to statistics, 1 MeV due to event selection systematics, and 1.3 MeV due to LEP energy uncertainty.
[2] The error includes 1.2 MeV due to LEP energy uncertainty.
[3] The error includes 1.3 MeV due to LEP energy uncertainty.
[4] BARATE 00C error includes approximately 3.8 MeV due to statistics, 0.9 MeV due to experimental systematics, and 1.3 MeV due to LEP energy uncertainty.
[5] ABBIENDI 04G obtain this result using the S–matrix formalism for a combined fit to their cross section and asymmetry data at the $Z$ peak and their data at 130–209 GeV. The authors have corrected the measurement for the 1 MeV shift with respect to the Breit–Wigner fits.
[6] ACCIARRI 00Q interpret the $s$-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to $Z$-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the $\gamma/Z$ interference term. The authors have corrected the measurement for the 0.9 MeV shift with respect to the Breit–Wigner fits.
[7] ABREU 96R obtain this value from a study of the interference between initial and final state radiation in the process $e^+e^- \to Z \to \mu^+\mu^-$.
[8] ABRAMS 89B uncertainty includes 50 MeV due to the miniSAM background subtraction error.
[9] ALBAJAR 89 result is from a total sample of 33 $Z \to e^+e^-$ events.
[10] Quoted values of ANSARI 87 are from direct fit. Ratio of $Z$ and $W$ production gives either $\Gamma(Z) < (1.09 \pm 0.07) \times \Gamma(W)$, CL = 90% or $\Gamma(Z) = (0.82^{+0.19}_{-0.14} \pm 0.06) \times \Gamma(W)$. Assuming Standard-Model value $\Gamma(W) = 2.65$ GeV then gives $\Gamma(Z) < 2.89 \pm 0.19$ or $= 2.17^{+0.50}_{-0.37} \pm 0.16$.

| $\Gamma_{68}$ | $p\mu$ | L,B | | < 1.8 | $\times 10^{-6}$ | CL=95% |

[a] This parameter is not directly used in the overall fit but is derived using the fit results; see the note "The $Z$ boson" and ref. LEP-SLC 06 (Physics Reports (Physics Letters C) **427** 257 (2006)).

[b] $\ell$ indicates each type of lepton ($e$, $\mu$, and $\tau$), not sum over them.

[c] Here $\ell$ indicates $e$ or $\mu$.

[d] The value is for the sum of the charge states or particle/antiparticle states indicated.

[e] This value is updated using the product of (i) the $Z \to b\overline{b}$ fraction from this listing and (ii) the $b$-hadron fraction in an unbiased sample of weakly decaying $b$-hadrons produced in $Z$-decays provided by the Heavy Flavor Averaging Group (HFLAV, http://www.slac.stanford.edu/xorg/hflav/osc/PDG_2009/#FRACZ).

[f] See the Particle Listings below for the $\gamma$ energy range used in this measurement.

[g] For $m_{\gamma\gamma} = (60 \pm 5)$ GeV.

## $Z$ PARTIAL WIDTHS

### $\Gamma(e^+e^-)$ $\Gamma_1$

For the LEP experiments, this parameter is not directly used in the overall fit but is derived using the fit results; see the note "The $Z$ boson" and ref. LEP-SLC 06.

| VALUE (MeV) | EVTS | DOCUMENT ID | | TECN | COMMENT |

### $\Gamma(\ell^+\ell^-)$ $\Gamma_4$

$\ell$ indicates each type of lepton ($e$, $\mu$, and $\tau$), not sum over them.

In our fit $\Gamma(\ell^+\ell^-)$ is defined as the partial $Z$ width for the decay into a pair of massless charged leptons. This parameter is not directly used in the 5-parameter fit assuming lepton universality but is derived using the fit results. See the note "The $Z$ boson" and ref. LEP-SLC 06.

## $Z$ BRANCHING RATIOS

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The $Z$ boson" and ref. LEP-SLC 06).

### $\Gamma(\mu^+\mu^-)/\Gamma(e^+e^-)$ $\Gamma_2/\Gamma_1$

| VALUE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| **1.0001±0.0024 OUR AVERAGE** | | | | |
| 0.9974±0.0050 | [1] AABOUD | 17Q | ATLS | $E_{cm}^{pp}$ = 7 TeV |
| 1.0009±0.0028 | [2] LEP-SLC | 06 | | $E_{cm}^{ee}$ = 88–94 GeV |

[1] AABOUD 17Q make a precise determination of $Z \to ee$ and $Z \to \mu\mu$ production in the lepton pseudo-rapidity range $|\eta| < 2.5$ and determine the ratio of the $Z$ branching fractions $B(Z \to e e)/B(Z \to \mu\mu) = 1.0026 \pm 0.0013 \pm 0.0048 = 1.0026 \pm 0.0050$.

[2] This parameter is not directly used in the overall fit but is derived using the fit results; see the note "The $Z$ boson" and ref. LEP-SLC 06.

### $\Gamma(\tau^+\tau^-)/\Gamma(e^+e^-)$ $\Gamma_3/\Gamma_1$

| VALUE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| **1.0020±0.0032 OUR AVERAGE** | | | | |
| 1.02 ±0.06 | [1] AAIJ | 18AR | LHCB | $E_{cm}^{pp}$ = 8 TeV |
| 1.0019±0.0032 | [2] LEP-SLC | 06 | | $E_{cm}^{ee}$ = 88–94 GeV |

[1] AAIJ 18AR obtain the result from the ratio of the measured $pp \to Z + X$ cross sections in the corresponding $Z$ decay channels.

[2] This parameter is not directly used in the overall fit but is derived using the fit results; see the note "The $Z$ boson" and ref. LEP-SLC 06.

### $\Gamma(\tau^+\tau^-)/\Gamma(\mu^+\mu^-)$ $\Gamma_3/\Gamma_2$

[1] AAIJ 18AR obtain the result from the ratio of the measured $pp \to Z + X$ cross sections in the corresponding $Z$ decay channels.

[2] This parameter is not directly used in the overall fit but is derived using the fit results; see the note "The $Z$ boson" and ref. LEP-SLC 06.

### $\Gamma(\ell^+\ell^-\ell^+\ell^-)/\Gamma_{total}$ $\Gamma_6/\Gamma$

Here $\ell$ indicates either $e$ or $\mu$. The branching fractions in this node are given within the phase-space defined by the requirements that (i) the 4-lepton invariant mass is between 80 GeV and 100 GeV, and (ii) any opposite-sign same-flavor lepton pair has a di-lepton invariant mass larger than 4 GeV.

[1] AABOUD 19N reports $(4.70 \pm 0.32 \pm 0.21 \pm 0.14) \times 10^{-6}$, where the uncertainties are statistical, systematic, and luminosity. We have combined the latter two in quadrature.

[2] SIRUNYAN 18BT report the $Z \to 4\ell$ branching fraction $= (4.83^{+0.23}_{-0.22} \pm 0.32 \pm 0.08 \pm 0.12) \times 10^{-6}$, where the uncertainties are statistical, systematic, due to theory, and luminosity. The last three have been added in quadrature to obtain the total systematic error.

[3] KHACHATRYAN 16CC reports $(4.9^{+0.8}_{-0.7} \pm 0.3 \pm 0.2 \pm 0.1) \times 10^{-6}$ value, where the uncertainties are statistical, systematic, theory, and due to luminosity. We have combined uncertainties in quadrature.

[4] CHATRCHYAN 12BN reports $(4.2^{+0.9}_{-0.8} \pm 0.2) \times 10^{-6}$ value. Their result (both central value and uncertainties) is scaled up by 10% to account for the different phase-space definition used here (see RAINBOLT 19).

## $\Gamma((u\overline{u}+c\overline{c})/2)/\Gamma(\text{hadrons})$ $\Gamma_9/\Gamma_8$

This quantity is the branching ratio of $Z \to$ "up-type" quarks to $Z \to$ hadrons. Except ACKERSTAFF 97T the values of $Z \to$ "up-type" and $Z \to$ "down-type" branchings are extracted from measurements of $\Gamma$(hadrons), and $\Gamma(Z \to \gamma +$ jets) where $\gamma$ is a high-energy (>5 or 7 GeV) isolated photon. As the experiments use different procedures and slightly different values of $M_Z$, $\Gamma$(hadrons) and $\alpha_s$ in their extraction procedures, our average has to be taken with caution.

| VALUE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|

| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| 0.1623 ± 0.0085 ± 0.0209 | [6] ABREU | 95D | DLPH | $E_{cm}^{ee}$ = 88–94 GeV |

[1] ABE 05F use hadronic $Z$ decays collected during 1996–98 to obtain an enriched sample of $c\overline{c}$ events using a double tag method. The single $c$–tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere). A multitag approach is used, defining 4 regions of the output value of the neural network and $R_c$ is extracted from a simultaneous fit to the count rates of the 4 different tags. The quoted systematic error includes an uncertainty of ±0.0006 due to the uncertainty on $R_b$.

[2] ABREU 00 obtain this result properly combining the measurement from the $D^{*+}$ production rate ($R_c = 0.1610 \pm 0.0104 \pm 0.0077 \pm 0.0043$ (BR)) with that from the overall charm counting ($R_c = 0.1692 \pm 0.0047 \pm 0.0063 \pm 0.0074$ (BR)) in $c\overline{c}$ events. The systematic error includes an uncertainty of ±0.0054 due to the uncertainty on the charmed hadron branching fractions.

[3] BARATE 00B use exclusive decay modes to independently determine the quantities $R_c \times f(c \to X)$, $X = D^0$, $D^+$, $D_s^+$, and $\Lambda_c$. Estimating $R_c \times f(c \to \Xi_c/\Omega_c) = 0.0034$, they simply sum over all the charm decays to obtain $R_c = 0.1738 \pm 0.0047 \pm 0.0088 \pm$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

0.0075(BR). This is combined with all previous ALEPH measurements (BARATE 98T and BUSKULIC 94G, $R_c = 0.1681 \pm 0.0054 \pm 0.0062$) to obtain the quoted value.

[4] ACKERSTAFF 98E use an inclusive/exclusive double tag. In one jet $D^{*\pm}$ mesons are exclusively reconstructed in several decay channels and in the opposite jet a slow pion (opposite charge inclusive $D^{*\pm}$) tag is used. The $b$ content of this sample is measured by the simultaneous detection of a lepton in one jet and an inclusively reconstructed $D^{*\pm}$ meson in the opposite jet. The systematic error includes an uncertainty of $\pm 0.006$ due to the external branching ratios.

[5] ALEXANDER 96R obtain this value via direct charm counting, summing the partial contributions from $D^0$, $D^+$, $D_s^+$, and $\Lambda_c^+$, and assuming that strange-charmed baryons account for the 15% of the $\Lambda_c^+$ production. An uncertainty of $\pm 0.005$ due to the uncertainties in the charm hadron branching ratios is included in the overall systematics.

[6] ABREU 95D perform a maximum likelihood fit to the combined $p$ and $p_T$ distributions of single and dilepton samples. The second error includes an uncertainty of $\pm 0.0124$ due to models and branching ratios.

## $R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$ $\Gamma_{12}/\Gamma_8$

OUR FIT is obtained by a simultaneous fit to several $c$- and $b$-quark measurements as explained in the note "The $Z$ boson" and ref. LEP-SLC 06.

The Standard Model predicts $R_b$=0.21581 for $m_t$=174.3 GeV and $M_H$=150 GeV.

[1] ABE 05F use hadronic $Z$ decays collected during 1996–98 to obtain an enriched sample of $b\overline{b}$ events using a double tag method. The single b-tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere; the key tag is obtained requiring the secondary vertex corrected mass to be above the $D$–meson mass). ABE 05F obtain $R_b = 0.21604 \pm 0.00098 \pm 0.00074$ where the systematic error includes an uncertainty of $\pm 0.00012$ due to the uncertainty on $R_c$. The value reported here is obtained properly combining with ABE 98D. The quoted systematic error includes an uncertainty of $\pm 0.00012$ due to the uncertainty on $R_c$.

[2] ACCIARRI 00 obtain this result using a double-tagging technique, with a high $p_T$ lepton tag and an impact parameter tag in opposite hemispheres.

[3] ABBIENDI 99B tag $Z \to b\overline{b}$ decays using leptons and/or separated decay vertices. The $b$-tagging efficiency is measured directly from the data using a double-tagging technique.

[4] ABREU 99B obtain this result combining in a multivariate analysis several tagging methods (impact parameter and secondary vertex reconstruction, complemented by event shape variables). For $R_c$ different from its Standard Model value of 0.172, $R_b$ varies as $-0.024\times(R_c - 0.172)$.

[5] BARATE 97F combine the lifetime-mass hemisphere tag (BARATE 97E) with event shape information and lepton tag to identify $Z \to b\overline{b}$ candidates. They further use $c$- and $uds$-selection tags to identify the background. For $R_c$ different from its Standard Model value of 0.172, $R_b$ varies as $-0.019\times(R_c - 0.172)$.

[6] ABREU 95D perform a maximum likelihood fit to the combined $p$ and $p_T$ distributions of single and dilepton samples. The second error includes an uncertainty of $\pm 0.0023$ due to models and branching ratios.

[7] BUSKULIC 94G perform a simultaneous fit to the $p$ and $p_T$ spectra of both single and dilepton events.

[8] JACOBSEN 91 tagged $b\overline{b}$ events by requiring coincidence of $\geq 3$ tracks with significant impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties ($\pm 0.014$).

## $\Gamma(b\overline{b}b\overline{b})/\Gamma(\text{hadrons})$ $\Gamma_{13}/\Gamma_8$

|---|---|---|---|---|---|
| **$<1.4\times10^{-6}$** | 95 | [1] SIRUNYAN | 19AJ | CMS | $E^{pp}_{cm}$ = 13 TeV |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| $<2.3\times10^{-6}$ | 95 | [2] AABOUD | 18BL | ATLS | $E^{pp}_{cm}$ = 13 TeV |
| $<2.6\times10^{-6}$ | 95 | [3] AAD | 15I | ATLS | $E^{pp}_{cm}$ = 8 TeV |

[1] SIRUNYAN 19AJ study $Z\to J/\psi\gamma$ with $J/\psi\to\mu^+\mu^-$. Candidate events are selected by requiring a pair of oppositely charged muons and a well isolated photon. The leading (subleading) muon is require to have a transverse momentum larger than 20 GeV (4 GeV), while the photon must have a transverse energy larger than 33 GeV. Requiring the invariant mass of the $\mu\mu$ ($\mu\mu\gamma$) system in the range 3.0 to 3.2 (81 to 101) GeV, selects 183 data events which is consistent with the expected background. The 95% C.L. limit on the $Z$ branching fraction is obtained assuming the $J/\psi$ to be unpolarized.

[2] AABOUD 18BL study $Z\to J/\psi\gamma$ in 13 TeV $pp$ interactions. Two triggers were used: isolated photon of $p_T>35(25)$ GeV and a muon with $p_T>18(24)$ GeV. The $J/\psi$ is detected via its dimuon decay and it is required that the azimuthal angle between the photon and the $J/\psi$ in the plane transverse to the beam direction is $>\pi/2$. The number of observed/expected background events is $92/89\pm6$ in the dimuon mass range 2.9–3.3 GeV leading to the quoted 95% C.L. limit.

[3] AAD 15I use events with the highest $p_T$ muon in the pair required to have $p_T>20$ GeV, the dimuon mass required to be within 0.2 GeV of the $J/\psi(1S)$ mass and it's transverse momentum required to be $>36$ GeV. The photon is also required to have it's $p_T>36$ GeV.

| VALUE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| **$0.67\pm0.18\pm0.05$** | [1] SIRUNYAN | 18DZ | CMS | $pp$ at 13 TeV |

[1] SIRUNYAN 18DZ observe the decay $Z\to\Psi\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s}=13$ TeV, where $\Psi$ includes $J/\psi$ as well as $\psi(2S)\to J/\psi X$, and $\ell^+\ell^-$ represents an electron or muon pair while the $J/\psi$ is detected via its $\mu^+\mu^-$ decay channel. To reduce systematic errors they determine the ratio of the branching fraction of this decay to that of $Z\to\mu^+\mu^-\mu^+\mu^-$ within phase-space cuts imposed on lepton transverse momentum and pseudo rapidity, dilepton invariant mass, and $J/\psi$ transverse momentum. The number of selected $\Psi\mu^+\mu^-$ ($\Psi e^+e^-$) candidate events is 29 (18). Analyzing the $\mu^+\mu^-$ and $\mu^+\mu^-\ell^+\ell^-$ invariant mass distributions, a yield of $13.0\pm3.9$ ($11.2\pm3.4$) events for the $\Psi\mu^+\mu^-$ ($\Psi e^+e^-$) mode is obtained. The ratio of the branching fractions is determined as $0.67\pm0.18\pm0.05$ within the selected phase-space cuts. Assuming extrapolation to full phase space cancels in the ratio, and using their measured value of $B(Z\to\mu^+\mu^-\mu^+\mu^-)=(1.20\pm0.08)\times10^{-6}$, they estimate $B(Z\to J/\psi\ell^+\ell^-)=8\times10^{-7}$.

## $Z$

### $\Gamma(\Upsilon(3S)\gamma)/\Gamma_{total}$ $\Gamma_{40}/\Gamma$

| VALUE | CL% | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **$<4.8\times10^{-6}$** | 95 | [1] AABOUD | 18BL | ATLS | $E_{cm}^{pp}$ = 13 TeV |

[1] AABOUD 18BL study $Z\to\Upsilon(3S)\gamma$ in 13 TeV $pp$ interactions. Two triggers were used: isolated photon of $p_T>35(25)$ GeV and a muon with $p_T>18(24)$ GeV. The $\Upsilon(3S)$ is detected via its dimuon decay and it is required that the azimuthal angle between the photon and the $\Upsilon(3S)$ in the plane transverse to the beam direction is $>\pi/2$. The number of observed/expected background events is 112/113 ± 8 in the dimuon mass range 10.0–11.0 GeV leading to the quoted 95% C.L. limit.

### $\Gamma(\Upsilon(1,2,3S)\,\Upsilon(1,2,3S))/\Gamma_{total}$ $\Gamma_{41}/\Gamma$

|---|---|---|---|---|---|---|
| **$<1.5\times10^{-6}$** | 95 | 106 | [1] SIRUNYAN | 19BR | CMS | $E_{cm}^{pp}$ = 13 TeV |

[1] SIRUNYAN 19BR search for $Z$ decays to a pair of $\Upsilon$ mesons in the channel $\Upsilon\to\mu^+\mu^-$. The invariant mass of the $\Upsilon$ candidates has to be in the range of 8.5 to 11 GeV. A total of 106 events are selected in the 20–140 GeV 4-muon invariant mass range. An un-binned extended maximum likelihood fit leads to the 95% C.L. upper limit, obtained assuming the $\Upsilon$ mesons to be unpolarised.

### $\Gamma((D^0/\overline{D}^0)X)/\Gamma(\text{hadrons})$ $\Gamma_{42}/\Gamma_8$

| 0.021±0.003±0.005 | [2] BUSKULIC | 96Y | ALEP | $E_{cm}^{ee}$ = 88–94 GeV |

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[1] ALEXANDER 96R measure $R_b \times f(b \to \Lambda_c^+ X) \times B(\Lambda_c^+ \to p K^- \pi^+) = (0.122 \pm 0.023 \pm 0.010)\%$ in hadronic $Z$ decays; the value quoted here is obtained using our best value $B(\Lambda_c^+ \to p K^- \pi^+) = (5.0 \pm 1.3)\%$. The first error is the total experiment's error and the second error is the systematic error due to the branching fraction uncertainty.

[2] BUSKULIC 96Y obtain the production fraction of $\Lambda_c^+$ baryons in hadronic $Z$ decays $f(b \to \Lambda_c^+ X) = 0.110 \pm 0.014 \pm 0.006$ using $B(\Lambda_c^+ \to p K^- \pi^+) = (4.4 \pm 0.6)\%$; we have rescaled using our best value $B(\Lambda_c^+ \to p K^- \pi^+) = (5.0 \pm 1.3)\%$ obtaining $f(b \to \Lambda_c^+ X) = 0.097 \pm 0.013 \pm 0.025$ where the first error is their total experiment's error and the second error is the systematic error due to the branching fraction uncertainty. The value quoted here is obtained multiplying this production fraction by our value of $R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$.

## $\Gamma(\Xi_c^0 X)/\Gamma(\text{hadrons})$ $\Gamma_{54}/\Gamma_8$

| VALUE | DOCUMENT ID | TECN | COMMENT |
|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | |
| seen | [1] ABDALLAH 05C | DLPH | $E_{cm}^{ee} = 88$–$94$ GeV |

[1] ABDALLAH 05C searched for the charmed strange baryon $\Xi_c^0$ in the decay channel $\Xi_c^0 \to \Xi^- \pi^+$ ($\Xi^- \to \Lambda \pi^-$). The production rate is measured to be $f_{\Xi_c^0} \times B(\Xi_c^0 \to \Xi^- \pi^+) = (4.7 \pm 1.4 \pm 1.1) \times 10^{-4}$ per hadronic Z decay.

## $\Gamma(\Xi_b X)/\Gamma(\text{hadrons})$ $\Gamma_{55}/\Gamma_8$

Here $\Xi_b$ is used as a notation for the strange $b$-baryon states $\Xi_b^-$ and $\Xi_b^0$.

| VALUE | DOCUMENT ID | TECN | COMMENT |
|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | |
| seen | [1] ABDALLAH 05C | DLPH | $E_{cm}^{ee} = 88$–$94$ GeV |
| seen | [2] BUSKULIC 96T | ALEP | $E_{cm}^{ee} = 88$–$94$ GeV |
| seen | [3] ABREU 95V | DLPH | $E_{cm}^{ee} = 88$–$94$ GeV |

[1] ABDALLAH 05C searched for the beauty strange baryon $\Xi_b$ in the inclusive semileptonic decay channel $\Xi_b \to \Xi^- \ell^- \overline{\nu}_\ell X$. Evidence for the $\Xi_b$ production is seen from the observation of $\Xi^\mp$ production accompanied by a lepton of the same sign. From the excess of "right-sign" pairs $\Xi^\mp \ell^\mp$ compared to "wrong-sign" pairs $\Xi^\mp \ell^\pm$ the production rate is measured to be $B(b \to \Xi_b) \times B(\Xi_b \to \Xi^- \ell^- X) = (3.0 \pm 1.0 \pm 0.3) \times 10^{-4}$ per lepton species, averaged over electrons and muons.

[2] BUSKULIC 96T investigate $\Xi$-lepton correlations and find a significant excess of "right–sign" pairs $\Xi^\mp \ell^\mp$ compared to "wrong–sign" pairs $\Xi^\mp \ell^\pm$. This excess is interpreted as evidence for $\Xi_b$ semileptonic decay. The measured product branching ratio is $B(b \to \Xi_b) \times B(\Xi_b \to X_c X \ell^- \overline{\nu}_\ell) \times B(X_c \to \Xi^- X') = (5.4 \pm 1.1 \pm 0.8) \times 10^{-4}$ per lepton species, averaged over electrons and muons, with $X_c$ a charmed baryon.

[3] ABREU 95V observe an excess of "right-sign" pairs $\Xi^\mp \ell^\mp$ compared to "wrong-sign" pairs $\Xi^\mp \ell^\pm$ in jets: this excess is interpreted as evidence for the beauty strange baryon $\Xi_b$ production, with $\Xi_b \to \Xi^- \ell^- \overline{\nu}_\ell X$. They find that the probability for this signal to come from non $b$-baryon decays is less than $5 \times 10^{-4}$ and that $\Lambda_b$ decays can account for less than 10% of these events. The $\Xi_b$ production rate is then measured to be $B(b \to \Xi_b) \times B(\Xi_b \to \Xi^- \ell^- X) = (5.9 \pm 2.1 \pm 1.0) \times 10^{-4}$ per lepton species, averaged over electrons and muons.

## $\Gamma(b\text{-baryon X})/\Gamma(\text{hadrons})$ $\Gamma_{56}/\Gamma_8$

"OUR EVALUATION" is obtained using our current values for $f(b \to b\text{-baryon})$ and $R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$. We calculate $\Gamma(b\text{-baryon X})/\Gamma(\text{hadrons}) = R_b \times f(b \to b\text{-baryon})$. The decay fraction $f(b \to b\text{-baryon})$ was provided by the Heavy Flavor Averaging Group (https://hflav.web.cern.ch/).

| VALUE | DOCUMENT ID | TECN | COMMENT |
|---|---|---|---|
| **0.0197±0.0032 OUR EVALUATION** | | | |
| **0.0221±0.0015±0.0058** | [1] BARATE 98V | ALEP | $E_{cm}^{ee} = 88$–$94$ GeV |

[1] BARATE 98V use the overall number of identified protons in $b$-hadron decays to measure $f(b \to b\text{-baryon}) = 0.102 \pm 0.007 \pm 0.027$. They assume $BR(b\text{-baryon} \to pX) = (58 \pm 6)\%$ and $BR(B_s^0 \to pX) = (8.0 \pm 4.0)\%$. The value quoted here is obtained multiplying this production fraction by our value of $R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$.

## $Z$ HADRONIC POLE CROSS SECTION

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The $Z$ boson" and ref. LEP-SLC 06). This quantity is defined as

$$\sigma_h^0 = \frac{12\pi}{M_Z^2} \frac{\Gamma(e^+e^-)\,\Gamma(\text{hadrons})}{\Gamma_Z^2}$$

It is one of the parameters used in the $Z$ lineshape fit.

## Z VECTOR COUPLINGS

These quantities are the effective vector couplings of the $Z$ to charged leptons and quarks. Their magnitude is derived from a measurement of the $Z$ lineshape and the forward-backward lepton asymmetries as a function of energy around the $Z$ mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the $Z$ asymmetry parameters, $A_e$, $A_\mu$, and $A_\tau$. By convention the sign of $g_A^e$ is fixed to be negative (and opposite to that of $g^{\nu_e}$ obtained using $\nu_e$ scattering measurements). For the light quarks, the sign of the couplings is assigned consistently with this assumption. The LEP/SLD-based fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and $A_e$, $A_\mu$, and $A_\tau$ measurements. See the note "The $Z$ boson" and ref. LEP-SLC 06 for details. Where $p\overline{p}$ and $ep$ data is quoted, OUR FIT value corresponds to a weighted average of this with the LEP/SLD fit result.

## Z COUPLINGS TO NEUTRAL LEPTONS

Averaging over neutrino species, the invisible $Z$ decay width determines the effective neutrino coupling $g^{\nu\ell}$. For $g^{\nu_e}$ and $g^{\nu_\mu}$, $\nu_e e$ and $\nu_\mu e$ scattering results are combined with $g_A^e$ and $g_V^e$ measurements at the $Z$ mass to obtain $g^{\nu_e}$ and $g^{\nu_\mu}$ following NOVIKOV 93C.

|---|---|---|---|---|
| **0.502±0.017** | [1] VILAIN | 94 | CHM2 | From $\nu_\mu e$ scattering |

[1] VILAIN 94 derive this value from their measurement of the couplings $g_A^{e\nu_\mu} = -0.503 \pm 0.017$ and $g_V^{e\nu_\mu} = -0.035 \pm 0.017$ obtained from $\nu_\mu e$ scattering. We have re-evaluated this value using the current PDG values for $g_A^e$ and $g_V^e$.

## Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the $Z$ these quantities are defined as

$$A_f = \frac{2g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$

where $g_V^f$ and $g_A^f$ are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the note "The $Z$ boson" and ref. LEP-SLC 06.

### $A_e$

Using polarized beams, this quantity can also be measured as $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$, where $\sigma_L$ and $\sigma_R$ are the $e^+e^-$ production cross sections for $Z$ bosons produced with left-handed and right-handed electrons respectively.

[1] ABBIENDI 01O fit for $A_e$ and $A_\tau$ from measurements of the $\tau$ polarization at varying $\tau$ production angles. The correlation between $A_e$ and $A_\tau$ is less than 0.03.

[2] ABE 01B use the left-right production and left-right forward-backward decay asymmetries in leptonic $Z$ decays to obtain a value of 0.1544 ± 0.0060. This is combined with left-right production asymmetry measurement using hadronic $Z$ decays (ABE 00B) to obtain the quoted value.

[3] HEISTER 01 obtain this result fitting the $\tau$ polarization as a function of the polar production angle of the $\tau$.

[4] ABREU 00E obtain this result fitting the $\tau$ polarization as a function of the polar $\tau$ production angle. This measurement is a combination of different analyses (exclusive $\tau$ decay modes, inclusive hadronic 1-prong reconstruction, and a neural network analysis).

[5] Derived from the measurement of forward-backward $\tau$ polarization asymmetry.

[6] ABE 97 obtain this result from a measurement of the observed left-right charge asymmetry, $A_Q^{obs} = 0.225 \pm 0.056 \pm 0.019$, in hadronic $Z$ decays. If they combine this value of $A_Q^{obs}$ with their earlier measurement of $A_{LR}^{obs}$ they determine $A_e$ to be 0.1574 ± 0.0197 ± 0.0067 independent of the beam polarization.

[7] ABE 95J obtain this result from polarized Bhabha scattering.

### $A_\mu$

This quantity is directly extracted from a measurement of the left-right forward-backward asymmetry in $\mu^+\mu^-$ production at SLC using a polarized electron beam. This double asymmetry eliminates the dependence on the $Z$-$e$-$e$ coupling parameter $A_e$.

| VALUE | EVTS | DOCUMENT ID | | TECN | COMMENT |

[1] ABE 01B obtain this direct measurement using the left-right production and left-right forward-backward polar angle asymmetries in $\mu^+\mu^-$ decays of the $Z$ boson obtained with a polarized electron beam.

[2] AAD 15BT study $pp \to Z \to \ell^+\ell^-$ events where $\ell$ is an electron or a muon in the dilepton mass region 70–1000 GeV. The background in the $Z$ peak region is estimated to be < 1% for the muon channel. The muon asymmetry parameter is derived from the measured forward-backward asymmetry assuming the value of the quark asymmetry parameter from the SM. For this reason it is not used in the average.

### $A_\tau$

The LEP Collaborations derive this quantity from the measurement of the $\tau$ polarization in $Z \to \tau^+\tau^-$. The SLD Collaboration directly extracts this quantity from its measured left-right forward-backward asymmetry in $Z \to \tau^+\tau^-$ produced using a polarized $e^-$ beam. This double asymmetry eliminates the dependence on the $Z$-$e$-$e$ coupling parameter $A_e$.

[1] ABE 05 use hadronic $Z$ decays collected during 1996–98 to obtain an enriched sample of $c\overline{c}$ events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying c–quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (9970 events) $A_c = 0.6747 \pm 0.0290 \pm 0.0233$. Taking into account all correlations with earlier results reported in ABE 02G and ABE 01C, they obtain the quoted overall SLD result.

[2] ABE 02G tag $b$ and $c$ quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously $A_b$ and $A_c$.

[3] ABE 01C tag $Z \to c\overline{c}$ events using two techniques: exclusive reconstruction of $D^{*+}$, $D^+$ and $D^0$ mesons and the soft pion tag for $D^{*+} \to D^0\pi^+$. The large background from $D$ mesons produced in $b\overline{b}$ events is separated efficiently from the signal using precision vertex information. When combining the $A_c$ values from these two samples, care is taken to avoid double counting of events common to the two samples, and common systematic errors are properly taken into account.

### $A_b$

This quantity is directly extracted from a measurement of the left-right forward-backward asymmetry in $b\overline{b}$ production at SLC using polarized electron beam. This double asymmetry eliminates the dependence on the $Z$-$e$-$e$ coupling parameter $A_e$. OUR FIT is obtained by a simultaneous fit to several $c$- and $b$-quark measurements as explained in the note "The $Z$ boson" and ref. LEP-SLC 06.

[1] ABE 05 use hadronic $Z$ decays collected during 1996–98 to obtain an enriched sample of $b\overline{b}$ events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying b–quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (25917 events) $A_b = 0.9173 \pm 0.0184 \pm 0.0173$. Taking into account all correlations with earlier results reported in ABE 03F, ABE 02G and ABE 99L, they obtain the quoted overall SLD result.

[2] ABE 03F obtain an enriched sample of $b\overline{b}$ events tagging on the invariant mass of a 3-dimensional topologically reconstructed secondary decay. The charge of the underlying $b$ quark is obtained using a self-calibrating track-charge method. For the 1996–1998 data sample they measure $A_b = 0.906 \pm 0.022 \pm 0.023$. The value quoted here is obtained combining the above with the result of ABE 98I (1993–1995 data sample).

[3] ABE 02G tag $b$ and $c$ quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously $A_b$ and $A_c$.

[4] ABE 99L obtain an enriched sample of $b\overline{b}$ events tagging with an inclusive vertex mass cut. For distinguishing $b$ and $\overline{b}$ quarks they use the charge of identified $K^\pm$.

## TRANSVERSE SPIN CORRELATIONS IN $Z \to \tau^+\tau^-$

The correlations between the transverse spin components of $\tau^+\tau^-$ produced in $Z$ decays may be expressed in terms of the vector and axial-vector couplings:

$$C_{TT} = \frac{|g_A^\tau|^2 - |g_V^\tau|^2}{|g_A^\tau|^2 + |g_V^\tau|^2}$$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

$$C_{TN} = -2\frac{|g_A^\tau||g_V^\tau|}{|g_A^\tau|^2+|g_V^\tau|^2}\sin(\Phi_{g_V^\tau}-\Phi_{g_A^\tau})$$

$C_{TT}$ refers to the transverse-transverse (within the collision plane) spin correlation and $C_{TN}$ refers to the transverse-normal (to the collision plane) spin correlation.

The longitudinal $\tau$ polarization $P_\tau$ ($=-A_\tau$) is given by:

$$P_\tau = -2\frac{|g_A^\tau||g_V^\tau|}{|g_A^\tau|^2+|g_V^\tau|^2}\cos(\Phi_{g_V^\tau}-\Phi_{g_A^\tau})$$

Here $\Phi$ is the phase and the phase difference $\Phi_{g_V^\tau}-\Phi_{g_A^\tau}$ can be obtained using both the measurements of $C_{TN}$ and $P_\tau$.

## FORWARD-BACKWARD $e^+e^-\to f\bar{f}$ CHARGE ASYMMETRIES

These asymmetries are experimentally determined by tagging the respective lepton or quark flavor in $e^+e^-$ interactions. Details of heavy flavor ($c$- or $b$-quark) tagging at LEP are described in the note on "The $Z$ boson" and ref. LEP-SLC 06. The Standard Model predictions for LEP data have been (re)computed using the ZFITTER package (version 6.36) with input parameters $M_Z$=91.187 GeV, $M_{top}$=174.3 GeV, $M_{Higgs}$=150 GeV, $\alpha_S$=0.119, $\alpha^{(5)}(M_Z)$= 1/128.877 and the Fermi constant $G_F=1.16637\times10^{-5}$ GeV$^{-2}$ (see the note on "The $Z$ boson" for references). For non-LEP data the Standard Model predictions are as given by the authors of the respective publications.

### $A_{FB}^{(0,e)}$ CHARGE ASYMMETRY IN $e^+e^-\to e^+e^-$

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The $Z$ boson" and ref. LEP-SLC 06). For the $Z$ peak, we report the pole asymmetry defined by $(3/4)A_e^2$ as determined by the nine-parameter fit to cross-section and lepton forward-backward asymmetry data.

| ASYMMETRY (%) | STD. MODEL | $\sqrt{s}$ (GeV) | DOCUMENT ID | | TECN |
|---|---|---|---|---|---|

[2] BARATE 00C error includes approximately 0.26 due to statistics and 0.11 due to experimental systematics.
[3] ABE 90I measurements in the range $50\le\sqrt{s}\le60.8$ GeV.
[4] BACALA 89 systematic error is about 5%.

### $A_{FB}^{(0,\ell)}$ CHARGE ASYMMETRY IN $e^+e^-\to\ell^+\ell^-$

For the $Z$ peak, we report the pole asymmetry defined by $(3/4)A_\ell^2$ as determined by the five-parameter fit to cross-section and lepton forward-backward asymmetry data assuming lepton universality. For details see the note "The $Z$ boson" and ref. LEP-SLC 06.

## $A_{FB}^{(0,u)}$ CHARGE ASYMMETRY IN $e^+e^- \to u\overline{u}$

| ASYMMETRY (%) | STD. MODEL | $\sqrt{s}$ (GeV) | DOCUMENT ID | | TECN |
|---|---|---|---|---|---|
| **4.0±6.7±2.8** | **7.2** | **91.2** | [1] ACKERSTAFF | 97T | OPAL |

[1] ACKERSTAFF 97T measure the forward-backward asymmetry of various fast hadrons made of light quarks. Then using SU(2) isospin symmetry and flavor independence for down and strange quarks authors solve for the different quark types.

## $A_{FB}^{(0,s)}$ CHARGE ASYMMETRY IN $e^+e^- \to s\overline{s}$

The $s$-quark asymmetry is derived from measurements of the forward-backward asymmetry of fast hadrons containing an $s$ quark.

| ASYMMETRY (%) | STD. MODEL | $\sqrt{s}$ (GeV) | DOCUMENT ID | | TECN |
|---|---|---|---|---|---|
| **9.8 ±1.1 OUR AVERAGE** | | | | | |
| 10.08±1.13±0.40 | 10.1 | 91.2 | [1] ABREU | 00B | DLPH |
| 6.8 ±3.5 ±1.1 | 10.1 | 91.2 | [2] ACKERSTAFF | 97T | OPAL |

[1] ABREU 00B tag the presence of an $s$ quark requiring a high-momentum-identified charged kaon. The $s$-quark pole asymmetry is extracted from the charged-kaon asymmetry taking the expected $d$- and $u$-quark asymmetries from the Standard Model and using the measured values for the $c$- and $b$-quark asymmetries.

[2] ACKERSTAFF 97T measure the forward-backward asymmetry of various fast hadrons made of light quarks. Then using SU(2) isospin symmetry and flavor independence for down and strange quarks authors solve for the different quark types. The value reported here corresponds then to the forward-backward asymmetry for "down-type" quarks.

## $A_{FB}^{(0,c)}$ CHARGE ASYMMETRY IN $e^+e^- \to c\overline{c}$

OUR FIT, which is obtained by a simultaneous fit to several $c$- and $b$-quark measurements as explained in the note "The $Z$ boson" and ref. LEP-SLC 06, refers to the **$Z$ pole** asymmetry. The experimental values, on the other hand, correspond to the measurements carried out at the respective energies.

[1] ABDALLAH 04F tag $b$– and $c$–quarks using semileptonic decays combined with charge flow information from the hemisphere opposite to the lepton. Enriched samples of $c\overline{c}$ and $b\overline{b}$ events are obtained using lifetime information.

[2] ABBIENDI 03P tag heavy flavors using events with one or two identified leptons. This allows the simultaneous fitting of the $b$ and $c$ quark forward-backward asymmetries as well as the average $B^0$-$\overline{B}^0$ mixing.

[3] HEISTER 02H measure simultaneously $b$ and $c$ quark forward-backward asymmetries using their semileptonic decays to tag the quark charge. The flavor separation is obtained with a discriminating multivariate analysis.

[4] ABREU 99Y tag $Z \to b\overline{b}$ and $Z \to c\overline{c}$ events by an exclusive reconstruction of several $D$ meson decay modes ($D^{*+}$, $D^0$, and $D^+$ with their charge-conjugate states).

[5] BARATE 98O tag $Z \to c\overline{c}$ events requiring the presence of high-momentum reconstructed $D^{*+}$, $D^+$, or $D^0$ mesons.

[6] ALEXANDER 97C identify the $b$ and $c$ events using a $D/D^*$ tag.

[7] ADRIANI 92D use both electron and muon semileptonic decays.

## $A_{FB}^{(0,b)}$ CHARGE ASYMMETRY IN $e^+e^- \to b\overline{b}$

OUR FIT, which is obtained by a simultaneous fit to several $c$- and $b$-quark measurements as explained in the note "The $Z$ boson" and ref. LEP-SLC 06, refers to the **$Z$ pole** asymmetry. The experimental values, on the other hand, correspond to the measurements carried out at the respective energies.

[1] ABDALLAH 05 obtain an enriched samples of $b\overline{b}$ events using lifetime information. The quark (or antiquark) charge is determined with a neural network using the secondary vertex charge, the jet charge and particle identification.

[2] ABDALLAH 04F tag $b$– and $c$–quarks using semileptonic decays combined with charge flow information from the hemisphere opposite to the lepton. Enriched samples of $c\overline{c}$ and $b\overline{b}$ events are obtained using lifetime information.

[3] ABBIENDI 03P tag heavy flavors using events with one or two identified leptons. This allows the simultaneous fitting of the $b$ and $c$ quark forward-backward asymmetries as well as the average $B^0$-$\overline{B}^0$ mixing.

[4] ABBIENDI 02I tag $Z^0 \to b\overline{b}$ decays using a combination of secondary vertex and lepton tags. The sign of the $b$-quark charge is determined using an inclusive tag based on jet, vertex, and kaon charges.

[5] HEISTER 02H measure simultaneously $b$ and $c$ quark forward-backward asymmetries using their semileptonic decays to tag the quark charge. The flavor separation is obtained with a discriminating multivariate analysis.

[6] HEISTER 01D tag $Z \to b\overline{b}$ events using the impact parameters of charged tracks complemented with information from displaced vertices, event shape variables, and lepton identification. The $b$-quark direction and charge is determined using the hemisphere charge method along with information from fast kaon tagging and charge estimators of primary and secondary vertices. The change in the quoted value due to variation of $A_{FB}^c$ and $R_b$ is given as $+0.103\ (A_{FB}^c - 0.0651) - 0.440\ (R_b - 0.21585)$.

[7] ABREU 99Y tag $Z \to b\overline{b}$ and $Z \to c\overline{c}$ events by an exclusive reconstruction of several $D$ meson decay modes ($D^{*+}$, $D^0$, and $D^+$ with their charge-conjugate states).

[8] ACCIARRI 99D tag $Z \to b\overline{b}$ events using high p and $p_T$ leptons. The analysis determines simultaneously a mixing parameter $\chi_b = 0.1192 \pm 0.0068 \pm 0.0051$ which is used to correct the observed asymmetry.

[9] ACCIARRI 98U tag $Z \to b\overline{b}$ events using lifetime and measure the jet charge using the hemisphere charge.

[10] ALEXANDER 97C identify the $b$ and $c$ events using a $D/D^*$ tag.

## CHARGE ASYMMETRY IN $e^+e^- \to q\overline{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on $B^0$-$\overline{B}^0$ mixing and on other electroweak parameters.

[1] ABREU 92I has 0.14 systematic error due to uncertainty of quark fragmentation.
[2] ACTON 92L use the weight function method on 259k selected $Z \to$ hadrons events. The systematic error includes a contribution of 0.2 due to $B^0$-$\overline{B}^0$ mixing effect, 0.4 due to Monte Carlo (MC) fragmentation uncertainties and 0.3 due to MC statistics. ACTON 92L derive a value of $\sin^2\theta_W^{\rm eff}$ to be 0.2321 ± 0.0017 ± 0.0028.

### ANOMALOUS $ZZ\gamma$, $Z\gamma\gamma$, AND $ZZV$ COUPLINGS

Revised September 2013 by M.W. Grünewald (U. College Dublin and U. Ghent) and A. Gurtu (Formerly Tata Inst.).

In on-shell $Z\gamma$ production, deviations from the Standard Model for the $Z\gamma\gamma^*$ and $Z\gamma Z^*$ couplings may be described in terms of eight parameters, $h_i^V$ $(i = 1, 4;\ V = \gamma, Z)$ [1]. The parameters $h_i^\gamma$ describe the $Z\gamma\gamma^*$ couplings and the parameters $h_i^Z$ the $Z\gamma Z^*$ couplings. In this formalism $h_1^V$ and $h_2^V$ lead to $CP$-violating and $h_3^V$ and $h_4^V$ to $CP$-conserving effects. All these anomalous contributions to the cross section increase rapidly with center-of-mass energy. In order to ensure unitarity, these parameters are usually described by a form-factor representation, $h_i^V(s) = h_{i\circ}^V/(1 + s/\Lambda^2)^n$, where $\Lambda$ is the energy scale for the manifestation of a new phenomenon and $n$ is a sufficiently large power. By convention one uses $n = 3$ for $h_{1,3}^V$ and $n = 4$ for $h_{2,4}^V$. Usually limits on $h_i^V$'s are put assuming some value of $\Lambda$, sometimes $\infty$.

In on-shell $ZZ$ production, deviations from the Standard Model for the $ZZ\gamma^*$ and $ZZZ^*$ couplings may be described by means of four anomalous couplings $f_i^V$ $(i = 4, 5; V = \gamma, Z)$ [2]. As above, the parameters $f_i^\gamma$ describe the $ZZ\gamma^*$ couplings and the parameters $f_i^Z$ the $ZZZ^*$ couplings. The anomalous couplings $f_5^V$ lead to violation of $C$ and $P$ symmetries while $f_4^V$ introduces $CP$ violation. Also here, formfactors depending on a scale $\Lambda$ are used.

All these couplings $h_i^V$ and $f_i^V$ are zero at tree level in the Standard Model; they are measured in $e^+e^-$, $p\bar{p}$ and $pp$ collisions at LEP, Tevatron and LHC.

### $h_i^V$

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:

$$-0.12 < h_1^Z < +0.11, \quad -0.07 < h_2^Z < +0.07,$$
$$-0.19 < h_3^Z < +0.06, \quad -0.04 < h_4^Z < +0.13,$$
$$-0.05 < h_1^\gamma < +0.05, \quad -0.04 < h_2^\gamma < +0.02,$$
$$-0.05 < h_3^\gamma < +0.00, \quad +0.01 < h_4^\gamma < +0.05.$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

[1] AAD 16Q study $Z\gamma$ production in $pp$ collisions. In events with no additional jets, 10268 (12738) $Z$ decays to electron (muon) pairs are selected, with an expected background of 1291 ± 340 (1537 ± 408) events, as well as 1039 $Z$ decays to neutrino pairs with an expected background of 450 ± 96 events. Analyzing the photon transverse momentum distribution above 250 GeV (400 GeV) for lepton (neutrino) events, yields the 95% C.L. limits: $-7.8 \times 10^{-4} < h_3^Z < 8.6 \times 10^{-4}$, $-3.0 \times 10^{-6} < h_4^Z < 2.9 \times 10^{-6}$, $-9.5 \times 10^{-4} < h_3^\gamma < 9.9 \times 10^{-4}$, $-3.2 \times 10^{-6} < h_4^\gamma < 3.2 \times 10^{-6}$.

[2] KHACHATRYAN 16AE determine the $Z\gamma \to \nu\overline{\nu}\gamma$ cross section by selecting events with a photon of $E_T > 145$ GeV and $\not{E}_T > 140$ GeV. 630 candidate events are observed with an expected SM background of 269 ± 26. The $E_T$ spectrum of the photon is used to set 95% C.L. limits as follows: $-1.5 \times 10^{-3} < h_3^Z < 1.6 \times 10^{-3}$, $-3.9 \times 10^{-6} < h_4^Z < 4.5 \times 10^{-6}$, $-1.1 \times 10^{-3} < h_3^\gamma < 0.9 \times 10^{-3}$, $-3.8 \times 10^{-6} < h_4^\gamma < 4.3 \times 10^{-6}$.

[3] KHACHATRYAN 15AC study $Z\gamma$ events in 8 TeV $pp$ interactions, where the $Z$ decays into 2 same-flavor, opposite sign leptons ($e$ or $\mu$) and a photon with $p_T > 15$ GeV. The $p_T$ of a lepton is required to be $> 20$ GeV/c, their effective mass $> 50$ GeV, and the photon should have a separation $\Delta R > 0.7$ with each lepton. The observed $p_T$ distribution of the photons is used to extract the 95% C.L. limits: $-3.8 \times 10^{-3} < h_3^Z < 3.7 \times 10^{-3}$, $-3.1 \times 10^{-5} < h_4^Z < 3.0 \times 10^{-5}$, $-4.6 \times 10^{-3} < h_3^\gamma < 4.6 \times 10^{-3}$, $-3.6 \times 10^{-5} < h_4^\gamma < 3.5 \times 10^{-5}$.

[4] CHATRCHYAN 14AB measure $Z\gamma$ production cross section for $p_T^\gamma > 15$ GeV and $R(\ell\gamma) > 0.7$, which is the separation between the $\gamma$ and the final state charged lepton ($e$ or $\mu$) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. The di-lepton mass is required to be $> 50$ GeV. After background subtraction the number of $ee\gamma$ and $\mu\mu\gamma$ events is determined to be 3160 ± 120 and 5030 ± 233 respectively, compatible with expectations from the SM. This leads to a 95% CL limits of $-1 \times 10^{-2} < h_3^\gamma < 1 \times 10^{-2}$, $-9 \times 10^{-5} < h_4^\gamma < 9 \times 10^{-5}$, $-9 \times 10^{-3} < h_3^Z < 9 \times 10^{-3}$, $-8 \times 10^{-5} < h_4^Z < 8 \times 10^{-5}$, assuming $h_1^V$ and $h_2^V$ have SM values, $V = \gamma$ or $Z$.

[5] AAD 13AN study $Z\gamma$ production in $pp$ collisions. In events with no additional jet, 1417 (2031) Z decays to electron (muon) pairs are selected, with an expected background of 156 ± 54 (244 ± 64) events, as well as 662 $Z$ decays to neutrino pairs with an expected background of 302±42 events. Analysing the photon $p_T$ spectrum above 100 GeV yields the 95% C.L. limts: $-0.013 < h_3^Z < 0.014$, $-8.7 \times 10^{-5} < h_4^Z < 8.7 \times 10^{-5}$, $-0.015 < h_3^\gamma < 0.016$, $-9.4 \times 10^{-5} < h_4^\gamma < 9.2 \times 10^{-5}$. Supersedes AAD 12BX.

[6] CHATRCHYAN 13BI determine the $Z\gamma \to \nu\overline{\nu}\gamma$ cross section by selecting events with a photon of $E_T > 145$ GeV and a $\not{E}_T > 130$ GeV. 73 candidate events are observed with an expected SM background of 30.2±6.5. The $E_T$ spectrum of the photon is used to set 95% C.L. limits as follows: $|h_3^Z| < 2.7 \times 10^{-3}$, $|h_4^Z| < 1.3 \times 10^{-5}$, $|h_3^\gamma| < 2.9 \times 10^{-3}$, $|h_4^\gamma| < 1.5 \times 10^{-5}$.

[7] ABAZOV 12S study $Z\gamma$ production in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV using 6.2 fb$^{-1}$ of data where the $Z$ decays to electron (muon) pairs and the photon has at least 10 GeV of transverse momentum. In data, 304 (308) di-electron (di-muon) events are observed with an expected background of 255 ± 16 (285 ± 24) events. Based on the photon $p_T$ spectrum, and including also earlier data and the $Z \to \nu\overline{\nu}$ decay mode (from ABAZOV 09L), the following 95% C.L. limits are reported: $|h_{03}^Z| < 0.026$, $|h_{04}^Z| < 0.0013$, $|h_{03}^\gamma| < 0.027$, $|h_{04}^\gamma| < 0.0014$ for a form factor scale of $\Lambda = 1.5$ TeV.

[8] AALTONEN 11S study $Z\gamma$ events in $p\overline{p}$ interactions at $\sqrt{s} = 1.96$ TeV with integrated luminosity 5.1 fb$^{-1}$ for $Z \to e^+e^-/\mu^+\mu^-$ and 4.9 fb$^{-1}$ for $Z \to \nu\overline{\nu}$. For the charged lepton case, the two leptons must be of the same flavor with the transverse momentum/energy of one $> 20$ GeV and the other $> 10$ GeV. The isolated photon must have $E_T > 50$ GeV. They observe 91 events with 87.2 ± 7.8 events expected from standard model processes. For the $\nu\overline{\nu}$ case they require solitary photons with $E_T > 25$ GeV and missing $E_T > 25$ GeV and observe 85 events with standard model expectation of 85.9 ± 5.6 events. Taking the form factor $\Lambda = 1.5$ TeV they derive 95% C.L. limits as $|h_3^{\gamma,Z}| < 0.022$ and $|h_4^{\gamma,Z}| < 0.0009$.

[9] CHATRCHYAN 11M study $Z\gamma$ production in $pp$ collisions at $\sqrt{s} = 7$ TeV using 36 pb$^{-1}$ $pp$ data, where the $Z$ decays to $e^+e^-$ or $\mu^+\mu^-$. The total cross sections are measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$ with

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

the dilepton invariant mass requirement of $M_{\ell\ell} > 50$ GeV. The number of $e^+e^-\gamma$ and $\mu^+\mu^-\gamma$ candidates is 81 and 90 with estimated backgrounds of $20.5\pm2.5$ and $27.3\pm3.2$ events respectively. The 95% CL limits for $ZZ\gamma$ couplings are $-0.05 < h_3^Z < 0.06$ and $-0.0005 < h_4^Z < 0.0005$, and for $Z\gamma\gamma$ couplings are $-0.07 < h_3^\gamma < 0.07$ and $-0.0005 < h_4^\gamma < 0.0006$.

[10] ABAZOV 09L study $Z\gamma$, $Z \to \nu\overline{\nu}$ production in $p\overline{p}$ collisions at 1.96 TeV C.M. energy. They select 51 events with a photon of transverse energy $E_T$ larger than 90 GeV, with an expected background of 17 events. Based on the photon $E_T$ spectrum and including also $Z$ decays to charged leptons (from ABAZOV 07M), the following 95% CL limits are reported: $|h_{30}^\gamma| < 0.033$, $|h_{40}^\gamma| < 0.0017$, $|h_{30}^Z| < 0.033$, $|h_{40}^Z| < 0.0017$.

[11] ABAZOV 07M use 968 $p\overline{p} \to e^+e^-/\mu^+\mu^-\gamma X$ candidates, at 1.96 TeV center of mass energy, to tag $p\overline{p} \to Z\gamma$ events by requiring $E_T(\gamma) > 7$ GeV, lepton-gamma separation $\Delta R_{\ell\gamma} > 0.7$, and di-lepton invariant mass $> 30$ GeV. The cross section is in agreement with the SM prediction. Using these $Z\gamma$ events they obtain 95% C.L. limits on each $h_i^V$, keeping all others fixed at their SM values. They report: $-0.083 < h_{30}^Z < 0.082$, $-0.0053 < h_{40}^Z < 0.0054$, $-0.085 < h_{30}^\gamma < 0.084$, $-0.0053 < h_{40}^\gamma < 0.0054$, for the form factor scale $\Lambda = 1.2$ TeV.

[12] Using data collected at $\sqrt{s} = 183$–$208$, ABDALLAH 07C select 1,877 $e^+e^- \to Z\gamma$ events with $Z \to q\overline{q}$ or $\nu\overline{\nu}$, 171 $e^+e^- \to ZZ$ events with $Z \to q\overline{q}$ or lepton pair (except an explicit $\tau$ pair), and 74 $e^+e^- \to Z\gamma^*$ events with a $q\overline{q}\mu^+\mu^-$ or $q\overline{q}e^+e^-$ signature, to derive 95% CL limits on $h_i^V$. Each limit is derived with other parameters set to zero. They report: $-0.23 < h_1^Z < 0.23$, $-0.30 < h_3^Z < 0.16$, $-0.14 < h_1^\gamma < 0.14$, $-0.049 < h_3^\gamma < 0.044$.

[13] ACHARD 04H select 3515 $e^+e^- \to Z\gamma$ events with $Z \to q\overline{q}$ or $\nu\overline{\nu}$ at $\sqrt{s} = 189$–$209$ GeV to derive 95% CL limits on $h_i^V$. For deriving each limit the other parameters are fixed at zero. They report: $-0.153 < h_1^Z < 0.141$, $-0.087 < h_2^Z < 0.079$, $-0.220 < h_3^Z < 0.112$, $-0.068 < h_4^Z < 0.148$, $-0.057 < h_1^\gamma < 0.057$, $-0.050 < h_2^\gamma < 0.023$, $-0.059 < h_3^\gamma < 0.004$, $-0.004 < h_4^\gamma < 0.042$.

[14] ABBIENDI,G 00C study $e^+e^- \to Z\gamma$ events (with $Z \to q\overline{q}$ and $Z \to \nu\overline{\nu}$) at 189 GeV to obtain the central values (and 95% CL limits) of these couplings: $h_1^Z = 0.000 \pm 0.100$ $(-0.190, 0.190)$, $h_2^Z = 0.000 \pm 0.068$ $(-0.128, 0.128)$, $h_3^Z = -0.074^{+0.102}_{-0.103}$ $(-0.269, 0.119)$, $h_4^Z = 0.046 \pm 0.068$ $(-0.084, 0.175)$, $h_1^\gamma = 0.000 \pm 0.061$ $(-0.115, 0.115)$, $h_2^\gamma = 0.000 \pm 0.041$ $(-0.077, 0.077)$, $h_3^\gamma = -0.080^{+0.039}_{-0.041}$ $(-0.164, -0.006)$, $h_4^\gamma = 0.064^{+0.033}_{-0.030}$ $(+0.007, +0.134)$. The results are derived assuming that only one coupling at a time is different from zero.

[15] ABBOTT 98M study $p\overline{p} \to Z\gamma + X$, with $Z \to e^+e^-$, $\mu^+\mu^-$, $\overline{\nu}\nu$ at 1.8 TeV, to obtain 95% CL limits at $\Lambda = 750$ GeV: $|h_{30}^Z| < 0.36$, $|h_{40}^Z| < 0.05$ (keeping $h_i^\gamma = 0$), and $|h_{30}^\gamma| < 0.37$, $|h_{40}^\gamma| < 0.05$ (keeping $h_i^Z = 0$). Limits on the *CP*-violating couplings are $|h_{10}^Z| < 0.36$, $|h_{20}^Z| < 0.05$ (keeping $h_i^\gamma = 0$), and $|h_{10}^\gamma| < 0.37$, $|h_{20}^\gamma| < 0.05$ (keeping $h_i^Z = 0$).

[16] ABREU 98K determine a 95% CL upper limit on $\sigma(e^+e^- \to \gamma +$ invisible particles$) < 2.5$ pb using 161 and 172 GeV data. This is used to set 95% CL limits on $|h_{30}^\gamma| < 0.8$ and $|h_{30}^Z| < 1.3$, derived at a scale $\Lambda = 1$ TeV and with $n = 3$ in the form factor representation.

## $f_i^V$

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:

$$-0.28 < f_4^Z < +0.32, \qquad -0.34 < f_5^Z < +0.35,$$
$$-0.17 < f_4^\gamma < +0.19, \qquad -0.35 < f_5^\gamma < +0.32.$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

[1] AABOUD 19AY study $ZZ$ production in the $\ell\ell\nu\nu$ decay channel. Events with a pair of isolated high-transverse momentum charged leptons (electron pairs or muon pairs), and with large missing energy, are selected. In the data, 371 (416) di-electron (di-muon) events are found, with a total expected background of $128 \pm 8$ ($143 \pm 8$) events. Analysing the transverse momentum distribution of the charged dilepton system above 150 GeV, the following 95% C.L. limits are derived in units of $10^{-3}$: $-1.2 < f_4^\gamma < 1.2$, $-1.0 < f_4^Z < 1.0$, $-1.2 < f_5^\gamma < 1.2$, $-1.0 < f_5^Z < 1.0$.

[2] AABOUD 18Q study $pp \to ZZ$ events at $\sqrt{s} = 13$ TeV with $Z \to e^+e^-$ or $Z \to \mu^+\mu^-$. The number of events observed in the $4e$, $2e\,2\mu$, and $4\mu$ channels is 249, 465, and 303 respectively. Analysing the $p_T$ spectrum of the leading $Z$ boson, the following the following 95% C.L. limits are derived in units of $10^{-4}$: $-1.8 < f_4^\gamma < 1.8$, $-1.5 < f_4^Z < 1.5$, $-1.8 < f_5^\gamma < 1.8$, $-1.5 < f_5^Z < 1.5$.

[3] SIRUNYAN 18BT study $ppZZ$ events at $\sqrt{s} = 13$ TeV with $Z \to e^+e^-$ or $Z \to \mu^+\mu^-$. The number of events observed in the $4e$, $2e2\mu$, and $4\mu$ channels is 220, 543 and 335 respectively. Analysing the 4-lepton invariant mass spectrum, the following 95% C.L. limits are derived in units of $10^{-3}$: $-1.2 < f_4^\gamma < 1.3$, $-1.2 < f_4^Z < 1.0$, $-1.2 < f_5^\gamma < 1.3$, $-1.0 < f_5^Z < 1.3$.

[4] KHACHATRYAN 15B study $ZZ$ production in 8 TeV $pp$ collisions. In the decay modes $ZZ \to 4e$, $4\mu$, $2e2\mu$, 54, 75, 148 events are observed, with an expected background of $2.2 \pm 0.9$, $1.2 \pm 0.6$, and $2.4 \pm 1.0$ events, respectively. Analysing the 4-lepton invariant mass spectrum in the range from 110 GeV to 1200 GeV, the following 95% C.L. limits are obtained: $|f_4^Z| < 0.004$, $|f_5^Z| < 0.004$, $|f_4^\gamma| < 0.005$, $|f_5^\gamma| < 0.005$.

[5] KHACHATRYAN 15BC use the cross section measurement of the final state $pp \to ZZ \to 2\ell2\nu$, ($\ell$ being an electron or a muon) at 7 and 8 TeV to put limits on these triple gauge couplings. Effective mass of the charged lepton pair is required to be in the range 83.5–98.5 GeV and the dilepton $p_T > 45$ GeV. The reduced missing $E_T$ is required to be $> 65$ GeV, which takes into account the fake missing $E_T$ due to detector effects. The numbers of $e^+e^-$ and $\mu^+\mu^-$ events selected are 35 and 40 at 7 TeV and 176 and 271 at 8 TeV respectively. The production cross sections so obtained are in agreement with SM predictions. The following 95% C.L. limits are set: $-0.0028 < f_4^Z < 0.0032$, $-0.0037 < f_4^\gamma < 0.0033$, $-0.0029 < f_5^Z < 0.0031$, $-0.0033 < f_5^\gamma < 0.0037$. Combining with previous results (KHACHATRYAN 15B and CHATRCHYAN 13B) which include 7 TeV and 8 TeV data on the final states $pp \to ZZ \to 2\ell2\ell'$ where $\ell$ and $\ell'$ are an electron or a muon, the best limits are $-0.0022 < f_4^Z < 0.0026$, $-0.0029 < f_4^\gamma < 0.0026$, $-0.0023 < f_5^Z < 0.0023$, $-0.0026 < f_5^\gamma < 0.0027$.

[6] AAD 13Z study $ZZ$ production in $pp$ collisions at $\sqrt{s} = 7$ TeV. In the $ZZ \to \ell^+\ell^-\ell'^+\ell'^-$ final state they observe a total of 66 events with an expected background of $0.9 \pm 1.3$. In the $ZZ \to \ell^+\ell^-\nu\nu$ final state they observe a total of 87 events with an expected background of $46.9 \pm 5.2$. The limits on anomalous TGCs are determined using the observed and expected numbers of these $ZZ$ events binned in $p_T^Z$. The 95% C.L. are as follows: for form factor scale $\Lambda = \infty$, $-0.015 < f_4^\gamma < 0.015$, $-0.013 < f_4^Z < 0.013$, $-0.016 < f_5^\gamma < 0.015$, $-0.013 < f_5^Z < 0.013$; for form factor scale $\Lambda = 3$ TeV, $-0.022 < f_4^\gamma < 0.023$, $-0.019 < f_4^Z < 0.019$, $-0.023 < f_5^\gamma < 0.023$, $-0.020 < f_5^Z < 0.019$.

[7] CHATRCHYAN 13B study $ZZ$ production in $pp$ collisions and select 54 $ZZ$ candidates in the $Z$ decay channel with electrons or muons with an expected background of $1.4 \pm 0.5$ events. The resulting 95% C.L. ranges are: $-0.013 < f_4^\gamma < 0.015$, $-0.011 < f_4^Z < 0.012$, $-0.014 < f_5^\gamma < 0.014$, $-0.012 < f_5^Z < 0.012$.

[8] Using data collected in the center of mass energy range 192–209 GeV, SCHAEL 09 select 318 $e^+e^- \to ZZ$ events with 319.4 expected from the standard model. Using this data they derive the following 95% CL limits: $-0.321 < f_4^\gamma < 0.318$, $-0.534 < f_4^Z < 0.534$, $-0.724 < f_5^\gamma < 0.733$, $-1.194 < f_5^Z < 1.190$.

[9] ABAZOV 08K search for $ZZ$ and $Z\gamma^*$ events with 1 fb$^{-1}$ $p\overline{p}$ data at $\sqrt{s} = 1.96$ TeV in $(ee)(ee)$, $(\mu\mu)(\mu\mu)$, $(ee)(\mu\mu)$ final states requiring the lepton pair masses to be $> 30$ GeV. They observe 1 event, which is consistent with an expected signal of $1.71 \pm 0.15$ events and a background of $0.13 \pm 0.03$ events. From this they derive the following limits, for a form factor ($\Lambda$) value of 1.2 TeV: $-0.28 < f_{40}^Z < 0.28$, $-0.31 < f_{50}^Z < 0.29$, $-0.26 < f_{40}^\gamma < 0.26$, $-0.30 < f_{50}^\gamma < 0.28$.

[10] Using data collected at $\sqrt{s} = 183$–$208$ GeV, ABDALLAH 07C select 171 $e^+e^- \to ZZ$ events with $Z \to q\overline{q}$ or lepton pair (except an explicit $\tau$ pair), and 74 $e^+e^- \to Z\gamma^*$ events with a $q\overline{q}\mu^+\mu^-$ or $q\overline{q}e^+e^-$ signature, to derive 95% CL limits on $f_i^V$. Each limit is derived with other parameters set to zero. They report: $-0.40 < f_4^Z < 0.42$, $-0.38 < f_5^Z < 0.62$, $-0.23 < f_4^\gamma < 0.25$, $-0.52 < f_5^\gamma < 0.48$.

[11] ABBIENDI 04C study $ZZ$ production in $e^+e^-$ collisions in the C.M. energy range 190–209 GeV. They select 340 events with an expected background of 180 events. Including the ABBIENDI 00N data at 183 and 189 GeV (118 events with an expected background of 65 events) they report the following 95% CL limits: $-0.45 < f_4^Z < 0.58$, $-0.94 < f_5^Z < 0.25$, $-0.32 < f_4^\gamma < 0.33$, and $-0.71 < f_5^\gamma < 0.59$.

[12] ACHARD 03D study $Z$-boson pair production in $e^+e^-$ collisions in the C.M. energy range 200–209 GeV. They select 549 events with an expected background of 432 events. Including the ACCIARRI 99G and ACCIARRI 99O data (183 and 189 GeV respectively, 286 events with an expected background of 241 events) and the 192–202 GeV ACCIARRI 01I results (656 events, expected background of 512 events), they report the following 95% CL limits: $-0.48 \le f_4^Z \le 0.46$, $-0.36 \le f_5^Z \le 1.03$, $-0.28 \le f_4^\gamma \le 0.28$, and $-0.40 \le f_5^\gamma \le 0.47$.

## ANOMALOUS $W/Z$ QUARTIC COUPLINGS

Revised November 2015 by M.W. Grünewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Quartic couplings, $WWZZ$, $WWZ\gamma$, $WW\gamma\gamma$, and $ZZ\gamma\gamma$, were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowers dimensional representation of operators (dimension 6) which presumes the SU(2)×U(1) gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. . In this representation possible quartic couplings, $a_0, a_c, a_n$, are expressed in terms of the following dimension-6 operators [1,2];

$$L_6^0 = -\frac{e^2}{16\Lambda^2}\, a_0\, F^{\mu\nu}\, F_{\mu\nu}\vec{W}^{\alpha}\cdot\vec{W}_{\alpha}$$
$$L_6^c = -\frac{e^2}{16\Lambda^2}\, a_c\, F^{\mu\alpha}\, F_{\mu\beta}\vec{W}^{\beta}\cdot\vec{W}_{\alpha}$$
$$L_6^n = -i\frac{e^2}{16\Lambda^2}\, a_n\epsilon_{ijk}\, W_{\mu\alpha}^{(i)}\, W_{\nu}^{(j)}\, W^{(k)\alpha}F^{\mu\nu}$$
$$\widetilde{L}_6^0 = -\frac{e^2}{16\Lambda^2}\, \widetilde{a}_0\, F^{\mu\nu}\, \widetilde{F}_{\mu\nu}\vec{W}^{\alpha}\cdot\vec{W}_{\alpha}$$
$$\widetilde{L}_6^n = -i\frac{e^2}{16\Lambda^2}\, \widetilde{a}_n\epsilon_{ijk}\, W_{\mu\alpha}^{(i)}\, W_{\nu}^{(j)}\, W^{(k)\alpha}\widetilde{F}^{\mu\nu}$$

where $F, W$ are photon and $W$ fields, $L_6^0$ and $L_6^c$ conserve $C$, $P$ separately ($\widetilde{L}_6^0$ conserves only $C$) and generate anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ couplings, $L_6^n$ violates $CP$ ($\widetilde{L}_6^n$ violates both $C$ and $P$) and generates an anomalous $W^+W^-Z\gamma$ coupling, and $\Lambda$ is an energy scale for new physics. For the $ZZ\gamma\gamma$ coupling the $CP$-violating term represented by $L_6^n$ does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the $WW\gamma\gamma$ and $ZZ\gamma\gamma$ couplings separately, leading to two sets parametrized as $a_0^V/\Lambda^2$ and $a_c^V/\Lambda^2$, where $V = W$ or $Z$.

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned}\mathcal{L}_{AQGC} = &-\frac{e^2}{8}\frac{a_0^W}{\Lambda^2}F_{\mu\nu}F^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2}{16}\frac{a_c^W}{\Lambda^2}F_{\mu\nu}F^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &-e^2g^2\frac{\kappa_0^W}{\Lambda^2}F_{\mu\nu}Z^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2g^2}{2}\frac{\kappa_c^W}{\Lambda^2}F_{\mu\nu}Z^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &+\frac{f_{T,0}}{\Lambda^4}Tr[\widehat{W}_{\mu\nu}\widehat{W}^{\mu\nu}]\times Tr[\widehat{W}_{\alpha\beta}\widehat{W}^{\alpha\beta}]\end{aligned}$$

The energy scale of possible new physics is $\Lambda$, and $g = e/sin(\theta_W)$, $e$ being the unit electric charge and $\theta_W$ the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators $a_0^W/\Lambda^2$ and $a_c^W/\Lambda^2$ are associated with the $WW\gamma\gamma$ vertex. Among dimension 8 operators, $\kappa_0^W/\Lambda^2$ and $\kappa_c^W/\Lambda^2$ are associated with the $WWZ\gamma$ vertex, whereas the parameter $f_{T,0}/\Lambda^4$ contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters $f_{M,i}/\Lambda^4$ as follows [3]:

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,2}}{\Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,3}}{\Lambda^4}$$

where $g' = e/cos(\theta_W)$ and $M_W$ is the invariant mass of the $W$ boson. This relation provides a translation between limits on dimension 6 operators $a_{0,c}^W$ and $f_{M,j}/\Lambda^4$. It is further required [4] that $f_{M,0} = 2f_{M,2}$ and $f_{M,1} = 2f_{M,3}$ which suppresses contributions to the $WWZ\gamma$ vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total – $f_{S,i},\ i = 1, 2$, $f_{M,i},\ i = 0, \ldots, 8$ and $f_{T,i}, i = 0, \ldots, 9$ – each scaled by $1/\Lambda^4$.

The ATLAS collaboration [6], on the other hand, follows a K-matrix driven approach of Ref. 7 in which the anomalous couplings can be expressed in terms of two parameters $\alpha_4$ and $\alpha_5$, which account for all BSM effects.

It is the early stages in the determination of quartic couplings by the LHC experiments. It is hoped that the two collaborations, ATLAS and CMS, will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison and allow for a possible LHC combination.

### $a_0/\Lambda^2$, $a_c/\Lambda^2$

Combining published and unpublished preliminary LEP results the following 95% CL intervals for the QGCs associated with the $ZZ\gamma\gamma$ vertex are derived (CERN-PH-EP/2005-051 or hep-ex/0511027):

$$-0.008 < a_0^Z/\Lambda^2 < +0.021$$
$$-0.029 < a_c^Z/\Lambda^2 < +0.039$$

Anomalous $Z$ quartic couplings have also been measured by the Tevatron and LHC experiments. As discussed in the review on "Anomalous $W/Z$ quartic couplings," the coupling parameters in the Anomalous QGC Lagrangian may relate to processes involving only the $W$ or only to the $Z$ or to both. Thus, results on all other AQGCs are reported together in the $W$ listings.

[1] ABBIENDI 04L select 20 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ acoplanar events in the energy range 180–209 GeV and 176 $e^+e^- \to q\overline{q}\gamma\gamma$ events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ quartic couplings. Further combining with the $W^+W^-\gamma$ sample of ABBIENDI 04B the following one–parameter 95% CL limits are obtained: $-0.007 < a_0^Z/\Lambda^2 < 0.023$ GeV$^{-2}$, $-0.029 < a_C^Z/\Lambda^2 < 0.029$ GeV$^{-2}$, $-0.020 < a_0^W/\Lambda^2 < 0.020$ GeV$^{-2}$, $-0.052 < a_C^W/\Lambda^2 < 0.037$ GeV$^{-2}$.

[2] In the CM energy range 183 to 209 GeV HEISTER 04A select 30 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ events with two acoplanar, high energy and high transverse momentum photons. The photon–photon acoplanarity is required to be $> 5^\circ$, $E_\gamma/\sqrt{s} > 0.025$ (the more energetic photon having energy $> 0.2\sqrt{s}$), $p_{T_\gamma}/E_{\rm beam} > 0.05$ and $|\cos\theta_\gamma| < 0.94$. A likelihood fit to the photon energy and recoil missing mass yields the following one–parameter 95% CL limits: $-0.012 < a_0^Z/\Lambda^2 < 0.019$ GeV$^{-2}$, $-0.041 < a_C^Z/\Lambda^2 < 0.044$ GeV$^{-2}$, $-0.060 < a_0^W/\Lambda^2 < 0.055$ GeV$^{-2}$, $-0.099 < a_C^W/\Lambda^2 < 0.093$ GeV$^{-2}$.

[3] ACHARD 02G study $e^+e^- \to Z\gamma\gamma \to q\overline{q}\gamma\gamma$ events using data at center-of-mass energies from 200 to 209 GeV. The photons are required to be isolated, each with energy $>5$ GeV and $|\cos\theta| < 0.97$, and the di-jet invariant mass to be compatible with that of the $Z$ boson (74–111 GeV). Cuts on $Z$ velocity ($\beta < 0.73$) and on the energy of the most energetic photon reduce the backgrounds due to non-resonant production of the $q\overline{q}\gamma\gamma$ state and due to ISR respectively, yielding a total of 40 candidate events of which 8.6 are expected to be due to background. The energy spectra of the least energetic photon are fitted for all ten center-of-mass energy values from 130 GeV to 209 GeV (as obtained adding to the present analysis 130–202 GeV data of ACCIARRI 01E, for a total of 137 events with an expected background of 34.1 events) to obtain the fitted values $a_0/\Lambda^2 = 0.00^{+0.02}_{-0.01}$ GeV$^{-2}$ and $a_C/\Lambda^2 = 0.03^{+0.01}_{-0.02}$ GeV$^{-2}$, where the other parameter is kept fixed to its Standard Model value (0). A simultaneous fit to both parameters yields the 95% CL limits $-0.02$ GeV$^{-2} < a_0/\Lambda^2 < 0.03$ GeV$^{-2}$ and $-0.07$ GeV$^{-2} < a_C/\Lambda^2 < 0.05$ GeV$^{-2}$.

# $H^0$

$J = 0$

In the following $H^0$ refers to the signal that has been discovered in the Higgs searches. Whereas the observed signal is labeled as a spin 0 particle and is called a Higgs Boson, the detailed properties of $H^0$ and its role in the context of electroweak symmetry breaking need to be further clarified. These issues are addressed by the measurements listed below.

Concerning mass limits and cross section limits that have been obtained in the searches for neutral and charged Higgs bosons, see the sections "Searches for Neutral Higgs Bosons" and "Searches for Charged Higgs Bosons ($H^\pm$ and $H^{\pm\pm}$)", respectively.

[1] Combined value from $\gamma\gamma$ and $ZZ^* \to 4\ell$ final states.

[2] SIRUNYAN 17AV use 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV with $H^0 \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[3] ATLAS and CMS data are fitted simultaneously.

[4] AABOUD 18BM use 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV with $H^0 \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[5] AABOUD 18BM use 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV with $H^0 \to \gamma\gamma$.

[6] AABOUD 18BM combine 13 TeV results with 7 and 8 TeV results. Other combined results are summarized in their Fig. 4.

[7] KHACHATRYAN 15AM use up to 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and up to 19.7 fb$^{-1}$ at $E_{cm} = 8$ TeV.

[8] AAD 14W use 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 20.3 fb$^{-1}$ at 8 TeV.

[9] CHATRCHYAN 14AA use 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 19.7 fb$^{-1}$ at $E_{cm} = 8$ TeV.

[10] CHATRCHYAN 14K use 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 19.7 fb$^{-1}$ at $E_{cm} = 8$ TeV.

[11] KHACHATRYAN 14P use 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 19.7 fb$^{-1}$ at $E_{cm} = 8$ TeV.

[12] AAD 13AK use 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$=7 TeV and 20.7 fb$^{-1}$ at $E_{cm}$=8 TeV. Superseded by AAD 14W.

[13] CHATRCHYAN 13J use 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 12.2 fb$^{-1}$ at $E_{cm} = 8$ TeV.

[14] AAD 12AI obtain results based on 4.6–4.8 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 5.8–5.9 fb$^{-1}$ at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.9 $\sigma$ is observed at $m_{H^0} = 126$ GeV. See also AAD 12DA.

[15] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 5.1–5.3 fb$^{-1}$ at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.0 $\sigma$ is observed at about $m_{H^0} = 125$ GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

## $H^0$ SPIN AND $CP$ PROPERTIES

The observation of the signal in the $\gamma\gamma$ final state rules out the possibility that the discovered particle has spin 1, as a consequence of the Landau-Yang theorem. This argument relies on the assumptions that the decaying particle is an on-shell resonance and that the decay products are indeed two photons rather than two pairs of boosted photons, which each could in principle be misidentified as a single photon.

Concerning distinguishing the spin 0 hypothesis from a spin 2 hypothesis, some care has to be taken in modelling the latter in order to ensure that the discriminating power is actually based on the spin properties rather than on unphysical behavior that may affect the model of the spin 2 state.

Under the assumption that the observed signal consists of a single state rather than an overlap of more than one resonance, it is sufficient to discriminate between distinct hypotheses in the spin analyses. On the other hand, the determination of the $CP$ properties is in general much more difficult since in principle the observed state could consist of any admixture of $CP$-even and $CP$-odd components. As a first step, the compatibility of the data with distinct hypotheses of pure $CP$-even and pure $CP$-odd states with different spin assignments has been investigated. In order to treat the case of a possible mixing of different $CP$ states, certain cross section ratios are considered. Those cross section ratios need to be distinguished from the amount of mixing between a $CP$-even and a $CP$-odd state, as the cross section ratios depend in addition also on the coupling strengths of the $CP$-even and $CP$-odd components to the involved particles. A small relative coupling implies a small sensitivity of the corresponding cross section ratio to effects of $CP$ mixing.

[1] SIRUNYAN 19BL measure the anomalous $HVV$ couplings from on-shell and off-shell production in the $4\ell$ final state. Data of 80.2 fb$^{-1}$ at 13 TeV, 19.7 fb$^{-1}$ at 8 TeV, and 5.1 fb$^{-1}$ at 7 TeV are used. See their Tables VI and VII for anomalous $HVV$ couplings of $CP$-violating and $CP$-conserving parameters with on- and off-shells.

[2] SIRUNYAN 19BZ constrain anomalous $HVV$ couplings of the Higgs boson with data of 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV using Higgs boson candidates with two jets produced in VBF, ggF, and $VH$ that decay to $\tau\tau$. See their Table 2 and Fig. 10, which show 68% CL and 95% CL intervals. Combining those with the $H^0 \to 4\ell$ (SIRUNYAN 19BL, on-shell scenario), results shown in their Tables 3, 4, and Fig. 11 are obtained. A $CP$-violating parameter is set to be $f_{a3}\cos(\phi_{a3}) = (0.00 \pm 0.27)\times 10^{-3}$ and $CP$-conserving parameters are $f_{a2}\cos(\phi_{a2}) = (0.08^{+1.04}_{-0.21}) \times 10^{-3}$, $f_{\Lambda 1}\cos(\phi_{\Lambda 1}) = (0.00^{+0.53}_{-0.09}) \times 10^{-3}$, and $f^{Z\gamma}_{\Lambda 1}\cos(\phi^{Z\gamma}_{\Lambda 1}) = (0.0^{+1.1}_{-1.3}) \times 10^{-3}$.

[3] AABOUD 18AJ study the tensor structure of the Higgs boson couplings using an effective Lagrangian using 36.1 fb$^{-1}$ of $pp$ collision data at $E_{cm}$ = 13 TeV. Constraints are set on the non-Standard-Model $CP$-even and $CP$-odd couplings to $Z$ bosons and on the $CP$-odd coupling to gluons. See their Figs. 9 and 10, and Tables 10 and 11.

[4] SIRUNYAN 17AM constrain anomalous couplings of the Higgs boson with 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV, 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV, and 38.6 fb$^{-1}$ at $E_{cm}$ = 13 TeV. See their Table 3 and Fig. 3, which show 68% CL and 95% CL intervals. A $CP$ violation parameter $f_{a3}$ is set to be $f_{a3}\cos(\phi_{a3}) = [-0.38, 0.46]$ at 95% CL ($\phi_{a3}$ = 0 or $\pi$).

[5] AAD 16 study $H^0 \to \gamma\gamma$ with an effective Lagrangian including $CP$ even and odd terms in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. The data is consistent with the expectations for the Higgs boson of the Standard Model. Limits on anomalous couplings are also given.

[6] AAD 16BL study VBF $H^0 \to \tau\tau$ with an effective Lagrangian including a $CP$ odd term in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. The measurement is consistent with the expectation of the Standard Model. The $CP$-mixing parameter $\tilde{d}$ (a dimensionless coupling $\tilde{d} = -(m^2_W/\Lambda^2) f_{\widetilde{W}W}$) is constrained to the interval of $(-0.11, 0.05)$ at 68% CL under the assumption of $\tilde{d} = \tilde{d}_B$.

[7] KHACHATRYAN 16AB search for anomalous pseudoscalar couplings of the Higgs boson to $W$ and $Z$ with 18.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Table 5 and Figs 5 and 6 for limits on possible anomalous pseudoscalar coupling parameters.

[8] AAD 15AX compare the $J^{CP} = 0^+$ Standard Model assignment with other $J^{CP}$ hypotheses in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV, using the process $H^0 \to WW^* \to e\nu\mu\nu$. $2^+$ hypotheses are excluded at 84.5–99.4%CL, $0^-$ at 96.5%CL, $0^+$ (field strength coupling) at 70.8%CL. See their Fig. 19 for limits on possible $CP$ mixture parameters.

[9] AAD 15CI compare the $J^{CP} = 0^+$ Standard Model assignment with other $J^{CP}$ hypotheses in 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV, using the processes $H^0 \to ZZ^* \to 4\ell$. $H^0 \to \gamma\gamma$ and combine with AAD 15AX data. $0^+$ (field strength coupling), $0^-$ and several $2^+$ hypotheses are excluded at more than 99.9% CL. See their Tables 7–9 for limits on possible $CP$ mixture parameters.

[10] AALTONEN 15 combine AALTONEN 15B and ABAZOV 14F data. An upper limit of 0.36 of the Standard Model production rate at 95% CL is obtained both for a $0^-$ and a $2^+$ state. Assuming the SM event rate, the $J^{CP} = 0^-$ ($2^+$) hypothesis is excluded at the $5.0\sigma$ ($4.9\sigma$) level.

[11] AALTONEN 15B compare the $J^{CP} = 0^+$ Standard Model assignment with other $J^{CP}$ hypotheses in 9.45 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV, using the processes $ZH^0 \to \ell\ell b\overline{b}$, $WH^0 \to \ell\nu b\overline{b}$, and $ZH^0 \to \nu\nu b\overline{b}$. Bounds on the production rates of $0^-$ and $2^+$ (graviton-like) states are set, see their tables II and III.

[12] KHACHATRYAN 15Y compare the $J^{CP} = 0^+$ Standard Model assignment with other $J^{CP}$ hypotheses in up to 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and up to 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV, using the processes $H^0 \to 4\ell$, $H^0 \to WW^*$, and $H^0 \to \gamma\gamma$. $0^-$ is excluded at 99.98% CL, and several $2^+$ hypotheses are excluded at more than 99% CL. Spin 1 models are excluded at more than 99.999% CL in $ZZ^*$ and $WW^*$ modes. Limits on anomalous couplings and several cross section fractions, treating the case of $CP$-mixed states, are also given.

[13] ABAZOV 14F compare the $J^{CP} = 0^+$ Standard Model assignment with $J^{CP} = 0^-$ and $2^+$ (graviton-like coupling) hypotheses in up to 9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. They use kinematic correlations between the decay products of the vector boson and the Higgs boson in the final states $ZH \to \ell\ell b\overline{b}$, $WH \to \ell\nu b\overline{b}$, and $ZH \to \nu\nu b\overline{b}$. The $0^-$ ($2^+$) hypothesis is excluded at 97.6% CL (99.0% CL). In order to treat the case of a possible mixture of a $0^+$ state with another $J^{CP}$ state, the cross section fractions $f_X = \sigma_X/(\sigma_{0^+} + \sigma_X)$ are considered, where $X = 0^-, 2^+$. Values for $f_{0^-}$ ($f_{2^+}$) above 0.80 (0.67) are excluded at 95% CL under the assumption that the total cross section is that of the SM Higgs boson.

[14] CHATRCHYAN 14AA compare the $J^{CP} = 0^+$ Standard Model assignment with various $J^{CP}$ hypotheses in 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. $J^{CP} = 0^-$ and $1^\pm$ hypotheses are excluded at 99% CL, and several $J = 2$ hypotheses are excluded at 95% CL. In order to treat the case of a possible mixture of a $0^+$ state with another $J^{CP}$ state, the cross section fraction $f_{a3} = |a_3|^2\sigma_3 / (|a_1|^2\sigma_1 + |a_2|^2\sigma_2 + |a_3|^2\sigma_3)$ is considered, where the case $a_3 = 1$, $a_1 = a_2 = 0$ corresponds to a pure $CP$-odd state. Assuming $a_2 = 0$, a value for $f_{a3}$ above 0.51 is excluded at 95% CL.

[15] CHATRCHYAN 14G compare the $J^{CP} = 0^+$ Standard Model assignment with $J^{CP} = 0^-$ and $2^+$ (graviton-like coupling) hypotheses in 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.4 fb$^{-1}$ at $E_{cm}$ = 8 TeV. Varying the fraction of the production of the $2^+$ state via $gg$ and $q\overline{q}$, $2^+$ hypotheses are disfavored at CL between 83.7 and 99.8%. The $0^-$ hypothesis is disfavored against $0^+$ at the 65.3% CL.

[16] KHACHATRYAN 14P compare the $J^{CP} = 0^+$ Standard Model assignment with a $2^+$ (graviton-like coupling) hypothesis in 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. Varying the fraction of the production of the $2^+$ state via $gg$ and $q\overline{q}$, $2^+$ hypotheses are disfavored at CL between 71 and 94%.

[17] AAD 13AJ compare the spin 0, $CP$-even hypothesis with specific alternative hypotheses of spin 0, $CP$-odd, spin 1, $CP$-even and $CP$-odd, and spin 2, $CP$-even models using the Higgs boson decays $H \to \gamma\gamma$, $H \to ZZ^* \to 4\ell$ and $H \to WW^* \to \ell\nu\ell\nu$ and combinations thereof. The data are compatible with the spin 0, $CP$-even hypothesis, while all other tested hypotheses are excluded at confidence levels above 97.8%.

[18] CHATRCHYAN 13J study angular distributions of the lepton pairs in the $ZZ^*$ channel where both $Z$ bosons decay to $e$ or $\mu$ pairs. Under the assumption that the observed particle has spin 0, the data are found to be consistent with the pure $CP$-even hypothesis, while the pure $CP$-odd hypothesis is disfavored.

## $H^0$ DECAY WIDTH

The total decay width for a light Higgs boson with a mass in the observed range is not expected to be directly observable at the LHC. For the case of the Standard Model the prediction for the total width is about 4 MeV, which is three orders of magnitude smaller than the experimental mass resolution. There is no indication from the results observed so far that the natural width is broadened by new physics effects to such an extent that it could be directly observable. Furthermore, as all LHC Higgs channels rely on the identification of Higgs decay products, the total Higgs width cannot be measured indirectly without additional assumptions. The different dependence of on-peak and off-peak contributions on the total width in Higgs decays to $ZZ^*$ and interference effects between signal and background in Higgs decays to $\gamma\gamma$ can provide additional information in this context. Constraints on the total width from the combination of on-peak and off-peak contributions in Higgs decays to $ZZ^*$ rely on the assumption of equal on- and off-shell effective couplings. Without an experimental determination of the total width or further theoretical assumptions, only ratios of couplings can be determined at the LHC rather than absolute values of couplings.

[1] SIRUNYAN 19BL measure the width and anomalous $HVV$ couplings from on-shell and off-shell production in the $4\ell$ final state. Data of 80.2 fb$^{-1}$ at 13 TeV, 19.7 fb$^{-1}$ at 8 TeV, and 5.1 fb$^{-1}$ at 7 TeV are used. The total width for the SM-like couplings is measured to be also [0.08, 9.16] MeV with 95% CL, assuming SM-like couplings for on- and off-shells (see their Table VIII). Constraints on the total width for anomalous $HVV$ interaction cases are found in their Table IX. See their Table X for the Higgs boson signal strength in the off-shell region.

[2] AABOUD 18BP use 36.1 fb$^{-1}$ at $E_{cm}$ = 13 TeV. An observed upper limit on the off-shell Higgs signal strength of 3.8 is obtained at 95% CL using off-shell Higgs boson production in the $ZZ \to 4\ell$ and $ZZ \to 2\ell 2\nu$ decay channels ($\ell = e, \mu$). Combining with the on-shell signal strength measurements, the quoted upper limit on the Higgs boson total width is obtained, assuming the ratios of the relevant Higgs-boson couplings to the SM predictions are constant with energy from on-shell production to the high-mass range.

[3] SIRUNYAN 17AV obtain an upper limit on the width from the $m_{4\ell}$ distribution in $ZZ^* \to 4\ell$ ($\ell = e, \mu$) decays. Data of 35.9 fb$^{-1}$ $pp$ collisions at $E_{cm}$ = 13 TeV is used. The expected limit is 1.60 GeV.

[4] KHACHATRYAN 16BA combine $WW^{(*)}$ result with $ZZ^{(*)}$ results of KHACHATRYAN 15BA and KHACHATRYAN 14D.

[5] KHACHATRYAN 15AM combine $\gamma\gamma$ and $ZZ^* \to 4\ell$ results. The expected limit is 2.3 GeV.

[6] KHACHATRYAN 15BA derive a lower limit on the total width from an upper limit on the decay flight distance $\tau < 1.9 \times 10^{-13}$ s. 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at 8 TeV are used.

[7] AAD 14W use 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.3 fb$^{-1}$ at 8 TeV. The expected limit is 6.2 GeV.

[8] KHACHATRYAN 16BA derive constraints on the total width from comparing $WW^{(*)}$ production via on-shell and off-shell $H^0$ using 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.4 fb$^{-1}$ at 8 TeV.

[9] AAD 15BE derive constraints on the total width from comparing $ZZ^{(*)}$ and $WW^{(*)}$ production via on-shell and off-shell $H^0$ using 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. The K factor for the background processes is assumed to be equal to that for the signal.

[10] KHACHATRYAN 15BA derive constraints on the total width from comparing $ZZ^{(*)}$ production via on-shell and off-shell $H^0$ with an unconstrained anomalous coupling. $4\ell$ final states in 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV are used.

[11] CHATRCHYAN 14AA use 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The expected limit is 2.8 GeV.

[12] KHACHATRYAN 14D derive constraints on the total width from comparing $ZZ^{(*)}$ production via on-shell and off-shell $H^0$. $4\ell$ and $\ell\ell\nu\nu$ final states in 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV are used.

[13] KHACHATRYAN 14P use 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The expected limit is 3.1 GeV.

[1] AABOUD 19AL combine results of 7, 8 (AAD 15CX), and 13 TeV for $H^0$ decaying to invisible final states.

[2] SIRUNYAN 19BO combine 13 TeV 35.9 fb$^{-1}$ results with 7, 8, 13 TeV (KHACHATRYAN 17F) for $H^0$ decaying to invisible final states. The quoted limit on the branching ratio is given for $m_{H^0} = 125.09$ GeV and assumes the Standard Model production rates. The branching ratio is obtained to be $0.05 \pm 0.03$ (stat) $\pm 0.07$(syst).

[3] AABOUD 19AI search for $pp \to qqH^0X$ (VBF) with $H^0$ decaying to invisible final states using 36.1 fb$^{-1}$ of data. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.

[4] AABOUD 19AL combine results of $H^0$ decaying to invisible final states with VBF(AABOUD 19AI), $ZH$, and $WH$ productions (AABOUD 18, AABOUD 18CA), which use 36.1 fb$^{-1}$ of data at 13 TeV. The quoted limit is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for gluon fusion, VBF, $ZH$, and $WH$ productions.

[5] SIRUNYAN 19AT perform a combined fit with visible decay using 35.9 fb$^{-1}$ of data at 13 TeV.

[6] SIRUNYAN 19BO search for $pp \to qqH^0X$ (VBF) with $H^0$ decaying to invisible final states using 35.9 fb$^{-1}$ of data. The quoted limit on the branching ratio is given for $m_{H^0} = 125.09$ GeV and assumes the Standard Model production rates.

[7] SIRUNYAN 19BO combine the VBF channel with results of other 13 TeV analyses: SIRUNYAN 18BV and SIRUNYAN 18S. The quoted limit on the branching ratio is given for $m_{H^0} = 125.09$ GeV and assumes the Standard Model production rates.

[8] AABOUD 18 search for $pp \to H^0ZX$, $Z \to ee$, $\mu\mu$ with $H^0$ decaying to invisible final states in 36.1 fb$^{-1}$ at $E_{cm} = 13$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rate for $H^0Z$ production.

[9] AABOUD 18CA search for $H^0$ decaying to invisible final states using $WH$, and $ZH$ productions, where $W$ and $Z$ hadronically decay. The data of 36.1 fb$^{-1}$ at $E_{cm} = 13$ TeV is used. The quoted limit assumes SM production cross sections with combining the contributions from $WH$, $ZH$, ggF and VBF production modes.

[10] SIRUNYAN 18BV search for $H^0$ decaying to invisible final states associated with a $Z$, $Z \to \ell\ell$ using 35.9 fb$^{-1}$ at 13 TeV.The limit is obtained for $m_{H^0} = 125$ GeV and assuming the SM $ZH^0$ production cross section.

[11] SIRUNYAN 18S search for $H^0$ decaying to invisible final states associated with an energetic jet or a $V$, $V \to q\overline{q}$ using 35.9 fb$^{-1}$ at 13 TeV.

[12] AABOUD 17BD search for $H^0$ decaying to invisible final states with $\geq 1$ jet and VBF events using 3.2 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. A cross-section ratio $R^{miss}$ is used in the measurement. The quoted limit is given for $m_{H^0} = 125$ GeV.

[13] KHACHATRYAN 17F search for $H^0$ decaying to invisible final states with gluon fusion, VBF, $ZH$, and $WH$ productions using 2.3 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV, 19.7 fb$^{-1}$ at 8 TeV, and 5.1 fb$^{-1}$ at 7 TeV. The quoted limit is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for gluon fusion, VBF, $ZH$, and $WH$ productions.

[14] AAD 16AF search for $pp \to qqH^0X$ (VBF) with $H^0$ decaying to invisible final states in 20.3 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.

[15] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The branching fraction of decays into BSM particles that are invisible or into undetected decay modes is measured for $m_{H^0} = 125.09$ GeV.

[16] AAD 15BD search for $pp \to H^0WX$ and $pp \to H^0ZX$ with $W$ or $Z$ decaying hadronically and $H^0$ decaying to invisible final states using data at $E_{cm} = 8$ TeV. The quoted limit is given for $m_{H^0} = 125$ GeV, assumes the Standard Model rates for the production processes and is based on a combination of the contributions from $H^0W$, $H^0Z$ and the gluon-fusion process.

[17] AAD 15CX search for $H^0$ decaying to invisible final states with VBF, $ZH$, and $WH$ productions using 20.3 fb$^{-1}$ at 8 TeV, and 4.7 fb$^{-1}$ at 7 TeV. The quoted limit is given for $m_{H^0} = 125.36$ GeV and assumes the Standard Model rates for gluon fusion, VBF, $ZH$, and $WH$ productions. The upper limit is improved to 0.23 by adding the measured visible decay rates.

[18] AAD 14O search for $pp \to H^0ZX$, $Z \to \ell\ell$, with $H^0$ decaying to invisible final states in 4.5 fb$^{-1}$ at $E_{cm} = 7$ TeV and 20.3 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125.5$ GeV and assumes the Standard Model rate for $H^0Z$ production.

[19] CHATRCHYAN 14B search for $pp \to H^0ZX$, $Z \to \ell\ell$ and $Z \to b\overline{b}$, and also $pp \to qqH^0X$ with $H^0$ decaying to invisible final states using data at $E_{cm} = 7$ and 8 TeV. The quoted limit on the branching ratio is obtained from a combination of the limits from $H^0Z$ and $qqH^0$. It is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for the two production processes.

[20] CHATRCHYAN 14B search for $pp \to H^0ZX$ with $H^0$ decaying to invisible final states and $Z \to \ell\ell$ in 4.9 fb$^{-1}$ at $E_{cm} = 7$ TeV and 19.7 fb$^{-1}$ at $E_{cm} = 8$ TeV, and also with $Z \to b\overline{b}$ in 18.9 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rate for $H^0Z$ production.

[21] CHATRCHYAN 14B search for $pp \to qqH^0X$ (vector boson fusion) with $H^0$ decaying to invisible final states in 19.5 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rate for $qqH^0$ production.

## $\Gamma(\gamma$invisible$)/\Gamma_{total}$ $\Gamma_{23}/\Gamma$

| VALUE | CL% | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **<0.046** | 95 | [1] SIRUNYAN | 19CG | CMS | $pp \to H^0Z$, $H^0 \to \gamma$invisible, $Z \to \ell\ell$, 13 TeV |

[1] SIRUNYAN 19CG search for $pp \to H^0Z$, $Z \to ee$, $\mu\mu$ with $H^0$ decaying to invisible final states plus a $\gamma$ in 137 fb$^{-1}$ at $E_{cm} = 13$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV assuming the Standard Model rate for $H^0Z$ production and is obtained in the context of a theoretical model, where the undetected (invisible) is massless.

## $H^0$ SIGNAL STRENGTHS IN DIFFERENT CHANNELS

The $H^0$ signal strength in a particular final state $xx$ is given by the cross section times branching ratio in this channel normalized to the Standard Model (SM) value, $\sigma \cdot B(H^0 \to xx) / (\sigma \cdot B(H^0 \to xx))_{SM}$, for the specified mass value of $H^0$. For the SM predictions, see DITTMAIER 11, DITTMAIER 12, and HEINEMEYER 13A. Results for fiducial and differential cross sections are also listed below.

### Combined Final States

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[1] AAD 20 combine results of up to 79.8 fb$^{-1}$ of data at $E_{cm}$ = 13 TeV, assuming $m_{H^0}$ = 125.09 GeV: $\gamma\gamma$, $ZZ^*$, $WW^*$, $\tau\tau$, $b\overline{b}$, $\mu\mu$, invisible, and off-shell analyses (see their Table I). The signal strengths for individual production processes are $1.04 \pm 0.09$ for gluon fusion, $1.21^{+0.24}_{-0.22}$ for vector boson fusion, $1.30^{+0.40}_{-0.38}$ for $WH^0$ production, $1.05^{+0.31}_{-0.29}$ for $ZH^0$ production, and $1.21^{+0.26}_{-0.24}$ for $t\overline{t}H^0+tH^0$ production (see their Fig. 2 and Table IV). Several results with the simplified template cross section and $\kappa$-frameworks are presented: see their Figs. 9–11, Figs 20, 21 and Table VIII for stage-1 simplified template cross sections, their Figs. 12–17 and Tables X–XII for the $\kappa$-framework.

[2] SIRUNYAN 19AT combine results of 35.9 fb$^{-1}$ of data at $E_{cm}$ = 13 TeV, assuming $m_{H^0}$ = 125.09 GeV. The signal strengths for individual production processes are $1.22^{+0.14}_{-0.12}$ for gluon fusion, $0.73^{+0.30}_{-0.27}$ for vector boson fusion, $2.18^{+0.58}_{-0.55}$ for $WH^0$ production, $0.87^{+0.44}_{-0.42}$ for $ZH^0$ production, and $1.18^{+0.30}_{-0.27}$ for $t\overline{t}H^0$ production. Several results with the simplified template cross section and $\kappa$-frameworks are presented: see their Fig. 8 and Table 5 for stage-0 simplified template cross sections, their Figs. 9–18 and Tables 7–11 for the $\kappa$-framework.

[3] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm}$ = 7 and 8 TeV. The signal strengths for individual production processes are $1.03^{+0.16}_{-0.14}$ for gluon fusion, $1.18^{+0.25}_{-0.23}$ for vector boson fusion, $0.89^{+0.40}_{-0.38}$ for $WH^0$ production, $0.79^{+0.38}_{-0.36}$ for $ZH^0$ production, and $2.3^{+0.7}_{-0.6}$ for $t\overline{t}H^0$ production.

[4] AAD 16AN: The uncertainties represent statistics, experimental systematics, theory systematics on the background, and theory systematics on the signal. The quoted signal strengths are given for $m_{H^0}$ = 125.09 GeV. In the fit, relative branching ratios and relative production cross sections are fixed to those in the Standard Model.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb$^{-1}$ and 9.7 fb$^{-1}$, respectively, of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[6] SIRUNYAN 19BA measure differential cross sections for the Higgs boson transverse momentum, the number of jets, the rapidity of the Higgs boson and the transverse momentum of the leading jet using 35.9 fb$^{-1}$ of data at $E_{cm}$ = 13 TeV with $H^0 \to \gamma\gamma$, $H^0 \to ZZ^*$, and $H^0 \to b\overline{b}$. The total cross section for Higgs boson production is measured to be $61.1 \pm 6.0 \pm 3.7$ pb using $H^0 \to \gamma\gamma$ and $H^0 \to ZZ^*$ channels. Several coupling measurements in the $\kappa$-framework are performed.

[7] AAD 16K use up to 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and up to 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The third uncertainty in the measurement is theory systematics. The signal strengths for individual production modes are $1.23 \pm 0.14^{+0.09}_{-0.08}{}^{+0.16}_{-0.12}$ for gluon fusion, $1.23^{+0.28}_{-0.27}{}^{+0.13}_{-0.12}{}^{+0.11}_{-0.09}$ for vector boson fusion, $0.80^{+0.31}_{-0.30} \pm 0.17^{+0.10}_{-0.05}$ for $W/ZH^0$ production, and $1.81^{+0.52}_{-0.50}{}^{+0.58}_{-0.55}{}^{+0.31}_{-0.12}$ for $t\overline{t}H^0$ production. The quoted signal strengths are given for $m_{H^0}$ = 125.36 GeV.

[8] AAD 15P measure total and differential cross sections of the process $pp \to H^0X$ at $E_{cm}$ = 8 TeV with 20.3 fb$^{-1}$. $\gamma\gamma$ and $4\ell$ final states are used. $\sigma(pp \to H^0X) = 33.0 \pm 5.3 \pm 1.6$ pb is given. See their Figs. 2 and 3 for data on differential cross sections.

[9] KHACHATRYAN 15AM use up to 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and up to 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The third uncertainty in the measurement is theory systematics. Fits to each production mode give the value of $0.85^{+0.19}_{-0.16}$ for gluon fusion, $1.16^{+0.37}_{-0.34}$ for vector boson fusion, $0.92^{+0.38}_{-0.36}$ for $WH^0$, $ZH^0$ production, and $2.90^{+1.08}_{-0.94}$ for $t\overline{t}H^0$ production.

[10] AAD 13AK use 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The combined signal strength is based on the $\gamma\gamma$, $ZZ^* \to 4\ell$, and $WW^* \to \ell\nu\ell\nu$ channels. The quoted signal strength is given for $m_{H^0}$ = 125.5 GeV. Reported statistical error value modified following private communication with the experiment.

[11] AALTONEN 13L combine all CDF results with 9.45–10.0 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[12] ABAZOV 13L combine all D0 results with up to 9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[13] AAD 12AI obtain results based on 4.6–4.8 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 5.8–5.9 fb$^{-1}$ at $E_{cm}$ = 8 TeV. An excess of events over background with a local significance of 5.9 $\sigma$ is observed at $m_{H^0}$ = 126 GeV. The quoted signal strengths are given for $m_{H^0}$ = 126 GeV. See also AAD 12DA.

[14] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 5.1–5.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. An excess of events over background with a local significance of 5.0 $\sigma$ is observed at about $m_{H^0}$ = 125 GeV. The combined signal strength is based on the $\gamma\gamma$, $ZZ^*$, $WW^*$, $\tau^+\tau^-$, and $b\overline{b}$ channels. The quoted signal strength is given for $m_{H^0}$ = 125.5 GeV. See also CHATRCHYAN 13Y.

[1] SIRUNYAN 19AT perform a combine fit to 35.9 fb$^{-1}$ of data at $E_{cm}$ = 13 TeV.

[2] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm}$ = 7 and 8 TeV. The signal strengths for individual production processes are $0.84 \pm 0.17$ for gluon fusion, $1.2 \pm 0.4$ for vector boson fusion, $1.6^{+1.2}_{-1.0}$ for $WH^0$ production, $5.9^{+2.6}_{-2.2}$ for $ZH^0$ production, and $5.0^{+1.8}_{-1.7}$ for $t\overline{t}H^0$ production.

[3] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0}$ = 125.09 GeV.

[4] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb$^{-1}$ and 9.7 fb$^{-1}$, respectively, of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[5] AABOUD 19F measure cross-sections times the $H^0 \to WW^*$ branching fraction in the $H^0 \to WW^* \to e\nu\mu\nu$ channel using 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV: $\sigma_{ggF} \times B(H^0 \to WW^*) = 11.4^{+1.2}_{-1.1}{}^{+1.8}_{-1.7}$ pb and $\sigma_{VBF} \times B(H^0 \to WW^*) = 0.50^{+0.24}_{-0.22} \pm 0.17$ pb.

[6] AAD 19A use 36.1 fb$^{-1}$ data at 13 TeV. The cross section times branching fraction values are measured to be $0.67^{+0.31}_{-0.27}{}^{+0.18}_{-0.14}$ pb for $WH^0$, $H^0 \to WW^*$ and $0.54^{+0.31}_{-0.24}{}^{+0.15}_{-0.07}$ pb for $ZH^0$, $H^0 \to WW^*$.

[7] SIRUNYAN 19AX measure the signal strengths, cross sections and so on using gluon fusion, VBF and $VH^0$ production processes with 35.9 fb$^{-1}$ of data. The quoted signal strength is given for $m_{H^0}$ = 125.09 GeV. Signal strengths for each production process is found in their Fig. 9. Measured cross sections and ratios to the SM predictions in the stage-0 simplified template cross section framework are shown in their Fig. 10. $\kappa_F = 1.52^{+0.48}_{-0.41}$ and $\kappa_V = 1.10 \pm 0.08$ are obtained (see their Fig. 11 (right)).

[8] AAD 16AO measure fiducial total and differential cross sections of gluon fusion process at $E_{cm}$ = 8 TeV with 20.3 fb$^{-1}$ using $H^0 \to WW^* \to e\nu\mu\nu$. The measured fiducial total cross section is $36.0 \pm 9.7$ fb in their fiducial region (Table 7). See their Fig. 6 for fiducial differential cross sections. The results are given for $m_{H^0}$ = 125 GeV.

[9] AAD 16K use up to 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and up to 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.36 GeV.

[10] AAD 15AA use 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The signal strength for the gluon fusion and vector boson fusion mode is $1.02 \pm 0.19^{+0.22}_{-0.18}$ and $1.27^{+0.44}_{-0.40}{}^{+0.30}_{-0.21}$, respectively. The quoted signal strengths are given for $m_{H^0}$ = 125.36 GeV.

[11] AAD 15AQ use 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.36 GeV.

[12] AAD 15AQ combine their result on $W/ZH^0$ production with the results of AAD 15AA (gluon fusion and vector boson fusion, slightly updated). The quoted signal strength is given for $m_{H^0}$ = 125.36 GeV.

[13] CHATRCHYAN 14G use 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.4 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_{H^0}$ = 125.6 GeV.

[14] AAD 13AK use 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.5 GeV. Superseded by AAD 15AA.

[15] AALTONEN 13L combine all CDF results with 9.45–10.0 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[16] ABAZOV 13L combine all D0 results with up to 9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[17] AAD 12AI obtain results based on 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 5.8 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strengths are given for $m_{H^0}$ = 126 GeV. See also AAD 12DA.

[18] CHATRCHYAN 12N obtain results based on 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 5.1 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.5 GeV. See also CHATRCHYAN 13Y.

[1] SIRUNYAN 19AT perform a combine fit to 35.9 fb$^{-1}$ of data at $E_{cm} = 13$ TeV.

[2] AABOUD 18AJ perform analyses using $H^0 \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 36.1 fb$^{-1}$ at $E_{cm} = 13$ TeV. Results are given for $m_{H^0} = 125.09$ GeV. The inclusive cross section times branching ratio for $H^0 \to ZZ^*$ decay ($|\eta(H^0)| < 2.5$) is measured to be $1.73^{+0.26}_{-0.24}$ pb (with $1.34^{+0.09}_{-0.09}$ pb expected in the SM).

[3] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are $1.13^{+0.34}_{-0.31}$ for gluon fusion and $0.1^{+1.1}_{-0.6}$ for vector boson fusion.

[4] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09$ GeV.

[5] AABOUD 19N measure the spectrum of the four-lepton invariant mass $m_{4\ell}$ ($\ell = e$ or $\mu$) using 36.1 fb$^{-1}$ of data at $E_{cm} = 13$ TeV. The quoted signal strength upper limit is obtained from 180 GeV $< m_{4\ell} <$ 1200 GeV.

[6] AABOUD 18BP measure an off-shell Higgs boson production using $ZZ \to 4\ell$ and $ZZ \to 2\ell 2\nu$ ($\ell = e,\ \mu$) decay channels with 36.1 fb$^{-1}$ of data at $E_{cm} = 13$ TeV. The quoted signal strength upper limit is obtained from a combination of these two channels, where 220 GeV $< m_{4\ell} <$ 2000 GeV for $ZZ \to 4\ell$ and 250 GeV $< m_T^{ZZ} <$ 2000 GeV for $ZZ \to 2\ell 2\nu$ ($m_T^{ZZ}$ is defined in their Section 5). See their Table 2 for each measurement.

[7] SIRUNYAN 17AV use 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. The quoted signal strength, obtained from the analysis of $H^0 \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) decays, is given for $m_{H^0} = 125.09$ GeV. The signal strengths for different production modes are given in their Table 3. The fiducial and differential cross sections are shown in their Fig. 10.

[8] AAD 16K use up to 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and up to 20.3 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.36$ GeV.

[9] KHACHATRYAN 16AR use data of 5.1 fb$^{-1}$ at $E_{cm} = 7$ TeV and 19.7 fb$^{-1}$ at 8 TeV. The fiducial cross sections for the production of 4 leptons via $H^0 \to 4\ell$ decays are measured to be $0.56^{+0.67}_{-0.44}{}^{+0.21}_{-0.06}$ fb at 7 TeV and $1.11^{+0.41}_{-0.35}{}^{+0.14}_{-0.10}$ fb at 8 TeV in their fiducial region (Table 2). The differential cross sections at $E_{cm} = 8$ TeV are also shown in Figs. 4 and 5. The results are given for $m_{H^0} = 125$ GeV.

[10] AAD 15F use 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 20.3 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.36$ GeV. The signal strength for the gluon fusion production mode is $1.66^{+0.45}_{-0.41}{}^{+0.25}_{-0.15}$, while the signal strength for the vector boson fusion production mode is $0.26^{+1.60}_{-0.91}{}^{+0.36}_{-0.23}$.

[11] AAD 14AR measure the cross section for $pp \to H^0X$, $H^0 \to ZZ^*$ using 20.3 fb$^{-1}$ at $E_{cm} = 8$ TeV. They give $\sigma \cdot B = 2.11^{+0.53}_{-0.47} \pm 0.08$ fb in their fiducial region, where $1.30 \pm 0.13$ fb is expected in the Standard Model for $m_{H^0} = 125.4$ GeV. Various differential cross sections are also given, which are in agreement with the Standard Model expectations.

[12] CHATRCHYAN 14AA use 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 19.7 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.6$ GeV. The signal strength for the gluon fusion and $t\bar{t}H$ production mode is $0.80^{+0.46}_{-0.36}$, while the signal strength for the vector boson fusion and $WH^0$, $ZH^0$ production mode is $1.7^{+2.2}_{-2.1}$.

[13] AAD 13AK use 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 20.7 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.5$ GeV.

[14] CHATRCHYAN 13J obtain results based on $ZZ \to 4\ell$ final states in 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 12.2 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.8$ GeV. Superseded by CHATRCHYAN 14AA.

[15] AAD 12AI obtain results based on 4.7–4.8 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 5.8 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted signal strengths are given for $m_{H^0} = 126$ GeV. See also AAD 12DA.

[16] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 5.1–5.3 fb$^{-1}$ at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.0 $\sigma$ is observed at about $m_{H^0} = 125$ GeV. The quoted signal strengths are given for $m_{H^0} = 125.5$ GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

| $1.54^{+0.46}_{-0.42}$ | [16] CHATRCHYAN | 12N | CMS | $pp \to H^0X$, 7, 8 TeV |

[1] SIRUNYAN 19AT perform a combine fit to 35.9 fb$^{-1}$ of data at $E_{cm} = 13$ TeV.

[2] AABOUD 18BO use 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. The signal strengths for the individual production modes are: $0.81^{+0.19}_{-0.18}$ for gluon fusion, $2.0^{+0.6}_{-0.5}$ for vector boson fusion, $0.7^{+0.9}_{-0.8}$ for $VH^0$ production ($V = W, Z$), and $0.5 \pm 0.6$ for $t\bar{t}H^0$ and $tH^0$ production. Other measurements of cross sections and couplings are summarized in their Section 10. The quoted values are given for $m_{H^0} = 125.09$ GeV.

[3] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are $1.10^{+0.23}_{-0.22}$ for gluon fusion, $1.3 \pm 0.5$ for vector boson fusion, $0.5^{+1.3}_{-1.2}$ for $WH^0$ production, $0.5^{+3.0}_{-2.5}$ for $ZH^0$ production, and $2.2^{+1.6}_{-1.3}$ for $t\bar{t}H^0$ production.

[4] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09$ GeV.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb$^{-1}$ and 9.7 fb$^{-1}$, respectively, of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[6] SIRUNYAN 19L measure fiducial and differential cross sections of the process $pp \to H^0 \to \gamma\gamma$ at $E_{cm} = 13$ TeV with 35.9 fb$^{-1}$. See their Figs. 4–11.

[7] SIRUNYAN 18DS use 35.9 fb$^{-1}$ of $pp \to H^0$ collisions with $H^0 \to \gamma\gamma$ at $E_{cm} = 13$ TeV. The Higgs mass is floated in the measurement of a signal strength. The result is $1.18^{+0.12}_{-0.11}(\text{stat.})^{+0.09}_{-0.07}(\text{syst.})^{+0.07}_{-0.06}(\text{theory})$, which is largely insensitive to the Higgs mass around 125 GeV.

[8] KHACHATRYAN 16G measure fiducial and differential cross sections of the process $pp \to H^0X$, $H^0 \to \gamma\gamma$ at $E_{cm} = 8$ TeV with 19.7 fb$^{-1}$. See their Figs. 4–6 and Table 1 for data.

[9] AAD 14BC use 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 20.3 fb$^{-1}$ at $E_{cm} = 8$ TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_{H^0} = 125.4$ GeV. The signal strengths for the individual production modes are: $1.32 \pm 0.38$ for gluon fusion, $0.8 \pm 0.7$ for vector boson fusion, $1.0 \pm 1.6$ for $WH^0$ production, $0.1^{+3.7}_{-0.1}$ for $ZH^0$ production, and $1.6^{+2.7}_{-1.8}$ for $t\bar{t}H^0$ production.

[10] AAD 14BJ measure fiducial and differential cross sections of the process $pp \to H^0X$, $H^0 \to \gamma\gamma$ at $E_{cm} = 8$ TeV with 20.3 fb$^{-1}$. See their Table 3 and Figs. 3–12 for data.

[11] KHACHATRYAN 14P use 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 19.7 fb$^{-1}$ at $E_{cm} = 8$ TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_{H^0} = 124.7$ GeV. The signal strength for the gluon fusion and $t\bar{t}H$ production mode is $1.13^{+0.37}_{-0.31}$, while the signal strength for the vector boson fusion and $WH^0$, $ZH^0$ production mode is $1.16^{+0.63}_{-0.58}$.

[12] AAD 13AK use 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 20.7 fb$^{-1}$ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.5$ GeV.

[13] AALTONEN 13L combine all CDF results with 9.45–10.0 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[14] ABAZOV 13L combine all D0 results with up to 9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[15] AAD 12AI obtain results based on 4.8 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 5.9 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strengths are given for $m_{H^0}$ = 126 GeV. See also AAD 12DA.

[16] CHATRCHYAN 12N obtain results based on 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$=7 TeV and 5.3 fb$^{-1}$ at $E_{cm}$=8 TeV. The quoted signal strength is given for $m_{H^0}$=125.5 GeV. See also CHATRCHYAN 13Y.

### $c\overline{c}$ Final State

[1] SIRUNYAN 19AT perform a combine fit to 35.9 fb$^{-1}$ of data at $E_{cm}$ = 13 TeV.

[2] AABOUD 18BN search for $VH^0$, $H^0 \to b\overline{b}$ ($V = W$, $Z$) using 79.8 fb$^{-1}$ of $pp$ collision data at $E_{cm}$ = 13 TeV. The quoted signal strength corresponds to a significance of 4.9 standard deviations and is given for $m_{H^0}$ = 125 GeV.

[3] SIRUNYAN 18DB search for $VH^0$, $H^0 \to b\overline{b}$ ($V = W$, $Z$) using 77.2 fb$^{-1}$ of $pp$ collision data at $E_{cm}$ = 13 TeV. The quoted signal strength corresponds to a significance of 4.4 standard deviations and is given for $m_{H^0}$ = 125.09 GeV.

[4] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm}$ = 7 and 8 TeV. The signal strengths for individual production processes are 1.0 ± 0.5 for $WH^0$ production, 0.4 ± 0.4 for $ZH^0$ production, and 1.1 ± 1.0 for $t\overline{t}H^0$ production.

[5] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0}$ = 125.09 GeV.

[6] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb$^{-1}$ and 9.7 fb$^{-1}$, respectively, of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[7] AABOUD 19U measure cross sections of $pp \to VH^0$, $H^0 \to b\overline{b}$ production as a function of the gauge boson transverse momentum using data of 79.8 fb$^{-1}$. The kinematic fiducial volumes used is based on the simplified template cross section framework (reduced stage-1). See their Table 3 and Fig. 3.

[8] AABOUD 18BN combine results of 79.8 fb$^{-1}$ at $E_{cm}$ = 13 TeV with results of $VH^0$ at $E_{cm}$ = 7 and 8 TeV.

[9] AABOUD 18BN combine results of $VH^0$ at $E_{cm}$ = 7, 8 and 13 TeV with results of VBF (+gluon fusion) and $t\overline{t}H^0$ at $E_{cm}$ = 7, 8, and 13 TeV to perform a search for the $H^0 \to b\overline{b}$ decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.4 standard deviations.

[10] AABOUD 18BQ search for $H^0 \to b\overline{b}$ produced through vector-boson fusion (VBF) and VBF+$\gamma$ with 30.6 fb$^{-1}$ $pp$ collision data at $E_{cm}$ = 13 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[11] The signal strength is measured including all production modes (VBF, ggF, $VH^0$, $t\overline{t}H^0$).

[12] The signal strength is measured for VBF-only and others (ggF, $VH^0$, $t\overline{t}H^0$) are constrained to Standard Model expectations with uncertainties described in their Section VIII B.

[13] AALTONEN 18C use 5.4 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The upper limit at 95% CL on $p\overline{p} \to H^0 \to b\overline{b}$ is 33 times the SM predicion, which corresponds to a cross section of 40.6 pb.

[14] SIRUNYAN 18AE use 35.9 fb$^{-1}$ of $pp$ collision data at $E_{cm}$ = 13 TeV. The quoted signal strength corresponds to 3.3 standard deviations and is given for $m_{H^0}$ = 125.09 GeV.

[15] SIRUNYAN 18AE combine the result of 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV with the results obtained from data of up to 5.1 fb$^{-1}$ at $E_{cm}$ = 7 TeV and up to 18.9 fb$^{-1}$ at $E_{cm}$ = 8 TeV (CHATRCHYAN 14AI and KHACHATRYAN 15Z). The quoted signal strength corresponds to 3.8 standard deviations and is given for $m_{H^0}$ = 125.09 GeV.

[16] SIRUNYAN 18DB combine the result of 77.2 fb$^{-1}$ at $E_{cm}$ = 13 TeV with the results obtained from data of up to 5.1 fb$^{-1}$ at $E_{cm}$ = 7 TeV and up to 18.9 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength corresponds to a significance of 4.8 standard deviations and is given for $m_{H^0}$ = 125.09 GeV.

[17] SIRUNYAN 18DB combine results of 77.2 fb$^{-1}$ at $E_{cm}$ = 13 TeV with results of gluon fusion (ggF), VBF and $t\overline{t}H^0$ at $E_{cm}$ = 7 TeV, 8 TeV and 13 TeV to perform a search for the $H^0 \to b\overline{b}$ decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.6 standard deviations and is given for $m_{H^0}$ = 125.09 GeV.

[18] SIRUNYAN 18E use 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV. They measure $\sigma \cdot B$ for gluon fusion production of $H^0 \to b\overline{b}$ with $p_T$ >450 GeV, $|\eta|$ <2.5 to be $74 \pm 48^{+17}_{-10}$ fb.

[19] AABOUD 17BA use 36.1 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV. They give $\sigma(W\,H)\cdot B(H^0 \to b\overline{b}) = 1.08^{+0.54}_{-0.47}$ pb and $\sigma(Z\,H)\cdot B(H^0 \to b\overline{b}) = 0.57^{+0.26}_{-0.23}$ pb.

[20] AABOUD 17BA combine 7, 8 and 13 TeV analyses. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[21] AABOUD 16X search for vector-boson fusion production of $H^0$ decaying to $b\overline{b}$ in 20.2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[22] AAD 16K use up to 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and up to 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.36 GeV.

[23] AAD 15G use 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.36 GeV.

[24] KHACHATRYAN 15Z search for vector-boson fusion production of $H^0$ decaying to $b\overline{b}$ in up to 19.8 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[25] KHACHATRYAN 15Z combined vector boson fusion, $WH^0$, $ZH^0$ production, and $t\overline{t}H^0$ production results. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[26] CHATRCHYAN 14AI use up to 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and up to 18.9 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV. See also CHATRCHYAN 14AJ.

[27] AALTONEN 13L combine all CDF results with 9.45–10.0 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[28] ABAZOV 13L combine all D0 results with up to 9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[29] AAD 12AI obtain results based on 4.6–4.8 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV. The quoted signal strengths are given in their Fig. 10 for $m_{H^0}$ = 126 GeV. See also Fig. 13 of AAD 12DA.

[30] AALTONEN 12T combine AALTONEN 12Q, AALTONEN 12R, AALTONEN 12S, ABAZOV 12O, ABAZOV 12P, and ABAZOV 12K. An excess of events over background is observed which is most significant in the region $m_{H^0}$ = 120–135 GeV, with a local significance of up to 3.3 $\sigma$. The local significance at $m_{H^0}$ = 125 GeV is 2.8 $\sigma$, which corresponds to $(\sigma(H^0W) + \sigma(H^0Z)) \cdot B(H^0 \to b\overline{b}) = (0.23^{+0.09}_{-0.08})$ pb, compared to the Standard Model expectation at $m_{H^0}$ = 125 GeV of 0.12 ± 0.01 pb. Superseded by AALTONEN 13M.

[31] CHATRCHYAN 12N obtain results based on 5.0 fb$^{-1}$ of $pp$ collisions at $E_{cm}$=7 TeV and 5.1 fb$^{-1}$ at $E_{cm}$=8 TeV. The quoted signal strength is given for $m_{H^0}$=125.5 GeV. See also CHATRCHYAN 13Y.

[1] SIRUNYAN 19E search for $H^0 \to \mu^+\mu^-$ using 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV and combine with results of 7 TeV (5.0 fb$^{-1}$) and 8 TeV (19.7 fb$^{-1}$). The upper limit at 95% CL on the signal strength is 2.9, which corresponds to the SM Higgs boson branching fraction to a muon pair of $6.4 \times 10^{-4}$.

[2] AABOUD 17Y use 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV, 20.3 fb$^{-1}$ at 8 TeV and 4.5 fb$^{-1}$ at 7 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[3] SIRUNYAN 19AT perform a combine fit to 35.9 fb$^{-1}$ of data at $E_{cm}$ = 13 TeV.

[4] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0}$ = 125.09 GeV.

[5] KHACHATRYAN 15H use 5.0 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[6] AAD 14AS search for $H^0 \to \mu^+\mu^-$ in 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.5 GeV.

[1] AABOUD 19AQ use 36.1 fb$^{-1}$ of data. The first, second and third quoted errors are statistical, experimental systematic and theory systematic uncertainties, respectively. The quoted signal strength is given for $m_{H^0}$ = 125 GeV and corresponds to 4.4 standard deviations. Combining with 7 TeV and 8 TeV results (AAD 15AH), the observed significance is 6.4 standard deviations. The cross sections in the $H^0 \to \tau\tau$ decay channel ($m_{H^0}$ = 125 GeV) are measured to $3.77^{+0.60}_{-0.59}$ (stat) $^{+0.87}_{-0.74}$ (syst) pb for the inclusive, $0.28 \pm 0.09^{+0.11}_{-0.09}$ pb for VBF, and $3.1 \pm 1.0^{+1.6}_{-1.3}$ pb for gluon-fusion production. See their Table XI for the cross sections in the framework of simplified template cross sections.

[2] SIRUNYAN 19AF use 35.9 fb$^{-1}$ of data. $H^0W/Z$ channels are added with a few updates on gluon fusion and vector boson fusion with respect to SIRUNYAN 18Y. The quoted signal strength is given for $m_{H^0}$ = 125 GeV and corresponds to 5.5 standard deviations. The signal strengths for the individual production modes are: $1.12^{+0.53}_{-0.50}$ for gluon fusion, $1.13^{+0.45}_{-0.42}$ for vector boson fusion, $3.39^{+1.68}_{-1.54}$ for $WH^0$ and $1.23^{+1.62}_{-1.35}$ for $ZH^0$. See their Fig. 7 for other couplings ($\kappa_V, \kappa_f$).

[3] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm}$ = 7 and 8 TeV. The signal strengths for individual production processes are $1.0 \pm 0.6$ for gluon fusion, $1.3 \pm 0.4$ for vector boson fusion, $-1.4 \pm 1.4$ for $WH^0$ production, $2.2^{+2.2}_{-1.8}$ for $ZH^0$ production, and $-1.9^{+3.7}_{-3.3}$ for $t\overline{t}H^0$ production.

[4] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0}$ = 125.09 GeV.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb$^{-1}$ and 9.7 fb$^{-1}$, respectively, of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[6] SIRUNYAN 19AF use 35.9 fb$^{-1}$ of data. The quoted signal strength is given for $m_{H^0}$ = 125 GeV and corresponds to 2.3 standard deviations.

[7] SIRUNYAN 19AT perform a combine fit to 35.9 fb$^{-1}$ of data at $E_{cm}$ = 13 TeV. This combination is based on SIRUNYAN 18Y.

[8] SIRUNYAN 18Y use 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.09 GeV and corresponds to 4.9 standard deviations.

[9] SIRUNYAN 18Y combine the result of 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV with the results obtained from data of 4.9 fb$^{-1}$ at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV (KHACHATRYAN 15AM). The quoted signal strength is given for $m_{H^0}$ = 125.09 GeV and corresponds to 5.9 standard deviations.

[10] AAD 16AC measure the signal strength with $pp \to H^0W/ZX$ processes using 20.3 fb$^{-1}$ of $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[11] AAD 16K use up to 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and up to 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.36 GeV.

[12] AAD 15AH use 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The third uncertainty in the measurement is theory systematics. The signal strength for the gluon fusion mode is $2.0 \pm 0.8^{+1.2}_{-0.8} \pm 0.3$ and that for vector boson fusion and $W/ZH^0$ production modes is $1.24^{+0.49}_{-0.45}{}^{+0.31}_{-0.29} \pm 0.08$. The quoted signal strength is given for $m_{H^0}$ = 125.36 GeV.

[13] CHATRCHYAN 14K use 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV. See also CHATRCHYAN 14AJ.

[14] AALTONEN 13L combine all CDF results with 9.45–10.0 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[15] ABAZOV 13L combine all D0 results with up to 9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[16] AAD 12AI obtain results based on 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV. The quoted signal strengths are given in their Fig. 10 for $m_{H^0}$ = 126 GeV. See also Fig. 13 of AAD 12DA.

[17] CHATRCHYAN 12N obtain results based on 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$=7 TeV and 5.1 fb$^{-1}$ at $E_{cm}$=8 TeV. The quoted signal strength is given for $m_{H^0}$=125.5 GeV. See also CHATRCHYAN 13Y .

### $Z\gamma$ Final State

| VALUE | CL% | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| **< 6.6** | 95 | [1] AABOUD | 17AW | ATLS | $pp \to H^0X$, 13 TeV |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| < 7.4 | 95 | [2] SIRUNYAN | 18DQ | CMS | $pp \to H^0X$, 13 TeV, $H^0 \to Z\gamma$ |

| < 9.5 | 95 | [4] CHATRCHYAN | 13BK | CMS | $pp \to H^0X$, 7, 8 TeV |

[1] AABOUD 17AW search for $H^0 \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.09 GeV. The upper limit on the branching ratio of $H^0 \to Z\gamma$ is 1.0% at 95% CL assuming the SM Higgs boson production.

[2] SIRUNYAN 18DQ search for $H^0 \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. The quoted signal strength (see their Figs. 6 and 7) is given for $m_{H^0}$ = 125 GeV.

[3] AAD 14J search for $H^0 \to Z\gamma \to \ell\ell\gamma$ in 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.5 GeV.

[4] CHATRCHYAN 13BK search for $H^0 \to Z\gamma \to \ell\ell\gamma$ in 5.0 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.6 fb$^{-1}$ at $E_{cm}$ = 8 TeV. A limit on cross section times branching ratio which corresponds to (4–25) times the expected Standard Model cross section is given in the range $m_{H^0}$ = 120–160 GeV at 95% CL. The quoted limit is given for $m_{H^0}$ = 125 GeV, where 10 is expected for no signal.

### $\gamma^*\gamma$ Final State

| VALUE | CL% | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |

[1] SIRUNYAN 20C search for the production of four top quarks with same-sign and multilepton final states with 137 fb$^{-1}$ $pp$ collision data at $E_{cm}$ = 13 TeV. The results constraint the ratio of the top quark Yukawa coupling $y_t$ to its the Standard Model by comparing to the central value of a theoretical prediction (see their Refs. [1-2]), yielding $|y_t/y_t^{SM}| < 1.7$ at 95% CL. See their Fig. 5.

[2] SIRUNYAN 19BY measure the top quark Yukawa coupling from $t\bar{t}$ kinematic distributions, the invariant mass of the top quark pair and the rapidity difference between $t$ and $\bar{t}$, in the $\ell$+jets final state with 35.8 fb$^{-1}$ $pp$ collision data at $E_{cm}$ = 13 TeV. The results constraint the ratio of the top quark Yukawa coupling to its the Standard Model to be $1.07^{+0.34}_{-0.43}$ with an upper limit of 1.67 at 95% CL (see their Table III).

[3] SIRUNYAN 18BU search for the production of four top quarks with same-sign and multilepton final states with 35.9 fb$^{-1}$ $pp$ collision data at $E_{cm}$ = 13 TeV. The results constraint the ratio of the top quark Yukawa coupling $y_t$ to its the Standard Model by comparing to the central value of a theoretical prediction (see their Ref. [16]), yielding $|y_t/y_t^{SM}| < 2.1$ at 95% CL.

## OTHER $H^0$ PRODUCTION PROPERTIES

### $t\bar{t}H^0$ Production

Signal strengh relative to the Standard Model cross section.

[1] AABOUD 18AC combine results of $t\bar{t}H^0$, $H^0 \to \tau\tau$, $WW^*(\to \ell\nu\ell\nu, \ell\nu q\bar{q})$, $ZZ^*(\to \ell\ell\nu\nu, \ell\ell q\bar{q})$ with results of $t\bar{t}H^0$, $H^0 \to b\bar{b}$ (AABOUD 18T), $\gamma\gamma$ (AABOUD 18BO), $ZZ^*(\to 4\ell)$ (AABOUD 18AJ) in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV. See their Table 14.

[2] SIRUNYAN 18L use up to 5.1, 19.7 and 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7, 8, and 13 TeV, respectively. The quoted signal strength corresponds to a significance of 5.2 standard deviations and is given for $m_{H^0}$ = 125.09 GeV. $H^0$ decay channels of $WW^*$, $ZZ^*$, $\gamma\gamma$, $\tau\tau$, and $b\bar{b}$ are used. See their Table 1 and Fig. 2 for results on individual channels.

[3] AAD 16AN: In the fit, relative branching ratios are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0}$ = 125.09 GeV.

[4] SIRUNYAN 19R search for $t\bar{t}H^0$ production with $H^0$ decaying to $b\bar{b}$ in 35.9 fb$^{-1}$ of data at $E_{cm}$ = 13 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[5] AABOUD 18AC search for $t\bar{t}H^0$ production with $H^0$ decaying to $\tau\tau$, $WW^*(\to \ell\nu\ell\nu, \ell\nu q\bar{q})$, $ZZ^*(\to \ell\ell\nu\nu, \ell\ell q\bar{q})$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV. See their Table 13 and Fig. 13.

[6] AABOUD 18BK use 79.8 fb$^{-1}$ data for $t\bar{t}H^0$ production with $H^0 \to \gamma\gamma$ and $ZZ^* \to 4\ell$ ($\ell = e, \mu$) and 36.1 fb$^{-1}$ for other decay channels at $E_{cm}$ = 13 TeV. A significance of 5.8 standard deviations is observed for $m_{H^0}$ = 125.09 GeV and its signal strength without the uncertainty of the $t\bar{t}H^0$ cross section is $1.32^{+0.28}_{-0.26}$. Combining with results of 7 and 8 TeV (AAD 16K), the significance is 6.3 standard deviations. Assuming Standard Model branching fractions, the total $t\bar{t}H^0$ production cross section at 13 TeV is measured to be 670 ± 90$^{+110}_{-100}$ fb.

[7] AABOUD 18T search for $t\bar{t}H^0$ production with $H^0$ decaying to $b\bar{b}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[8] SIRUNYAN 18BD search for $t\bar{t}H^0$, $H^0 \to b\bar{b}$ in the all-jet final state with 35.9 fb$^{-1}$ $pp$ collision data at $E_{cm}$ = 13 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[9] SIRUNYAN 18BQ search for $t\bar{t}H^0$ in final states with electrons, muons and hadronically decaying $\tau$ leptons ($H^0 \to WW^*$, $ZZ^*$, $\tau\tau$) with 35.9 fb$^{-1}$ of $pp$ collision data at $E_{cm}$ = 13 TeV. The quoted signal strength corresponds to a significance of 3.2 standard deviations and is given for $m_{H^0}$ = 125 GeV.

[10] AAD 16AL search for $t\bar{t}H^0$ production with $H^0$ decaying to $\gamma\gamma$ in 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and $b\bar{b}$, $\tau\tau$, $\gamma\gamma$, $WW^*$, and $ZZ^*$ in 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV. This paper combines the results of previous papers, and the new result of this paper only is: $\mu = 1.6 \pm 2.6$.

[11] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm}$ = 7 and 8 TeV.

[12] AAD 16K use up to 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and up to 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The third uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_{H^0}$ = 125.36 GeV.

[13] AAD 15 search for $t\bar{t}H^0$ production with $H^0$ decaying to $\gamma\gamma$ in 4.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted result on the signal strength is equivalent to an upper limit of 6.7 at 95% CL and is given for $m_{H^0}$ = 125.4 GeV.

[14] AAD 15BC search for $t\bar{t}H^0$ production with $H^0$ decaying to $b\bar{b}$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. The corresponding upper limit is 3.4 at 95% CL. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[15] AAD 15T search for $t\bar{t}H^0$ production with $H^0$ resulting in multilepton final states (mainly from $WW^*$, $\tau\tau$, $ZZ^*$) in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. The quoted result on the signal strength is given for $m_{H^0}$ = 125 GeV and corresponds to an upper limit of 4.7 at 95% CL. The data sample is independent from AAD 15 and AAD 15BC.

[16] KHACHATRYAN 15AN search for $t\bar{t}H^0$ production with $H^0$ decaying to $b\bar{b}$ in 19.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. The quoted result on the signal strength is equivalent to an upper limit of 4.2 at 95% CL and is given for $m_{H^0}$ = 125 GeV.

[17] KHACHATRYAN 14H search for $t\bar{t}H^0$ production with $H^0$ decaying to $b\bar{b}$, $\tau\tau$, $\gamma\gamma$, $WW^*$, and $ZZ^*$, in 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The quoted signal strength is given for $m_{H^0}$ = 125.6 GeV.

[18] AALTONEN 13L combine all CDF results with 9.45–10.0 fb$^{-1}$ of $p\bar{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted signal strength is given for $m_{H^0}$ = 125 GeV.

[19] CHATRCHYAN 13X search for $t\bar{t}H^0$ production followed by $H^0 \to b\bar{b}$, one top decaying to $\ell\nu$ and the other to either $\ell\nu$ or $q\bar{q}$ in 5.0 fb$^{-1}$ and 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 and 8 TeV. A limit on cross section times branching ratio which corresponds to (4.0–8.6) times the expected Standard Model cross section is given for $m_{H^0}$ = 110–140 GeV at 95% CL. The quoted limit is given for $m_{H^0}$ = 125 GeV, where 5.2 is expected for no signal.

### $H^0H^0$ Production

The 95% CL limits are for the cross section (CS) and Higgs self coupling ($\kappa_\lambda$) scaling factors both relative to the SM predictions.

[1] AAD 20C combine results of up to 36.1 fb$^{-1}$ data at $E_{cm}$ = 13 TeV for $pp \to H^0H^0 \to b\bar{b}\gamma\gamma$, $b\bar{b}\tau\tau$, $b\bar{b}b\bar{b}$, $b\bar{b}WW^*$, $WW^*\gamma\gamma$, $WW^*WW^*$ (AABOUD 18CW, AABOUD 18CQ, AABOUD 19A, AABOUD 19O, AABOUD 18BU, and AABOUD 19T).

[2] AAD 20E search non-resonant for $H^0H^0$ production using $H^0H^0 \to b\bar{b}\ell\nu\ell\nu$, where one of the Higgs bosons decays to $b\bar{b}$ and the other decays to either $WW^*$, $ZZ^*$, or $\tau\tau$, with data of 139 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0$ production cross section at 95% CL is measured to be 1.2 pb, which corresponds to about 40 times the SM prediction.

[3] AABOUD 19A search for $H^0H^0$ production using $H^0H^0 \to b\bar{b}b\bar{b}$ with data of 36.1 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0 \to b\bar{b}b\bar{b}$ production cross section at 95% is measured to be 147 fb, which corresponds to about 12.9 times the SM prediction.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[4] AABOUD 19O search for $H^0H^0$ production using $H^0H^0 \to b\bar{b}WW^*$ with data of 36.1 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0$ production cross section at 95% CL is calculated to be 10 pb from the observed upper limit on the $pp \to H^0H^0 \to b\bar{b}WW^*$ production cross section of 2.5 pb assuming the SM branching fractions. The former corresponds to about 300 times the SM prediction.

[5] AABOUD 19T search for $H^0H^0$ production using $H^0H^0 \to WW^*WW^*$ with data of 36.1 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0$ production cross section at 95% is measured to be 5.3 pb, which corresponds to about 160 times the SM prediction.

[6] SIRUNYAN 19 search for $H^0H^0$ production using $H^0H^0 \to \gamma\gamma b\bar{b}$ with data of 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0 \to \gamma\gamma b\bar{b}$ production cross section at 95% CL is measured to be 2.0 fb, which corresponds to about 24 times the SM prediction. The effective Higgs boson self-coupling $\kappa_\lambda$ ( $= \lambda_{HHH} / \lambda^{SM}_{HHH}$) is constrainted to be $-11 < \kappa_\lambda < 17$ at 95% CL assuming all other Higgs boson couplings are at their SM value.

[7] SIRUNYAN 19AB search for $H^0H^0$ production using $H^0H^0 \to b\bar{b}b\bar{b}$, where 4 heavy flavor jets from two Higgs bosons are resolved, with data of 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0 \to b\bar{b}b\bar{b}$ production cross section at 95% is measured to be 847 fb, which corresponds to about 75 times the SM prediction.

[8] SIRUNYAN 19BE combine results of 13 TeV 35.9 fb$^{-1}$ data: SIRUNYAN 19, SIRUNYAN 18A, SIRUNYAN 19AB, SIRUNYAN 19H, and SIRUNYAN 18F.

[9] SIRUNYAN 19H search for $H^0H^0$ production using $H^0H^0 \to b\bar{b}b\bar{b}$, where one of $b\bar{b}$ pairs is highly boosted and the other one is resolved, with data of 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0 \to b\bar{b}b\bar{b}$ production cross section at 95% is measured to be 1980 fb, which corresponds to about 179 times the SM prediction.

[10] AABOUD 18BU search for $H^0H^0$ production using $\gamma\gamma WW^*$ with the final state of $\gamma\gamma\ell\nu jj$ using data of 36.1 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0$ production cross section at 95% CL is measured to be 7.7 pb, which corresponds to about 230 times the SM prediction. The upper limit on the $pp \to H^0H^0 \to \gamma\gamma WW^*$ at 95% CL is measured to be 7.5 fb (see thier Table 6).

[11] AABOUD 18CQ search for $H^0H^0$ production using $H^0H^0 \to b\bar{b}\tau\tau$ with data of 36.1 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0 \to b\bar{b}\tau\tau$ production cross section at 95% is measured to be 30.9 fb, which corresponds to about 12.7 times the SM prediction.

[12] AABOUD 18CW search for $H^0H^0$ production using $H^0H^0 \to \gamma\gamma b\bar{b}$ with data of 36.1 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0$ production cross section at 95% is measured to be 0.73 pb, which corresponds to about 22 times the SM prediction. The effective Higgs boson self-coupling $\kappa_\lambda$ is constrained to be $-8.2 < \kappa_\lambda < 13.2$ at 95% CL assuming all other Higgs boson couplings are at their SM value.

[13] SIRUNYAN 18A search for $H^0H^0$ production using $H^0H^0 \to b\bar{b}\tau\tau$ with data of 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $gg \to H^0H^0 \to b\bar{b}\tau\tau$ production cross section is measured to be 75.4 fb, which corresponds to about 30 times the SM prediction. Limits on Higgs-boson trilinear coupling $\lambda_{HHH}$ and top Yukawa coupling $y_t$ are also given (see their Fig. 6).

[14] SIRUNYAN 18F search non-resonant for $H^0H^0$ production using $H^0H^0 \to b\bar{b}\ell\nu\ell\nu$, where $\ell\nu\ell\nu$ is either $WW \to \ell\nu\ell\nu$ or $ZZ \to \ell\ell\nu\nu$ ($\ell$ is $e$, $\mu$ or a leptonically decaying $\tau$), with data of 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $H^0H^0 \to b\bar{b}\ell\nu\ell\nu$ production cross section at 95% CL is measured to be 72 fb, which corresponds to about 79 times the SM prediction.

[15] SIRUNYAN 17CN search for $H^0H^0$ production using $H^0H^0 \to b\bar{b}\tau\tau$ with data of 18.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. Results are then combined with the published results of the $H^0H^0 \to \gamma\gamma b\bar{b}$ and $H^0H^0 \to b\bar{b}b\bar{b}$, which use data of up to 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The upper limit on the $gg \to H^0H^0$ production cross section is measured to be 0.59 pb from $b\bar{b}\tau\tau$, which corresponds to about 59 times the SM prediction (gluon fusion). The combined upper limit is 0.43 pb, which is about 43 times the SM prediction. The quoted values are given for $m_{H^0}$ = 125 GeV.

[16] AABOUD 16I search for $H^0H^0$ production using $H^0H^0 \to b\bar{b}b\bar{b}$ with data of 3.2 fb$^{-1}$ at $E_{cm}$ = 13 TeV. The upper limit on the $pp \to H^0H^0 \to b\bar{b}b\bar{b}$ production cross section is measured to be 1.22 pb. This result corresponds to about 108 times the SM prediction (gluon fusion), which is $11.3^{+0.9}_{-1.0}$ fb (NNLO+NNLL) including top quark mass effects. The quoted values are given for $m_{H^0}$ = 125 GeV .

[17] KHACHATRYAN 16BQ search for $H^0H^0$ production using $H^0H^0 \to \gamma\gamma b\bar{b}$ with data of 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The upper limit on the $gg \to H^0H^0 \to \gamma\gamma b\bar{b}$ production is measured to be 1.85 fb, which corresponds to about 74 times the SM prediction and is translated into 0.71 pb for $gg \to H^0H^0$ production cross section. Limits on Higgs-boson trilinear coupling $\lambda$ are also given.

[18] AAD 15CE search for $H^0H^0$ production using $H^0H^0 \to b\bar{b}\tau\tau$ and $H^0H^0 \to \gamma\gamma WW$ with data of 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. These results are then combined with the published results of the $H^0H^0 \to \gamma\gamma b\bar{b}$ and $H^0H^0 \to b\bar{b}b\bar{b}$, which use data of up to 20.3 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The upper limits on the $gg \to H^0H^0$ production cross section are measured to be 1.6 pb, 11.4 pb, 2.2 pb and 0.62 pb from $b\bar{b}\tau\tau$, $\gamma\gamma WW$, $\gamma\gamma b\bar{b}$ and $b\bar{b}b\bar{b}$, respectively. The combined upper limit is 0.69 pb, which corresponds to about 70 times the SM prediction. The quoted results are given for $m_{H^0}$ = 125.4 GeV. See their Table 4.

### $tH^0$ associated production cross section

| VALUE | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| | [1] SIRUNYAN | 19BK | CMS | $pp$, 13 TeV |
| | [2] KHACHATRY...16AU | | CMS | $pp$, 8 TeV |

[1] SIRUNYAN 19BK search for the $tH^0$ associated production using multilepton signatures ($H^0 \to WW^*$, $H^0 \to \tau\tau$, $H^0 \to ZZ^*$) and signatures with a single lepton and a $b\bar{b}$ pair ($H^0 \to b\bar{b}$) using 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV. Results are combined with $H^0 \to \gamma\gamma$ (SIRUNYAN 18DS). The observed 95% CL upper limit on the $tH^0$ production cross section times $H^0 \to WW^* + \tau\tau + ZZ^* + b\bar{b} + \gamma\gamma$ branching fraction is 1.94 pb (assuming SM $t\bar{t}H^0$ production cross section). See their Table X and Fig. 14. The values outside the ranges of $[-0.9, -0.5]$ and $[1.0, 2.1]$ times the standard model top quark Yukawa coupling are excluded at 95% CL.

[2] KHACHATRYAN 16AU search for the $tH^0$ associated production in 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. The 95% CL upper limits on the $tH^0$ associated production cross section is measured to be 600–1000 fb depending on the assumed $\gamma\gamma$ branching ratios of the Higgs boson. The $\gamma\gamma$ branching ratio is varied to be by a factor of 0.5–3.0 of the Standard Model Higgs boson ($m_{H^0}$ = 125 GeV). The results of the signal strengths for a negative Higgs-boson trilinear coupling are given. The results are given for $m_{H^0}$ = 125 GeV.

### $H^0$ Production Cross Section in $pp$ Collisions at $\sqrt{s}$ = 13 TeV

Assumes $m_{H^0}$ = 125 GeV

### MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN SUPERSYMMETRIC MODELS

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars [$H_1^0$ and $H_2^0$, where we define $m_{H_1^0} < m_{H_2^0}$], a pseudoscalar ($A^0$), and a charged Higgs pair ($H^\pm$). $H_1^0$ and $H_2^0$ are also called $h$ and $H$ in the literature. There are two free parameters in the Higgs sector which can be chosen to be $m_{A^0}$ and $\tan\beta = v_2/v_1$, the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be $m_{H_1^0} \leq m_Z$, $m_{H_2^0} \geq m_Z$, $m_{A^0} \geq m_{H_1^0}$, and $m_{H^\pm} \geq m_W$. However, as described in the review on "Status of Higgs Boson Physics" in this Volume these relations are violated by radiative corrections.

The observed signal at about 125 GeV, see section "$H^0$", can be interpreted as one of the neutral Higgs bosons of supersymmetric models. Unless otherwise noted, we identify the lighter scalar $H_1^0$ with the Higgs discovered at 125 GeV at the LHC (AAD 12AI, CHATRCHYAN 12N).

Unless otherwise noted, the experiments in $e^+e^-$ collisions search for the processes $e^+e^- \to H_1^0 Z^0$ in the channels used for the Standard Model Higgs searches and $e^+e^- \to H_1^0 A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$. Unless otherwise stated, the following results assume no invisible $H_1^0$ or $A^0$ decays. Unless otherwise noted, the results are given in the $m_h^{max}$ scenario, CARENA 13.

In $p\overline{p}$ and $pp$ collisions the experiments search for a variety of processes, as explicitly specified for each entry. Limits on the $A^0$ mass arise from these direct searches, as well as from the relations valid in the minimal supersymmetric model between $m_{A^0}$ and $m_{H_1^0}$. As discussed in the review on "Status of Higgs Boson Physics" in this Volume, these relations depend, via potentially large radiative corrections, on the mass of the $t$ quark and on the supersymmetric parameters, in particular those of the stop sector. These indirect limits are weaker for larger $t$ and $\tilde{t}$ masses. To include the radiative corrections to the Higgs masses, unless otherwise stated, the listed papers use theoretical predictions incorporating two-loop corrections, and the results are given for the $m_h^{mod+}$ benchmark scenario, see CARENA 13.

### Mass Limits for heavy neutral Higgs bosons ($H_2^0$, $A^0$) in the MSSM

The limits rely on $pp \to H_2^0/A^0 \to \tau^+\tau^-$ and assume that $H_2^0$ and $A^0$ are (sufficiently) mass degenerate. The limits depend on $\tan\beta$.

[1] AABOUD 18G search for production of $H^0_2/A^0 \to \tau^+\tau^-$ by gluon fusion and $b$-associated prodution in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 10 for excluded regions in the $m_{A^0}$– $\tan\beta$ plane in several MSSM scenarios.

[2] SIRUNYAN 18CX search for production of $H^0_{1,2}/A^0 \to \tau^+\tau^-$ by gluon fusion and $b$-associated prodution in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in the $m_{A^0}$– $\tan(\beta)$ plane in several MSSM scenarios.

[3] AAD 20 combine measurements on $H^0$ production and decay using data taken in years 2015–2017 (up to 79.8 fb$^{-1}$) of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 19 for excluded region in the hMSSM parameter space.

[4] AAD 20C combine searches for a scalar resonance decaying to $H^0H^0$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV from AABOUD 19A, AABOUD 19O, AABOUD 18CQ, AABOUD 19T, AABOUD 18CW, and AABOUD 18BU. See their Fig. 7(b) for the excluded region in the hMSSM parameter space.

[5] SIRUNYAN 19CR search for production of $H^0_2/A^0$ in gluon fusion and in association with a $b\overline{b}$ pair, decaying to $\mu^+\mu^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for the excluded region in the MSSM parameter space in the $m_h^{mod+}$ and hMSSM scenarios.

[6] SIRUNYAN 18A search for production of a scalar resonance decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 5 (lower) for excluded regions in the $m_{A^0}$ – $\tan\beta$ plane in the hMSSM scenario.

[7] SIRUNYAN 18BP search for production of $H^0_2/A^0 \to b\overline{b}$ by $b$-associated prodution in 35.7 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H^0_2}$, $m_{A^0} = 0.3$–1.3 TeV, and Fig. 7 for excluded regions in the $m_{A^0}$– $\tan(\beta)$ plane in several MSSM scenarios.

[8] AABOUD 16AA search for production of a Higgs boson in gluon fusion and in association with a $b\overline{b}$ pair followed by the decay $A^0 \to \tau^+\tau^-$ in 3.2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 5(a, b) for limits on cross section times branching ratio for $m_{A^0}$ = 200–1200 GeV, and Fig. 5(c, d) for the excluded region in the MSSM parameter space in the $m_h^{mod+}$ and hMSSM scenarios.

[9] KHACHATRYAN 16A search for production of a Higgs boson in gluon fusion and in association with a $b\overline{b}$ pair followed by the decay $H^0_{1,2}/A^0 \to \mu^+\mu^-$ in 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 19.3 fb$^{-1}$ at $E_{cm} = 8$ TeV. See their Fig. 7 for the excluded region in the MSSM parameter space in the $m_h^{mod+}$ benchmark scenario and Fig. 9 for limits on cross section times branching ratio.

[10] KHACHATRYAN 16P search for gluon fusion production of an $H^0_2$ decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ and an $A^0$ decaying to $ZH^0 \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 12 for excluded region in the $\tan\beta - \cos(\beta-\alpha)$ plane for $m_{H^0_2} = m_{A^0} = 300$ GeV.

[11] KHACHATRYAN 15AY search for production of a Higgs boson in association with a $b$ quark in the decay $H^0_{1,2}/A^0 \to b\overline{b}$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV and combine with CHATRCHYAN 13AG 7 TeV data. See their Fig. 6 for the limits on cross section times branching ratio for $m_{A^0}$ = 100–900 GeV and Figs. 7–9 for the excluded region in the MSSM parameter space in various benchmark scenarios.

[12] AAD 14AW search for production of a Higgs boson followed by the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ in 19.5–20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 11 for the limits on cross section times branching ratio and their Figs. 9 and 10 for the excluded region in the MSSM parameter space. For $m_{A^0} = 140$ GeV, the region $\tan\beta > 5.4$ is excluded at 95% CL in the $m_h^{max}$ scenario.

[13] KHACHATRYAN 14M search for production of a Higgs boson in gluon fusion and in association with a $b$ quark followed by the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ in 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and 19.7 fb$^{-1}$ at $E_{cm} = 8$ TeV. See their Figs. 7 and 8 for one- and two-dimensional limits on cross section times branching ratio and their Figs. 5 and 6 for the excluded region in the MSSM parameter space. For $m_{A^0} = 140$ GeV, the region $\tan\beta > 3.8$ is excluded at 95% CL in the $m_h^{max}$ scenario.

[14] AAD 13O search for production of a Higgs boson in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ and $\mu^+\mu^-$ with 4.7–4.8 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and their Fig. 7 for the limits on cross section times branching ratio. For $m_{A^0} = 110$–170 GeV, $\tan\beta \gtrsim 10$ is excluded, and for $\tan\beta = 50$, $m_{A^0}$ below 470 GeV is excluded at 95% CL in the $m_h^{max}$ scenario.

[15] AAIJ 13T search for production of a Higgs boson in the forward region in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ in 1.0 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. See their Fig. 2 for the limits on cross section times branching ratio and the excluded region in the MSSM parameter space.

[16] CHATRCHYAN 13AG search for production of a Higgs boson in association with a $b$ quark in the decay $H^0_{1,2}/A^0 \to b\overline{b}$ in 2.7–4.8 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and Fig. 5 for the limits on cross section times branching ratio. For $m_{A^0}$ = 90–350 GeV, upper bounds on $\tan\beta$ of 18–42 at 95% CL are obtained in the $m_h^{max}$ scenario with $\mu = +200$ GeV.

[17] AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.

[18] AALTONEN 12X search for associated production of a Higgs boson and a $b$ quark in the decay $H^0_{1,2}/A^0 \to b\overline{b}$, with 2.6 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Table III and Fig. 15 for the limit on cross section times branching ratio and Figs. 17, 18 for the excluded region in the MSSM parameter space.

[19] ABAZOV 12G search for production of a Higgs boson in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ with 7.3 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV and combine with ABAZOV 11W and ABAZOV 11K. See their Figs. 4, 5, and 6 for the excluded region in the MSSM parameter space. For $m_{A^0}$ = 90–180 GeV, $\tan\beta \gtrsim 30$ is excluded at 95% CL. in the $m_h^{max}$ scenario.

[20] CHATRCHYAN 12K search for production of a Higgs boson in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ with 4.6 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. See their Fig. 3 and Table 4 for the excluded region in the MSSM parameter space. For $m_{A^0} = 160$ GeV, the region $\tan\beta > 7.1$ is excluded at 95% CL in the $m_h^{max}$ scenario. Superseded by KHACHATRYAN 14M.

[21] ABAZOV 11K search for associated production of a Higgs boson and a $b$ quark, followed by the decay $H^0_{1,2}/A^0 \to b\overline{b}$, in 5.2 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 5/Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for $\mu = -200$ GeV.

[22] ABAZOV 11W search for associated production of a Higgs boson and a $b$ quark, followed by the decay $H^0_{1,2}/A^0 \to \tau\tau$, in 7.3 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.

[23] AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 2 for the limit on $\sigma \cdot B(H^0_{1,2}/A^0 \to \tau^+\tau^-)$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.

[24] ABDALLAH 08B give limits in eight *CP*-conserving benchmark scenarios and some *CP*-violating scenarios. See paper for excluded regions for each scenario. Supersedes ABDALLAH 04.

[25] SCHAEL 06B make a combined analysis of the LEP data. The quoted limit is for the $m_h^{max}$ scenario with $m_t = 174.3$ GeV. In the *CP*-violating CPX scenario no lower bound on $m_{H^0_1}$ can be set at 95% CL. See paper for excluded regions in various scenarios. See Figs. 2–6 and Tabs. 14–21 for limits on $\sigma(ZH^0) \cdot B(H^0 \to b\overline{b}, \tau^+\tau^-)$ and $\sigma(H^0_1H^0_2) \cdot B(H^0_1, H^0_2 \to b\overline{b}, \tau^+\tau^-)$.

[26] ACOSTA 05Q search for $H^0_{1,2}/A^0$ production in $p\overline{p}$ collisions at $E_{cm} = 1.8$ TeV with $H^0_{1,2}/A^0 \to \tau^+\tau^-$. At $m_{A^0} = 100$ GeV, the obtained cross section upper limit is above theoretical expectation.

[27] Search for $e^+e^- \to H^0_1A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$, and $e^+e^- \to H^0_1Z$. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 200 GeV, and $\mu = -200$ GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for $m_t$=175 GeV, and for the $m_h^{max}$ scenario.

[28] ABBIENDI 04M exclude $0.7 < \tan\beta < 1.9$, assuming $m_t = 174.3$ GeV. Limits for other MSSM benchmark scenarios, as well as for *CP* violating cases, are also given.

[29] ABBIENDI 03G search for $e^+e^- \to H^0_1Z$ followed by $H^0_1 \to A^0A^0$, $A^0 \to c\overline{c}$, $gg$, or $\tau^+\tau^-$. In the no-mixing scenario, the region $m_{H^0_1}$ = 45–85 GeV and $m_{A^0}$ = 2–9.5 GeV is excluded at 95% CL.

[30] ACHARD 02H also search for the final state $H^0_1Z \to 2A^0q\overline{q}$, $A^0 \to q\overline{q}$. In addition, the MSSM parameter set in the "large-$\mu$" and "no-mixing" scenarios are examined.

[31] AKEROYD 02 examine the possibility of a light $A^0$ with $\tan\beta$ <1. Electroweak measurements are found to be inconsistent with such a scenario.

[32] HEISTER 02 excludes the range 0.7 <$\tan\beta$ < 2.3. A wider range is excluded with different stop mixing assumptions. Updates BARATE 01C.

on $m_{H_1^0}$ can be set at 95% CL. See paper for excluded regions in various scenarios. See Figs. 2–6 and Tabs. 14–21 for limits on $\sigma(ZH^0)\cdot$ B($H^0 \to b\overline{b}, \tau^+\tau^-$) and $\sigma(H_1^0 H_2^0)\cdot$ B($H_1^0, H_2^0 \to b\overline{b}, \tau^+\tau^-$).

[3] Search for $e^+e^- \to H_1^0 A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$, and $e^+e^- \to H_1^0 Z$. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 200 GeV, and $\mu = -200$ GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for $m_t$=175 GeV, and for the $m_h^{\rm max}$ scenario.

[4] ABBIENDI 04M exclude $0.7 < \tan\beta < 1.9$, assuming $m_t = 174.3$ GeV. Limits for other MSSM benchmark scenarios, as well as for *CP* violating cases, are also given.

[5] ACHARD 02H also search for the final state $H_1^0 Z \to 2A^0 q\overline{q}$, $A^0 \to q\overline{q}$. In addition, the MSSM parameter set in the "large-$\mu$" and "no-mixing" scenarios are examined.

[6] HEISTER 02 excludes the range $0.7 < \tan\beta < 2.3$. A wider range is excluded with different stop mixing assumptions. Updates BARATE 01C.

[7] AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.

## MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN EXTENDED HIGGS MODELS

This Section covers models which do not fit into either the Standard Model or its simplest minimal Supersymmetric extension (MSSM), leading to anomalous production rates, or nonstandard final states and branching ratios. In particular, this Section covers limits which may apply to generic two-Higgs-doublet models (2HDM), or to special regions of the MSSM parameter space where decays to invisible particles or to photon pairs are dominant (see the review on "Status of Higgs Boson Physics"). Concerning the mass limits for $H^0$ and $A^0$ listed below, see the footnotes or the comment lines for details on the nature of the models to which the limits apply.

The observed signal at about 125 GeV, see section "$H^0$", can be interpreted as one of the neutral Higgs bosons of an extended Higgs sector.

### Mass Limits in General two-Higgs-doublet Models

[1] AAD 20 combine measurements on $H^0$ production and decay using data taken in years 2015–2017 (up to 79.8 fb$^{-1}$) of $pp$ collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 18 for excluded regions in various 2HDMs.

[2] SIRUNYAN 19AE search for a pseudoscalar resonance produced in association with a $b\overline{b}$ pair, decaying to $\tau^+\tau^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 4 for cross section limits for $m_{A^0}$ = 25–70 GeV and comparison with some representative 2HDMs.

[3] SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or $b$ associated production, decaying to $ZH^0 \to \ell^+\ell^- b\overline{b}$ ($\ell = e, \mu$) or $\nu\overline{\nu}b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 13$ TeV. See their Figs. 6 and 7 for excluded regions in the parameter space of various 2HDMs.

[4] AABOUD 18AH search for production of an $A^0$ in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH_2^0 \to \ell^+\ell^- b\overline{b}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 6 for excluded regions in the parameter space of various 2HDMs.

[5] AABOUD 18AI search for production of an $A^0$ in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH^0$ in the final states $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^- b\overline{b}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 13$ TeV. See their Figs. 7 and 8 for excluded regions in the parameter space in various 2HDMs.

[6] AABOUD 18BF search for production of a heavy $H_2^0$ state decaying to $ZZ$ in the final states $\ell^+\ell^-\ell^+\ell^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 13$ TeV. See their Figs. 8 and 9 for excluded parameter regions in 2HDM Type I and II.

[7] AABOUD 18CE search for the process $pp \to H_2^0/A^0 t\overline{t}$ followed by the decay $H_2^0/A^0 \to t\overline{t}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 12 for limits on cross section times branching ratio, and for lower limits on $\tan\beta$ for $m_{H_2^0}$, $m_{A^0}$ = 0.4–1.0 TeV in the 2HDM type II.

[8] HALLER 18 perform global fits in the framework of two-Higgs-doublet models (type I, II, lepton specific, flipped). See their Fig. 8 for allowed parameter regions from fits to LHC $H^0$ measurements, Fig. 9 bottom and charm decays, Fig. 10 muon anomalous magnetic moment, Fig. 11 electroweak precision data, and Fig. 12 by combination of all data.

[9] SIRUNYAN 18BP search for production of $H_2^0/A^0 \to b\overline{b}$ by $b$-associated prodution in 35.7 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H_2^0}$, $m_{A^0}$ = 0.3–1.3 TeV, and Figs. 8 and 9 for excluded regions in the parameter space of type-II and flipped 2HDMs.

[10] SIRUNYAN 18ED search for production of an $A^0$ in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH^0$ in the final states $\nu\overline{\nu}b\overline{b}$ or $\ell^+\ell^- b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 9 for excluded regions in the parameter space in Type I and II 2HDMs.

[11] AABOUD 17AN search for production of a heavy $H_2^0$ and/or $A^0$ decaying to $t\overline{t}$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Fig. 3 and Table III for excluded parameter regions in Type II Two-Higgs-Doublet-Models.

[12] SIRUNYAN 17AX search for $A^0 b\overline{b}$ production followed by the decay $A^0 \to \mu^+\mu^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. Limits are set in the range $m_{A^0}$ = 25–60 GeV. See their Fig. 5 for upper limits on $\sigma(A^0 b\overline{b})\cdot$B($A^0 \to \mu^+\mu^-$).

[13] AAD 16AX search for production of a heavy $H^0$ state decaying to $ZZ$ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-\nu\overline{\nu}$, $\ell^+\ell^- q\overline{q}$, and $\nu\overline{\nu}q\overline{q}$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Figs. 13 and 14 for excluded parameter regions in Type I and II models.

[14] KHACHATRYAN 16P search for gluon fusion production of an $H_2^0$ decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ and an $A^0$ decaying to $ZH^0 \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Fig. 11 for limits on $\tan\beta$ for $m_{A^0}$ = 230–350 GeV.

[15] KHACHATRYAN 16W search for $A^0 b\overline{b}$ production followed by the decay $A^0 \to \tau^+\tau^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Fig. 3 for upper limits on $\sigma(A^0 b\overline{b})\cdot$B($A^0 \to \tau^+\tau^-$).

[16] KHACHATRYAN 16Z search for $H_2^0 \to ZA^0$ followed by $A^0 \to b\overline{b}$ or $\tau^+\tau^-$, and $A^0 \to ZH_2^0$ followed by $H_2^0 \to b\overline{b}$ or $\tau^+\tau^-$, in 19.8 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Fig. 4 for cross section limits and Fig. 5 for excluded region in the parameter space.

[17] AAD 15BK search for production of a heavy $H_2^0$ decaying to $H^0H^0$ in the final state $b\overline{b}b\overline{b}$ in 19.5 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Figs. 15–18 for excluded regions in the parameter space.

[18] AAD 15S search for production of $A^0$ decaying to $ZH^0 \to \ell^+\ell^- b\overline{b}$, $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-\tau^+\tau^-$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Figs. 4 and 5 for excluded regions in the parameter space.

[19] KHACHATRYAN 15BB search for $H_2^0$, $A^0 \to \gamma\gamma$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Fig. 10 for excluded regions in the two-Higgs-doublet model parameter space.

[20] KHACHATRYAN 15N search for production of $A^0$ decaying to $ZH^0 \to \ell^+\ell^- b\overline{b}$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Fig. 5 for excluded regions in the $\tan\beta - \cos(\beta-\alpha)$ plane for $m_{A^0}$ = 300 GeV.

[21] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to H^0 W^\pm W^\mp$, $H^0$ decaying to $b\overline{b}$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Table IV for limits in a two-Higgs-doublet model for $m_{H_2^0}$ = 325–1025 GeV and $m_{H^+}$ = 225–825 GeV.

[22] KHACHATRYAN 14Q search for $H_2^0 \to H^0H^0$ and $A^0 \to ZH^0$ in 19.5 fb$^{-1}$ of $pp$ collisions at $E_{\rm cm} = 8$ TeV. See their Figs. 4 and 5 for limits on cross section times branching ratio for $m_{H_2,A^0}$ = 260–360 GeV and their Figs. 7–9 for limits in two-Higgs-doublet models.

[23] AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm} = 1.96$ TeV. See their Fig. 2 for the limit on $\sigma\cdot$B($H_{1,2}^0/A^0 \to \tau^+\tau^-$) for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.

[24] ABBIENDI 05A search for $e^+e^- \to H_1^0A^0$ in general Type-II two-doublet models, with decays $H_1^0$, $A^0 \to q\overline{q}$, $gg$, $\tau^+\tau^-$, and $H_1^0 \to A^0A^0$.

[25] ABDALLAH 05D search for $e^+e^- \to H^0Z$ and $H^0A^0$ with $H^0$, $A^0$ decaying to two jets of any flavor including $gg$. The limit is for SM $H^0Z$ production cross section with B($H^0 \to jj$) = 1.

[26] ABDALLAH 04O search for $Z \to b\overline{b}H^0$, $b\overline{b}A^0$, $\tau^+\tau^-H^0$ and $\tau^+\tau^-A^0$ in the final states $4b$, $b\overline{b}\tau^+\tau^-$, and $4\tau$. See paper for limits on Yukawa couplings.

[27] ABDALLAH 04O search for $e^+e^- \to H^0Z$ and $H^0A^0$, with $H^0$, $A^0$ decaying to $b\overline{b}$, $\tau^+\tau^-$, or $H^0 \to A^0A^0$ at $E_{\rm cm}$ = 189–208 GeV. See paper for limits on couplings.

[28] ABBIENDI 02D search for $Z \to b\overline{b}H_1^0$ and $b\overline{b}A^0$ with $H_1^0/A^0 \to \tau^+\tau^-$, in the range $4 < m_H < 12$ GeV. See their Fig. 8 for limits on the Yukawa coupling.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[29] ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{cm} \leq 189$ GeV. In addition to usual final states, the decays $H_1^0, A^0 \to q\overline{q}, gg$ are searched for. See their Figs. 15,16 for excluded regions.

[30] ABBIENDI 99E search for $e^+e^- \to H^0A^0$ and $H^0Z$ at $E_{cm} = 183$ GeV. The limit is with $m_H = m_A$ in general two Higgs-doublet models. See their Fig. 18 for the exclusion limit in the $m_H$–$m_A$ plane. Updates the results of ACKERSTAFF 98S.

[31] See Fig. 4 of ABREU 95H for the excluded region in the $m_{H^0} - m_{A^0}$ plane for general two-doublet models. For $\tan\beta > 1$, the region $m_{H^0} + m_{A^0} \lesssim 87$ GeV, $m_{H^0} < 47$ GeV is excluded at 95% CL.

[32] PICH 92 analyse $H^0$ with $m_{H^0} < 2m_\mu$ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and $\pi^\pm$, $\eta$ rare decays are shown in Figs. 3,4. The considered mass region is not totally excluded.

## Mass Limits for $H^0$ with Vanishing Yukawa Couplings

These limits assume that $H^0$ couples to gauge bosons with the same strength as the Standard Model Higgs boson, but has no coupling to quarks and leptons (this is often referred to as "fermiophobic").

[1] AALTONEN 13K search for $H^0 \to WW^{(*)}$ in 9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. A limit on cross section times branching ratio which corresponds to (1.3–6.6) times the expected cross section is given in the range $m_{H^0} = 110$–$200$ GeV at 95% CL.

[2] AALTONEN 13L combine all CDF searches with 9.45–10.0 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV.

[3] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV.

[4] ABAZOV 13G search for $H^0 \to WW^{(*)}$ in 9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. A limit on cross section times branching ratio which corresponds to (2–9) times the expected cross section is given for $m_{H^0} = 100$–$200$ GeV at 95% CL.

[5] ABAZOV 13H search for $H^0 \to \gamma\gamma$ in 9.6 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV.

[6] ABAZOV 13I search for $H^0$ production in the final state with one lepton and two or more jets plus missing $E_T$ in 9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The search is sensitive to $WH^0$, $ZH^0$ and vector-boson fusion Higgs production with $H^0 \to WW^{(*)}$. A limit on cross section times branching ratio which corresponds to (8–30) times the expected cross section is given in the range $m_{H^0} = 100$–$200$ GeV at 95% CL.

[7] ABAZOV 13J search for $H^0$ production in the final states $e e\mu$, $e\mu\mu$, $\mu\tau\tau$, and $e^\pm\mu^\pm$ in 8.6–9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The search is sensitive to $WH^0$, $ZH^0$ production with $H^0 \to WW^{(*)}$, $ZZ^{(*)}$, decaying to leptonic final states. A limit on cross section times branching ratio which corresponds to (2.4–13.0) times the expected cross section is given in the range $m_{H^0} = 100$–$200$ GeV at 95% CL.

[8] ABAZOV 13L combine all D0 results with up to 9.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV.

[9] CHATRCHYAN 13AL search for $H^0 \to \gamma\gamma$ in 5.1 fb$^{-1}$ and 5.3 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ and 8 TeV.

[10] AAD 12N search for $H^0 \to \gamma\gamma$ with 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV in the mass range $m_{H^0} = 110$–$150$ GeV.

[11] AALTONEN 12AN search for $H^0 \to \gamma\gamma$ with 10 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV in the mass range $m_{H^0} = 100$–$150$ GeV.

[12] CHATRCHYAN 12AO use data from CHATRCHYAN 12G, CHATRCHYAN 12E, CHATRCHYAN 12H, CHATRCHYAN 12I, CHATRCHYAN 12D, and CHATRCHYAN 12C.

[13] AALTONEN 09AB search for $H^0 \to \gamma\gamma$ in 3.0 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV in the mass range $m_{H^0} = 70$–$150$ GeV. Associated $H^0W$, $H^0Z$ production and $WW$, $ZZ$ fusion are considered.

[14] ABAZOV 08U search for $H^0 \to \gamma\gamma$ in $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV in the mass range $m_{H^0} = 70$–$150$ GeV. Associated $H^0W$, $H^0Z$ production and $WW$, $ZZ$ fusion are considered. See their Tab. 1 for the limit on $\sigma \cdot B(H^0 \to \gamma\gamma)$, and see their Fig. 3 for the excluded region in the $m_{H^0}$ — $B(H^0 \to \gamma\gamma)$ plane.

[15] SCHAEL 07 search for Higgs bosons in association with a fermion pair and decaying to $WW^*$. The limit is from this search and HEISTER 02L for a $H^0$ with SM production cross section.

[16] Search for associated production of a $\gamma\gamma$ resonance with a $Z$ boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq 209$ GeV. The limit is for a $H^0$ with SM production cross section.

[17] Updates ABREU 01F.

[18] ACHARD 03C search for $e^+e^- \to ZH^0$ followed by $H^0 \to WW^*$ or $ZZ^*$ at $E_{cm} =$ 200-209 GeV and combine with the ACHARD 02C result. The limit is for a $H^0$ with SM production cross section. For $B(H^0 \to WW^*) + B(H^0 \to ZZ^*) = 1$, $m_{H^0} > 108.1$ GeV is obtained. See fig. 6 for the limits under different BR assumptions.

[19] For $B(H^0 \to \gamma\gamma) = 1$, $m_{H^0} > 117$ GeV is obtained.

[20] ACHARD 02C search for associated production of a $\gamma\gamma$ resonance with a $Z$ boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq 209$ GeV. The limit is for a $H^0$ with SM production cross section. For $B(H^0 \to \gamma\gamma) = 1$, $m_{H^0} > 114$ GeV is obtained.

[21] AFFOLDER 01H search for associated production of a $\gamma\gamma$ resonance and a $W$ or $Z$ (tagged by two jets, an isolated lepton, or missing $E_T$). The limit assumes Standard Model values for the production cross section and for the couplings of the $H^0$ to $W$ and $Z$ bosons. See their Fig. 11 for limits with $B(H^0 \to \gamma\gamma) < 1$.

[22] ACCIARRI 00S search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in $e^+e^-$ collisions at $E_{cm} = 189$ GeV. The limit is for a $H^0$ with SM production cross section. For $B(H^0 \to \gamma\gamma) = 1$, $m_{H^0} > 98$ GeV is obtained. See their Fig. 5 for limits on $B(H \to \gamma\gamma) \cdot \sigma(e^+e^- \to Hf\overline{f})/\sigma(e^+e^- \to Hf\overline{f})$ (SM).

[23] BARATE 00L search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in $e^+e^-$ collisions at $E_{cm} =$ 88–202 GeV. The limit is for a $H^0$ with SM production cross section. For $B(H^0 \to \gamma\gamma) = 1$, $m_{H^0} > 109$ GeV is obtained. See their Fig. 3 for limits on $B(H \to \gamma\gamma) \cdot \sigma(e^+e^- \to Hf\overline{f})/\sigma(e^+e^- \to Hf\overline{f})$ (SM).

[24] ABBIENDI 99O search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in $e^+e^-$ collisions at 189 GeV. The limit is for a $H^0$ with SM production cross section. See their Fig. 4 for limits on $\sigma(e^+e^- \to H^0Z^0) \times B(H^0 \to \gamma\gamma) \times B(X^0 \to f\overline{f})$ for various masses. Updates the results of ACKERSTAFF 98Y.

[25] ABBOTT 99B search for associated production of a $\gamma\gamma$ resonance and a dijet pair. The limit assumes Standard Model values for the production cross section and for the couplings of the $H^0$ to $W$ and $Z$ bosons. Limits in the range of $\sigma(H^0 + Z/W) \cdot B(H^0 \to \gamma\gamma) =$ 0.80–0.34 pb are obtained in the mass range $m_{H^0} =$ 65–150 GeV.

[26] ABREU 99P search for $e^+e^- \to H^0\gamma$ with $H^0 \to b\overline{b}$ or $\gamma\gamma$, and $e^+e^- \to H^0q\overline{q}$ with $H^0 \to \gamma\gamma$. See their Fig. 4 for limits on $\sigma \times B$. Explicit limits within an effective interaction framework are also given.

## Mass Limits for $H^0$ Decaying to Invisible Final States

These limits are for a neutral scalar $H^0$ which predominantly decays to invisible final states. Standard Model values are assumed for the couplings of $H^0$ to ordinary particles unless otherwise stated.

[1] AABOUD 19AI search for $H^0_{1,2}$ production by vector boson fusion and decay to invisible final states in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 6(b) for limits on cross section times branching ratios for $m_{H^0_{1,2}} = 0.1$–$3$ TeV.

[2] AAD 15BD search for $pp \to H^0WX$ and $pp \to H^0ZX$ with $W$ or $Z$ decaying hadronically and $H^0$ decaying to invisible final states in 20.3 fb$^{-1}$ at $E_{cm} = 8$TeV. See their Fig. 6 for a limit on the cross section times branching ratio for $m_{H^0} = 115$–$300$ GeV.

[3] AAD 15BH search for events with a jet and missing $E_T$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. Limits on $\sigma(H'^0)$ B($H'^0 \to$ invisible) < (44–10) pb (95%CL) is given for $m_{H'^0} = 115$–$300$ GeV.

[4] AAD 14BA search for $H^0$ production in the decay mode $H^0 \to X^0X^0$, where $X^0$ is a long-lived particle which decays to collimated pairs of $e^+e^-$, $\mu^+\mu^-$, or $\pi^+\pi^-$ plus invisible particles, in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. See their Figs. 15 and 16 for limits on cross section times branching ratio.

[5] AAD 14O search for $pp \to H^0ZX$, $Z \to \ell\ell$, with $H^0$ decaying to invisible final states in 4.5 fb$^{-1}$ at $E_{cm} = 7$ TeV and 20.3 fb$^{-1}$ at $E_{cm} = 8$ TeV. See their Fig. 3 for a limit on the cross section times branching ratio for $m_{H^0} = 110$–$400$ GeV.

[6] CHATRCHYAN 14B search for $pp \to H^0ZX$, $Z \to \ell\ell$ and $Z \to b\overline{b}$, and also $pp \to qqH^0X$ with $H^0$ decaying to invisible final states using data at $E_{cm} = 7$ and 8 TeV. See their Figs. 10, 11 for limits on the cross section times branching ratio for $m_{H^0} =$ 100–400 GeV.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[7] AAD 13AG search for $H^0$ production in the decay mode $H^0 \to X^0X^0$, where $X^0$ is a long-lived particle which decays to $\mu^+\mu^- X'^0$, in 1.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. See their Fig. 7 for limits on cross section times branching ratio.

[8] AAD 13AT search for $H^0$ production in the decay $H^0 \to X^0X^0$, where $X^0$ eventually decays to clusters of collimated $e^+e^-$ pairs, in 2.04 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. See their Fig. 3 for limits on cross section times branching ratio.

[9] CHATRCHYAN 13BJ search for $H^0$ production in the decay chain $H^0 \to X^0X^0$, $X^0 \to \mu^+\mu^- X'^0$ in 5.3 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. See their Fig. 2 for limits on cross section times branching ratio.

[10] AAD 12AQ search for $H^0$ production in the decay mode $H^0 \to X^0X^0$, where $X^0$ is a long-lived particle which decays mainly to $b\overline{b}$ in the muon detector, in 1.94 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^0} = 120$, 140 GeV, $m_{X^0} = 20$, 40 GeV in the $c\tau$ range of 0.5–35 m.

[11] AALTONEN 12AB search for $H^0$ production in the decay $H^0 \to X^0X^0$, where $X^0$ eventually decays to clusters of collimated $\ell^+\ell^-$ pairs, in 5.1 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. Cross section limits are provided for a benchmark MSSM model incorporating the parameters given in Table VI.

[12] AALTONEN 12U search for $H^0$ production in the decay mode $H^0 \to X^0X^0$, where $X^0$ is a long-lived particle with $c\tau \approx 1$ cm which decays mainly to $b\overline{b}$, in 3.2 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Figs. 9 and 10 for limits on cross section times branching ratio for $m_{H^0} = (130$–$170)$ GeV, $m_{X^0} = 20$, 40 GeV.

[13] ABBIENDI 10 search for $e^+e^- \to H^0Z$ with $H^0$ decaying invisibly. The limit assumes SM production cross section and B($H^0 \to$ invisible) = 1.

[14] ABBIENDI 07 search for $e^+e^- \to H^0Z$ with $Z \to q\overline{q}$ and $H^0$ decaying to invisible final states. The $H^0$ width is varied between 1 GeV and 3 TeV. A limit $\sigma \cdot$B($H^0 \to$ invisible) $<$ (0.07–0.57) pb (95%CL) is obtained at $E_{cm} = 206$ GeV for $m_{H^0} = 60$–$114$ GeV.

[15] Search for $e^+e^- \to H^0Z$ with $H^0$ decaying invisibly. The limit assumes SM production cross section and B($H^0 \to$ invisible) = 1.

[16] ACCIARRI 00M search for $e^+e^- \to ZH^0$ with $H^0$ decaying invisibly at $E_{cm}$=183–189 GeV. The limit assumes SM production cross section and B($H^0 \to$ invisible)=1. See their Fig. 6 for limits for smaller branching ratios.

## Mass Limits for Light $A^0$

These limits are for a pseudoscalar $A^0$ in the mass range below $\mathcal{O}(10)$ GeV.

[1] AABOUD 18AP search for the decay $H^0 \to A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 10(b) for limits on B($H^0 \to A^0A^0$) in the range $m_{A^0} = 1$–2.5, 4.5–8 GeV, assuming a type-II two-doublet plus singlet model with $\tan(\beta) = 5$.

[2] KHACHATRYAN 17AZ search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$, $\mu^+\mu^-b\overline{b}$, and $\mu^+\mu^-\tau^+\tau^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. See their Figs. 4, 5, and 6 for cross section limits in the range $m_{A^0} = 5$–62.5 GeV. See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[3] ABLIKIM 16E search for the process $J/\psi \to A^0\gamma$ with $A^0$ decaying to $\mu^+\mu^-$ and give limits on B($J/\psi \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $2.8\times10^{-8}$–$5.0\times10^{-6}$ (90% CL) for $0.212 \le m_{A^0} \le 3.0$ GeV. See their Fig. 5.

[4] KHACHATRYAN 16F search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 8 for cross section limits for $m_{A^0} =$ 4–8 GeV.

[5] LEES 15H search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with $A^0$ decaying to $c\overline{c}$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to c\overline{c}$) in the range $7.4\times10^{-5}$–$2.4\times10^{-3}$ (90% CL) for $4.00 \le m_{A^0} \le 8.95$ and $9.10 \le m_{A^0} \le 9.25$ GeV. See their Fig. 6.

[6] LEES 13C search for the process $\Upsilon(2S,3S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with $A^0$ decaying to $\mu^+\mu^-$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3$–$9.7)\times10^{-6}$ (90% CL) for $0.212 \le m_{A^0} \le 9.20$ GeV. See their Fig. 5(e) for limits on the $b-A^0$ Yukawa coupling derived by combining this result with AUBERT 09Z.

[7] LEES 13L search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with $A^0$ decaying to $gg$ or $s\overline{s}$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to gg$) between $1\times10^{-6}$ and $2\times10^{-2}$ (90% CL) for $0.5 \le m_{A^0} \le 9.0$ GeV, and B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to s\overline{s}$) between $4\times10^{-6}$ and $1\times10^{-3}$ (90%CL) for $1.5 \le m_{A^0} \le 9.0$ GeV. See their Fig. 4.

[8] LEES 13R search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with $A^0$ decaying to $\tau^+\tau^-$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \tau^+\tau^-$) in the range $0.9$–$13\times10^{-5}$ (90% CL) for $3.6 \le m_{A^0} \le 9.2$ GeV. See their Fig. 4 for limits on the $b-A^0$ Yukawa coupling derived by combining this result with AUBERT 09P.

[9] ABLIKIM 12 searches for the process $\psi(3686) \to \pi\pi J/\psi$, $J/\psi \to A^0\gamma$ with $A^0$ decaying to $\mu^+\mu^-$. It gives mass dependent limits on B($J/\psi \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $4\times10^{-7}$–$2.1\times10^{-5}$ (90% C.L.) for $0.212 \le m_{A^0} \le 3.0$ GeV. See their Fig. 2.

[10] CHATRCHYAN 12V search for $A^0$ production in the decay $A^0 \to \mu^+\mu^-$ with 1.3 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. A limit on $\sigma(A^0)$·B($A^0 \to \mu^+\mu^-$) in the range (1.5–7.5) pb is given for $m_{A^0} =$ (5.5–8.7) and (11.5–14) GeV at 95% CL.

[11] AALTONEN 11P search in 2.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with $m_{A^0}$ between 4 and 9 GeV. See their Fig. 4 for limits on B($t \to bH^+$) for $90 < m_{H^+} < 160$ GeV.

[12] ABOUZAID 11A search for the decay chain $K_L \to \pi^0\pi^0A^0$, $A^0 \to \mu^+\mu^-$ and give a limit B($K_L \to \pi^0\pi^0A^0$) · B($A^0 \to \mu^+\mu^-$) $< 1.0\times10^{-10}$ at 90% CL for $m_{A^0} =$ 214.3 MeV.

[13] The search was motivated by PARK 05.

[14] DEL-AMO-SANCHEZ 11J search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with $A^0$ decaying to invisible final states. They give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to$ invisible) in the range $(1.9$–$4.5)\times10^{-6}$ (90% CL) for $0 \le m_{A^0} \le$ 8.0 GeV, and $(2.7$–$37)\times10^{-6}$ for $8.0 \le m_{A^0} \le 9.2$ GeV.

[15] LEES 11H search for the process $\Upsilon(2S,3S) \to A^0\gamma$ with $A^0$ decaying hadronically and give limits on B($\Upsilon(2S,3S) \to A^0\gamma$)·B($A^0 \to$ hadrons) in the range $1\times10^{-6}$–$8\times10^{-5}$ (90% CL) for $0.3 < m_{A^0} < 7$ GeV. The decay rates for $\Upsilon(2S)$ and $\Upsilon(3S)$ are assumed to be equal up to the phase space factor. See their Fig. 5.

[16] ANDREAS 10 analyze constraints from rare decays and other processes on a light $A^0$ with $m_{A^0} < 2m_\mu$ and give limits on its coupling to fermions at the level of $10^{-4}$ times the Standard Model value.

[17] HYUN 10 search for the decay chain $B^0 \to K^{*0}A^0$, $A^0 \to \mu^+\mu^-$ and give a limit on B($B^0 \to K^{*0}A^0$) · B($A^0 \to \mu^+\mu^-$) in the range $(2.26$–$5.53)\times10^{-8}$ at 90%CL for $m_{A^0} =$ 212–300 MeV. The limit for $m_{A^0} = 214.3$ MeV is $2.26\times10^{-8}$.

[18] HYUN 10 search for the decay chain $B^0 \to \rho^0A^0$, $A^0 \to \mu^+\mu^-$ and give a limit on B($B^0 \to \rho^0A^0$) · B($A^0 \to \mu^+\mu^-$) in the range $(1.73$–$4.51)\times10^{-8}$ at 90%CL for $m_{A^0} =$ 212–300 MeV. The limit for $m_{A^0} = 214.3$ MeV is $1.73\times10^{-8}$.

[19] AUBERT 09P search for the process $\Upsilon(3S) \to A^0\gamma$ with $A^0 \to \tau^+\tau^-$ for $4.03 < m_{A^0} < 9.52$ and $9.61 < m_{A^0} < 10.10$ GeV, and give limits on B($\Upsilon(3S) \to A^0\gamma$)·B($A^0 \to \tau^+\tau^-$) in the range $(1.5$–$16)\times10^{-5}$ (90% CL).

[20] AUBERT 09Z search for the process $\Upsilon(2S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ for $0.212 < m_{A^0} < 9.3$ GeV and give limits on B($\Upsilon(2S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3$–$8)\times10^{-6}$ (90% CL).

[21] AUBERT 09Z search for the process $\Upsilon(3S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ for $0.212 < m_{A^0} < 9.3$ GeV and give limits on B($\Upsilon(3S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3$–$5)\times10^{-6}$ (90% CL).

[22] TUNG 09 search for the decay chain $K_L \to \pi^0\pi^0A^0$, $A^0 \to \gamma\gamma$ and give a limit on B($K_L \to \pi^0\pi^0A^0$) · B($A^0 \to \gamma\gamma$) in the range $(2.4$–$10.7)\times10^{-7}$ at 90%CL for $m_{A^0} =$ 194.3–219.3 MeV. The limit for $m_{A^0} = 214.3$ MeV is $2.4\times10^{-7}$.

[23] LOVE 08 search for the process $\Upsilon(1S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ (for $m_{A^0} < 2m_\tau$) and $A^0 \to \tau^+\tau^-$. Limits on B($\Upsilon(1S) \to A^0\gamma$) · B($A^0 \to \ell^+\ell^-$) in the range $10^{-6}$–$10^{-4}$ (90% CL) are given.

[24] BESSON 07 give a limit B($\Upsilon(1S) \to \eta_b\gamma$) · B($\eta_b \to \tau^+\tau^-$) $< 0.27\%$ (95% CL), which constrains a possible $A^0$ exchange contribution to the $\eta_b$ decay.

[25] PARK 05 found three candidate events for $\Sigma^+ \to p\mu^+\mu^-$ in the HyperCP experiment. Due to a narrow spread in dimuon mass, they hypothesize the events as a possible signal of a new boson. It can be interpreted as a neutral particle with $m_{A^0} = 214.3 \pm 0.5$ MeV and the branching fraction B($\Sigma^+ \to pA^0$)·B($A^0 \to \mu^+\mu^-$) $= (3.1^{+2.4}_{-1.9} \pm 1.5)\times10^{-8}$.

[26] BALEST 95 give limits B($\Upsilon(1S) \to A^0\gamma$) ¡ $1.5\times10^{-5}$ at 90% CL for $m_{A^0} < 5$ GeV. The limit becomes $< 10^{-4}$ for $m_{A^0} < 7.7$ GeV.

[27] ANTREASYAN 90C give limits B($\Upsilon(1S) \to A^0\gamma$) ¡ $5.6\times10^{-5}$ at 90% CL for $m_{A^0} <$ 7.2 GeV. $A^0$ is assumed not to decay in the detector.

## Other Mass Limits

We use a symbol $H_1^0$ if mass $< 125$ GeV or $H_2^0$ if mass $> 125$ GeV. The notation $H^0$ is reserved for the 125 GeV particle.

[1] AAD 20C combine searches for a scalar resonance decaying to $H^0H^0$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV from AABOUD 19A, AABOUD 19O, AABOUD 18CQ, AABOUD 19T, AABOUD 18CW, and AABOUD 18BU. See their Fig. 5(a) for limits on cross section times branching ratio for $m_{H^0_2}$ = 0.26–3 TeV.

[2] SIRUNYAN 20 search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ or $\tau^+\tau^-\mu^+\mu^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 10 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range $m_{A^0}$ = 4–15 GeV.

[3] AABOUD 19A search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}b\overline{b}$ in 27.5–36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 9(a) for limits on cross section times branching ratios for $m_{H^0_2}$ = 0.26–3 TeV.

[4] AABOUD 19AG search for the decay $H^0 \to A^0A^0 \to \mu^+\mu^-b\overline{b}$ in 36.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 6 (a) for limits on the product of production cross section (normalized to the SM) and branching ratios in the range $m_{A^0}$ = 20–60 GeV.

[5] AABOUD 19O search for a scalar resonance decaying to $H^0H^0 \to b\overline{b}WW^*$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 12 (left) for limits on cross section times branching ratio for $m_{H^0_2}$ = 0.5–3 TeV.

[6] AABOUD 19T search for a scalar resonance decaying to $H^0H^0 \to WW^*WW^*$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^0_2}$ = 260–500 GeV, assuming SM decay rates for the $H^0$.

[7] AABOUD 19V combine published ATLAS data to constrain two-Higgs-doublet plus singlet pseudoscalar model with $A^0_1$ decaying to invisible final states. See their Fig. 19 for excluded parameter regions.

[8] AABOUD 19Y search for a narrow scalar resonance produced by gluon fusion or $b$ associated production, decaying to $\mu^+\mu^-$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Figs. 4 and 5(a) for cross section limits for $m_{H^0_2}$ = 0.2–1.0 TeV.

[9] AALTONEN 19 search for $b$ associated production of a scalar particle decaying to $b\overline{b}$ in 5.4 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^0_{1,2}}$ = 100–300 GeV.

[10] SIRUNYAN 19 search for a narrow scalar resonance decaying to $H^0H^0 \to \gamma\gamma b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 9 (left) for limits on cross section times branching ratios for $m_{H^0_2}$ = 260–900 GeV.

[11] SIRUNYAN 19AE search for a scalar resonance produced in association with a $b\overline{b}$ pair, decaying to $\tau^+\tau^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 4 for cross section limits for $m_{A^0}$ = 25–70 GeV.

[12] SIRUNYAN 19AN search for production of $A^0_2$ decaying to $H^0A^0_1$ followed by $H^0 \to b\overline{b}$, $A^0_1 \to$ invisible in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV, in the mass range $m_{A^0_2}$ = 0.2–1.6 TeV, $m_{A^0_1}$ = 0.15–0.5 TeV. See their Fig. 6 for limits in terms of two-Higgs-doublet plus singlet pseudoscalar model.

[13] SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or $b$-associated production, decaying to $ZH^0 \to \ell^+\ell^-b\overline{b}$ ($\ell$ = $e$, $\mu$) or $\nu\overline{\nu}b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 5 for cross section limits for $m_{A^0}$ = 0.22–1.0 TeV.

[14] SIRUNYAN 19B search for gluon fusion production of narrow scalar resonance with large transverse momentum, decaying to $b\overline{b}$, in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Figs. 7 and 8 for limits on cross section times branching ratio for the resonance mass of 50–350 GeV.

[15] SIRUNYAN 19BB search for the decay $H^0_1 \to \gamma\gamma$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV and 35.9 fb$^{-1}$ at $E_{cm}$ = 13 TeV. See their Figs. 4–6 for limits on cross section times branching ratio for $m_{H^0_1}$ = 80–110 GeV (some results in Fig. 5 for $m_{H^0_1}$ = 70–110 GeV).

[16] SIRUNYAN 19BD search for the decay $H^0 \to A^0A^0 \to \mu^+\mu^-b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 5 for limits on the product of cross section times branching ratios in the range $m_{A^0}$ = 20–62.5 GeV. See also their Figs. 6 and 7 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[17] SIRUNYAN 19BE combine searches for $H^0_2 \to H^0H^0$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV in various $H^0$ decay modes, from SIRUNYAN 18A, SIRUNYAN 18AF, SIRUNYAN 18CW, SIRUNYAN 19, and SIRUNYAN 19H. See their Fig. 3 for limits on cross section times branching ratios for $m_{H^0_2}$ = 0.25–3 TeV.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[18] SIRUNYAN 19BQ search for production of $H^0_{1,2}$ decaying to $A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H^0_{1,2}}$ = 90–150 GeV, $m_{A^0}$ = 0.25–3.55 GeV.

[19] SIRUNYAN 19CR search for production of $H^0_2/A^0$ in gluon fusion and in association with a $b\overline{b}$ pair, decaying to $\mu^+\mu^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 6 for limits on cross section times branching ratio.

[20] SIRUNYAN 19H search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV, where one $b\overline{b}$ pair is resolved and the other not. Limits on cross section times branching ratios for $m_{H^0_2}$ = 0.75–1.6 TeV are obtained and combined with data from SIRUNYAN 18AF. See their Fig. 5 (right).

[21] AABOUD 18AA search for production of a scalar resonance decaying to $Z\gamma$, with $Z$ decaying hadronically, in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 8(a) for limits on cross section times branching ratio for $m_{H^0_2}$ = 1.0–6.8 TeV.

[22] AABOUD 18AG search for the decay $H^0 \to A^0A^0 \to \gamma\gamma gg$ in 36.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 2 and Table 6 for cross section limits in the range $m_{A^0}$ = 20–60 GeV.

[23] AABOUD 18AH search for production of an $A^0$ in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH^0_2 \to \ell^+\ell^-b\overline{b}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 5 for cross section limits for $m_{A^0}$ = 230–800 GeV and $m_{H^0_2}$ = 130–700 GeV.

[24] AABOUD 18AI search for production of an $A^0$ in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH^0$ in the final states $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-b\overline{b}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 6 for cross section limits for $m_{A^0}$ = 0.2–2 TeV. See also AABOUD 18CC.

[25] AABOUD 18BF search for production of a heavy $H^0_2$ state decaying to $ZZ$ in the final states $\ell^+\ell^-\ell^+\ell^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 6 for upper limits on cross section times branching ratio for $m_{H^0_2}$ = 0.2–1.2 TeV assuming ggF or VBF with the NWA. See their Fig. 7 for upper limits on cross section times branching ratio for $m_{H^0_2}$ = 0.4–1.0 TeV assuming ggF, and with several assumptions on its width.

[26] AABOUD 18BU search for a narrow scalar resonance decaying to $H^0H^0 \to \gamma\gamma WW^*$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 4 for limits on cross section times branching ratios for $m_{H^0_2}$ = 260–500 GeV.

[27] AABOUD 18BX search for associated production of $WH^0$ or $ZH^0$ followed by the decay $H^0 \to A^0A^0 \to b\overline{b}b\overline{b}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 9 for limits on cross section times branching ratios for $m_{A^0}$ = 20–60 GeV. See also their Fig. 10 for the dependence of the limit on $A^0$ lifetime.

[28] AABOUD 18CQ search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 2 (above) for limits on cross section times branching ratios for $m_{H^0_2}$ = 260–1000 GeV.

[29] AABOUD 18F search for production of a narrow scalar resonance decaying to $W^+W^-$ and $ZZ$, followed by hadronic decays of $W$ and $Z$, in 36.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 5(c) for limits on cross section times branching ratio for $m_{H^0_2}$ = 1.2–3.0 TeV.

[30] AAIJ 18AM search for gluon-fusion production of $H^0_{1,2}$ decaying to $\mu\tau$ in 2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H^0_{1,2}}$ = 45–195 GeV.

[31] AAIJ 18AQ search for gluon-fusion production of a scalar particle $A^0$ decaying to $\mu^+\mu^-$ in 1.99 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV and 0.98 fb$^{-1}$ at $E_{cm}$ = 7 TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{A^0}$ = 5.5–15 GeV (using the $E_{cm}$ = 8 TeV data set).

[32] AAIJ 18AQ search for the decay $H^0 \to A^0A^0$, with one of the $A^0$ decaying to $\mu^+\mu^-$, in 1.99 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV and 0.98 fb$^{-1}$ at $E_{cm}$ = 7 TeV. See their Fig. 5 (right) for limits on the product of branching ratios for $m_{A^0}$ = 5.5–15 GeV (using the $E_{cm}$ = 8 TeV data set).

[33] SIRUNYAN 18AF search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV, where both $b\overline{b}$ pairs are not resolved. See their Fig. 9 for limits on cross section times branching ratios for $m_{H^0_2}$ = 0.75–3 TeV.

[34] SIRUNYAN 18BA search for production of a heavy $H^0_2$ state decaying to $ZZ$ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-q\overline{q}$, and $\ell^+\ell^-\nu\overline{\nu}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Figs. 10 and 11 for upper limits on cross section times branching ratio for $m_{H^0_2}$ = 0.13–3 TeV with several assumptions on its width and on the fraction of Vector-Boson-Fusion of the total production cross section.

[35] SIRUNYAN 18CW search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV, where both $b\overline{b}$ pairs are resolved. See their Fig. 9 for limits on cross section times branching ratios for $m_{H^0_2}$ = 260–1200 GeV.

[36] SIRUNYAN 18DK search for production of a scalar resonance decaying to $Z\gamma$, with $Z$ decaying to $\ell^+\ell^-$ or hadronically, in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^0_2}$ = 0.35–4 TeV for different assumptions on the width of the resonance.

[37] SIRUNYAN 18DT search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 7 for limits on the product of branching ratios in the range $m_{A^0}$ = 15–60 GeV. See also their Fig. 8 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[38] SIRUNYAN 18DU search for production of a narrow scalar resonance decaying to $\gamma\gamma$ in 35.9 fb$^{-1}$ (taken in 2016) of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 3 (right) for limits on cross section times branching ratio for $m_{H^0_2}$ = 0.5–5 TeV for several values of its width-to-mass ratio.

[39] SIRUNYAN 18ED search for production of an $A^0$ in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH^0$ in the final states $\nu\overline{\nu}b\overline{b}$ or $\ell^+\ell^-b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 8 for cross section limits for $m_{A^0}$ = 0.8–2 TeV.

[40] SIRUNYAN 18EE search for the decay $H^0 \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 4 for limits on the product of branching ratios in the range $m_{A^0}$ = 15–62.5 GeV, normalized to the SM production cross section. See also their Fig. 5 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[41] SIRUNYAN 18F search for a narrow scalar resonance decaying to $H^0H^0 \to WWb\overline{b}$ or $ZZb\overline{b}$ in the final state $\ell\ell\nu\nu b\overline{b}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 7 for limits on cross section times branching ratios for $m_{H^0_2}$ = 250–900 GeV.

[42] AABOUD 17 search for production of a scalar resonance decaying to $Z\gamma$ in 3.2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 4 for the limits on cross section times branching ratio for $m_{H^0_2}$ = 0.25–3.0 TeV.

[43] AABOUD 17AW search for production of a scalar resonance decaying to $Z\gamma$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^0_2}$ = 0.25–2.4 TeV.

[44] KHACHATRYAN 17AZ search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$, $\mu^+\mu^-b\overline{b}$, and $\mu^+\mu^-\tau^+\tau^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Figs. 4, 5, and 6 for cross section limits in the range $m_{A^0}$ = 5–62.5 GeV. See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[45] KHACHATRYAN 17D search for production of a scalar resonance decaying to $Z\gamma$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV and 2.7 fb$^{-1}$ at $E_{cm}$ = 13 TeV. See their Figs. 3 and 4 for the limits on cross section times branching ratio for $m_{H^0_2}$ = 0.2–2.0 TeV.

[46] KHACHATRYAN 17R search for production of a narrow scalar resonance decaying to $\gamma\gamma$ in 12.9 fb$^{-1}$ (taken in 2016) of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H^0_2}$ = 0.5–4.5 TeV for several values of its width-to-mass ratio. Limits from combination with KHACHATRYAN 16M are shown in their Figs. 4 and 6.

[47] SIRUNYAN 17CN search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ in 18.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 5 (above) and Table II for limits on the cross section times branching ratios for $m_{H^0_2}$ = 0.3–1 TeV, and Fig. 6 (above) and Table III for the corresponding limits by combining with data from KHACHATRYAN 16BQ and KHACHATRYAN 15R.

[48] SIRUNYAN 17Y search for production of a scalar resonance decaying to $Z\gamma$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV and 2.7 fb$^{-1}$ at $E_{cm}$ = 13 TeV. See their Figs. 3, 4 and Table 3 for limits on cross section times branching ratio for $m_{H^0_2}$ = 0.7–3.0 TeV, and Fig. 5 for the corresponding limits for $m_{H^0_2}$ = 0.2–3.0 TeV from combination with KHACHATRYAN 17D data.

[49] AABOUD 16AB search for associated production of $WH^0$ with the decay $H^0 \to A^0A^0 \to b\overline{b}b\overline{b}$ in 3.2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 8 for limits on cross section times branching ratios for $m_{A^0}$ = 20–60 GeV.

[50] AABOUD 16AE search for production of a narrow scalar resonance decaying to $W^+W^-$ and $ZZ$ in 3.2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H^0_2}$ = 0.5–3 TeV.

[51] AABOUD 16H search for production of a scalar resonance decaying to $\gamma\gamma$ in 3.2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 12 for limits on cross section times branching ratio for $m_{H^0_2}$ = 0.2–2 TeV with different assumptions on the width.

[52] AABOUD 16I search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}b\overline{b}$ in 3.2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 10(c) for limits on cross section times branching ratios for $m_{H^0_2}$ = 0.5–3 TeV.

[53] AAD 16AX search for production of a heavy $H^0$ state decaying to $ZZ$ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-\nu\overline{\nu}$, $\ell^+\ell^-q\overline{q}$, and $\nu\overline{\nu}q\overline{q}$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig.12 for upper limits on $\sigma(H^0)$ B($H^0 \to ZZ$) for $m_{H^0}$ ranging from 140 GeV to 1000 GeV.

[54] AAD 16C search for production of a heavy $H^0$ state decaying to $W^+W^-$ in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Figs. 12, 13, and 16 for upper limits on $\sigma(H^0)$ B($H^0 \to W^+W^-$) for $m_{H^0}$ ranging from 300 GeV to 1000 or 1500 GeV with various assumptions on the total width of $H^0$.

[55] AAD 16L search for the decay $H^0 \to A^0A^0 \to \gamma\gamma\gamma\gamma$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 4 (upper right) for limits on cross section times branching ratios (normalized to the SM $H^0$ cross section) for $m_{A^0}$ = 10–60 GeV.

[56] AAD 16L search for the decay $H^0_2 \to A^0A^0 \to \gamma\gamma\gamma\gamma$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 4 (lower right) for limits on cross section times branching ratios for $m_{H^0_2}$ = 600 GeV and $m_{A^0}$ = 10–245 GeV, and Table 5 for limits for $m_{H^0_2}$= 300 and 900 GeV.

[57] AALTONEN 16C search for electroweak associated production of $H^0_1H^\pm$ followed by the decays $H^\pm \to H^0_1W^*$, $H^0_1 \to \gamma\gamma$ for $m_{H^0_1}$ = 10–105 GeV and $m_{H^\pm}$ = 30–300 GeV. See their Fig. 3 for excluded parameter region in a two-doublet model in which $H^0_1$ has no direct decay to fermions.

[58] KHACHATRYAN 16BG search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}b\overline{b}$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 6 for limits on the cross section times branching ratios for $m_{H^0_2}$ = 1.15–3 TeV.

[59] KHACHATRYAN 16BQ search for a resonance decaying to $H^0H^0 \to \gamma\gamma b\overline{b}$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 9 for limits on the cross section times branching ratios for $m_{H^0_2}$ = 0.26–1.1 TeV.

[60] KHACHATRYAN 16F search for the decay $H^0 \to H^0_1H^0_1 \to \tau^+\tau^-\tau^+\tau^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 8 for cross section limits for $m_{H^0_1}$ = 4–8 GeV.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[61] KHACHATRYAN 16M search for production of a narrow resonance decaying to $\gamma\gamma$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV and 3.3 fb$^{-1}$ at $E_{cm}$ = 13 TeV. See their Fig. 3 (top) for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–4 TeV.

[62] KHACHATRYAN 16P search for gluon fusion production of an $H_2^0$ decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 8 (lower right) for cross section limits for $m_{H_2^0}$ = 260–350 GeV.

[63] KHACHATRYAN 16P search for gluon fusion production of an $A^0$ decaying to $ZH^0 \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 10 for cross section limits for $m_{H_2^0}$ = 220–350 GeV.

[64] AAD 15BK search for production of a heavy $H_2^0$ decaying to $H^0H^0$ in the final state $b\overline{b}b\overline{b}$ in 19.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 14(c) for $\sigma(H_2^0)$ B($H_2^0 \to H^0H^0$) for $m_{H_2^0}$ = 500–1500 GeV with $\Gamma_{H_2^0}$ = 1 GeV.

[65] AAD 15BZ search for the decay $H^0 \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ ($m_{H^0}$ = 125 GeV) in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 6 for limits on cross section times branching ratio for $m_{A^0}$ = 3.7–50 GeV.

[66] AAD 15BZ search for a state $H_2^0$ via the decay $H_2^0 \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 6 for limits on cross section times branching ratio for $m_{H_2^0}$ = 100–500 GeV and $m_{A^0}$ = 5 GeV.

[67] AAD 15CE search for production of a heavy $H_2^0$ decaying to $H^0H^0$ in the final states $b\overline{b}\tau^+\tau^-$ and $\gamma\gamma WW^*$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV and combine with data from AAD 15H and AAD 15BK. A limit $\sigma(H_2^0)$ B($H_2^0 \to H^0H^0$) < 2.1–0.011 pb (95% CL) is given for $m_{H_2^0}$ = 260–1000 GeV. See their Fig. 6.

[68] AAD 15H search for production of a heavy $H_2^0$ decaying to $H^0H^0$ in the finalstate $\gamma\gamma b\overline{b}$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV.A limit of $\sigma(H_2^0)$ B($H_2^0 \to H^0H^0$) < 3.5–0.7 pb is given for $m_{H_2^0}$ = 260–500 GeV at 95% CL. See their Fig. 3.

[69] AAD 15S search for production of $A^0$ decaying to $ZH^0 \to \ell^+\ell^-b\overline{b}$, $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-\tau^+\tau^-$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 3 for cross section limits for $m_{A^0}$ = 200–1000 GeV.

[70] KHACHATRYAN 15AW search for production of a heavy state $H_2^0$ of an electroweak singlet extension of the Standard Model via the decays of $H_2^0$ to $W^+W^-$ and $ZZ$ in up to 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and up to 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV in the range $m_{H_2^0}$ = 145–1000 GeV. See their Figs. 8 and 9 for limits in the parameter space of the model.

[71] KHACHATRYAN 15BB search for production of a resonance $H^0$ decaying to $\gamma\gamma$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^0}$ = 150–850 GeV.

[72] KHACHATRYAN 15N search for production of $A^0$ decaying to $ZH^0 \to \ell^+\ell^-b\overline{b}$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 3 for limits on cross section times branching ratios for $m_{A^0}$ = 225–600 GeV.

[73] KHACHATRYAN 15O search for production of a high-mass narrow resonance $A^0$ decaying to $ZH^0 \to q\overline{q}\tau^+\tau^-$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 6 for limits on cross section times branching ratios for $m_{A^0}$ = 800–2500 GeV.

[74] KHACHATRYAN 15R search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}b\overline{b}$ in 17.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 5 (top) for limits on cross section times branching ratios for $m_{H_2^0}$ = 0.27–1.1 TeV.

[75] AAD 14AP search for a second $H^0$ state decaying to $\gamma\gamma$ in addition to the state at about 125 GeV in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H^0}$ = 65–600 GeV.

[76] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to H^0W^\pm W^\mp$, $H^0$ decaying to $b\overline{b}$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Table III for limits on cross section times branching ratio for $m_{H_2^0}$= 325–1025 GeV and $m_{H^+}$= 225–925 GeV.

[77] CHATRCHYAN 14G search for a second $H^0$ state decaying to $WW^{(*)}$ in addition to the observed signal at about 125 GeV using 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.4 fb$^{-1}$ at $E_{cm}$ = 8 TeV. See their Fig. 21 (right) for cross section limits in the mass range 110–600 GeV.

[78] KHACHATRYAN 14P search for a second $H^0$ state decaying to $\gamma\gamma$ in addition to the observed signal at about 125 GeV using 5.1 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV and 19.7 fb$^{-1}$ at $E_{cm}$ = 8 TeV. See their Figs. 27 and 28 for cross section limits in the mass range 110–150 GeV.

[79] AALTONEN 13P search for production of a heavy Higgs boson $H'^0$ that decays into a charged Higgs boson $H^\pm$ and a lighter Higgs boson $H^0$ via the decay chain $H'^0 \to H^\pm W^\mp$, $H^\pm \to W^\pm H^0$, $H^0 \to b\overline{b}$ in the final state $\ell\nu$ plus 4 jets in 8.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. See their Fig. 4 for limits on cross section times branching ratio in the $m_{H^\pm}$–$m_{H^0}$ plane for $m_{H^0}$ = 126 GeV.

[80] CHATRCHYAN 13BJ search for $H^0$ production in the decay chain $H^0 \to A^0A^0$, $A^0 \to \mu^+\mu^-$ in 5.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV. See their Fig. 2 for limits on cross section times branching ratio.

[81] AALTONEN 11P search in 2.7 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with $m_{A^0}$ between 4 and 9 GeV. See their Fig. 4 for limits on B($t \to bH^+$) for 90 < $m_{H^+}$ < 160 GeV.

[82] ABBIENDI 10 search for $e^+e^- \to ZH^0$ with the decay chain $H^0 \to \widetilde{\chi}_1^0\widetilde{\chi}_2^0$, $\widetilde{\chi}_2^0 \to \widetilde{\chi}_1^0 + (\gamma$ or $Z^*)$, when $\widetilde{\chi}_1^0$ and $\widetilde{\chi}_2^0$ are nearly degenerate. For a mass difference of 2 (4) GeV, a lower limit on $m_{H^0}$ of 108.4 (107.0) GeV (95% CL) is obtained for SM $ZH^0$ cross section and B($H^0 \to \widetilde{\chi}_1^0\widetilde{\chi}_2^0$) = 1.

[83] SCHAEL 10 search for the process $e^+e^- \to H^0Z$ followed by the decay chain $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ with $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$ at $E_{cm}$ = 183–209 GeV. For a $H^0ZZ$ coupling equal to the SM value, B($H^0 \to A^0A^0$) = B($A^0 \to \tau^+\tau^-$) = 1, and $m_{A^0}$ = 4–10 GeV, $m_{H^0}$ up to 107 GeV is excluded at 95% CL.

[84] ABAZOV 09V search for $H^0$ production followed by the decay chain $H^0 \to A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ or $\mu^+\mu^-\tau^+\tau^-$ in 4.2 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. See their Fig. 3 for limits on $\sigma(H^0)$·B($H^0 \to A^0A^0$) for $m_{A^0}$ = 3.6–19 GeV.

[85] ABBIENDI 05A search for $e^+e^- \to H_1^0A^0$ in general Type-II two-doublet models, with decays $H_1^0$, $A^0 \to q\overline{q}$, $gg$, $\tau^+\tau^-$, and $H_1^0 \to A^0A^0$.

[86] ABBIENDI 04K search for $e^+e^- \to H^0Z$ with $H^0$ decaying to two jets of any flavor including $gg$. The limit is for SM production cross section with B($H^0 \to jj$) = 1.

[87] ABDALLAH 04 consider the full combined LEP and LEP2 datasets to set limits on the Higgs coupling to $W$ or $Z$ bosons, assuming SM decays of the Higgs. Results in Fig. 26.

[88] ACHARD 04B search for $e^+e^- \to H^0Z$ with $H^0$ decaying to $b\overline{b}$, $c\overline{c}$, or $gg$. The limit is for SM production cross section with B($H^0 \to jj$) = 1.

[89] ACHARD 04F search for $H^0$ with anomalous coupling to gauge boson pairs in the processes $e^+e^- \to H^0\gamma$, $e^+e^-H^0$, $H^0Z$ with decays $H^0 \to f\overline{f}$, $\gamma\gamma$, $Z\gamma$, and $W^*W$ at $E_{cm}$ = 189–209 GeV. See paper for limits.

[90] ABBIENDI 03F search for $H^0 \to$ anything in $e^+e^- \to H^0Z$, using the recoil mass spectrum of $Z \to e^+e^-$ or $\mu^+\mu^-$. In addition, it searched for $Z \to \nu\overline{\nu}$ and $H^0 \to e^+e^-$ or photons. Scenarios with large width or continuum $H^0$ mass distribution are considered. See their Figs. 11–14 for the results.

[91] ABBIENDI 03G search for $e^+e^- \to H_1^0Z$ followed by $H_1^0 \to A^0A^0$, $A^0 \to c\overline{c}$, $gg$, or $\tau^+\tau^-$ in the region $m_{H_1^0}$ = 45-86 GeV and $m_{A^0}$ = 2-11 GeV. See their Fig. 7 for the limits.

[92] Search for associated production of a $\gamma\gamma$ resonance with a $Z$ boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq$ 209 GeV. The limit is for a $H^0$ with SM production cross section and B($H^0 \to f\overline{f}$)=0 for all fermions $f$.

[93] For B($H^0 \to \gamma\gamma$)=1, $m_{H^0}$ > 113.1 GeV is obtained.

[94] HEISTER 02M search for $e^+e^- \to H^0Z$, assuming that $H^0$ decays to $q\overline{q}$, $gg$, or $\tau^+\tau^-$ only. The limit assumes SM production cross section.

[95] ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{cm} \leq$ 189 GeV. In addition to usual final states, the decays $H_1^0$, $A^0 \to q\overline{q}$, $gg$ are searched for. See their Figs. 15,16 for excluded regions.

[96] ACCIARRI 00R search for $e^+e^- \to H^0\gamma$ with $H^0 \to b\overline{b}$, $Z\gamma$, or $\gamma\gamma$. See their Fig. 3 for limits on $\sigma$·B. Explicit limits within an effective interaction framework are also given, for which the Standard Model Higgs search results are used in addition.

[97] ACCIARRI 00R search for the two-photon type processes $e^+e^- \to e^+e^-H^0$ with $H^0 \to b\overline{b}$ or $\gamma\gamma$. See their Fig. 4 for limits on $\Gamma(H^0 \to \gamma\gamma)$·B($H^0 \to \gamma\gamma$or $b\overline{b}$) for $m_{H^0}$=70–170 GeV.

[98] GONZALEZ-GARCIA 98B use DØ limit for $\gamma\gamma$ events with missing $E_T$ in $p\overline{p}$ collisions (ABBOTT 98) to constrain possible $ZH$ or $WH$ production followed by unconventional $H \to \gamma\gamma$ decay which is induced by higher-dimensional operators. See their Figs. 1 and 2 for limits on the anomalous couplings.

[99] KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no $H_1^0ZZ$ coupling and obtain $m_{H_1^0} \gtrsim$ 5 GeV or $m_{A^0} \gtrsim$ 5 GeV for tan$\beta$ > 50. Other Higgs bosons are assumed to be much heavier.

[100] ALEXANDER 96H give B($Z \to H^0\gamma$)×B($H^0 \to q\overline{q}$) < 1–4 × $10^{-5}$ (95%CL) and B($Z \to H^0\gamma$)×B($H^0 \to b\overline{b}$) < 0.7–2 × $10^{-5}$ (95%CL) in the range 20 < $m_{H^0}$ <80 GeV.

## SEARCHES FOR A HIGGS BOSON WITH STANDARD MODEL COUPLINGS

These listings are based on experimental searches for a scalar boson whose couplings to $W$, $Z$ and fermions are precisely those of the Higgs boson predicted by the three-generation Standard Model with the minimal Higgs sector.

For a review and a bibliography, see the review on "Status of Higgs Boson Physics."

### Indirect Mass Limits for $H^0$ from Electroweak Analysis

The mass limits shown below apply to a Higgs boson $H^0$ with Standard Model couplings whose mass is a priori unknown.

For limits obtained before the direct measurement of the top quark mass, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review. Other studies based on data available prior to 1996 can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

# Gauge & Higgs Boson Particle Listings

## Neutral Higgs Bosons, Searches for

[1] HALLER 18 make Standard Model fits to $Z$ and neutral current parameters, $m_t$, $m_W$, and $\Gamma_W$ measurements available in 2018. The direct mass measurement at the LHC is not used in the fit.

[2] BAAK 12 make Standard Model fits to $Z$ and neutral current parameters, $m_t$, $m_W$, and $\Gamma_W$ measurements available in 2010 (using also preliminary data). The quoted result is obtained from a fit that does not include the limit from the direct Higgs searches. The result including direct search data from LEP2, the Tevatron and the LHC is $120^{+12}_{-5}$ GeV.

[3] BAAK 12A make Standard Model fits to $Z$ and neutral current parameters, $m_t$, $m_W$, and $\Gamma_W$ measurements available in 2012 (using also preliminary data). The quoted result is obtained from a fit that does not include the measured mass value of the signal observed at the LHC and also no limits from direct Higgs searches.

[4] ERLER 10A makes Standard Model fits to $Z$ and neutral current parameters, $m_t$, $m_W$ measurements available in 2009 (using also preliminary data). The quoted result is obtained from a fit that does not include the limits from the direct Higgs searches. With direct search data from LEP2 and Tevatron added to the fit, the 90% CL (99% CL) interval is 115–148 (114–197) GeV.

[5] LEP-SLC 06 make Standard Model fits to $Z$ parameters from LEP/SLC and $m_t$, $m_W$, and $\Gamma_W$ measurements available in 2005 with $\Delta\alpha^{(5)}_{\rm had}(m_Z) = 0.02758 \pm 0.00035$. The 95% CL limit is 285 GeV.

# Charged Higgs Bosons ($H^\pm$ and $H^{\pm\pm}$), Searches for

**CONTENTS:**

$H^\pm$ (charged Higgs) mass limits for $m_{H^+} < m(top)$

$H^\pm$ (charged Higgs) mass limits for $m_{H^+} > m(top)$

$H^{\pm\pm}$ (doubly-charged Higgs boson) mass limits

– Limits for $H^{\pm\pm}$ with $T_3 = \pm 1$

– Limits for $H^{\pm\pm}$ with $T_3 = 0$

## $H^\pm$ (charged Higgs) mass limits for $m_{H^+} < m(top)$

Unless otherwise stated, LEP limits assume $B(H^+ \to \tau^+\nu)+B(H^+ \to c\overline{s})=1$, and hold for all values of $B(H^+ \to \tau^+\nu_\tau)$, and assume $H^+$ weak isospin of $T_3=+1/2$. In the following, $\tan\beta$ is the ratio of the two vacuum expectation values in two-doublet models (2HDM).

The limits are also applicable to point-like technipions. For a discussion of techniparticles, see the Review of Dynamical Electroweak Symmetry Breaking in this Review.

Limits obtained at the LHC are given in the $m_h^{mod-}$ benchmark scenario, see CARENA 13, and hold for all $\tan\beta$ values.

For limits obtained in hadronic collisions before the observation of the top quark, and based on the top mass values inconsistent with the current measurements, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review.

Searches in $e^+e^-$ collisions at and above the $Z$ pole have conclusively ruled out the existence of a charged Higgs in the region $m_{H^+} \lesssim 45$ GeV, and are meanwhile superseded by the searches in higher energy $e^+e^-$ collisions at LEP. Results that are by now obsolete are therefore not included in this compilation, and can be found in a previous Edition (The European Physical Journal **C15** 1 (2000)) of this Review.

In the following, and unless otherwise stated, results from the LEP experiments (ALEPH, DELPHI, L3, and OPAL) are assumed to derive from the study of the $e^+e^- \to H^+H^-$ process. Limits from $b \to s\gamma$ decays are usually stronger in generic 2HDM models than in Supersymmetric models.

[1] AAD 15AF search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ in 19.5 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. Upper limits on $B(t \to bH^+)$ $B(H^+ \to \tau\nu)$ between $2.3\times10^{-3}$ and $1.3\times10^{-2}$ (95% CL) are given for $m_{H^+} = 80$–160 GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM. The region $m_{H^+} < 140$ GeV is excluded for $\tan\beta > 1$ in the considered scenarios.

[2] KHACHATRYAN 15AX search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. Upper limits on $B(t \to bH^+)$ $B(H^+ \to \tau\nu)$ between $1.2\times10^{-2}$ and $1.5\times10^{-3}$ (95% CL) are given for $m_{H^+} = 80$–160 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM. The region $m_{H^+} < 155$ GeV is excluded for $\tan\beta > 1$ in the considered scenarios.

[3] LEP 13 give a limit that refers to the Type II scenario. The limit for $B(H^+ \to \tau\nu) = 1$ is 94 GeV (95% CL), and for $B(H^+ \to cs) = 1$ the region below 80.5 as well as the region 83–88 GeV is excluded (95% CL). LEP 13 also search for the decay mode $H^+ \to A^0W^*$ with $A^0 \to b\overline{b}$, which is not negligible in Type I models. The limit in Type I models is 72.5 GeV (95% CL) if $m_{A^0} > 12$ GeV.

[4] ABBIENDI 12 also search for the decay mode $H^+ \to A^0W^*$ with $A^0 \to b\overline{b}$.

[5] SIRUNYAN 19AH search for $H^+$ in the decay of a pair-produced $t$ quark, or in associated $tbH^+$ or nonresonant $b\overline{b}H^+W^-$ production, followed by $H^+ \to \tau^+\nu$, in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. Upper limits on cross section times branching ratio between 6 pb and 5 fb (95% CL) are given for $m_{H^+} = 80$–3000 GeV (including the non-resonant production near the top quark mass), see their Fig. 6 (left). See their Fig. 6 (right) for the excluded regions in the $m_h^{mod-}$ scenario of the MSSM.

[6] SIRUNYAN 19BP search for vector boson fusion production of $H^+$ decaying to $H^+ \to W^+Z \to \ell^+\nu\ell^+\ell^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^+} = 0.3$–2.0 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[7] SIRUNYAN 19CC search for $t \to bH^+$ from pair produced top quarks, with the decay chain $H^+ \to W^+A^0$, $A^0 \to \mu^+\mu^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 2 for limits on the product of branching ratios for $m_{A^0} = 15$–75 GeV.

[8] SIRUNYAN 19CQ search for vector boson fusion production of $H^+$ decaying to $H^+ \to W^+Z \to \ell^+\nu q\overline{q}$ or $q\overline{q}\ell^+\ell^-$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H^+} = 0.6$–2.0 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[9] AABOUD 18BW search for $\overline{t}bH^+$ associated production or the decay $t \to bH^+$, followed by $H^+ \to \tau^+\nu$, in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 8(a) for upper limits on cross section times branching ratio for $m_{H^+} = 90$–2000 GeV, and Fig. 8(b) for limits on $B(t \to bH^+)$ $B(H^+ \to \tau^+\nu)$ for $m_{H^+} = 90$–160 GeV. See also their Fig. 9 for the excluded region in the hMSSM parameter space.

[10] AABOUD 18CD search for $\overline{t}bH^+$ associated production followed by $H^+ \to t\overline{b}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for upper limits on cross section times branching ratio for $m_{H^+} = 0.2$–2 TeV. See also their Fig. 9 for the excluded region in the parameter space of the $m_h^{mod-}$ and hMSSM scenarios of the MSSM. The theory predictions overlaid to the experimental limits to determine the excluded $m_{H^+}$ range are shown without their respective uncertainty band.

[11] AABOUD 18CH search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to \ell^\pm\nu\ell^+\ell^-$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^\pm} = 0.2$–0.9 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[12] HALLER 18 give 95% CL lower limits on $m_{H^+}$ of 590 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for $B(b \to s\gamma)$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[13] SIRUNYAN 18DO search for $t\bar{t}$ production followed by $t \to bH^+$, $H^+ \to c\bar{b}$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 3 for upper limits on B($t \to bH^+$) for $m_{H^+}$ = 90–150 GeV assuming that B($H^+ \to c\bar{b}$) = 1 and B($t \to bH^+$) + B($t \to bW^+$) = 1.

[14] MISIAK 17 give 95% CL lower limits on $m_{H^+}$ between 570 and 800 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for B($b \to s(d)\gamma$).

[15] SIRUNYAN 17AE search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to \ell^\pm\nu\ell^+\ell^-$ in 15.2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^\pm}$ = 0.2–2.0 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[16] AABOUD 16A search for $t(b)\,H^\pm$ associated production followed by $H^+ \to \tau^+\nu$ in 3.2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 13 TeV. Upper limits on $\sigma(t(b)\,H^\pm)$ B($H^+ \to \tau\nu$) between 1.9 pb and 15 fb (95% CL) are given for $m_{H^+}$ = 200–2000 GeV, see their Fig. 6. See their Fig. 7 for the excluded regions in the hMSSM scenario.

[17] AAD 16AJ search for $t(b)\,H^\pm$ associated production followed by $H^\pm \to tb$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 6 for upper limits on $\sigma(t(b)\,H^\pm)$ B($H^+ \to tb$) for $m_{H^+}$ = 200–600 GeV.

[18] AAD 16AJ search for $H^\pm$ production from quark-antiquark annihilation, followed by $H^\pm \to tb$, in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 10 for upper limits on $\sigma(H^\pm)$ B($H^+ \to tb$) for $m_{H^+}$ = 400–3000 GeV.

[19] AAD 15AF search for $tH^\pm$ associated production followed by $H^\pm \to \tau^\pm\nu$ in 19.5 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. Upper limits on $\sigma(tH^\pm)$ B($H^+ \to \tau\nu$) between 760 and 4.5 fb (95% CL) are given for $m_{H^+}$ = 180–1000 GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM.

[20] AAD 15M search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to q\bar{q}\ell^+\ell^-$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H^\pm}$ = 200–1000 GeV, and Fig. 3 for limits on thetriplet vacuum expectation value fraction in the Georgi-Machacek model.

[21] KHACHATRYAN 15AX search for $tH^\pm$ associated production followed by $H^\pm \to tb$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. Upper limits on $\sigma(tH^\pm)$ B($H^+ \to t\bar{b}$) between 2.0 and 0.13 pb (95% CL) are given for $m_{H^+}$ = 180–600 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.

[22] KHACHATRYAN 15AX search for $tH^\pm$ associated production followed by $H^\pm \to \tau^\pm\nu$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. Upper limits on $\sigma(tH^\pm)$ B($H^+ \to \tau\nu$) between 380 and 25 fb (95% CL) are given for $m_{H^+}$ = 180–600 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.

[23] KHACHATRYAN 15BF search for $t\bar{t}$ production followed by $t \to bH^+$, $H^+ \to c\bar{s}$ in 19.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. Upper limits on B($t \to bH^+$) B($H^+ \to c\bar{s}$) between $1.2 \times 10^{-2}$ and $6.5 \times 10^{-2}$ (95% CL) are given for $m_{H^+}$ = 90–160 GeV.

[24] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to H^0 W^\pm W^\mp$, $H^0$ decaying to $b\bar{b}$ in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. See their Table III for limits on cross section times branching ratio for $m_{H_2^0}$= 325–1025 GeV and $m_{H^+}$= 225–925 GeV.

[25] AALTONEN 14A measure B($t \to b\tau\nu$) = 0.096 ± 0.028 using 9 fb$^{-1}$ of $p\bar{p}$ collisions at $E_{cm}$ = 1.96 TeV. For $m_{H^+}$= 80–140 GeV, this measured value is translated to a limit B($t \to bH^+$) < 0.059 at 95% CL assuming B($H^+ \to \tau^+\nu$) = 1.

[26] AAD 13AC search for $t\bar{t}$ production followed by $t \to bH^+$, $H^+ \to c\bar{s}$ (flavor unidentified) in 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV. Upper limits on B($t \to bH^+$) between 0.05 and 0.01 (95%CL) are given for $m_{H^+}$=90–150 GeV and B($H^+ \to c\bar{s}$)=1.

[27] AAD 13V search for $t\bar{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ through violation of lepton universality with 4.6 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV. Upper limits on B($t \to bH^+$) between 0.032 and 0.044 (95% CL) are given for $m_{H^+}$ = 90–140 GeV and B($H^+ \to \tau^+\nu$) = 1. By combining with AAD 12BH, the limits improve to 0.008 to 0.034 for $m_{H^+}$ = 90–160 GeV. See their Fig. 7 for the excluded region in the $m_h^{max}$ scenario of the MSSM.

[28] AAD 12BH search for $t\bar{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ with 4.6 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV. Upper limits on B($t \to bH^+$) between 0.01 and 0.05 (95% CL) are given for $m_{H^+}$ = 90–160 GeV and B($H^+ \to \tau^+\nu$) = 1. See their Fig. 8 for the excluded region in the $m_h^{max}$ scenario of the MSSM.

[29] CHATRCHYAN 12AA search for $t\bar{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ with 2 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV. Upper limits on B($t \to bH^+$) between 0.019 and 0.041 (95% CL) are given for $m_{H^+}$ = 80–160 GeV and B($H^+ \to \tau^+\nu$)=1.

[30] AALTONEN 11P search in 2.7 fb$^{-1}$ of $p\bar{p}$ collisions at $E_{cm}$ = 1.96 TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with $m_{A^0}$ between 4 and 9 GeV. See their Fig. 4 for limits on B($t \to bH^+$) for $90 < m_{H^+} < 160$ GeV.

[31] DESCHAMPS 10 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays, $b \to s\gamma$, $B$, $B_s$ mixings, and $Z \to b\bar{b}$. The limit holds irrespective of tan$\beta$.

[32] AALTONEN 09AJ search for $t \to bH^+$, $H^+ \to c\bar{s}$ in $t\bar{t}$ events in 2.2 fb$^{-1}$ of $p\bar{p}$ collisions at $E_{cm}$ = 1.96 TeV. Upper limits on B($t \to bH^+$) between 0.08 and 0.32 (95% CL) are given for $m_{H^+}$ = 60–150 GeV and B($H^+ \to c\bar{s}$) = 1.

[33] ABAZOV 09AC search for $t \to bH^+$, $H^+ \to \tau^+\nu$ in $t\bar{t}$ events in 0.9 fb$^{-1}$ of $p\bar{p}$ collisions at $E_{cm}$ = 1.96 TeV. Upper limits on B($t \to bH^+$) between 0.19 and 0.25 (95% CL) are given for $m_{H^+}$ = 80–155 GeV and B($H^+ \to \tau^+\nu$) = 1. See their Fig. 4 for an excluded region in a MSSM scenario.

[34] ABAZOV 09AG measure $t\bar{t}$ cross sections in final states with $\ell$ + jets ($\ell = e, \mu$), $\ell\ell$, and $\tau\ell$ in 1 fb$^{-1}$ of $p\bar{p}$ collisions at $E_{cm}$ = 1.96 TeV, which constrains possible $t \to bH^+$ branching fractions. Upper limits (95% CL) on B($t \to bH^+$) between 0.15 and 0.40 (0.48 and 0.57) are given for B($H^+ \to \tau^+\nu$) = 1 (B($H^+ \to c\bar{s}$) = 1) for $m_{H^+}$ = 80–155 GeV.

[35] ABAZOV 09AI search for $t \to bH^+$ in $t\bar{t}$ events in 1 fb$^{-1}$ of $p\bar{p}$ collisions at $E_{cm}$ = 1.96 TeV. Final states with $\ell$ + jets ($\ell = e, \mu$), $\ell\ell$, and $\tau\ell$ are examined. Upper limits on B($t \to bH^+$) (95% CL) between 0.15 and 0.19 (0.19 and 0.22) are given for B($H^+ \to \tau^+\nu$) = 1 (B($H^+ \to c\bar{s}$) = 1) for $m_{H^+}$ = 80–155 GeV. For B($H^+ \to \tau^+\nu$) = 1 also a simultaneous extraction of B($t \to bH^+$) and the $t\bar{t}$ cross section is performed, yielding a limit on B($t \to bH^+$) between 0.12 and 0.26 for $m_{H^+}$ = 80–155 GeV. See their Figs. 5–8 for excluded regions in several MSSM scenarios.

[36] ABAZOV 09P search for $H^+$ production by $q\bar{q}'$ annihilation followed by $H^+ \to t\bar{b}$ decay in 0.9 fb$^{-1}$ of $p\bar{p}$ collisions at $E_{cm}$ = 1.96 TeV. Cross section limits in several two-doublet models are given for $m_{H^+}$ = 180–300 GeV. A region with $20 \lesssim \tan\beta \lesssim 70$ is excluded (95% CL) for 180 GeV $\lesssim m_{H^+} \lesssim$ 184 GeV in type-I models.

[37] ABULENCIA 06E search for associated $H^0 W$ production in $p\bar{p}$ collisions at $E_{cm}$ = 1.96 TeV. A fit is made for $t\bar{t}$ production processes in dilepton, lepton + jets, and lepton + $\tau$ final states, with the decays $t \to W^+b$ and $t \to H^+b$ followed by $H^+ \to \tau^+\nu$, $c\bar{s}$, $t^*\bar{b}$, or $W^+H^0$. Within the MSSM the search is sensitive to the region tan$\beta$ < 1 or > 30 in the mass range $m_{H^+}$ = 80–160 GeV. See Fig. 2 for the excluded region in a certain MSSM scenario.

[38] ABDALLAH 04I search for $e^+e^- \to H^+H^-$ with $H^\pm$ decaying to $\tau\nu$, $cs$, or $W^*A^0$ in Type-I two-Higgs-doublet models.

[39] ABBIENDI 03 give a limit $m_{H^+} > 1.28\tan\beta$ GeV (95%CL) in Type II two-doublet models.

[40] ABAZOV 02B search for a charged Higgs boson in top decays with $H^+ \to \tau^+\nu$ at $E_{cm}$=1.8 TeV. For $m_{H^+}$=75 GeV, the region tan$\beta > 32.0$ is excluded at 95%CL. The excluded mass region extends to over 140 GeV for tan$\beta$ values above 100.

[41] BORZUMATI 02 point out that the decay modes such as $b\bar{b}\,W$, $A^0\,W$, and supersymmetric ones can have substantial branching fractions in the mass range explored at LEP II and Tevatron.

[42] ABBIENDI 01Q give a limit $\tan\beta/m_{H^+} < 0.53$ GeV$^{-1}$ (95%CL) in Type II two-doublet models.

[43] BARATE 01E give a limit $\tan\beta/m_{H^+} < 0.40$ GeV$^{-1}$ (90% CL) in Type II two-doublet models. An independent measurement of $B \to \tau\nu_\tau X$ gives $\tan\beta/m_{H^+} < 0.49$ GeV$^{-1}$ (90% CL).

[44] GAMBINO 01 use the world average data in the summer of 2001 B($b \to s\gamma$) = (3.23 ± 0.42) × $10^{-4}$. The limit applies for Type-II two-doublet models.

[45] AFFOLDER 00I search for a charged Higgs boson in top decays with $H^+ \to \tau^+\nu$ in $p\bar{p}$ collisions at $E_{cm}$=1.8 TeV. The excluded mass region extends to over 120 GeV for tan$\beta$ values above 100 and B($\tau\nu$) = 1. If B($t \to bH^+$) $\gtrsim$ 0.6, $m_{H^+}$ up to 160 GeV is excluded. Updates ABE 97L.

[46] ABBOTT 99E search for a charged Higgs boson in top decays in $p\bar{p}$ collisions at $E_{cm}$=1.8 TeV, by comparing the observed $t\bar{t}$ cross section (extracted from the data assuming the dominant decay $t \to bW^+$) with theoretical expectation. The search is sensitive to regions of the domains tan$\beta \lesssim 1$, $50 < m_{H^+}$(GeV) $\lesssim 120$ and tan$\beta \gtrsim 40$, $50 < m_{H^+}$(GeV) $\lesssim 160$. See Fig. 3 for the details of the excluded region.

[47] ACKERSTAFF 99D measure the Michel parameters $\rho$, $\xi$, $\eta$, and $\xi\delta$ in leptonic $\tau$ decays from $Z \to \tau\tau$. Assuming $e$-$\mu$ universality, the limit $m_{H^+} > 0.97\tan\beta$ GeV (95%CL) is obtained for two-doublet models in which only one doublet couples to leptons.

[48] ACCIARRI 97F give a limit $m_{H^+} > 2.6\tan\beta$ GeV (90% CL) from their limit on the exclusive $B \to \tau\nu_\tau$ branching ratio.

[49] AMMAR 97B measure the Michel parameter $\rho$ from $\tau \to e\nu\nu$ decays and assumes $e/\mu$ universality to extract the Michel $\eta$ parameter from $\tau \to \mu\nu\nu$ decays. The measurement is translated to a lower limit on $m_{H^+}$ in a two-doublet model $m_{H^+} > 0.97\tan\beta$ GeV (90% CL).

[50] COARASA 97 reanalyzed the constraint on the ($m_{H^\pm}$,tan$\beta$) plane derived from the inclusive $B \to \tau\nu_\tau X$ branching ratio in GROSSMAN 95B and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.

[51] GUCHAIT 97 studies the constraints on $m_{H^+}$ set by Tevatron data on $\ell\tau$ final states in $t\bar{t} \to (Wb)(Hb)$, $W \to \ell\nu$, $H \to \tau\nu_\tau$. See Fig. 2 for the excluded region.

[52] MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large $B_c \to \tau\nu_\tau$ background to $B_u \to \tau\nu_\tau$ decays. Stronger limits are obtained.

[53] STAHL 97 fit $\tau$ lifetime, leptonic branching ratios, and the Michel parameters and derive limit $m_{H^+} > 1.5\tan\beta$ GeV (90% CL) for a two-doublet model. See also STAHL 94.

[54] ALAM 95 measure the inclusive $b \to s\gamma$ branching ratio at $\Upsilon(4S)$ and give B($b \to s\gamma$)< $4.2 \times 10^{-4}$ (95% CL), which translates to the limit $m_{H^+} > [244 + 63/(\tan\beta)^{1.3}]$ GeV in the Type II two-doublet model. Light supersymmetric particles can invalidate this bound.

[55] BUSKULIC 95 give a limit $m_{H^+} > 1.9\tan\beta$ GeV (90% CL) for Type-II models from $b \to \tau\nu_\tau X$ branching ratio, as proposed in GROSSMAN 94.

## $H^\pm$ (charged Higgs) mass limits for $m_{H^+} > m(top)$

Limits obtained at the LHC are given in the $m_h^{mod-}$ benchmark scenario, see CARENA 13, and depend on the tan$\beta$ values.

## $H^{\pm\pm}$ (doubly-charged Higgs boson) mass limits

This section covers searches for a doubly-charged Higgs boson with couplings to lepton pairs. Its weak isospin $T_3$ is thus restricted to two possibilities depending on lepton chiralities: $T_3(H^{\pm\pm}) = \pm 1$, with the coupling $g_{\ell\ell}$ to $\ell_L^- \ell_L'^-$ and $\ell_R^+ \ell_R'^+$ ("left-handed") and $T_3(H^{\pm\pm}) = 0$, with the coupling to $\ell_R^- \ell_R'^-$ and $\ell_L^+ \ell_L'^+$ ("right-handed"). These Higgs bosons appear in some left-right symmetric models based on the gauge group $SU(2)_L \times SU(2)_R \times U(1)$, the type-II seesaw model, and the Zee-Babu model. The two cases are listed separately in the following. Unless noted, one of the lepton flavor combinations is assumed to be dominant in the decay.

### Limits for $H^{\pm\pm}$ with $T_3 = \pm 1$

[1] AABOUD 19K search for pair production of $H^{++} H^{--}$ followed by the decay $H^{\pm\pm} \to W^{\pm} W^{\pm}$ in 36.1 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. The search is interpreted in a doublet-triplet extension of the scalar sector with a vev of 0.1 GeV, leading to $B(H^{\pm\pm} \to W^{\pm} W^{\pm}) = 1$. See their Fig. 5 for limits on the cross section for $m_{H^{++}}$ between 200 and 700 GeV.

[2] See their Figs. 11(b) and 13 for limits with smaller branching ratios.

[3] AAD 15AG search for $H^{++} H^{--}$ production in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.

[4] AAD 15AP search for $H^{++} H^{--}$ production in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. The limit assumes 100% branching ratio to the specified final state.

[5] CHATRCHYAN 12AU search for $H^{++} H^{--}$ production with 4.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 6 for limits including associated $H^{++} H^{-}$ production or assuming different scenarios.

[6] ABDALLAH 03 search for $H^{++} H^{--}$ pair production either followed by $H^{++} \to \tau^+ \tau^+$, or decaying outside the detector.

[7] ABBIENDI 02C searches for pair production of $H^{++} H^{--}$, with $H^{\pm\pm} \to \ell^{\pm} \ell^{\pm}$ ($\ell$,$\ell'$ = $e$,$\mu$,$\tau$). The limit holds for $\ell$=$\ell'$=$\tau$, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$.

[8] SIRUNYAN 19CQ search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^{\pm} W^{\pm} \to qq\ell\nu$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 0.6 and 2 TeV.

[9] SIRUNYAN 18CC search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^{\pm} W^{\pm}$ in 35.9 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 200 and 1000 GeV.

[10] KANEMURA 15 examine the case where $H^{++}$ decays preferentially to $W^{(*)} W^{(*)}$ and estimate that a lower mass limit of $\sim$ 84 GeV can be derived from the same-sign dilepton data of AAD 15AG if $H^{++}$ decays with 100% branching ratio to $W^{(*)} W^{(*)}$.

[11] KHACHATRYAN 15D search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^{\pm} W^{\pm}$ in 19.4 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H^{++}}$ between 160 and 800 GeV.

[12] KANEMURA 14 examine the case where $H^{++}$ decays preferentially to $W^{(*)} W^{(*)}$ and estimate that a lower mass limit of $\sim$ 60 GeV can be derived from the same-sign dilepton data of AAD 12CY.

[13] AAD 13Y search for $H^{++} H^{--}$ production in a generic search of events with three charged leptons in 4.6 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state.

[14] AAD 12AY search for $H^{++} H^{--}$ production with 1.6 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state.

[15] AAD 12CQ search for $H^{++} H^{--}$ production with 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

[16] ABAZOV 12A search for $H^{++} H^{--}$ production in 7.0 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV.

[17] AALTONEN 11AF search for $H^{++} H^{--}$ production in 6.1 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV.

[18] AALTONEN 08AA search for $H^{++} H^{--}$ production in $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit assumes 100% branching ratio to the specified final state.

[19] ABAZOV 08V search for $H^{++} H^{--}$ production in $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit is for $B(H \to \mu\mu) = 1$. The limit is updated in ABAZOV 12A.

[20] AKTAS 06A search for single $H^{\pm\pm}$ production in $ep$ collisions at HERA. Assuming that $H^{++}$ only couples to $e^+ \mu^+$ with $g_{e\mu} = 0.3$ (electromagnetic strength), a limit $m_{H^{++}} > 141$ GeV (95% CL) is derived. For the case where $H^{++}$ couples to $e\tau$ only the limit is 112 GeV.

[21] ACOSTA 05L search for $H^{++} H^{--}$ pair production in $p\overline{p}$ collisions. The limit is valid for $g_{\ell\ell'} < 10^{-8}$ so that the Higgs decays outside the detector.

[22] ABAZOV 04E search for $H^{++} H^{--}$ pair production in $H^{\pm\pm} \to \mu^{\pm} \mu^{\pm}$. The limit is valid for $g_{\mu\mu} \gtrsim 10^{-7}$.

[23] ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+ e^- \to e^{\mp} e^{\mp} H^{\pm\pm}$, and via $t$-channel exchange in $e^+ e^- \to e^+ e^-$. In the direct case, and assuming $B(H^{\pm\pm} \to \ell^{\pm} \ell^{\pm}) = 1$, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} < 160$ GeV (see Fig. 6). In the second case, indirect limits on $h_{ee}$ are set for $m_{H^{\pm\pm}} < 2$ TeV (see Fig. 8).

[24] GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210$ GeV if the Yukawa couplings of $H^{++}$ to $ee$ and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

[25] ASAKA 95 point out that $H^{++}$ decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does not apply.

[26] ACTON 92M limit assumes $H^{\pm\pm} \to \ell^{\pm} \ell^{\pm}$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.

[27] ACTON 92M from $\Delta\Gamma_Z < 40$ MeV.

[28] SWARTZ 90 assume $H^{\pm\pm} \to \ell^{\pm} \ell^{\pm}$ (any flavor). The limits are valid for the Higgs-lepton coupling $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for $ee$ and $\mu\mu$ decay modes.

### Limits for $H^{\pm\pm}$ with $T_3 = 0$

[1] See their Figs. 12(b) and 14 for limits with smaller branching ratios.

[2] AAD 15AG search for $H^{++}H^{--}$ production in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.

[3] AAD 15AP search for $H^{++}H^{--}$ production in 20.3 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 8 TeV. The limit assumes 100% branching ratio to the specified final state.

[4] ABDALLAH 03 search for $H^{++}H^{--}$ pair production either followed by $H^{++} \to \tau^+\tau^+$, or decaying outside the detector.

[5] ACHARD 03F search for $e^+e^- \to H^{++}H^{--}$ with $H^{\pm\pm} \to \ell^\pm\ell'^\pm$. The limit holds for $\ell = \ell' = \tau$, and slightly different limits apply for other flavor combinations. The limit is valid for $g_{\ell\ell'} \gtrsim 10^{-7}$.

[6] ABBIENDI 02C searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm} \to \ell^\pm\ell^\pm$ ($\ell,\ell' = e,\mu,\tau$). the limit holds for $\ell=\ell'=\tau$, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$.

[7] AAD 12AY search for $H^{++}H^{--}$ production with 1.6 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV. The limit assumes 100% branching ratio to the specified final state.

[8] AAD 12CQ search for $H^{++}H^{--}$ production with 4.7 fb$^{-1}$ of $pp$ collisions at $E_{cm}$ = 7 TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

[9] ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV.

[10] AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb$^{-1}$ of $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV.

[11] ABAZOV 08V search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at $E_{cm}$= 1.96 TeV. The limit is for B($H \to \mu\mu$) = 1. The limit is updated in ABAZOV 12A.

[12] AKTAS 06A search for single $H^{\pm\pm}$ production in $ep$ collisions at HERA. Assuming that $H^{++}$ only couples to $e^+\mu^+$ with $g_{e\mu} = 0.3$ (electromagnetic strength), a limit $m_{H^{++}} > 141$ GeV (95% CL) is derived. For the case where $H^{++}$ couples to $e\tau$ only the limit is 112 GeV.

[13] ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\overline{p}$ collisions. The limit is valid for $g_{\ell\ell'} < 10^{-8}$ so that the Higgs decays outside the detector.

[14] ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm} \to \mu^\pm\mu^\pm$. The limit is valid for $g_{\mu\mu} \gtrsim 10^{-7}$.

[15] ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \to e^\mp e^\mp H^{\pm\pm}$, and via $t$-channel exchange in $e^+e^- \to e^+e^-$. In the direct case, and assuming B($H^{\pm\pm} \to \ell^\pm\ell^\pm$) = 1, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} < 160$ GeV (see Fig. 6). In the second case, indirect limits on $h_{ee}$ are set for $m_{H^{\pm\pm}} < 2$ TeV (see Fig. 8).

[16] GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210$ GeV if the Yukawa couplings of $H^{++}$ to $ee$ and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

[17] ACTON 92M limit assumes $H^{\pm\pm} \to \ell^\pm\ell^\pm$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.

[18] ACTON 92M from $\Delta\Gamma_Z$ <40 MeV.

[19] SWARTZ 90 assume $H^{\pm\pm} \to \ell^\pm\ell^\pm$ (any flavor). The limits are valid for the Higgs-lepton coupling g($H\ell\ell$) $\gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for $ee$ and $\mu\mu$ decay modes.

# New Heavy Bosons ($W'$, $Z'$, leptoquarks, etc.), Searches for

We list here various limits on charged and neutral heavy vector bosons (other than $W$'s and $Z$'s), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axigluons. The latest unpublished results are described in "$W'$ Searches" and "$Z'$ Searches" reviews. For recent searches on scalar bosons which could be identified as Higgs bosons, see the listings in the Higgs boson section.

**CONTENTS:**

Mass Limits for $W'$ (Heavy Charged Vector Boson Other Than $W$) in Hadron Collider Experiments
$W_R$ (Right-Handed $W$ Boson) Mass Limits
Limit on $W_L$-$W_R$ Mixing Angle $\zeta$
Mass Limits for $Z'$ (Heavy Neutral Vector Boson Other Than $Z$)
– Limits for $Z'_{SM}$
– Limits for $Z_{LR}$
– Limits for $Z_\chi$
– Limits for $Z_\psi$
– Limits for $Z_\eta$
– Limits for other $Z'$
– Searches for $Z'$ with Lepton-Flavor-Violating decays
Indirect Constraints on Kaluza-Klein Gauge Bosons
Mass Limits for Leptoquarks from Pair Production
Mass Limits for Leptoquarks from Single Production
Indirect Limits for Leptoquarks
Mass Limits for Diquarks
Mass Limits for $g_A$ (axigluon) and Other Color-Octet Gauge Bosons
Mass Limits for Color-Octet Scalar Bosons
$X^0$ (Heavy Boson) Searches in $Z$ Decays
Mass Limits for a Heavy Neutral Boson Coupling to $e^+e^-$
Search for $X^0$ Resonance in $e^+e^-$ Collisions
Search for $X^0$ Resonance in $ep$ Collisions

*$W'$-Boson Searches*

### MASS LIMITS for $W'$ (Heavy Charged Vector Boson Other Than $W$) in Hadron Collider Experiments

Couplings of $W'$ to quarks and leptons are taken to be identical with those of $W$. The following limits are obtained from $p\overline{p}$ or $pp \to W'X$ with $W'$ decaying to the mode indicated in the comments. New decay channels (*e.g.*, $W' \to WZ$) are assumed to

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

be suppressed. The most recent preliminary results can be found in the "$W'$-boson searches" review above.

[1] AABOUD 19B search for right-handed $W_R$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. $W_R$ is assumed to decay into $\ell$ and hypothetical heavy neutrino $N$, with $N$ decaying to $\ell jj$. See their Figs. 7 and 8 for excluded regions in $M_{W_R} - M_N$ plane.

[2] AABOUD 19E search for right-handed $W'$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limit on on $\sigma \cdot B$.

[3] AAD 19C search for $W'$ with SM-like couplings in $pp$ collisions at $\sqrt{s} = 13$ TeV. Bosonic decays and $W - W'$ interference are neglected. The limits on $e$ and $\mu$ separately are 6.0 and 5.1 TeV respectively. See their Fig. 2 for limits on $\sigma \cdot B$.

[4] AAD 19D search for resonances decaying to $WZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 3400$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 3800$ GeV and $M_{W'} > 3500$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 9 for limits on $\sigma \cdot B$.

[5] SIRUNYAN 19AY limits shown for $W'$ with SM-like coupling using $pp$ collisions at $\sqrt{s} = 13$ TeV. $W - W'$ interference and bosonic decays of $W'$ are not included. See their Fig. 5 for limits on $\sigma \cdot B$. Limits in the context of a nonuniversal gauge interaction are shown in Fig. 7. Model independent limits on $\sigma B A \epsilon$ can be seen in Fig. 8.

[6] SIRUNYAN 19CP present a statistical combinations of searches for $W'$ decaying to pairs of bosons or leptons in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$. If we assume $M_{W'} = M_{Z'}$, the limit becomes $M_{W'} > 4500$ GeV for $g_V = 3$ and $M_{W'} > 5000$ GeV for $g_V = 1$. See their Figs. 2 and 3 for limits on $\sigma \cdot B$.

[7] SIRUNYAN 19I search for resonances decaying to $HW$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 2800$ GeV if we assume $M_{W'} = M_{Z'}$.

[8] AABOUD 18AF give the limit above for right-handed $W'$ using $pp$ collisions at $\sqrt{s} = 13$ TeV. These limits also exclude $W$ bosons with left-handed couplings with masses below 2.9 TeV, at the 95% confidence level. $W' \to \ell\nu_R$ is assumed to be forbidden. See their Fig.5 for limits on $\sigma \cdot B$ for both cases of left- and right-handed $W'$.

[9] AABOUD 18AI search for resonances decaying to $HW$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 2670$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2930$ GeV and $M_{W'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 5 for limits on $\sigma \cdot B$.

[10] AABOUD 18AK search for resonances decaying to $WZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 2800$ GeV for $g_V = 1$.

[11] AABOUD 18AL search for resonances decaying to $WZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 2900$ GeV for $g_V = 1$.

[12] AABOUD 18BG limit is for $W'$ with SM-like couplings using $pp$ collisions at $\sqrt{s} = 13$ TeV. Bosonic decays of $W'$ and $W - W'$ interference are neglected. See Fig. 2 for limits on $\sigma \cdot B$.

[13] AABOUD 18CH search for resonances decaying to $WZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 2260$ GeV for $g_V = 1$.

[14] AABOUD 18F search for resonances decaying to $WZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 3000$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{W'} > 3500$ GeV and $M_{W'} > 3100$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.5 for limits on $\sigma \cdot B$.

[15] AABOUD 18K limit is for $W'$ with SM-like coupling using $pp$ collisions at $\sqrt{s} = 13$ TeV. $W - W'$ interference and bosonic decays of $W'$ are not included. See their Fig. 4 for limit on $\sigma \cdot B$.

[16] SIRUNYAN 18 limit is for right-handed $W'$ using $pp$ collisions at $\sqrt{s} = 13$ TeV. $W' \to \ell\nu_R$ decay is assumed to be forbidden. The limit becomes $M_{W'} > 3.4$ TeV if $M_{\nu_R} \ll M_{W'}$. See their Fig. 5 for exclusion limits on $W'$ models having both left- and right-handed couplings.

[17] SIRUNYAN 18AX search for resonances decaying to $WZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$. See their Fig.6 for limits on $\sigma \cdot B$.

[18] SIRUNYAN 18AZ limit is derived for $W'$ with SM-like coupling using $pp$ collisions at $\sqrt{s} = 13$ TeV. No interference with SM $W$ process is considered. The bosonic decays are assumed to be negligible. See their Fig.6 for limits on $\sigma \cdot B$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[19] SIRUNYAN 18BK search for resonances decaying to $WZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 3100$ GeV for $g_V = 1$.

[20] SIRUNYAN 18BO limit is for $W'$ with SM-like coupling using $pp$ collisions at $\sqrt{s} = 13$ TeV.

[21] SIRUNYAN 18CV search for right-handed $W_R$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. $W_R$ is assumed to decay into $\ell$ and hypothetical heavy neutrino $N$, with $N$ decaying to $\ell jj$. The quoted limit is for $M_N = M_{W_R}/2$. See their Fig. 6 for excluded regions in the $M_{W_R} - M_N$ plane.

[22] SIRUNYAN 18DJ search for resonances decaying to $WZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 2270$ GeV for $g_V = 1$.

[23] SIRUNYAN 18ED search for resonances decaying to $HW$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit above is for heavy-vector-triplet $W'$ with $g_V = 3$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2900$ GeV and $M_{W'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively.

[24] SIRUNYAN 18P give this limit for a heavy-vector-triplet $W'$ with $g_V = 3$. If they assume $M_{Z'} = M_{W'}$, the limit increases to $M_{W'} > 3800$ GeV.

[25] AABOUD 17AK search for a new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit above is for a $W'$ boson having axial-vector SM couplings and decaying to quarks with 75% branching fraction.

[26] AABOUD 17AO search for resonances decaying to $HW$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a $W'$ in the heavy-vector-triplet model with $g_V = 3$. See their Fig.4 for limits on $\sigma \cdot B$.

[27] AABOUD 17B search for resonances decaying to $HW$ ($H \to b\overline{b}$, $c\overline{c}$; $W \to \ell\nu$) in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 1750$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2310$ GeV and $M_{W'} > 1730$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.3 for limits on $\sigma \cdot B$.

[28] KHACHATRYAN 17J search for right-handed $W_R$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. $W_R$ is assumed to decay into $\tau$ and hypothetical heavy neutrino $N_\tau$, with $N_\tau$ decaying into $\tau jj$. The quoted limit is for $M_{N_\tau} = M_{W_R}/2$. The limit becomes $M_{W_R} > 2350$ GeV (1630 GeV) for $M_{W_R}/M_{N_\tau} = 0.8$ (0.2). See their Fig. 4 for excluded regions in the $M_{W_R} - M_{N_\tau}$ plane.

[29] KHACHATRYAN 17W search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV.

[30] KHACHATRYAN 17Z limit is for $W'$ with SM-like coupling using $pp$ collisions at $\sqrt{s} = 13$ TeV. The bosonic decays of $W'$ and the interference with SM $W$ process are neglected.

[31] SIRUNYAN 17A search for resonances decaying to $WZ$ with $WZ \to \ell\nu q\overline{q}$, $q\overline{q}q\overline{q}$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 2000$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{W'} > 2400$ GeV and $M_{W'} > 2300$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.6 for limits on $\sigma \cdot B$.

[32] SIRUNYAN 17AK search for resonances decaying to $WZ$ or $HW$ in $pp$ collisions at $\sqrt{s} = 8$ and 13 TeV. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$. The limit becomes $M_{W'} > 2300$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2400$ GeV for both $g_V = 3$ and $g_V = 1$. See their Fig.1 and 2 for limits on $\sigma \cdot B$.

[33] SIRUNYAN 17H search for right-handed $W'$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. $W'$ is assumed to decay into $\tau$ and a heavy neutrino $N$, with $N$ decaying to $\tau q\overline{q}$. The limit above assumes $M_N = M_{W'}/2$.

[34] SIRUNYAN 17I limit is for a right-handed $W'$ using $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit becomes $M_{W'} > 2400$ GeV for $M_{\nu_R} \ll M_{W'}$.

[35] SIRUNYAN 17R search for resonances decaying to $HW$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$. Mass regions $M_{W'} < 2370$ GeV and $2870 < M_{W'} < 2970$ GeV are excluded for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the excluded mass regions are $1000 < M_{W'} < 2500$ GeV and $2760 < M_{W'} < 3300$ GeV for $g_V = 3$; $1000 < M_{W'} < 2430$ GeV and $2810 < M_{W'} < 3130$ GeV for $g_V = 1$. See their Fig.5 for limits on $\sigma \cdot B$.

[36] AABOUD 16AE search for resonances decaying to $VV$ ($V = W$ or $Z$) in $pp$ collisions at $\sqrt{s} = 13$ TeV. Results from $\nu\nu qq$, $\nu\ell qq$, $\ell\ell qq$ and $qqqq$ final states are combined. The quoted limit is for a heavy-vector-triplet $W'$ with $g_V = 3$ and $M_{W'} = M_{Z'}$.

[37] AABOUD 16V limit is for $W'$ with SM-like coupling using $pp$ collisions at $\sqrt{s} = 13$ TeV. The bosonic decays of $W'$ and the interference with SM $W$ process are neglected.

[38] AAD 16R search for $W' \to WZ$ in $pp$ collisions at $\sqrt{s} = 8$ TeV. $\ell\nu\ell'\ell'$, $\ell\ell q\overline{q}$, $\ell\nu q\overline{q}$, and all hadronic channels are combined. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[39] AAD 16S search for a new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a $W'$ having SM-like couplings to quarks.

[40] KHACHATRYAN 16AO limit is for a SM-like right-handed $W'$ using $pp$ collisions at $\sqrt{s} = 8$ TeV. The quoted limit combines $t \to qqb$ and $t \to \ell\nu b$ events.

[41] KHACHATRYAN 16AP search for a resonance decaying to $HW$ in $pp$ collisions at $\sqrt{s} = 8$ TeV. Both $H$ and $W$ are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet $W'$ with $g_V = 3$.

[42] KHACHATRYAN 16BD search for resonance decaying to $HW$ in $pp$ collisions at $\sqrt{s} = 8$ TeV. The quoted limit is for heavy-vector-triplet (HVT) $W'$ with $g_V = 3$. The HVT model $m_{W'} = m_{Z'} > 1.8$ TeV is also obtained by combining $W'/Z' \to WH/ZH \to \ell\nu bb$, $qq\tau\tau$, $qqbb$, and $qqqqqq$ channels.

[43] KHACHATRYAN 16K search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV.

[44] KHACHATRYAN 16L search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 8$ TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.

[45] KHACHATRYAN 16O limit is for $W'$ having universal couplings. Interferences with the SM amplitudes are assumed to be absent.

[46] AAD 15AU search for $W'$ decaying into the $WZ$ final state with $W \to q\overline{q}'$, $Z \to \ell^+\ell^-$ using $pp$ collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[47] AAD 15AV limit is for a SM like right-handed $W'$ using $pp$ collisions at $\sqrt{s} = 8$ TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[48] AAD 15AZ search for $W'$ decaying into the $WZ$ final state with $W \to \ell\nu$, $Z \to q\overline{q}$ using $pp$ collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[49] AAD 15CP search for $W'$ decaying into the $WZ$ final state with $W \to q\overline{q}$, $Z \to q\overline{q}$ using $pp$ collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[50] AAD 15R limit is for a SM like right-handed $W'$ using $pp$ collisions at $\sqrt{s} = 8$ TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[51] AAD 15V search for new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 8$ TeV.

[52] KHACHATRYAN 15C search for $W'$ decaying via $WZ$ to fully leptonic final states using $pp$ collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = M_W M_Z/M^2_{W'}$.

[53] KHACHATRYAN 15T limit is for $W'$ with SM-like coupling which interferes the SM $W$ boson constructively using $pp$ collisions at $\sqrt{s} = 8$ TeV. For $W'$ without interference, the limit becomes $> 3280$ GeV.

[54] KHACHATRYAN 14O search for right-handed $W_R$ in $pp$ collisions at $\sqrt{s} = 8$ TeV. $W_R$ is assumed to decay into $\ell$ and hypothetical heavy neutrino $N$, with $N$ decaying into $\ell jj$. The quoted limit is for $M_{\nu_{eR}} = M_{\nu_{\mu R}} = M_{W_R}/2$. See their Fig. 3 and Fig. 5 for excluded regions in the $M_{W_R} - M_\nu$ plane.

[55] AABOUD 19BB search for right handed $W_R$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. $W_R$ is assumed to decay into $\ell$ and a boosted hypothetical heavy neutrino $N$, with $N$ decaying to $\ell$ and a large radius jet $j = q\overline{q}$. See their Fig. 7 for excluded regions in $M_{W_R} - M_N$ plane.

[56] SIRUNYAN 19V search for a new resonance decaying to a top quark and a heavy vector-like bottom partner $B$ decaying to $Hb$ (or a bottom quark and a heavy vector-like top partner $T$ decaying to $Ht$) in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on $\sigma \cdot B$.

[57] AABOUD 18AA search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 9 for the exclusion limit in $M_{W'} - \sigma B$ plane.

[58] AABOUD 18AD search for resonances decaying to $HX$ ($H \to b\overline{b}$, $X \to q\overline{q}'$) in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their Figs. 3–5 for limits on $\sigma \cdot B$.

[59] AABOUD 18CJ search for heavy-vector-triplet $W'$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for model with $g_V = 3$ assuming $M_{W'} = M_{Z'}$. The limit becomes $M_{W'} > 5500$ GeV for model with $g_V = 1$.

[60] KHACHATRYAN 17U search for resonances decaying to $HW$ ($H \to b\overline{b}$; $W \to \ell\nu$) in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit on the heavy-vector-triplet model is $M_{Z'} = M_{W'} > 2$ TeV for $g_V = 3$, in which constraints from the $Z' \to HZ$ ($H \to b\overline{b}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) are combined. See their Fig.3 and Fig.4 for limits on $\sigma \cdot B$.

[61] AAD 15BB search for $W'$ decaying into $WH$ with $W \to \ell\nu$, $H \to b\overline{b}$. See their Fig. 4 for the exclusion limits in the heavy vector triplet benchmark model parameter space.

[62] AALTONEN 15C limit is for a SM-like right-handed $W'$ assuming $W' \to \ell\nu$ decays are forbidden, using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. See their Fig. 3 for limit on $g_{W'}/g_W$.

[63] KHACHATRYAN 15V search new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 8$ TeV.

[64] AAD 14AT search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 3a for the exclusion limit in $m_{W'} - \sigma B$ plane.

[65] AAD 14S search for $W'$ decaying into the $WZ$ final state with $W \to \ell\nu$, $Z \to \ell\ell$ using $pp$ collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[66] KHACHATRYAN 14 search for $W'$ decaying into $WZ$ final state with $W \to q\overline{q}$, $Z \to q\overline{q}$ using $pp$ collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[67] KHACHATRYAN 14A search for $W'$ decaying into the $WZ$ final state with $W \to \ell\nu$, $Z \to q\overline{q}$, or $W \to q\overline{q}$, $Z \to \ell\ell$. $pp$ collisions data at $\sqrt{s}$=8 TeV are used for the search. See their Fig. 13 for the exclusion limit on the number of events in the mass−width plane.

[68] AAD 13AO search for $W'$ decaying into the $WZ$ final state with $W \to \ell\nu$, $Z \to 2j$ using $pp$ collisions at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[69] CHATRCHYAN 13AJ search for resonances decaying to $WZ$ pair, using the hadronic decay modes of $W$ and $Z$, in $pp$ collisions at $\sqrt{s}$=7 TeV. See their Fig. 7 for the limit on the cross section.

[70] CHATRCHYAN 13AQ limit is for $W'$ with SM-like coupling which interferes with the SM $W$ boson using $pp$ collisions at $\sqrt{s}$=7 TeV.

[71] CHATRCHYAN 13E limit is for $W'$ with SM-like coupling which intereferes with the SM $W$ boson using $pp$ collisions at $\sqrt{s}$=7 TeV. For $W'$ with right-handed coupling, the bound becomes >1850 GeV (>1910 GeV) if $W'$ decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings are present, the limit becomes >1640 GeV.

[72] CHATRCHYAN 13U search for $W'$ decaying to the $WZ$ final state, with $W$ decaying into jets, in $pp$ collisions at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[73] The AAD 12AV quoted limit is for a SM-like right-handed $W'$ using $pp$ collisions at $\sqrt{s}$=7 TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[74] AAD 12BB use $pp$ collisions data at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[75] AAD 12CK search for $pp \to tW'$, $W' \to \overline{t}q$ events in $pp$ collisions. See their Fig. 5 for the limit on $\sigma \cdot B$.

[76] AAD 12CR use $pp$ collisions at $\sqrt{s}$=7 TeV.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[77] AAD 12M search for right-handed $W_R$ in $pp$ collisions at $\sqrt{s} = 7$ TeV. $W_R$ is assumed to decay into $\ell$ and hypothetical heavy neutrino $N$, with $N$ decaying into $\ell jj$. See their Fig. 4 for the limit in the $m_N - m_{W'}$ plane.

[78] AALTONEN 12N search for $p\overline{p} \rightarrow t W'$, $W' \rightarrow \overline{t} d$ events in $p\overline{p}$ collisions. See their Fig. 3 for the limit on $\sigma \cdot B$.

[79] CHATRCHYAN 12AR search for $pp \rightarrow t W'$, $W' \rightarrow \overline{t} d$ events in $pp$ collisions. See their Fig. 2 for the limit on $\sigma \cdot B$.

[80] CHATRCHYAN 12BG search for right-handed $W_R$ in $pp$ collisions $\sqrt{s} = 7$ TeV. $W_R$ is assumed to decay into $\ell$ and hypothetical heavy neutrino $N$, with $N$ decaying into $\ell jj$. See their Fig. 3 for the limit in the $m_N - m_{W'}$ plane.

[81] ABAZOV 11H use data from $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. The quoted limit is obtained assuming $W'WZ$ coupling strength is the same as the ordinary $WWZ$ coupling strength in the Standard Model.

[82] ABAZOV 11L limit is for $W'$ with SM-like coupling which interferes with the SM $W$ boson, using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. For $W'$ with right-handed coupling, the bound becomes >885 GeV (>890 GeV) if $W'$ decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings present, the limit becomes >916 GeV.

[83] AALTONEN 10N use $p\overline{p}$ collision data at $\sqrt{s}$=1.96 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$. See their Fig. 4 for limits in mass-coupling plane.

[84] AALTONEN 09AC search for new particle decaying to dijets using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV.

[85] The ACOSTA 03B quoted limit is for $M_{W'} \gg M_{\nu_R}$, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV. For $M_{W'} < M_{\nu_R}$, $M_{W'}$ between 225 and 566 GeV is excluded.

[86] The quoted limit is obtained assuming $W'WZ$ coupling strength is the same as the ordinary $WWZ$ coupling strength in the Standard Model, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV. See their Fig. 2 for the limits on the production cross sections as a function of the $W'$ width.

[87] AFFOLDER 01I combine a new bound on $W' \rightarrow e\nu$ of 754 GeV, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV, with the bound of ABE 00 on $W' \rightarrow \mu\nu$ to obtain quoted bound.

[88] ABE 97G search for new particle decaying to dijets using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV.

[89] For bounds on $W_R$ with nonzero right-handed mass, see Fig. 5 from ABACHI 96C.

[90] ABACHI 95E assume that the decay $W' \rightarrow WZ$ is suppressed and that the neutrino from $W'$ decay is stable and has a mass significantly less $m_{W'}$.

[91] RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed $K$ factor.

## $W_R$ (Right-Handed $W$ Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89B, and COLANGELO 91. $g_R = g_L$ assumed. [Limits in the section MASS LIMITS for $W'$ below are also valid for $W_R$ if $m_{\nu_R} \ll m_{W_R}$.] Some limits assume manifest left-right symmetry, *i.e.*, the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 89B. Limits on the $W_L$-$W_R$ mixing angle $\zeta$ are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] The quoted limit is for manifest left-right symmetric model.

[2] CZAKON 99 perform a simultaneous fit to charged and neutral sectors.

[3] PRIEELS 14 limit is from $\mu^+ \rightarrow e^+\nu\overline{\nu}$ decay parameter $\xi''$, which is determined by the positron polarization measurement.

[4] WAUTERS 10 limit is from a measurement of the asymmetry parameter of polarized $^{60}$Co $\beta$ decays. The listed limit assumes no mixing.

[5] ZHANG 08 limit uses a lattice QCD calculation of the relevant hadronic matrix elements, while BEALL 82 limit used the vacuum saturation approximation.

[6] MELCONIAN 07 measure the neutrino angular asymmetry in $\beta^+$-decays of polarized $^{37}$K, stored in a magneto-optical trap. Result is consistent with SM prediction and does not constrain the $W_L - W_R$ mixing angle appreciably.

[7] SCHUMANN 07 limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the $\beta$ decay of polarized neutrons. Zero mixing is assumed.

[8] CYBURT 05 limit follows by requiring that three light $\nu_R$'s decouple when $T_{dec} > 140$ MeV. For different $T_{dec}$, the bound becomes $M_{W_R} > 3.3$ TeV $(T_{dec} / 140\ \text{MeV})^{3/4}$.

[9] THOMAS 01 limit is from measurement of $\beta^+$ polarization in decay of polarized $^{12}$N. The listed limit assumes no mixing.

[10] ACKERSTAFF 99D limit is from $\tau$ decay parameters. Limit increase to 145 GeV for zero mixing.

[11] BARENBOIM 98 assumes minimal left-right model with Higgs of $SU(2)_R$ in $SU(2)_L$ doublet. For Higgs in $SU(2)_L$ triplet, $m_{W_R}$ >1100 GeV. Bound calculated from effect of corresponding $Z_{LR}$ on electroweak data through $Z$–$Z_{LR}$ mixing.

[12] The quoted limit is from $\mu$ decay parameters. BARENBOIM 97 also evaluate limit from $K_L$-$K_S$ mass difference.

[13] STAHL 97 limit is from fit to $\tau$-decay parameters.

[14] ALLET 96 measured polarization-asymmetry correlation in $^{12}$N$\beta^+$ decay. The listed limit assumes zero $L$-$R$ mixing.

[15] KUZNETSOV 95 limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the $\beta$ decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94B.

[16] KUZNETSOV 94B limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the $\beta$ decay of polarized neutrons. Zero mixing assumed.

[17] BHATTACHARYYA 93 uses $Z$-$Z'$ mixing limit from LEP '90 data, assuming a specific Higgs sector of $SU(2)_L \times SU(2)_R \times U(1)$ gauge model. The limit is for $m_t$=200 GeV and slightly improves for smaller $m_t$.

[18] SEVERIJNS 93 measured polarization-asymmetry correlation in $^{107}$In$\beta^+$ decay. The listed limit assumes zero $L$-$R$ mixing. Value quoted here is from SEVERIJNS 94 erratum.

[19] IMAZATO 92 measure positron asymmetry in $K^+ \rightarrow \mu^+\nu_\mu$ decay and obtain $\xi P_\mu > 0.990$ (90% CL). If $W_R$ couples to $u\overline{s}$ with full weak strength ($V^R_{us}$=1), the result corresponds to $m_{W_R}$ >653 GeV. See their Fig. 4 for $m_{W_R}$ limits for general $|V^R_{us}|^2 = 1 - |V^R_{ud}|^2$.

[20] POLAK 92B limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming $\zeta$=0. Supersedes POLAK 91.

[21] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.

[22] COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.

[23] POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming $\zeta$=0. Superseded by POLAK 92B.

[24] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.

[25] LANGACKER 89B limit is for any $\nu_R$ mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.

[26] BALKE 88 limit is for $m_{\nu_{eR}} = 0$ and $m_{\nu_{\mu R}} \leq 50$ MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.

[27] JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point $e^+$ spectrum in the decay of the highly polarized $\mu^+$.

[28] STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay $e^+$ spectrum asymmetry above 46 MeV/$c$ using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.

[29] BERGSMA 83 set limit $m_{W_2}/m_{W_1}$ >1.9 at CL = 90%.

[30] CARR 83 is TRIUMF experiment with a highly polarized $\mu^+$ beam. Looked for deviation from $V-A$ at the high momentum end of the decay $e^+$ energy spectrum. Limit from previous world-average muon polarization parameter is $m_{W_R}$ >240 GeV. Assumes a light right-handed neutrino.

[31] BEALL 82 limit is obtained assuming that $W_R$ contribution to $K_L^0$–$K_S^0$ mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

## Limit on $W_L$-$W_R$ Mixing Angle $\zeta$

Lighter mass eigenstate $W_1 = W_L \cos\zeta - W_R \sin\zeta$. Light $\nu_R$ assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

# Gauge & Higgs Boson Particle Listings

## New Heavy Bosons

[1] ACKERSTAFF 99D limit is from $\tau$ decay parameters.
[2] CZAKON 99 perform a simultaneous fit to charged and neutral sectors.
[3] The quoted limit is from $\mu$ decay parameters. BARENBOIM 97 also evaluate limit from $K_L$-$K_S$ mass difference.
[4] MISHRA 92 limit is from the absence of extra large-$x$, large-$y$ $\overline{\nu}_\mu N \to \overline{\nu}_\mu X$ events at Tevatron, assuming left-handed $\nu$ and right-handed $\overline{\nu}$ in the neutrino beam. The result gives $\zeta^2(1-2m^2_{W_1}/m^2_{W_2}) < 0.0015$. The limit is independent of $\nu_R$ mass.
[5] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed.
[6] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.
[7] First JODIDIO 86 result assumes $m_{W_R}=\infty$, second is for unconstrained $m_{W_R}$.

### MASS LIMITS for $Z'$ (Heavy Neutral Vector Boson Other Than $Z$)

#### Limits for $Z'_{SM}$

$Z'_{SM}$ is assumed to have couplings with quarks and leptons which are identical to those of $Z$, and decays only to known fermions. The most recent preliminary results can be found in the "$Z'$-boson searches" review above.

[1] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[2] AABOUD 18AB search for resonances decaying to $b\overline{b}$ in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[3] AABOUD 18G search for resonances decaying to $\tau^+\tau^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[4] SIRUNYAN 18BB search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their Fig.5 for limits on the $Z'$ coupling strengths with light quarks.
[5] SIRUNYAN 18BO search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[6] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[7] KHACHATRYAN 17H search for resonances decaying to $\tau^+\tau^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[8] KHACHATRYAN 17T search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s} = 8, 13$ TeV.
[9] KHACHATRYAN 17W search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[10] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[11] KHACHATRYAN 15AE search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s} = 8$ TeV.
[12] KHACHATRYAN 15V search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 8$ TeV.
[13] AAD 14V search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s} = 8$ TeV.
[14] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the $Z$-$Z'$ mixing parameter $\xi$. See their Fig. 11 for limits in $M_{Z'} - \xi$ plane.
[15] AABOUD 16AA search for resonances decaying to $\tau^+\tau^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[16] AAD 15AM search for resonances decaying to $\tau^+\tau^-$ in $pp$ collisions at $\sqrt{s} = 8$ TeV.
[17] AAD 13S search for resonances decaying to $\tau^+\tau^-$ in $pp$ collisions at $\sqrt{s} = 7$ TeV.
[18] CHATRCHYAN 13A use $pp$ collisions at $\sqrt{s}$=7 TeV.
[19] CHATRCHYAN 13AF search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s} = 7$ TeV and 8 TeV.
[20] AAD 12CC search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s} = 7$ TeV.
[21] CHATRCHYAN 12O search for resonances decaying to $\tau^+\tau^-$ in $pp$ collisions at $\sqrt{s} = 7$ TeV.
[22] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
[23] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to $e^+e^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
[24] The quoted limit assumes $g_{WWZ'}/g_{WWZ} = (M_W/M_{Z'})^2$. See their Fig. 4 for limits in mass-coupling plane.
[25] AALTONEN 09AC search for new particle decaying to dijets.
[26] ERLER 09 give 95% CL limit on the $Z$-$Z'$ mixing $-0.0026 < \theta < 0.0006$.
[27] ABDALLAH 06C use data $\sqrt{s} = 130$–207 GeV.
[28] ACOSTA 05R search for resonances decaying to tau lepton pairs in $\overline{p}p$ collisions at $\sqrt{s} = 1.96$ TeV.
[29] ABBIENDI 04G give 95% CL limit on $Z$-$Z'$ mixing $-0.00422 < \theta < 0.00091$. $\sqrt{s} = 91$ to 207 GeV.
[30] ABAZOV 01B search for resonances in $p\overline{p} \to e^+e^-$ at $\sqrt{s}$=1.8 TeV. They find $\sigma \cdot B(Z' \to ee) < 0.06$ pb for $M_{Z'} > 500$ GeV.
[31] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.
[32] ABREU 00S uses LEP data at $\sqrt{s}$=90 to 189 GeV.
[33] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume $\theta$=0. Bounds in the mass-mixing plane are shown in their Figure 18.
[34] ERLER 99 give 90%CL limit on the $Z$-$Z'$ mixing $-0.0041 < \theta < 0.0003$. $\rho_0$=1 is assumed.
[35] ABE 97S find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.
[36] VILAIN 94B assume $m_t = 150$ GeV.
[37] ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes $B(Z' \to q\overline{q})$=0.7. See their Fig. 5 for limits in the $m_{Z'}$–$B(q\overline{q})$ plane.
[38] RIZZO 93 analyses CDF limit on possible two-jet resonances.
[39] ABE 90F use data for $R$, $R_{\ell\ell}$, and $A_{\ell\ell}$. They fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

#### Limits for $Z_{LR}$

$Z_{LR}$ is the extra neutral boson in left-right symmetric models. $g_L = g_R$ is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by specific left-right symmetric models (see the Note on the $W'$). Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. Direct search bounds assume decays to Standard Model fermions only, unless noted.

[1] DEL-AGUILA 10 give 95% CL limit on the $Z$-$Z'$ mixing $-0.0012 < \theta < 0.0004$.
[2] ABE 97S find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s} = 1.8$ TeV.
[3] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the $Z$-$Z'$ mixing parameter $\xi$. See their Fig. 10 for limits in $M_{Z'} - \xi$ plane.
[4] ERLER 09 give 95% CL limit on the $Z$-$Z'$ mixing $-0.0013 < \theta < 0.0006$.
[5] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0028$. See their Fig. 14 for limit contours in the mass-mixing plane.
[6] ABBIENDI 04G give 95% CL limit on $Z$-$Z'$ mixing $-0.00098 < \theta < 0.00190$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.
[7] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.
[8] ABREU 00S give 95% CL limit on $Z$-$Z'$ mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.
[9] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume $\theta$=0. Bounds in the mass-mixing plane are shown in their Figure 18.
[10] CHAY 00 also find $-0.0003 < \theta < 0.0019$. For $g_R$ free, $m_{Z'} > 430$ GeV.
[11] ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of $Q_W$(Cs) is due to the exchange of $Z'$. The data are better described in a certain class of the $Z'$ models including $Z_{LR}$ and $Z_\chi$.
[12] CASALBUONI 99 discuss the discrepancy between the observed and predicted values of $Q_W$(Cs). It is shown that the data are better described in a class of models including the $Z_{LR}$ model.
[13] CZAKON 99 perform a simultaneous fit to charged and neutral sectors. Assumes manifest left-right symmetric model. Finds $|\theta| < 0.0042$.
[14] ERLER 99 give 90% CL limit on the $Z$-$Z'$ mixing $-0.0009 < \theta < 0.0017$.
[15] ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in $E_6$.
[16] BARENBOIM 98 also gives 68% CL limits on the $Z$-$Z'$ mixing $-0.0005 < \theta < 0.0033$. Assumes Higgs sector of minimal left-right model.
[17] CONRAD 98 limit is from measurements at CCFR, assuming no $Z$-$Z'$ mixing.
[18] VILAIN 94B assume $m_t = 150$ GeV and $\theta$=0. See Fig. 2 for limit contours in the mass-mixing plane.
[19] RIZZO 93 analyses CDF limit on possible two-jet resonances.
[20] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. A specific Higgs sector is assumed. See also GRIFOLS 90D, RIZZO 91.
[21] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV. Bounds depend on assumed supernova core temperature.

## Limits for $Z_\chi$

$Z_\chi$ is the extra neutral boson in SO(10) $\to$ SU(5) $\times$ U(1)$_\chi$. $g_\chi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[2] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[3] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the $Z$-$Z'$ mixing parameter $\xi$. See their Fig. 9 for limits in $M_{Z'} - \xi$ plane.
[4] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV.
[5] AAD 14V search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s} = 8$ TeV.
[6] AAD 12CC search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s} = 7$ TeV.
[7] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
[8] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to $e^+e^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
[9] DEL-AGUILA 10 give 95% CL limit on the $Z$-$Z'$ mixing $-0.0011 < \theta < 0.0007$.
[10] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
[11] ERLER 09 give 95% CL limit on the $Z$-$Z'$ mixing $-0.0016 < \theta < 0.0006$.
[12] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0031$. See their Fig. 14 for limit contours in the mass-mixing plane.
[13] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
[14] ABBIENDI 04G give 95% CL limit on $Z$-$Z'$ mixing $-0.00099 < \theta < 0.00194$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.
[15] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino $\delta N_\nu$ <1. The quark-hadron transition temperature $T_c$=150 MeV is assumed. The limit with $T_c$=400 MeV is >4300 GeV.
[16] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.
[17] ABREU 00S give 95% CL limit on $Z$-$Z'$ mixing $|\theta| < 0.0017$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.
[18] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume $\theta$=0. Bounds in the mass-mixing plane are shown in their Figure 18.
[19] CHO 00 use various electroweak data to constrain $Z'$ models assuming $m_H$=100 GeV. See Fig. 3 for limits in the mass-mixing plane.
[20] ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of $Q_W$(Cs) is due to the exchange of $Z'$. The data are better described in a certain class of the $Z'$ models including $Z_{LR}$ and $Z_\chi$.
[21] ROSNER 00 discusses the possibility that a discrepancy between the observed and predicted values of $Q_W$(Cs) is due to the exchange of $Z'$. The data are better described in a certain class of the $Z'$ models including $Z_\chi$.
[22] ERLER 99 give 90% CL limit on the $Z$-$Z'$ mixing $-0.0020 < \theta < 0.0015$.
[23] ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in $E_6$.
[24] CONRAD 98 limit is from measurements at CCFR, assuming no $Z$-$Z'$ mixing.
[25] ABE 97S find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s} = 1.8$ TeV.
[26] $Z$-$Z'$ mixing is assumed to be zero. $\sqrt{s} = 57.77$ GeV.
[27] VILAIN 94B assume $m_t = 150$ GeV and $\theta$=0. See Fig. 2 for limit contours in the mass-mixing plane.
[28] FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos $\Delta N_\nu < 0.5$ and is valid for $m_{\nu_R} < 1$ MeV.
[29] ABE 90F use data for $R$, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.
[30] Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that $\nu_R$ is light ( $\lesssim 1$ MeV).
[31] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.

## Limits for $Z_\psi$

$Z_\psi$ is the extra neutral boson in $E_6 \to$ SO(10) $\times$ U(1)$_\psi$. $g_\psi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s}$ = 13 TeV.
[2] SIRUNYAN 18BB search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s}$ = 13 TeV.
[3] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s}$ = 13 TeV.
[4] KHACHATRYAN 17T search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s}$ = 8, 13 TeV.
[5] CHATRCHYAN 12O search for resonances decaying to $\tau^+\tau^-$ in $pp$ collisions at $\sqrt{s}$ = 7 TeV.
[6] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the $Z$-$Z'$ mixing parameter $\xi$. See their Fig. 10 for limits in $M_{Z'} - \xi$ plane.
[7] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s}$ = 13 TeV.
[8] KHACHATRYAN 15AE search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s}$ = 8 TeV.
[9] AAD 14V search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s}$ = 8 TeV.
[10] CHATRCHYAN 13AF search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s}$ = 7 TeV and 8 TeV.
[11] AAD 12CC search for resonances decaying to $e^+e^-$, $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s}$ = 7 TeV.
[12] CHATRCHYAN 12M search for resonances decaying to $e^+e^-$ or $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s}$ = 7 TeV.
[13] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.
[14] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to $e^+e^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.
[15] DEL-AGUILA 10 give 95% CL limit on the $Z$-$Z'$ mixing $-0.0019 < \theta < 0.0007$.
[16] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.
[17] ERLER 09 give 95% CL limit on the $Z$-$Z'$ mixing $-0.0018 < \theta < 0.0009$.
[18] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0027$. See their Fig. 14 for limit contours in the mass-mixing plane.
[19] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.
[20] ABBIENDI 04G give 95% CL limit on $Z$-$Z'$ mixing $-0.00129 < \theta < 0.00258$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s}$ = 91 to 207 GeV.
[21] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino $\delta N_\nu$ <1. The quark-hadron transition temperature $T_c$=150 MeV is assumed. The limit with $T_c$=400 MeV is >1100 GeV.
[22] ABREU 00S give 95% CL limit on $Z$-$Z'$ mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.
[23] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume $\theta$=0. Bounds in the mass-mixing plane are shown in their Figure 18.
[24] CHO 00 use various electroweak data to constrain $Z'$ models assuming $m_H$=100 GeV. See Fig. 3 for limits in the mass-mixing plane.
[25] ERLER 99 give 90% CL limit on the $Z$-$Z'$ mixing $-0.0013 < \theta < 0.0024$.
[26] CONRAD 98 limit is from measurements at CCFR, assuming no $Z$-$Z'$ mixing.
[27] ABE 97S find $\sigma(Z') \times B(e^+e^-,\mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.
[28] VILAIN 94B assume $m_t$ = 150 GeV and $\theta$=0. See Fig. 2 for limit contours in the mass-mixing plane.
[29] ABE 90F use data for $R$, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.
[30] Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that $\nu_R$ is light ($\lesssim$ 1 MeV).
[31] GRIFOLS 90D limit holds for $m_{\nu_R} \lesssim$ 1 MeV. See also RIZZO 91.

## Limits for $Z_\eta$

$Z_\eta$ is the extra neutral boson in $E_6$ models, corresponding to $Q_\eta = \sqrt{3/8}\ Q_\chi - \sqrt{5/8}\ Q_\psi$. $g_\eta = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] AABOUD 19AS search for a resonance decaying to $t\overline{t}$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a top-color $Z'$ with $\Gamma_{Z'}/M_{Z'} = 0.01$. Limits are also set on $Z'$ masses in simplified Dark Matter models.

[2] AAD 19D search for resonances decaying to $WW$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 3$. The limit becomes $M_{Z'} > 2900$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 3800$ GeV and $M_{Z'} > 3500$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 9 for limits on $\sigma \cdot B$.

[3] SIRUNYAN 19AA search for a resonance decaying to $t\overline{t}$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a leptophobic top-color $Z'$ with $\Gamma_{Z'}/M_{Z'} = 0.01$.

[4] SIRUNYAN 19CP present a statistical combinations of searches for $Z'$ decaying to pairs of bosons or leptons in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 3$. If we assume $M_{Z'} = M_{W'}$, the limit becomes $M_{Z'} > 4500$ GeV for $g_V = 3$ and $M_{Z'} > 5000$ GeV for $g_V = 1$. See their Figs. 2 and 3 for limits on $\sigma \cdot B$.

[5] SIRUNYAN 19I search for resonances decaying to $ZW$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 3$. The limit becomes $M_{Z'} > 2800$ GeV if we assume $M_{Z'} = M_{W'}$.

[6] AABOUD 18AB search for resonances decaying to $b\overline{b}$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic $Z'$ with SM-like couplings to quarks. See their Fig. 6 for limits on $\sigma \cdot$ B.

[7] AABOUD 18AI search for resonances decaying to $HZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 3$. The limit becomes $M_{Z'} > 2650$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{Z'} > 2930$ GeV and $M_{Z'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 5 for limits on $\sigma \cdot B$.

[8] AABOUD 18AK search for resonances decaying to $WW$ in $pp$ collisions at $\sqrt{s}$ =1 3 TeV. The limit quoted above is for heavy-vector-triplet $Z'$ with $g_V = 3$. The limit becomes $M_{Z'} > 2750$ GeV for $g_V = 1$.

[9] AABOUD 18B search for resonances decaying to $WW$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 1$. See their Fig.11 for limits on $\sigma \cdot B$.

[10] AABOUD 18BI search for a resonance decaying to $t\overline{t}$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a top-color assisted TC $Z'$ with $\Gamma_{Z'}/M_{Z'} = 0.01$. The limits for wider resonances are available. See their Fig. 14 for limits on $\sigma \cdot B$.

[11] AABOUD 18F search for resonances decaying to $WW$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 3500$ GeV and $M_{Z'} > 3100$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.5 for limits on $\sigma \cdot B$.

[12] SIRUNYAN 18ED search for resonances decaying to $HZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit above is for heavy-vector-triplet $Z'$ with $g_V = 3$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2900$ GeV and $M_{Z'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively.

[13] SIRUNYAN 18P give this limit for a heavy-vector-triplet $Z'$ with $g_V = 3$. If they assume $M_{Z'} = M_{W'}$, the limit increases to $M_{Z'} > 3800$ GeV.

[14] AABOUD 17AK search for a new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic $Z'$ boson having axial-vector coupling strength with quarks $g_q = 0.2$. The limit is 2100 GeV if $g_q = 0.1$.

[15] AABOUD 17AO search for resonances decaying to $HZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a $Z'$ in the heavy-vector-triplet model with $g_V = 3$. See their Fig.4 for limits on $\sigma \cdot B$.

[16] SIRUNYAN 17AK search for resonances decaying to $WW$ or $HZ$ in $pp$ collisions at $\sqrt{s}$ = 8 and 13 TeV. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for $g_V$ =1. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2400$ GeV for both $g_V = 3$ and $g_V = 1$. See their Fig.1 and 2 for limits on $\sigma \cdot B$.

[17] SIRUNYAN 17Q search for a resonance decaying to $t\overline{t}$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a resonance with relative width $\Gamma_{Z'}\ /\ M_{Z'} = 0.01$. Limits for wider resonances are available. See their Fig.6 for limits on $\sigma \cdot B$.

[18] SIRUNYAN 17R search for resonances decaying to $HZ$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 3$. Mass regions $M_{Z'} < 1150$ GeV and 1250 GeV $< M_{Z'} < 1670$ GeV are excluded for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the excluded mass regions are 1000 $< M_{Z'} <$ 2500 GeV and 2760 $< M_{Z'} <$ 3300 GeV for $g_V = 3$; 1000 $< M_{Z'} <$ 2430 GeV and 2810 $< M_{Z'} <$ 3130 GeV for $g_V = 1$. See their Fig.5 for limits on $\sigma \cdot B$.

[19] AABOUD 19AJ search in $pp$ collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\overline{q}$ and produced in association with a high $p_T$ photon. For a leptophobic axial-vector $Z'$ in the mass region 250 GeV $< M_{Z'} <$ 950 GeV, the $Z'$ coupling with quarks $g_q$ is constrained below 0.18. See their Fig.2 for limits in $M_{Z'} - g_q$ plane.

[20] AABOUD 19D search in $pp$ collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\overline{q}$ and produced in association with a high-$p_T$ photon or jet. For a leptophobic axial-vector $Z'$ in the mass region 100 GeV $< M_{Z'} <$ 220 GeV, the $Z'$ coupling with quarks $g_q$ is constrained below 0.23. See their Fig. 6 for limits in $M_{Z'} - g_q$ plane.

[21] AABOUD 19V search for Dark Matter simplified $Z'$ decaying invisibly or decaying to fermion pair in $pp$ collisions at $\sqrt{s} = 13$ TeV.

[22] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their Fig. 4 for limits in the heavy vector triplet model couplings.

[23] LONG 19 uses the weak charge data of Cesium and proton to constrain mass of $Z'$ in the 3-3-1 models.

[24] PANDEY 19 obtain limits on $Z'$ induced neutrino non-standard interaction (NSI) parameter $\epsilon$ from LHC and IceCube data. See their Fig.2 for limits in $M_{Z'} - \epsilon$ plane, where $\epsilon = g_q\ g_\nu\ v^2\ /\ (2\ M^2_{Z'})$.

[25] SIRUNYAN 19AL search for a new resonance decaying to a top quark and a heavy vector-like top partner in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on $Z'$ production cross section.

[26] SIRUNYAN 19AN search for a Dark Matter (DM) simplified model $Z'$ decaying to $H$ DM DM in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their Fig. 7 for limits on the signal strength modifiers.

[27] SIRUNYAN 19CB search in $pp$ collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\overline{q}$. For a leptophobic $Z'$ in the mass region 50–300 GeV, the $Z'$ coupling with quarks $g'_q$ is constrained below 0.2. See their Figs. 4 and 5 for limits on $g'_q$ in the mass range 50 $< M_{Z'} <$ 450 GeV.

[28] SIRUNYAN 19CD search in $pp$ collisions at $\sqrt{s}$=13 TeV for a leptophobic $Z'$ produced in association of high $p_T$ ISR photon and decaying to $q\overline{q}$. See their Fig. 2 for limits on the $Z'$ coupling strength $g'_q$ to $q\overline{q}$ in the mass range between 10 and 125 GeV.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[29] SIRUNYAN 19D search for a narrow neutral vector resonance decaying to $H\gamma$. See their Fig. 3 for exclusion limit in $M_{Z'} - \sigma\cdot B$ plane. Upper limits on the production of $H\gamma$ resonances are set as a function of the resonance mass in the range of 720–3250 GeV.

[30] AABOUD 18AA search for a narrow neutral vector boson decaying to $H\gamma$. See their Fig. 10 for the exclusion limit in $M_{Z'} - \sigma B$ plane.

[31] AABOUD 18CJ search for heavy-vector-triplet $Z'$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for model with $g_V = 3$ assuming $M_{Z'} = M_{W'}$. The limit becomes $M_{Z'} > 5500$ GeV for model with $g_V = 1$.

[32] AABOUD 18N search for a narrow resonance decaying to $q\overline{q}$ in $pp$ collisions at $\sqrt{s} = 13$ TeV using trigger level analysis to improve the low mass region sensitivity. See their Fig. 5 for limits in the mass-coupling plane in the $Z'$ mass range 450–1800 GeV.

[33] AAIJ 18AQ search for spin-0 and spin-1 resonances decaying to $\mu^+\mu^-$ in $pp$ collisions at $\sqrt{s} = 7$ and 8 TeV in the mass region near 10 GeV. See their Figs. 4 and 5 for limits on $\sigma\cdot B$.

[34] SIRUNYAN 18DR searches for $\mu^+\mu^-$ resonances produced in association with $b$-jets in the $pp$ collision data with $\sqrt{s} = 8$ TeV and 13 TeV. An excess of events near $m_{\mu\mu} = 28$ GeV is observed in the 8 TeV data. See their Fig. 3 for the measured fiducial signal cross sections at $\sqrt{s} = 8$ TeV and the 95% CL upper limits at $\sqrt{s} = 13$ TeV.

[35] SIRUNYAN 18G search for a new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV in the mass range 50–300 GeV. See their Fig.7 for limits in the mass-coupling plane.

[36] SIRUNYAN 18I search for a narrow resonance decaying to $b\overline{b}$ in $pp$ collisions at $\sqrt{s} = 8$ TeV using dedicated b-tagged dijet triggers to improve the sensitivity in the low mass region. See their Fig. 3 for limits on $\sigma\cdot B$ in the $Z'$ mass range 325–1200 GeV.

[37] AABOUD 17B search for resonances decaying to $HZ$ ($H \to b\overline{b}$, $c\overline{c}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 3$. The limit becomes $M_{Z'} > 1490$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2310$ GeV and $M_{Z'} > 1730$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.3 for limits on $\sigma\cdot B$.

[38] KHACHATRYAN 17AX search for lepto-phobic resonances decaying to four leptons in $pp$ collisions at $\sqrt{s} = 8$ TeV.

[39] KHACHATRYAN 17U search for resonances decaying to $HZ$ ($H \to b\overline{b}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit on the heavy-vector-triplet model is $M_{Z'} = M_{W'} > 2$ TeV for $g_V = 3$, in which constraints from the $W' \to HW$ ($H \to b\overline{b}$; $W \to \ell\nu$) are combined. See their Fig.3 and Fig.4 for limits on $\sigma\cdot B$.

[40] KHACHATRYAN 17A search for resonances decaying to $WW$ with $WW \to \ell\nu q\overline{q}$, $q\overline{q}q\overline{q}$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 3$. The limit becomes $M_{Z'} > 1600$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2400$ GeV and $M_{Z'} > 2300$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.6 for limits on $\sigma\cdot B$.

[41] SIRUNYAN 17AP search for resonances decaying into a SM-like Higgs scalar $H$ and a light pseudo scalar $A$. $A$ is assumed to decay invisibly. See their Fig.9 for limits on $\sigma\cdot B$.

[42] SIRUNYAN 17T search for a new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV in the mass range 100–300 GeV. See their Fig.3 for limits in the mass-coupling plane.

[43] SIRUNYAN 17V search for a new resonance decaying to a top quark and a heavy vector-like top partner $T$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their table 5 for limits on the $Z'$ production cross section for various values of $M_{Z'}$ and $M_T$ in the range of $M_{Z'} = 1500$–2500 GeV and $M_T = 700$–1500 GeV.

[44] AABOUD 16 search for a narrow resonance decaying into $b\overline{b}$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic $Z'$ with SM-like couplings to quarks. See their Fig.6 for limits on $\sigma\cdot B$.

[45] AAD 16L search for $Z' \to a\gamma$, $a \to \gamma\gamma$ in $pp$ collisions at $\sqrt{s} = 8$ TeV. See their Table 6 for limits on $\sigma\cdot B$.

[46] AAD 16S search for a new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic $Z'$ having coupling strength with quark $g_q = 0.3$ and is taken from their Figure 3.

[47] KHACHATRYAN 16AP search for a resonance decaying to $HZ$ in $pp$ collisions at $\sqrt{s} = 8$ TeV. Both $H$ and $Z$ are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet $Z'$ with $g_V = 3$.

[48] KHACHATRYAN 16E search for a leptophobic top-color $Z'$ decaying to $t\overline{t}$ using $pp$ collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes that $\Gamma_{Z'}/m_{Z'} = 0.012$. Also $m_{Z'} < 2.9$ TeV is excluded for wider topcolor $Z'$ with $\Gamma_{Z'}/m_{Z'} = 0.1$.

[49] AAD 15AO search for narrow resonance decaying to $t\overline{t}$ using $pp$ collisions at $\sqrt{s} = 8$ TeV. See Fig. 11 for limit on $\sigma B$.

[50] AAD 15AT search for monotop production plus large missing $E_T$ events in $pp$ collisions at $\sqrt{s} = 8$ TeV and give constraints on a $Z'$ model having $Z'u\overline{t}$ coupling. $Z'$ is assumed to decay invisibly. See their Fig. 6 for limits on $\sigma\cdot B$.

[51] AAD 15CD search for decays of Higgs bosons to 4 $\ell$ states via $Z'$ bosons, $H \to ZZ' \to 4\ell$ or $H \to Z'Z' \to 4\ell$. See Fig. 5 for the limit on the signal strength of the $H \to ZZ' \to 4\ell$ process and Fig. 16 for the limit on $H \to Z'Z' \to 4\ell$.

[52] KHACHATRYAN 15F search for monotop production plus large missing $E_T$ events in $pp$ collisions at $\sqrt{s} = 8$ TeV and give constraints on a $Z'$ model having $Z'u\overline{t}$ coupling. $Z'$ is assumed to decay invisibly. See Fig. 3 for limits on $\sigma B$.

[53] KHACHATRYAN 15O search for narrow $Z'$ resonance decaying to $ZH$ in $pp$ collisions at $\sqrt{s} = 8$ TeV. See their Fig. 6 for limit on $\sigma B$.

[54] AAD 14AT search for a narrow neutral vector boson decaying to $Z\gamma$. See their Fig. 3b for the exclusion limit in $m_{Z'} - \sigma B$ plane.

[55] KHACHATRYAN 14A search for new resonance in the $WW$ ($\ell\nu q\overline{q}$) and the $ZZ$ ($\ell\ell q\overline{q}$) channels using $pp$ collisions at $\sqrt{s}$=8 TeV. See their Fig.13 for the exclusion limit on the number of events in the mass-width plane.

[56] MARTINEZ 14 use various electroweak data to constrain the $Z'$ boson in the 3-3-1 models.

[57] AAD 13AQ search for a leptophobic top-color $Z'$ decaying to $t\overline{t}$. The quoted limit assumes that $\Gamma_{Z'}/m_{Z'} = 0.012$.

[58] CHATRCHYAN 13BM search for top-color $Z'$ decaying to $t\overline{t}$ using $pp$ collisions at $\sqrt{s}$=8 TeV. The quoted limit is for $\Gamma_{Z'}/m_{Z'} = 0.012$.

[59] CHATRCHYAN 13AP search for top-color leptophobic $Z'$ decaying to $t\overline{t}$ using $pp$ collisions at $\sqrt{s}$=7 TeV. The quoted limit is for $\Gamma_{Z'}/m_{Z'} = 0.012$.

[60] AAD 12BV search for narrow resonance decaying to $t\overline{t}$ using $pp$ collisions at $\sqrt{s}$=7 TeV. See their Fig. 7 for limit on $\sigma\cdot B$.

[61] AAD 12K search for narrow resonance decaying to $t\overline{t}$ using $pp$ collisions at $\sqrt{s}$=7 TeV. See their Fig. 5 for limit on $\sigma\cdot B$.

[62] AALTONEN 12AR search for chromophilic $Z'$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. See their Fig. 5 for limit on $\sigma\cdot B$.

[63] AALTONEN 12N search for $p\overline{p} \to tZ'$, $Z' \to \overline{t}u$ events in $p\overline{p}$ collisions. See their Fig. 3 for the limit on $\sigma\cdot B$.

[64] ABAZOV 12R search for top-color $Z'$ boson decaying exclusively to $t\overline{t}$. The quoted limit is for $\Gamma_{Z'}/m_{Z'}$= 0.012.

[65] CHATRCHYAN 12AI search for $pp \to tt$ events and give constraints on a $Z'$ model having $Z't\overline{t}$ coupling. See their Fig. 4 for the limit in mass-coupling plane.

[66] Search for resonance decaying to $t\overline{t}$. See their Fig. 6 for limit on $\sigma\cdot B$.

[67] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 4 for limit on $\sigma\cdot B$.

[68] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 3 for limit on $\sigma\cdot B$.

[69] CHATRCHYAN 11O search for same-sign top production in $pp$ collisions induced by a hypothetical FCNC $Z'$ at $\sqrt{s} = 7$ TeV. See their Fig. 3 for limit in mass-coupling plane.

[70] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 3 for limit on $\sigma\cdot B$.

[71] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 2 for limit on $\sigma\cdot B$.

[72] BARGER 03B use the nucleosynthesis bound on the effective number of light neutrino $\delta N_\nu$. See their Figs. 4–5 for limits in general $E_6$ motivated models.

[73] CHO 00 use various electroweak data to constrain $Z'$ models assuming $m_H$=100 GeV. See Fig. 2 for limits in general $E_6$-motivated models.

[74] CHO 98 study constraints on four-Fermi contact interactions obtained from low-energy electroweak experiments, assuming no $Z$-$Z'$ mixing.

[75] Search for $Z'$ decaying to dijets at $\sqrt{s}$=1.8 TeV. For $Z'$ with electromagnetic strength coupling, no bound is obtained.

## Searches for $Z'$ with Lepton-Flavor-Violating decays

The following limits are obtained from $p\overline{p}$ or $pp \to Z'X$ with $Z'$ decaying to the mode indicated in the comments.

[1] AABOUD 18CM search for a new particle with lepton-flavor violating decay in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their Figs. 4, 5, and 6 for limits on $\sigma\cdot B$.

[2] SIRUNYAN 18AT search for a narrow resonance $Z'$ decaying into $e\mu$ in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their Fig.5 for limit on $\sigma\cdot B$ in the range of 600 GeV $< M_{Z'} <$ 5000 GeV.

[3] AABOUD 16P search for new particle with lepton flavor violating decay in $pp$ collisions at $\sqrt{s} = 13$ TeV. See their Figs.2, 3, and 4 for limits on $\sigma\cdot B$.

[4] KHACHATRYAN 16BE search for new particle $Z'$ with lepton flavor violating decay in $pp$ collisions at $\sqrt{s} = 8$ TeV in the range of 200 GeV $< M_{Z'} <$ 2000 GeV. See their Fig.4 for limits on $\sigma\cdot B$ and their Table 5 for bounds on various masses.

[5] AAD 15O search for new particle $Z'$ with lepton flavor violating decay in $pp$ collisions at $\sqrt{s} = 8$ TeV in the range of 500 GeV $< M_{Z'} <$ 3000 GeV. See their Fig. 2 for limits on $\sigma B$.

[6] AAD 11H search for new particle $Z'$ with lepton flavor violating decay in $pp$ collisions at $\sqrt{s} = 7$ TeV in the range of 700 GeV $< M_{Z'} <$ 1000 GeV. See their Fig. 3 for limits on $\sigma\cdot B$.

[7] AAD 11Z search for new particle $Z'$ with lepton flavor violating decay in $pp$ collisions at $\sqrt{s} = 7$ TeV in the range 700 GeV $< M_{Z'} <$ 2000 GeV. See their Fig. 3 for limits on $\sigma\cdot B$.

[8] ABULENCIA 06M search for new particle $Z'$ with lepton flavor violating decay in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV in the range of 100 GeV $< M_{Z'} <$ 800 GeV. See their Fig. 4 for limits in the mass-coupling plane.

## Indirect Constraints on Kaluza-Klein Gauge Bosons

Bounds on a Kaluza-Klein excitation of the $Z$ boson or photon in $d$=1 extra dimension. These bounds can also be interpreted as a lower bound on $1/R$, the size of the extra dimension. Unless otherwise stated, bounds assume all fermions live on a single brane and all gauge fields occupy the $4+d$-dimensional bulk. See also the section on "Extra Dimensions" in the "Searches" Listings in this *Review*.

[1] MUECK 02 limit is $2\sigma$ and is from global electroweak fit ignoring correlations among observables. Higgs is assumed to be confined on the brane and its mass is fixed. For scenarios of bulk Higgs, of brane-SU(2)$_L$, bulk-U(1)$_Y$, and of bulk-SU(2)$_L$, brane-U(1)$_Y$, the corresponding limits are $> 4.6$ TeV, $> 4.3$ TeV and $> 3.0$ TeV, respectively.

[2] Bound is derived from limits on $e\nu qq'$ contact interaction, using data from HERA and the Tevatron.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[3] Bound holds only if first two generations of quarks lives on separate branes. If quark mixing is not complex, then bound lowers to 400 TeV from $\Delta m_K$.

[4] See Figs. 1 and 2 of DELGADO 00 for several model variations. Special boundary conditions can be found which permit KK states down to 950 GeV and that agree with the measurement of $Q_W$(Cs). Quoted bound assumes all Higgs bosons confined to brane; placing one Higgs doublet in the bulk lowers bound to 2.3 TeV.

[5] Bound is derived from global electroweak analysis assuming the Higgs field is trapped on the matter brane. If the Higgs propagates in the bulk, the bound increases to 3.8 TeV.

[6] Bound is derived from global electroweak analysis but considering only presence of the KK $W$ bosons.

[7] Global electroweak analysis used to obtain bound independent of position of Higgs on brane or in bulk.

[8] Bounds from effect of KK states on $G_F$, $\alpha$, $M_W$, and $M_Z$. Hard cutoff at string scale determined using gauge coupling unification. Limits for $d$=2,3,4 rise to 3.5, 5.7, and 7.8 TeV.

[9] Bound obtained for Higgs confined to the matter brane with $m_H$=500 GeV. For Higgs in the bulk, the bound increases to 3.5 TeV.

[1] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ ($q$ = $u$, $d$, $s$, $c$). The limit quoted above assumes scalar leptoquark with B($\nu b$) = 1.

[2] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ ($q$ = $u$, $d$, $s$, $c$). The limit quoted above assumes scalar leptoquark with B($\nu t$) = 1.

[3] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ ($q$ = $u$, $d$, $s$, $c$). The limit quoted above assumes scalar leptoquark with B($\nu q$) = 1.

[4] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ ($q$ = $u$, $d$, $s$, $c$). The limit quoted above assumes vector leptoquark with B($\nu b$) = 1 and $\kappa$ = 1. If we assume $\kappa$ = 0, the limit becomes $M_{LQ} > 1560$ GeV.

[5] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ ($q$ = $u$, $d$, $s$, $c$). The limit quoted above assumes vector leptoquark with B($\nu t$) = 1 and $\kappa$ = 1. If we assume $\kappa$ = 0, the limit becomes $M_{LQ} > 1475$ GeV.

[6] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ ($q$ = $u$, $d$, $s$, $c$). The limit quoted above assumes vector leptoquark with B($\nu q$) = 1 and $\kappa$ = 1. If we assume $\kappa$ = 0, the limit becomes $M_{LQ} > 1560$ GeV.

[7] AABOUD 19AX search for leptoquarks using $eejj$ events in $pp$ collisions at $\sqrt{s}$ = 13 TeV. The limit above assumes B($eq$) = 1.

[8] AABOUD 19AX search for leptoquarks using $\mu\mu jj$ events in $pp$ collisions at $\sqrt{s}$ = 13 TeV. The limit above assumes B($\mu q$) = 1.

[9] AABOUD 19X search for scalar leptoquarks decaying to $t\nu$ in $pp$ collisions at $\sqrt{s}$ = 13 TeV.

[10] AABOUD 19X search for scalar leptoquarks decaying to $b\tau$ in $pp$ collisions at $\sqrt{s}$ = 13 TeV.

[11] AABOUD 19X search for scalar leptoquarks decaying to $b\nu$ in $pp$ collisions at $\sqrt{s}$ = 13 TeV.

[12] AABOUD 19X search for scalar leptoquarks decaying to $t\tau$ in $pp$ collisions at $\sqrt{s}$ = 13 TeV.

[13] SIRUNYAN 19BI search for a pair of scalar leptoquarks decaying to $\mu\mu jj$ and to $\mu\nu jj$ final states in $pp$ collisions at $\sqrt{s}$ = 13 TeV. Limits are shown as a function of $\beta$ where $\beta$ is the branching fraction to a muon and a quark. For $\beta$ = 1.0 (0.5) LQ masses up to 1530 (1285) GeV are excluded. See Fig. 9 for exclusion limits in the plane of $\beta$ and LQ mass.

[14] SIRUNYAN 19BJ search for a pair of scalar leptoquarks decaying to $eejj$ and $e\nu jj$ final states in $pp$ collisions at $\sqrt{s}$ = 13 TeV. Limits are shown as a function of the branching fraction $\beta$ to an electron and a quark. For $\beta$ = 1.0 (0.5) LQ masses up to 1435 (1270) GeV are excluded. See Fig. 9 for exclusion limits in the plane of $\beta$ and LQ mass.

[15] SIRUNYAN 19Y search for a pair of third generation scalar leptoquarks, each decaying to $\tau$ and a jet. Assuming B($\tau b$) = 1, leptoquark masses below 1.02 TeV are excluded.

[16] SIRUNYAN 18CZ search for scalar leptoquarks decaying to $\tau t$ in $pp$ collisions at $\sqrt{s}$ = 13 TeV. The limit above assumes B($\tau t$) = 1.

[17] SIRUNYAN 18EC set limits for scalar and vector leptoquarks decaying to $\mu t$, $\tau t$, and $\nu b$. The limit quoted above assumes scalar leptoquark with B($\mu t$) = 1.

[18] SIRUNYAN 18EC set limits for scalar and vector leptoquarks decaying to $\mu t$, $\tau t$, and $\nu b$. The limit quoted above assumes vector leptoquark with all possible combinations of branching fractions to $\mu t$, $\tau t$, and $\nu b$.

[19] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with B($b\nu$) = 1. Vector leptoquarks with $\kappa$ = 1 are excluded below masses of 1810 GeV.

[20] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with B($q\nu$) = 1. Vector leptoquarks with $\kappa$ = 1 are excluded below masses of 1790 GeV.

[21] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with B($\nu t$) = 1. Vector leptoquarks with $\kappa$ = 1 are excluded below masses of 1780 GeV.

[22] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. $\kappa$ = 1 and LQ$\rightarrow$ $b\nu$ are assumed.

[23] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. $\kappa$ = 1 and LQ$\rightarrow$ $q\nu$ with $q$ = $u$,$d$,$s$,$c$ are assumed.

[24] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. $\kappa$ = 1 and LQ$\rightarrow$ $t\nu$ are assumed.

[25] KHACHATRYAN 17J search for scalar leptoquarks decaying to $\tau b$ using $pp$ collisions at $\sqrt{s}$ = 13 TeV. The limit above assumes B($\tau b$) = 1.

[26] SIRUNYAN 17H search for scalar leptoquarks using $\tau\tau bb$ events in $pp$ collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B($\tau b$) = 1.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[27] AAD 16G search for scalar leptoquarks using $eejj$ events in collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes $B(eq) = 1$.

[28] AAD 16G search for scalar leptoquarks using $\mu\mu jj$ events in collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes $B(\mu q) = 1$.

[29] AAD 16G search for scalar leptoquarks decaying to $b\nu$. The limit above assumes $B(b\nu) = 1$.

[30] AAD 16G search for scalar leptoquarks decaying to $t\nu$. The limit above assumes $B(t\nu) = 1$.

[31] KHACHATRYAN 16AF search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $pp$ collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B($eq$)= 1. For B($eq$) = 0.5, the limit becomes 850 GeV.

[32] KHACHATRYAN 16AF search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in $pp$ collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B($\mu q$) = 1. For B($\mu q$) = 0.5, the limit becomes 760 GeV.

[33] KHACHATRYAN 15AJ search for scalar leptoquarks using $\tau\tau tt$ events in $pp$ collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes $B(\tau t) = 1$.

[34] KHACHATRYAN 14T search for scalar leptoquarks decaying to $\tau b$ using $pp$ collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B($\tau b$) = 1. See their Fig. 5 for the exclusion limit as function of B($\tau b$).

[35] SIRUNYAN 19BC search for scalar leptoquark (LQ) pair production in $pp$ collisions at $\sqrt{s}$ = 13 TeV. One LQ is assumed to decay to $\mu q$, while the other decays to dark matter pair and SM particles. See their Fig. 4 for limits in $M_{LQ}$–$M_{DM}$ plane.

[36] AAD 13AE search for scalar leptoquarks using $\tau\tau bb$ events in $pp$ collisions at $E_{cm}$ = 7 TeV. The limit above assumes B($\tau b$) = 1.

[37] CHATRCHYAN 13M search for scalar and vector leptoquarks decaying to $\tau b$ in $pp$ collisions at $E_{cm}$ = 7 TeV. The limit above is for scalar leptoquarks with B($\tau b$) = 1.

[38] AAD 12H search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $pp$ collisions at $E_{cm}$ = 7 TeV. The limit above assumes B($eq$) = 1. For B($eq$) = 0.5, the limit becomes 607 GeV.

[39] AAD 12O search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in $pp$ collisions at $E_{cm}$ = 7 TeV. The limit above assumes B($\mu q$) = 1. For B($\mu q$) = 0.5, the limit becomes 594 GeV.

[40] CHATRCHYAN 12AG search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $pp$ collisions at $E_{cm}$ = 7 TeV. The limit above assumes B($eq$) = 1. For B($eq$) = 0.5, the limit becomes 640 GeV.

[41] CHATRCHYAN 12AG search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in $pp$ collisions at $E_{cm}$ = 7 TeV. The limit above assumes B($\mu q$) = 1. For B($\mu q$) = 0.5, the limit becomes 650 GeV.

[42] CHATRCHYAN 12BO search for scalar leptoquarks decaying to $\nu b$ in $pp$ collisions at $\sqrt{s}$ = 7 TeV. The limit above assumes B($\nu b$) = 1.

[43] AAD 11D search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $pp$ collisions at $E_{cm}$ = 7 TeV.The limit above assumes B($eq$) = 1. For B($eq$) = 0.5, the limit becomes 319 GeV.

[44] AAD 11D search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in $pp$ collisions at $E_{cm}$ = 7 TeV. The limit above assumes B($\mu q$) = 1. For B($\mu q$) = 0.5, the limit becomes 362 GeV.

[45] ABAZOV 11V search for scalar leptoquarks using $e\nu jj$ events in $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The limit above assumes B($eq$) = 0.5.

[46] CHATRCHYAN 11N search for scalar leptoquarks using $e\nu jj$ events in $pp$ collisions at $E_{cm}$ = 7 TeV. The limit above assumes B($eq$) = 0.5.

[47] KHACHATRYAN 11D search for scalar leptoquarks using $eejj$ events in $pp$ collisions at $E_{cm}$ = 7 TeV. The limit above assumes B($eq$) = 1.

[48] KHACHATRYAN 11E search for scalar leptoquarks using $\mu\mu jj$ events in $pp$ collisions at $E_{cm}$ = 7 TeV. The limit above assumes B($\mu q$) = 1.

[49] ABAZOV 10L search for pair productions of scalar leptoquark state decaying to $\nu b$ in $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The limit above assumes B($\nu b$) = 1.

[50] ABAZOV 09 search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The limit above assumes B($\mu q$) = 1. For B($\mu q$) = 0.5, the limit becomes 270 GeV.

[51] ABAZOV 09AF search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The limit above assumes B($eq$) = 1. For B($eq$) = 0.5 the bound becomes 284 GeV.

[52] AALTONEN 08P search for vector leptoquarks using $\tau^+\tau^- b\overline{b}$ events in $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. Assuming Yang-Mills (minimal) couplings, the mass limit is >317 GeV (251 GeV) at 95% CL for B($\tau b$) = 1.

[53] Search for pair production of scalar leptoquark state decaying to $\tau b$ in $p\overline{p}$ collisions at $E_{cm}$= 1.96 TeV. The limit above assumes B($\tau b$) = 1.

[54] Search for scalar leptoquarks using $\nu\nu jj$ events in $\overline{p}p$ collisions at $E_{cm}$ = 1.96 TeV. The limit above assumes B($\nu q$) = 1.

[55] ABAZOV 07J search for pair productions of scalar leptoquark state decaying to $\nu b$ in $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The limit above assumes B($\nu b$) = 1.

[56] ABAZOV 06A search for scalar leptoquarks using $\mu\mu jj$ events in $p\overline{p}$ collisions at $E_{cm}$ = 1.8 TeV and 1.96 TeV. The limit above assumes B($\mu q$) = 1. For B($\mu q$) = 0.5, the limit becomes 204 GeV.

[57] ABAZOV 06L search for scalar leptoquarks using $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{cm}$ = 1.8 TeV and at 1.96 TeV. The limit above assumes B($\nu q$) = 1.

[58] ABULENCIA 06T search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{cm}$ = 1.96 TeV. The quoted limit assumes B($\mu q$) = 1. For B($\mu q$) = 0.5 or 0.1, the bound becomes 208 GeV or 143 GeV, respectively. See their Fig. 4 for the exclusion limit as a function of B($\mu q$).

[59] ABAZOV 05H search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $\overline{p}p$ collisions at $E_{cm}$ = 1.8 TeV and 1.96 TeV. The limit above assumes B($eq$) = 1. For B($eq$) = 0.5 the bound becomes 234 GeV.

[60] ACOSTA 05P search for scalar leptoquarks using $eejj$, $e\nu jj$ events in $\overline{p}p$ collisions at $E_{cm}$ = 1.96TeV. The limit above assumes B($eq$) = 1. For B($eq$) = 0.5 and 0.1, the bound becomes 205 GeV and 145 GeV, respectively.

[61] ABBIENDI 03R search for scalar/vector leptoquarks in $e^+e^-$ collisions at $\sqrt{s}$ = 189–209 GeV. The quoted limits are for charge $-4/3$ isospin 0 scalar-leptoquark with B($\ell q$) = 1. See their table 12 for other cases.

[62] ABAZOV 02 search for scalar leptoquarks using $\nu\nu jj$ events in $\overline{p}p$ collisions at $E_{cm}$=1.8 TeV. The bound holds for all leptoquark generations. Vector leptoquarks are likewise constrained to lie above 200 GeV.

[63] ABAZOV 01D search for scalar leptoquarks using $e\nu jj$, $eejj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{cm}$=1.8 TeV. The limit above assumes B($eq$)=1. For B($eq$)=0.5 and 0, the bound becomes 204 and 79 GeV, respectively. Bounds for vector leptoquarks are also given. Supersedes ABBOTT 98E.

[64] ABBIENDI 00M search for scalar/vector leptoquarks in $e^+e^-$ collisions at $\sqrt{s}$=183 GeV. The quoted limits are for charge $-4/3$ isospin 0 scalar-leptoquarks with B($\ell q$)=1. See their Table 8 and Figs. 6–9 for other cases.

[65] ABBOTT 00C search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{cm}$=1.8 TeV. The limit above assumes B($\mu q$)=1. For B($\mu q$)=0.5 and 0, the bound becomes 180 and 79 GeV respectively. Bounds for vector leptoquarks are also given.

[66] AFFOLDER 00K search for scalar leptoquark using $\nu\nu cc$ events in $p\overline{p}$ collisions at $E_{cm}$=1.8 TeV. The quoted limit assumes B($\nu c$)=1. Bounds for vector leptoquarks are also given.

[67] AFFOLDER 00K search for scalar leptoquark using $\nu\nu bb$ events in $p\overline{p}$ collisions at $E_{cm}$=1.8 TeV. The quoted limit assumes B($\nu b$)=1. Bounds for vector leptoquarks are also given.

[68] ABBOTT 99J search for leptoquarks using $\mu\nu jj$ events in $p\overline{p}$ collisions at $E_{cm}$= 1.8TeV. The quoted limit is for a scalar leptoquark with B($\mu q$) = B($\nu q$) = 0.5. Limits on vector leptoquarks range from 240 to 290 GeV.

[69] ABBOTT 98E search for scalar leptoquarks using $e\nu jj$, $eejj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{cm}$=1.8 TeV. The limit above assumes B($eq$)=1. For B($eq$)=0.5 and 0, the bound becomes 204 and 79 GeV, respectively.

[70] ABBOTT 98J search for charge $-1/3$ third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at $E_{cm}$= 1.8 TeV. The quoted limit is for scalar leptoquark with B($\nu b$)=1.

[71] ABE 98S search for scalar leptoquarks using $\mu\mu jj$ events in $p\overline{p}$ collisions at $E_{cm}$= 1.8 TeV. The limit is for B($\mu q$)= 1. For B($\mu q$)=B($\nu q$)=0.5, the limit is > 160 GeV.

[72] GROSS-PILCHER 98 is the combined limit of the CDF and DØ Collaborations as determined by a joint CDF/DØ working group and reported in this FNAL Technical Memo. Original data published in ABE 97X and ABBOTT 98E.

[73] ABE 97F search for third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at $E_{cm}$ = 1.8 TeV. The quoted limit is for scalar leptoquark with B($\tau b$) = 1.

[74] ABE 97X search for scalar leptoquarks using $eejj$ events in $p\overline{p}$ collisions at $E_{cm}$=1.8 TeV. The limit is for B($eq$)=1.

[75] Limit is for charge $-1/3$ isospin-0 leptoquark with B($\ell q$) = 2/3.

[76] First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.

[77] Limits are for charge $-1/3$, isospin-0 scalar leptoquarks decaying to $\ell^- q$ or $\nu q$ with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks.

[78] KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of $de^+$ and $u\overline{\nu}$ ($s\mu^+$ and $c\overline{\nu}$). See paper for limits for specific branching ratios.

[79] BARTEL 87B limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint B(X $\rightarrow$ $c\overline{\nu}_\mu$) + B(X $\rightarrow$ $s\mu^+$) = 1.

[80] BEHREND 86B assumed that a charge 2/3 spinless leptoquark, $\chi$, decays either into $s\mu^+$ or $c\overline{\nu}$: B($\chi \rightarrow$ $s\mu^+$) + B($\chi \rightarrow$ $c\overline{\nu}$) = 1.

## MASS LIMITS for Leptoquarks from Single Production

These limits depend on the $q$-$\ell$-leptoquark coupling $g_{LQ}$. It is often assumed that $g^2_{LQ}/4\pi$=1/137. Limits shown are for a scalar, weak isoscalar, charge $-1/3$ leptoquark.

[1] SIRUNYAN 18BJ search for single production of charge 2/3 scalar leptoquarks decaying to $\tau b$ in $pp$ collisions at $\sqrt{s}$ = 13 TeV. The limit above assumes B($\tau b$) =1 and the leptoquark coupling strength $\lambda = 1$.

[2] KHACHATRYAN 16AG search for single production of charge $\pm 1/3$ scalar leptoquarks using $eej$ events in $pp$ collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B($eq$) = 1 and the leptoquark coupling strength $\lambda = 1$.

[3] KHACHATRYAN 16AG search for single production of charge $\pm 1/3$ scalar leptoquarks using $\mu\mu j$ events in $pp$ collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B($\mu q$) = 1 and the leptoquark coupling strength $\lambda = 1$.

[4] ABRAMOWICZ 12A limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with $e_R$. See their Figs. 12–17 and Table 4 for states with different quantum numbers.

[5] Limit from single production in $Z$ decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes B($\ell q$) = 2/3. The limit is 77 GeV if first and second leptoquarks are degenerate.

[6] DEY 16 use the 2010-2012 IceCube PeV energy data set to constrain the leptoquark production cross section through the $\nu q \rightarrow$ LQ $\rightarrow \nu q$ process. See their Figure 4 for the exclusion limit in the mass-coupling plane.

[7] AARON 11A search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 2–3 and Tables 1–4 for detailed limits.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[8] The quoted limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with $e_R$. See their Figs. 3–5 for limits on states with different quantum numbers.

[9] ABAZOV 07E search for leptoquark single production through $qg$ fusion process in $p\overline{p}$ collisions. See their Fig. 4 for exclusion plot in mass-coupling plane.

[10] AKTAS 05B limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with $e_R$. See their Fig. 3 for limits on states with different quantum numbers.

[11] CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs.6–10 and Tables 1–8 for detailed limits.

[12] CHEKANOV 03B limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with $e_R$. See their Figs. 11–12 and Table 5 for limits on states with different quantum numbers.

[13] For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 4 and Fig. 5.

[14] CHEKANOV 02 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–7 and Tables 5–6 for detailed limits.

[15] For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 3.

[16] See their Fig. 14 for limits in the mass-coupling plane.

[17] BREITWEG 00E search for $F$=0 leptoquarks in $e^+p$ collisions. For limits in mass-coupling plane, see their Fig. 11.

[18] ABREU 99G limit obtained from process $e\gamma \to LQ+q$. For limits on vector and scalar states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 4 and Table 2.

[19] For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 13 and Fig. 14. ADLOFF 99 also search for leptoquarks with lepton-flavor violating couplings. ADLOFF 99 supersedes AID 96B.

[20] DERRICK 97 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 5–8 and Table 1 for detailed limits.

[21] DERRICK 93 search for single leptoquark production in $ep$ collisions with the decay $eq$ and $\nu q$. The limit is for leptoquark coupling of electromagnetic strength and assumes B($eq$) = B($\nu q$) = 1/2. The limit for B($eq$) = 1 is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

[1] ABRAMOWICZ 19 obtain a limit on $\lambda/M_{LQ} > 1.16$ TeV$^{-1}$ for weak isotriplet spin-0 leptoquark $S_1^L$. We obtain the limit quoted above by converting the limit on $\lambda/M_{LQ}$ for $S_1^L$ assuming $\lambda = \sqrt{4\pi}$. See their Table 5 for the limits of leptoquarks with different quantum numbers. These limits are derived from bounds of $eq$ contact interactions.

[2] MANDAL 19 give bounds on leptoquarks from $\tau$-decays, leptonic dipole moments, lepton-flavor-violating processes, and $K$ decays.

[3] ZHANG 18A give bounds on leptoquark induced four-fermion interactions from $D \to K\ell\nu$. The authors inform us that the shape parameter of the vector form factor in both the abstract and the conclusions of ZHANG 18A should be $r_{+1} = 2.16 \pm 0.07$ rather than $\pm 0.007$. The numbers listed in their Table 7 are correct.

[4] BARRANCO 16 give bounds on leptoquark induced four-fermion interactions from $D \to K\ell\nu$ and $D_s \to \ell\nu$.

[5] KUMAR 16 gives bound on SU(2) singlet scalar leptoquark with chrge $-1/3$ from $K^0 - \overline{K}^0$ mixing, $K \to \pi\nu\overline{\nu}$, $K_L^0 \to \mu^+\mu^-$, and $K_L^0 \to \mu^\pm e^\mp$ decays.

[6] BESSAA 15 obtain limit on leptoquark induced four-fermion interactions from the ATLAS and CMS limit on the $\overline{q}q\overline{e}e$ contact interactions.

[7] SAHOO 15A obtain limit on leptoquark induced four-fermion interactions from $B_{s,d} \to \mu^+\mu^-$ for $\lambda \simeq O(1)$.

[8] SAKAKI 13 explain the $B \to D^{(*)}\tau\overline{\nu}$ anomaly using Wilson coefficients of leptoquark-induced four-fermion operators.

[9] KOSNIK 12 obtains limits on leptoquark induced four-fermion interactions from $b \to s\ell^+\ell^-$ decays.

[10] AARON 11C limit is for weak isotriplet spin-0 leptoquark at strong coupling $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds of $eq$ contact intereractions.

[11] DORSNER 11 give bounds on scalar, weak singlet, charge 4/3 leptoquark from $K$, $B$, $\tau$ decays, meson mixings, $LFV$, $g-2$ and $Z \to b\overline{b}$.

[12] AKTAS 07A search for lepton-flavor violation in $ep$ collision. See their Tables 4–7 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

[13] SCHAEL 07A limit is for the weak-isoscalar spin-0 left-handed leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 35.

[14] SMIRNOV 07 obtains mass limits for the vector and scalar chiral leptoquark states from $K \to e\mu$, $B \to e\tau$ decays.

[15] CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs.6–10 and Tables 1–8 for detailed limits.

[16] ADLOFF 03 limit is for the weak isotriplet spin-0 leptoquark at strong coupling $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds on $e^\pm q$ contact interactions.

[17] The bound is derived from B($B^0 \to e^\pm\mu^\mp$) $< 1.7 \times 10^{-7}$.

[18] CHEKANOV 02 search for lepton-flavor violation in $ep$ collisions. See their Tables 1–4 for limits on lepton-flavor violating and four-fermion interactions induced by various leptoquarks.

[19] CHEUNG 01B quoted limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark with a coupling of electromagnetic strength. The limit is derived from bounds on contact interactions in a global electroweak analysis. For the limits of leptoquarks with different quantum numbers, see Table 5.

[20] ACCIARRI 00P limit is for the weak isoscalar spin-0 leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 4.

[21] ADLOFF 00 limit is for the weak isotriplet spin-0 leptoquark at strong coupling, $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 2. ADLOFF 00 limits are from the $Q^2$ spectrum measurement of $e^+p \to e^+$X.

[22] BARATE 00I search for deviations in cross section and jet-charge asymmetry in $e^+e^- \to \overline{q}q$ due to $t$-channel exchange of a leptoquark at $\sqrt{s}$=130 to 183 GeV. Limits for other scalar and vector leptoquarks are also given in their Table 22.

[23] BARGER 00 explain the deviation of atomic parity violation in cesium atoms from prediction is explained by scalar leptoquark exchange.

[24] GABRIELLI 00 calculate various process with lepton flavor violation in leptoquark models.

[25] ZARNECKI 00 limit is derived from data of HERA, LEP, and Tevatron and from various low-energy data including atomic parity violation. Leptoquark coupling with electromagnetic strength is assumed.

[26] ABBIENDI 99 limits are from $e^+e^- \to q\overline{q}$ cross section at 130–136, 161–172, 183 GeV. See their Fig. 8 and Fig. 9 for limits in mass-coupling plane.

[27] ABE 98V quoted limit is from B($B_s \to e^\pm\mu^\mp$)$< 8.2 \times 10^{-6}$. ABE 98V also obtain a similar limit on $M_{LQ} > 20.4$ TeV from B($B_d \to e^\pm\mu^\mp$)$< 4.5 \times 10^{-6}$. Both bounds assume the non-canonical association of the $b$ quark with electrons or muons under SU(4).

[28] ACCIARRI 98J limit is from $e^+e^- \to q\overline{q}$ cross section at $\sqrt{s}$= 130–172 GeV which can be affected by the $t$- and $u$-channel exchanges of leptoquarks. See their Fig. 4 and Fig. 5 for limits in the mass-coupling plane.

[29] ACKERSTAFF 98V limits are from $e^+e^- \to q\overline{q}$ and $e^+e^- \to b\overline{b}$ cross sections at $\sqrt{s}$ = 130–172 GeV, which can be affected by the $t$- and $u$-channel exchanges of leptoquarks. See their Fig. 21 and Fig. 22 for limits of leptoquarks in mass-coupling plane.

[30] DEANDREA 97 limit is for $\tilde{R}_2$ leptoquark obtained from atomic parity violation (APV). The coupling of leptoquark is assumed to be electromagnetic strength. See Table 2 for limits of the four-fermion interactions induced by various scalar leptoquark exchange. DEANDREA 97 combines APV limit and limits from Tevatron and HERA. See Fig. 1–4 for combined limits of leptoquark in mass-coupling plane.

[31] DERRICK 97 search for lepton-flavor violation in $ep$ collision. See their Tables 2–5 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

[32] GROSSMAN 97 estimate the upper bounds on the branching fraction $B \to \tau^+\tau^-$(X) from the absence of the $B$ decay with large missing energy. These bounds can be used to constrain leptoquark induced four-fermion interactions.

[33] JADACH 97 limit is from $e^+e^- \to q\overline{q}$ cross section at $\sqrt{s}$=172.3 GeV which can be affected by the $t$- and $u$-channel exchanges of leptoquarks. See their Fig. 1 for limits on vector leptoquarks in mass-coupling plane.

[34] KUZNETSOV 95B use $\pi$, $K$, $B$, $\tau$ decays and $\mu e$ conversion and give a list of bounds on the leptoquark mass and the fermion mixing matrix in the Pati-Salam model. The quoted limit is from $K_L \to \mu e$ decay assuming zero mixing.

[35] MIZUKOSHI 95 calculate the one-loop radiative correction to the $Z$-physics parameters in various scalar leptoquark models. See their Fig. 4 for the exclusion plot of third generation leptoquark models in mass-coupling plane.

[36] BHATTACHARYYA 94 limit is from one-loop radiative correction to the leptonic decay width of the $Z$. $m_H$=250 GeV, $\alpha_s(m_Z)$=0.12, $m_t$=180 GeV, and the electroweak strength of leptoquark coupling are assumed. For leptoquark coupled to $\overline{e}_L\, t_R$, $\overline{\mu}t$, and $\overline{\tau}t$, see Fig. 2 in BHATTACHARYYA 94B erratum and Fig. 3.

[37] DAVIDSON 94 gives an extensive list of the bounds on leptoquark-induced four-fermion interactions from $\pi$, $K$, $D$, $B$, $\mu$, $\tau$ decays and meson mixings, *etc.* See Table 15 of DAVIDSON 94 for detail.

# Gauge & Higgs Boson Particle Listings

## New Heavy Bosons

[38] KUZNETSOV 94 gives mixing independent bound of the Pati-Salam leptoquark from the cosmological limit on $\pi^0 \to \overline{\nu}\nu$.

[39] LEURER 94, LEURER 94B limits are obtained from atomic parity violation and apply to any chiral leptoquark which couples to the first generation with electromagnetic strength. For a nonchiral leptoquark, universality in $\pi_{\ell 2}$ decay provides a much more stringent bound.

[40] MAHANTA 94 gives bounds of $P$- and $T$-violating scalar-leptoquark couplings from atomic and molecular experiments.

[41] From $(\pi \to e\nu)/(\pi \to \mu\nu)$ ratio. SHANKER 82 assumes the leptoquark induced four-fermion coupling $4g^2/M^2\ (\overline{\nu}_{eL}\ u_R)\ (\overline{d}_L\ e_R)$with $g$=0.004 for spin-0 leptoquark and $g^2/M^2\ (\overline{\nu}_{eL}\ \gamma_\mu u_L)\ (\overline{d}_R\ \gamma^\mu e_R)$ with $g \simeq 0.6$ for spin-1 leptoquark.

[2] KHACHATRYAN 17W search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV.

[3] KHACHATRYAN 16K search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV.

[4] KHACHATRYAN 16L search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 8$ TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.

[5] KHACHATRYAN 15V search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 8$ TeV.

[6] CHATRCHYAN 13A search for new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 7$ TeV.

[7] CHATRCHYAN 13AS search for new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 8$ TeV.

[8] CHATRCHYAN 11Y search for new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 7$ TeV.

[9] KHACHATRYAN 10 search for new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 7$ TeV.

[10] AALTONEN 09AC search for new narrow resonance decaying to dijets.

[11] ABE 97G search for new particle decaying to dijets.

[12] ABREU 94O limit is from $e^+e^- \to \overline{cs}cs$. Range extends up to 43 GeV if diquarks are degenerate in mass.

### MASS LIMITS for $g_A$ (axigluon) and Other Color-Octet Gauge Bosons

Axigluons are massive color-octet gauge bosons in chiral color models and have axial-vector coupling to quarks with the same coupling strength as gluons.

[1] SIRUNYAN 18BO search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV.

[2] KHACHATRYAN 17W search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV.

[3] KHACHATRYAN 16K search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 13$ TeV.

[4] KHACHATRYAN 16L search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 8$ TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.

[5] KHACHATRYAN 15V search for resonances decaying to dijets in $pp$ collisions at $\sqrt{s} = 8$ TeV.

[6] KHACHATRYAN 17Y search for pair production of color-octet gauge boson $g_A$ each decaying to $4j$ in $pp$ collisions at $\sqrt{s} = 8$ TeV.

[7] AAD 16W search for a new resonance decaying to a pair of $b$ and $B_H$ in $pp$ collisions at $\sqrt{s} = 8$ TeV. The vector-like quark $B_H$ is assumed to decay to $bH$. See their Fig. 3 and Fig. 4 for limits on $\sigma \cdot B$.

[8] KHACHATRYAN 16E search for KK gluon decaying to $t\overline{t}$ in $pp$ collisions at $\sqrt{s} = 8$ TeV.

[9] KHACHATRYAN 15AV search for pair productions of neutral color-octet weak-triplet scalar particles ($\Theta^0$), decaying to $b\overline{b}$, $Zg$ or $\gamma g$, in $pp$ collisions at $\sqrt{s} = 8$ TeV. The $\Theta^0$ particle is often predicted in coloron ($G'$, color-octet gauge boson) models and appear in the $pp$ collisions through $G' \to \Theta^0\Theta^0$ decays. Assuming $B(\Theta^0 \to b\overline{b}) = 0.5$, they give limits $m_{\Theta^0} > 623$ GeV (426 GeV) for $m_{G'} = 2.3\ m_{\Theta^0}$ ($m_{G'} = 5\ m_{\Theta^0}$).

[10] AALTONEN 13R search for new resonance decaying to $\sigma\sigma$, with hypothetical strongly interacting $\sigma$ particle subsequently decaying to 2 jets, in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV, using data corresponding to an integrated luminosity of 6.6 fb$^{-1}$. For 50 GeV $< m_\sigma <$ $m_{g_A}/2$, axigluons in mass range 150–400 GeV are excluded.

[11] CHATRCHYAN 13A search for new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 7$ TeV.

[12] CHATRCHYAN 13AS search for new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 8$ TeV.

[13] CHATRCHYAN 13AU search for the pair produced color-octet vector bosons decaying to $q\overline{q}$ pairs in $pp$ collisions. The quoted limit is for $B(g_A \to q\overline{q}) = 1$.

[14] ABAZOV 12R search for massive color octet vector particle decaying to $t\overline{t}$. The quoted limit assumes $g_A$ couplings with light quarks are suppressed by 0.2.

[15] CHATRCHYAN 11Y search for new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 7$ TeV.

[16] AALTONEN 10L search for massive color octet non-chiral vector particle decaying into $t\overline{t}$ pair with mass in the range 400 GeV $<$ M $<$ 800 GeV. See their Fig. 6 for limit in the mass-coupling plane.

[17] KHACHATRYAN 10 search for new resonance decaying to dijets in $pp$ collisions at $\sqrt{s} = 7$ TeV.

[18] AALTONEN 09AC search for new narrow resonance decaying to dijets.

[19] CHOUDHURY 07 limit is from the $t\overline{t}$ production cross section measured at CDF.

[20] DONCHESKI 98 compare $\alpha_s$ derived from low-energy data and that from $\Gamma(Z \to$ hadrons$)/\Gamma(Z \to$ leptons).

[21] ABE 97G search for new particle decaying to dijets.

[22] ABE 95N assume axigluons decaying to quarks in the Standard Model only.

[23] ABE 93G assume $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 10$.

[24] CUYPERS 91 compare $\alpha_s$ measured in $\Upsilon$ decay and that from $R$ at PEP/PETRA energies.

[25] ABE 90H assumes $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 5$ ($\Gamma(g_A) = 0.09 m_{g_A}$). For $N = 10$, the excluded region is reduced to 120–150 GeV.

[26] ROBINETT 89 result demands partial-wave unitarity of $J = 0$ $t\overline{t} \to t\overline{t}$ scattering amplitude and derives a limit $m_{g_A} > 0.5\ m_t$. Assumes $m_t > 56$ GeV.

[27] ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution. $\Gamma(g_A) < 0.4\ m_{g_A}$ assumed. See also BAGGER 88.

[28] CUYPERS 88 requires $\Gamma(\Upsilon \to g g_A) < \Gamma(\Upsilon \to ggg)$. A similar result is obtained by DONCHESKI 88.

[29] DONCHESKI 88B requires $\Gamma(\Upsilon \to g q\overline{q})/\Gamma(\Upsilon \to ggg) < 0.25$, where the former decay proceeds via axigluon exchange. A more conservative estimate of $< 0.5$ leads to $m_{g_A} > 21$ GeV.

### MASS LIMITS for Color-Octet Scalar Bosons

[1] SIRUNYAN 18BO search for color octet scalar boson produced through gluon fusion process in $pp$ collisions at $\sqrt{s} = 13$ TeV. The limit above assumes $S_{8gg}$ coupling $k_s^2 = 1/2$.

[2] KHACHATRYAN 15AV search for pair productions of neutral color-octet weak-triplet scalar particles ($\Theta^0$), decaying to $b\overline{b}$, $Zg$ or $\gamma g$, in $pp$ collisions at $\sqrt{s} = 8$ TeV. The $\Theta^0$ particle is often predicted in coloron ($G'$, color-octet gauge boson) models and appear in the $pp$ collisions through $G' \to \Theta^0\Theta^0$ decays. Assuming $B(\Theta^0 \to b\overline{b}) = 0.5$, they give limits $m_{\Theta^0} > 623$ GeV (426 GeV) for $m_{G'} = 2.3\ m_{\Theta^0}$ ($m_{G'} = 5\ m_{\Theta^0}$).

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[3] AAD 13K search for pair production of color-octet scalar particles in $pp$ collisions at $\sqrt{s}$ = 7 TeV. Cross section limits are interpreted as mass limits on scalar partners of a Dirac gluino.

## $X^0$ (Heavy Boson) Searches in $Z$ Decays

Searches for radiative transition of $Z$ to a lighter spin-0 state $X^0$ decaying to hadrons, a lepton pair, a photon pair, or invisible particles as shown in the comments. The limits are for the product of branching ratios.

[1] RAINBOLT 19 limits are from B($Z \to \ell^+\ell^-\ell^+\ell^-$). See their Figs. 5 and 6 for limits in mass-coupling plane.

[2] SIRUNYAN 19AZ search for $pp \to Z \to X^0\mu^+\mu^- \to \mu^+\mu^-\mu^+\mu^-$ events in $pp$ collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 5 for limits on $\sigma(pp \to X^0\mu^+\mu^-)\cdot$B($X^0 \to \mu^+\mu^-$).

[3] BARATE 98U obtain limits on B($Z \to \gamma X^0$)B($X^0 \to \ell\overline{\ell}$, $q\overline{q}$, $gg$, $\gamma\gamma$, $\nu\overline{\nu}$). See their Fig. 17.

[4] See Fig. 4 of ACCIARRI 97Q for the upper limit on B($Z \to \gamma X^0$; $E_\gamma > E_{\min}$) as a function of $E_{\min}$.

[5] ACTON 93E give $\sigma(e^+e^- \to X^0\gamma)\cdot$B($X^0 \to \gamma\gamma$)$<$ 0.4 pb (95%CL) for $m_{X^0}$=60 $\pm$ 2.5 GeV. If the process occurs via $s$-channel $\gamma$ exchange, the limit translates to $\Gamma(X^0)\cdot$B($X^0 \to \gamma\gamma$)$^2$ $<$20 MeV for $m_{X^0}$ = 60 $\pm$ 1 GeV.

[6] ABREU 92D give $\sigma_Z \cdot$ B($Z \to \gamma X^0$) $\cdot$ B($X^0 \to$ hadrons) $<$(3–10) pb for $m_{X^0}$ = 10–78 GeV. A very similar limit is obtained for spin-1 $X^0$.

[7] ADRIANI 92F search for isolated $\gamma$ in hadronic $Z$ decays. The limit $\sigma_Z \cdot$ B($Z \to \gamma X^0$) $\cdot$ B($X^0 \to$ hadrons) $<$(2–10) pb (95%CL) is given for $m_{X^0}$ = 25–85 GeV.

[8] ACTON 91 searches for $Z \to Z^*X^0$, $Z^* \to e^+e^-$, $\mu^+\mu^-$, or $\nu\overline{\nu}$. Excludes any new scalar $X^0$ with $m_{X^0} < 9.5$ GeV/$c$ if it has the same coupling to $ZZ^*$ as the MSM Higgs boson.

[9] ACTON 91B limits are for $m_{X^0}$ = 60–85 GeV.

[10] ADEVA 91D limits are for $m_{X^0}$ = 30–89 GeV.

[11] ADEVA 91D limits are for $m_{X^0}$ = 30–86 GeV.

[12] AKRAWY 90J give $\Gamma(Z \to \gamma X^0)\cdot$B($X^0 \to$ hadrons) $<$ 1.9 MeV (95%CL) for $m_{X^0}$ = 32–80 GeV. We divide by $\Gamma(Z)$ = 2.5 GeV to get product of branching ratios. For nonresonant transitions, the limit is B($Z \to \gamma q\overline{q}$) $<$ 8.2 MeV assuming three-body phase space distribution.

## MASS LIMITS for a Heavy Neutral Boson Coupling to $e^+e^-$

| VALUE (GeV) | CL% | DOCUMENT ID | | TECN | COMMENT |

| >47 | 95 | [5] BEHREND | 84C | CELL | $\Gamma(X^0 \to e^+e^-)$=4 MeV |

[1] ODAKA 89 looked for a narrow or wide scalar resonance in $e^+e^- \to$ hadrons at $E_{\rm cm}$ = 55.0–60.8 GeV.

[2] DERRICK 86 found no deviation from the Standard Model Bhabha scattering at $E_{\rm cm}$= 29 GeV and set limits on the possible scalar boson $e^+e^-$ coupling. See their figure 4 for excluded region in the $\Gamma(X^0 \to e^+e^-)$-$m_{X^0}$ plane. Electronic chiral invariance requires a parity doublet of $X^0$, in which case the limit applies for $\Gamma(X^0 \to e^+e^-)$ = 3 MeV.

[3] ADEVA 85 first limit is from 2$\gamma$, $\mu^+\mu^-$, hadrons assuming $X^0$ is a scalar. Second limit is from $e^+e^-$ channel. $E_{\rm cm}$ = 40–47 GeV. Supersedes ADEVA 84.

[4] BERGER 85B looked for effect of spin-0 boson exchange in $e^+e^- \to e^+e^-$ and $\mu^+\mu^-$ at $E_{\rm cm}$ = 34.7 GeV. See Fig. 5 for excluded region in the $m_{X^0} - \Gamma(X^0)$ plane.

[5] ADEVA 84 and BEHREND 84C have $E_{\rm cm}$ = 39.8–45.5 GeV. MARK-J searched $X^0$ in $e^+e^-$ $\to$ hadrons, 2$\gamma$, $\mu^+\mu^-$, $e^+e^-$ and CELLO in the same channels plus $\tau$ pair. No narrow or broad $X^0$ is found in the energy range. They also searched for the effect of $X^0$ with $m_X > E_{\rm cm}$. The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for $\Gamma(X^0 \to e^+e^-)$ = 2 MeV if $X^0$ is a spin-0 doublet. The second limit of BEHREND 84C was read off from their figure 2. The original papers also list limits in other channels.

## Search for $X^0$ Resonance in $e^+e^-$ Collisions

The limit is for $\Gamma(X^0 \to e^+e^-)\cdot$B($X^0 \to f$), where $f$ is the specified final state. Spin 0 is assumed for $X^0$.

| | [2] ABREU | 00Z | DLPH | $X^0$ decaying invisibly |
| | [3] ADAM | 96C | DLPH | $X^0$ decaying invisibly |

[1] ABBIENDI 03D measure the $e^+e^- \to \gamma\gamma\gamma$ cross section at $\sqrt{s}$=181–209 GeV. The upper bound on the production cross section, $\sigma(e^+e^- \to X^0\gamma)$ times the branching ratio for $X^0 \to \gamma\gamma$, is less than 0.03 pb at 95%CL for $X^0$ masses between 20 and 180 GeV. See their Fig. 9b for the limits in the mass-cross section plane.

[2] ABREU 00Z is from the single photon cross section at $\sqrt{s}$=183, 189 GeV. The production cross section upper limit is less than 0.3 pb for $X^0$ mass between 40 and 160 GeV. See their Fig. 4 for the limit in mass-cross section plane.

[3] ADAM 96C is from the single photon production cross at $\sqrt{s}$=130, 136 GeV. The upper bound is less than 3 pb for $X^0$ masses between 60 and 130 GeV. See their Fig. 5 for the exact bound on the cross section $\sigma(e^+e^- \to \gamma X^0)$.

## Search for $X^0$ Resonance in $Z \to f\overline{f}X^0$

The limit is for B($Z \to f\overline{f}X^0$) $\cdot$ B($X^0 \to F$) where $f$ is a fermion and $F$ is the specified final state. Spin 0 is assumed for $X^0$.

# Gauge & Higgs Boson Particle Listings

## New Heavy Bosons

[1] AALTONEN 13AA search for $X^0$ production associated with $W$ (or $Z$) in $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The upper limit on the cross section $\sigma(p\overline{p} \to WX^0)$ is 2.2 pb for $M_{X^0} = 145$ GeV.

[2] CHATRCHYAN 12BR search for $X^0$ production associated with $W$ in $pp$ collisions at $E_{cm} = 7$ TeV. The upper limit on the cross section is 5.0 pb at 95% CL for $m_{X^0} = 150$ GeV.

[3] ABAZOV 11I search for $X^0$ production associated with $W$ in $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The 95% CL upper limit on the cross section ranges from 2.57 to 1.28 pb for $X^0$ mass between 110 and 170 GeV.

[4] ABE 97W search for $X^0$ production associated with $W$ in $p\overline{p}$ collisions at $E_{cm}$=1.8 TeV. The 95%CL upper limit on the production cross section times the branching ratio for $X^0 \to b\overline{b}$ ranges from 14 to 19 pb for $X^0$ mass between 70 and 120 GeV. See their Fig. 3 for upper limits of the production cross section as a function of $m_{X^0}$.

### Search for $X^0$ Resonance in Quarkonium Decays

Limits are for branching ratios to modes shown. Spin 1 is assumed for $X^0$.

Axions and Other Similar Particles

### $A^0$ (Axion) MASS LIMITS from Astrophysics and Cosmology

These bounds depend on model-dependent assumptions (i.e. — on a combination of axion parameters).

| VALUE (MeV) | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | |
| >0.2 | BARROSO | 82 | ASTR | Standard Axion |
| >0.25 | [1] RAFFELT | 82 | ASTR | Standard Axion |
| >0.2 | [2] DICUS | 78C | ASTR | Standard Axion |
| | MIKAELIAN | 78 | ASTR | Stellar emission |
| >0.3 | [2] SATO | 78 | ASTR | Standard Axion |
| >0.2 | VYSOTSKII | 78 | ASTR | Standard Axion |

[1] Lower bound from 5.5 MeV $\gamma$-ray line from the sun.
[2] Lower bound from requiring the red giants' stellar evolution not be disrupted by axion emission.

### $A^0$ (Axion) and Other Light Boson ($X^0$) Searches in Hadron Decays

Limits are for branching ratios.

[1] The limit is for $\tau_{X^0} = 10$ ps. See their Fig. 4 for limits in the range of $m_{X^0} = 250$–4700 MeV and $\tau_{X^0} = 0.1$–1000 ps.
[2] The limit as a function of $m_{X^0}$ from 0 to 250 MeV is provided in their Fig. 5 .
[3] The limit is for $m_{X^0} = 216$ MeV and $\tau_{X^0} \leq 10$ ps. See their Fig. 4(c) for limits in the range of $m_{X^0} = 211$–354 MeV and longer lifetimes.
[4] WON 16 look for a vector boson coupled to baryon number. Derived limits on $\alpha' < 10^{-3}$–$10^{-2}$ for $m_{X^0} = 290$–520 MeV at 95% CL. See their Fig. 4 for mass-dependent limits.
[5] The limit is for $\tau_{X^0} = 10$ ps and $m_{X^0} = 214$–4350 MeV. See their Fig. 4 for mass- and lifetime-dependent limits.
[6] Limits between $2.0 \times 10^{-5}$ and $1.5 \times 10^{-6}$ are obtained for $m_{X^0} = 20$–100 MeV (see their Fig. 8). Angular momentum conservation requires that $X^0$ has spin $\geq 1$.
[7] The limit is for $B(\phi \to \eta X^0) \cdot B(X^0 \to e^+e^-)$ and applies to $m_{X^0} = 410$ MeV. It is derived by analyzing $\eta \to \pi^0\pi^0\pi^0$ and $\pi^-\pi^+\pi^0$. Limits between $1 \times 10^{-6}$ and $2 \times 10^{-8}$ are obtained for $m_{X^0} \leq 450$ MeV (see their Fig. 6).
[8] ARCHILLI 12 analyzed $\eta \to \pi^+\pi^-\pi^0$ decays. Derived limits on $\alpha'/\alpha < 2 \times 10^{-5}$ for $m_{X^0} = 50$–420 MeV at 90% CL. See their Fig. 8 for mass-dependent limits.
[9] This limit is for $B(\pi^0 \to \gamma X^0) \cdot B(X^0 \to e^+e^-)$ and applies for $m_{X^0} = 90$ MeV and $\tau_{X^0} \simeq 1 \times 10^{-8}$ sec. Limits between $10^{-8}$ and $2 \times 10^{-15}$ are obtained for $m_{X^0} = 3$–120 MeV and $\tau_{X^0} = 1 \times 10^{-11}$–1 sec. See their Fig. 3 for limits at different masses and lifetimes.
[10] This limit is for $B(\eta \to \gamma X^0) \cdot B(X^0 \to e^+e^-)$ and applies for $m_{X^0} = 100$ MeV and $\tau_{X^0} \simeq 6 \times 10^{-9}$ sec. Limits between $10^{-5}$ and $3 \times 10^{-14}$ are obtained for $m_{X^0} \lesssim 550$ MeV and $\tau_{X^0} = 10^{-10}$–10 sec. See their Fig. 5 for limits at different mass and lifetime and for $\eta'$ decays.
[11] This limit applies for a mass near 180 MeV. For other masses in the range $m_{X^0} = 150$–250 MeV the limit is less restrictive, but still improves ADLER 02C and ATIYA 93B.
[12] ANISIMOVSKY 04 bound is for $m_{X^0} = 0$.
[13] ADLER 02C bound is for $m_{X^0} < 60$ MeV. See Fig. 2 for limits at higher masses.
[14] The quoted limit is for $m_{X^0} = 0$–80 MeV. See their Fig. 5 for the limit at higher mass. The branching fraction limit assumes pure phase space decay distributions.
[15] ALTEGOER 98 looked for $X^0$ from $\pi^0$ decay which penetrate the shielding and convert to $\pi^0$ in the external Coulomb field of a nucleus.
[16] KITCHING 97 limit is for $B(K^+ \to \pi^+ X^0) \cdot B(X^0 \to \gamma\gamma)$ and applies for $m_{X^0} \simeq 50$ MeV, $\tau_{X^0} < 10^{-10}$ s. Limits are provided for $0 < m_{X^0} < 100$ MeV, $\tau_{X^0} < 10^{-8}$ s.
[17] ADLER 96 looked for a peak in missing-mass distribution. This work is an update of ATIYA 93. The limit is for massless stable $X^0$ particles and extends to $m_{X^0} = 80$ MeV at the same level. See paper for dependence on finite lifetime.
[18] AMSLER 94B and AMSLER 96B looked for a peak in missing-mass distribution.
[19] The MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of $X^0$ decay modes. It applies to $\tau(X^0) > 10^{-23}$ sec.
[20] ATIYA 93B looked for a peak in missing mass distribution. The bound applies for stable $X^0$ of $m_{X^0} = 150$–250 MeV, and the limit becomes stronger ($10^{-8}$) for $m_{X^0} = 180$–240 MeV.
[21] NG 93 studied the production of $X^0$ via $\gamma\gamma \to \pi^0 \to \gamma X^0$ in the early universe at $T \simeq 1$ MeV. The bound on extra neutrinos from nucleosynthesis $\Delta N_\nu < 0.3$ (WALKER 91) is employed. It applies to $m_{X^0} \ll 1$ MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier $X^0$.
[22] ALLIEGRO 92 limit applies for $m_{X^0} = 150$–340 MeV and is the branching ratio times the decay probability. Limit is $< 1.5 \times 10^{-8}$ at 99%CL.
[23] ATIYA 92 looked for a peak in missing mass distribution. The limit applies to $m_{X^0} = 0$–130 MeV in the narrow resonance limit. See paper for the dependence on lifetime. Covariance requires $X^0$ to be a vector particle.
[24] BARABASH 92 is a beam dump experiment that searched for a light Higgs. Limits between $1 \times 10^{-12}$ and $1 \times 10^{-7}$ are obtained for $3 < m_{X^0} < 40$ MeV.
[25] Limits between $1 \times 10^{-12}$ and 1 are obtained for $4 < m_{X^0} < 69$ MeV.
[26] Limits between $1 \times 10^{-11}$ and $5 \times 10^{-3}$ are obtained for $4 < m_{X^0} < 63$ MeV.
[27] Limits between $1 \times 10^{-14}$ and 1 are obtained for $3 < m_{X^0} < 82$ MeV.
[28] MEIJERDREES 92 limit applies for $\tau_{X^0} = 10^{-23}$–$10^{-11}$ sec. Limits between $2 \times 10^{-4}$ and $4 \times 10^{-6}$ are obtained for $m_{X^0} = 25$–120 MeV. Angular momentum conservation requires that $X^0$ has spin $\geq 1$.
[29] ATIYA 90B limit is for $B(K^+ \to \pi^+ X^0) \cdot B(X^0 \to \gamma\gamma)$ and applies for $m_{X^0} = 50$ MeV, $\tau_{X^0} < 10^{-10}$ s. Limits are also provided for $0 < m_{X^0} < 100$ MeV, $\tau_{X^0} < 10^{-8}$ s.
[30] KORENCHENKO 87 limit assumes $m_{A^0} = 1.7$ MeV, $\tau_{A^0} \lesssim 10^{-12}$ s, and $B(A^0 \to e^+e^-) = 1$.
[31] EICHLER 86 looked for $\pi^+ \to e^+ \nu A^0$ followed by $A^0 \to e^+e^-$. Limits on the branching fraction depend on the mass and and lifetime of $A^0$. The quoted limits are valid when $\tau(A^0) \gtrsim 3. \times 10^{-10}$s if the decays are kinematically allowed.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[32] YAMAZAKI 84 looked for a discrete line in $K^+ \to \pi^+ X$. Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.

[33] ASANO 82 at KEK set limits for $B(K^+ \to \pi^+ X^0)$ for $m_{X^0}$ <100 MeV as BR $< 4. \times 10^{-8}$ for $\tau(X^0 \to n\gamma\text{'s}) > 1. \times 10^{-9}$ s, BR $< 1.4 \times 10^{-6}$ for $\tau < 1. \times 10^{-9}$s.

[34] ASANO 81B is KEK experiment. Set $B(K^+ \to \pi^+ X^0) < 3.8 \times 10^{-8}$ at CL = 90%.

[35] ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 ($3 < m < 40$ MeV) contradicts experimental muon anomalous magnetic moments.

## $A^0$ (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| $<2.8 \times 10^{-8}$ | 90 | [1] ABLIKIM | 16E | BES3 | $J/\psi \to A^0\gamma\,(A^0 \to \mu^+\mu^-)$ |
| $<4 \times 10^{-7}$ | 90 | [2] ABLIKIM | 12 | BES3 | $J/\psi \to A^0\gamma\,(A^0 \to \mu^+\mu^-)$ |
| $<4.0 \times 10^{-5}$ | 90 | [3] ANTREASYAN | 90C | CBAL | $\Upsilon(1S) \to A^0\gamma$ |
| $<5 \times 10^{-5}$ | 90 | [4] DRUZHININ | 87 | ND | $\phi \to A^0\gamma\,(A^0 \to e^+e^-)$ |
| $<2 \times 10^{-3}$ | 90 | [5] DRUZHININ | 87 | ND | $\phi \to A^0\gamma\,(A^0 \to \gamma\gamma)$ |
| $<7 \times 10^{-6}$ | 90 | [6] DRUZHININ | 87 | ND | $\phi \to A^0\gamma\,(A^0 \to$ missing) |
| $<1.4 \times 10^{-5}$ | 90 | [7] EDWARDS | 82 | CBAL | $J/\psi \to A^0\gamma$ |

[1] ABLIKIM 16E limits between 2.8–495.3 $\times 10^{-8}$ were obtained for 0.212 GeV $< m_{A^0} <$ 3.0 GeV. See their Fig. 5 for mass-dependent limits.

[2] ABLIKIM 12 derived limits between $4 \times 10^{-7}$–$2.1 \times 10^{-5}$ for 0.212 GeV $< m_{A^0} <$ 3.0 GeV. See their Fig. 2(c) for mass-dependent limits.

[3] ANTREASYAN 90C assume that $A^0$ does not decay in the detector.

[4] The first DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 3 \times 10^{-13}$ s/MeV and $m_{A^0} < 20$ MeV.

[5] The second DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 5 \times 10^{-13}$ s/MeV and $m_{A^0} < 20$ MeV.

[6] The third DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} > 7 \times 10^{-12}$ s/MeV and $m_{A^0} < 200$ MeV.

[7] EDWARDS 82 looked for $J/\psi \to \gamma A^0$ decays by looking for events with a single $\gamma$ [of energy $\sim 1/2$ the $J/\psi(1S)$ mass], plus nothing else in the detector. The limit is inconsistent with the axion interpretation of the FAISSNER 81B result.

## $A^0$ (Axion) Searches in Positronium Decays

Decay or transition of positronium. Limits are for branching ratio.

| | | [7] AMALDI | 85 | CNTR | Ortho-positronium |
| | | [8] CARBONI | 83 | CNTR | Ortho-positronium |

[1] BADERTSCHER 02 looked for a three-body decay of ortho-positronium into a photon and two penetrating (neutral or milli-charged) particles.

[2] The ASAI 94 limit is based on inclusive photon spectrum and is independent of $A^0$ decay modes.

[3] The AKOPYAN 91 limit applies for a short-lived $A^0$ with $\tau_{A^0} < 10^{-13}$ $m_{A^0}$ [keV] s.

[4] ASAI 91 limit translates to $g^2_{A^0 e^+ e^-}/4\pi < 1.1 \times 10^{-11}$ (90% CL) for $m_{A^0} <$ 800 keV.

[5] The TSUCHIAKI 90 limit is based on inclusive photon spectrum and is independent of $A^0$ decay modes.

[6] ORITO 89 limit translates to $g^2_{A^0 ee}/4\pi < 6.2 \times 10^{-10}$. Somewhat more sensitive limits are obtained for larger $m_{A^0}$: $B < 7.6 \times 10^{-6}$ at 100 keV.

[7] AMALDI 85 set limits $B(A^0\gamma)$ / $B(\gamma\gamma\gamma) < (1–5) \times 10^{-6}$ for $m_{A^0}$ = 900–100 keV which are about 1/10 of the CARBONI 83 limits.

[8] CARBONI 83 looked for orthopositronium $\to A^0\gamma$. Set limit for $A^0$ electron coupling squared, $g(eeA^0)^2/(4\pi) < 6. \times 10^{-10}$–$7. \times 10^{-9}$ for $m_{A^0}$ from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from $g-2$ experiments.

## $A^0$ (Axion) Search in Photoproduction

| | [1] BASSOMPIE... | 95 | $m_{A^0} = 1.8 \pm 0.2$ MeV |

[1] BASSOMPIERRE 95 is an extension of BASSOMPIERRE 93. They looked for a peak in the invariant mass of $e^+e^-$ pairs in the region $m_{e^+e^-} = 1.8 \pm 0.2$ MeV. They obtained bounds on the production rate $A^0$ for $\tau(A^0) = 10^{-18}$–$10^{-9}$ sec. They also found an excess of events in the range $m_{e^+e^-} = 2.1$–$3.5$ MeV.

## $A^0$ (Axion) Production in Hadron Collisions

[1] SIRUNYAN 19BQ look for the pair production of a new light boson decaying into a pair of muons, and set limits on the product of the production cross section times branching fraction to dimuons squared times acceptance over a range of $m_{X^0}$ = 0.25–8.5 GeV. See the right panel of their Fig. 1 for mass-dependent limits.

[2] JAIN 07 claims evidence for $A^0 \to e^+e^-$ produced in $^{207}$Pb collision on nuclear emulsion (Ag/Br) for $m(A^0) = 7 \pm 1$ or $19 \pm 1$ MeV and $\tau(A^0) \leq 10^{-13}$ s.

[3] AHMAD 97 reports a result of APEX Collaboration which studied positron production in $^{238}$U+$^{232}$Ta and $^{238}$U+$^{181}$Ta collisions, without requiring a coincident electron. No narrow lines were found for $250 < E_{e^+} < 750$ keV.

[4] LEINBERGER 97 (ORANGE Collaboration) at GSI looked for a narrow sum-energy $e^+e^-$-line at $\sim$ 635 keV in $^{238}$U+$^{181}$Ta collision. Limits on the production probability for a narrow sum-energy $e^+e^-$ line are set. See their Table 2.

[5] GANZ 96 (EPos II Collaboration) has placed upper bounds on the production cross section of $e^+e^-$ pairs from $^{238}$U+$^{181}$Ta and $^{238}$U+$^{232}$Th collisions at GSI. See Table 2 for limits both for back-to-back and isotropic configurations of $e^+e^-$ pairs. These limits rule out the existence of peaks in the $e^+e^-$ sum-energy distribution, reported by an earlier version of this experiment.

[6] KAMEL 96 looked for $e^+e^-$ pairs from the collision of $^{32}$S (200 GeV/nucleon) and emulsion. No evidence of mass peaks is found in the region of sensitivity $m_{ee} > 2$ MeV.

[7] BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of $e^+e^-$ or $\mu^+\mu^-$ from the produce $A^0$. See Fig. 5 for the excluded region in $m_{A^0}$-$x$ plane. For the standard axion, $0.3 < x < 25$ is excluded at 95% CL. If combined with BLUEMLEIN 91, $0.008 < x < 32$ is excluded.

[8] MEIJERDREES 92 give $\Gamma(\pi^- p \to nA^0)\cdot B(A^0 \to e^+e^-)/\Gamma(\pi^- p \to$ all$) < 10^{-5}$ (90% CL) for $m_{A^0} = 100$ MeV, $\tau_{A^0} = 10^{-11}$–$10^{-23}$ sec. Limits ranging from $2.5 \times 10^{-3}$ to $10^{-7}$ are given for $m_{A^0}$ = 25–136 MeV.

[9] BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for $A^0 \to e^+e^-$, $2\gamma$ are found. Fig. 6 gives the excluded region in $m_{A^0}$-$x$ plane ($x = \tan\beta = v_2/v_1$). Standard axion is excluded for $0.2 < m_{A^0} < 3.2$ MeV for most $x > 1$, 0.2–11 MeV for most $x < 1$.

[10] FAISSNER 89 searched for $A^0 \to e^+e^-$ in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass $2m_e$–20 MeV is excluded. Lower limit on $f_{A^0}$ of $\simeq 10^4$ GeV is given for $m_{A^0} = 2m_e$–20 MeV.

[11] DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass $\sim$ 1.1, $\sim$ 2.1, and $\sim$ 9 MeV, lifetimes $10^{-16}$–$10^{-15}$ s decaying to $e^+e^-$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

# Gauge & Higgs Boson Particle Listings

## Axions ($A^0$) and Other Very Light Bosons

and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A **A22** 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with $\pi^0$ Dalitz decay. DEBOER 89B is a reply which contests the criticism.

[12] EL-NADI 88 claim the existence of a neutral particle decaying into $e^+e^-$ with mass 1.60 ± 0.59 MeV, lifetime $(0.15 \pm 0.01) \times 10^{-14}$ s, which is produced in heavy ion interactions with emulsion nuclei at ∼ 4 GeV/$c$/nucleon.

[13] FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for $A^0 \to \gamma\gamma$. A standard axion decaying to 2$\gamma$ is excluded except for a region $x \simeq 1$. Lower limit on $f_{A^0}$ of $10^2$–$10^3$ GeV is given for $m_{A^0} = 0.1$–1 MeV.

[14] BADIER 86 did not find long-lived $A^0$ in 300 GeV $\pi^-$ Beam Dump Experiment that decays into $e^+e^-$ in the mass range $m_{A^0}$ = (20–200) MeV, which excludes the $A^0$ decay constant $f(A^0)$ in the interval (60–600) GeV. See their figure 6 for excluded region on $f(A^0)$-$m_{A^0}$ plane.

[15] BERGSMA 85 look for $A^0 \to 2\gamma$, $e^+e^-$, $\mu^+\mu^-$. First limit above is for $m_{A^0} = 1$ MeV; second is for 200 MeV. See their figure 4 for excluded region on $f_{A^0}$–$m_{A^0}$ plane, where $f_{A^0}$ is $A^0$ decay constant. For Peccei-Quinn PECCEI 77 $A^0$, $m_{A^0}$ <180 keV and $\tau$ >0.037 s. (CL = 90%). For the axion of FAISSNER 81B at 250 keV, BERGSMA 85 expect 15 events but observe zero.

[16] FAISSNER 83 observed 19 1-$\gamma$ and 12 2-$\gamma$ events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.

[17] FAISSNER 83B extrapolate SIN $\gamma$ signal to LAMPF $\nu$ experimental condition. Resulting 370 $\gamma$'s are not at variance with LAMPF upper limit of 450 $\gamma$'s. Derived from LAMPF limit that $[d\sigma(A^0)/d\omega$ at $90^\circ] m_{A^0}/\tau_{A^0} < 14 \times 10^{-35}$ cm$^2$ sr$^{-1}$ MeV ms$^{-1}$. See comment on FRANK 83B.

[18] FRANK 83B stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-A0 are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450 $\gamma$'s. See comment on FAISSNER 83B.

[19] HOFFMAN 83 set CL = 90% limit $d\sigma/dt\ \mathrm{B}(e^+e^-) < 3.5 \times 10^{-32}$ cm$^2$/GeV$^2$ for 140 $< m_{A^0} <$160 MeV. Limit assumes $\tau(A^0) < 10^{-9}$ s.

[20] FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since 2-$\gamma$ peak rate remarkably decreases if iron wall is set in front of the decay region.

[21] FAISSNER 81 see excess $\mu e$ events. Suggest axion interactions.

[22] FAISSNER 81B is SIN 590 MeV proton beam dump. Observed 14.5 ± 5.0 events of 2$\gamma$ decay of long-lived neutral penetrating particle with $m_{2\gamma} \lesssim 1$ MeV. Axion interpretation with $\eta$-$A^0$ mixing gives $m_{A^0} = 250 \pm 25$ keV, $\tau_{(2\gamma)} = (7.3 \pm 3.7) \times 10^{-3}$ s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83B, FRANK 83B, and BERGSMA 85. Also see in the next subsection ALEKSEEV 82B, CAVAIGNAC 83, and ANANEV 85.

[23] KIM 81 analyzed 8 candidates for $A^0 \to 2\gamma$ obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is $(0.86 \sim 5.6) \times 10^{-3}$ s depending on models. Faissner (private communication), says axion production underestimated and mass overestimated. Correct value around 200 keV.

[24] FAISSNER 80 is SIN beam dump experiment with 590 MeV protons looking for $A^0 \to e^+e^-$ decay. Assuming $A^0/\pi^0 = 5.5 \times 10^{-7}$, obtained decay rate limit 20/($A^0$ mass) MeV/s (CL = 90%), which is about $10^{-7}$ below theory and interpreted as upper limit to $m_{A^0} < 2m_{e^-}$.

[25] JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events $[\sigma(\text{production})\sigma(\text{interaction}) < 7. \times 10^{-68}$ cm$^4$, CL = 90%]. Second limit is from nonobservation of axion decays into 2$\gamma$'s or $e^+e^-$, and for axion mass a few MeV.

[26] SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.

[27] BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either 2$\gamma$ or $e^+e^-$. No signal found. CL = 90% limits for model parameter(s) are given.

[28] COTEUS 79 is a beam dump experiment at BNL.

[29] DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distributions due to energy lost to weakly interacting particles.

[30] BELLOTTI 78 first value comes from search for $A^0 \to e^+e^-$. Second value comes from search for $A^0 \to 2\gamma$, assuming mass $< 2m_{e^-}$. For any mass satisfying this, limit is above value×(mass$^{-4}$). Third value uses data of PL 60B 401 and quotes $\sigma(\text{production})\sigma(\text{interaction}) < 10^{-67}$ cm$^4$.

[31] BOSETTI 78B quotes $\sigma(\text{production})\sigma(\text{interaction}) < 2. \times 10^{-67}$ cm$^4$.

[32] DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.

[33] MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).

[34] VYSOTSKII 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

### $A^0$ (Axion) Searches in Reactor Experiments

| VALUE | | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|---|
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| | | [1] CHANG | 07 | | Primakoff or Compton |
| | | [2] ALTMANN | 95 | CNTR | Reactor; $A^0 \to e^+e^-$ |
| | | [3] KETOV | 86 | SPEC | Reactor, $A^0 \to \gamma\gamma$ |
| | | [4] KOCH | 86 | SPEC | Reactor; $A^0 \to \gamma\gamma$ |
| | | [5] DATAR | 82 | CNTR | Light water reactor |
| | | [6] VUILLEUMIER | 81 | CNTR | Reactor, $A^0 \to 2\gamma$ |

[1] CHANG 07 looked for monochromatic photons from Primakoff or Compton conversion of axions from the Kuo-Sheng reactor due to axion coupling to photon or electron, respectively. The search places model-independent limits on the products $G_{A\gamma\gamma}G_{ANN}$ and $G_{Aee}G_{ANN}$ for $m(A^0)$ less than the MeV range.

[2] ALTMANN 95 looked for $A^0$ decaying into $e^+e^-$ from the Bugey 5 nuclear reactor. They obtain an upper limit on the $A^0$ production rate of $\omega(A^0)/\omega(\gamma) \times \mathrm{B}(A^0 \to e^+e^-) < 10^{-16}$ for $m_{A^0} = 1.5$ MeV at 90% CL. The limit is weaker for heavier $A^0$. In the case of a standard axion, this limit excludes a mass in the range $2m_e < m_{A^0} < 4.8$ MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances $Z^0$ in the ($m_{X^0}$,$f_{X^0}$) plane.

[3] KETOV 86 searched for $A^0$ at the Rovno nuclear power plant. They found an upper limit on the $A^0$ production probability of $0.8\ [100\ \text{keV}/m_{A^0}]^6 \times 10^{-6}$ per fission. In the standard axion model, this corresponds to $m_{A^0}$ >150 keV. Not valid for $m_{A^0} \gtrsim 1$ MeV.

[4] KOCH 86 searched for $A^0 \to \gamma\gamma$ at nuclear power reactor Biblis A. They found an upper limit on the $A^0$ production rate of $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$ (CL=95%). Standard axion with $m_{A^0} = 250$ keV gives $10^{-5}$ for the ratio. Not valid for $m_{A^0}$ >1022 keV.

[5] DATAR 82 looked for $A^0 \to 2\gamma$ in neutron capture ($np \to dA^0$) at Tarapur 500 MW reactor. Sensitive to sum of $I = 0$ and $I = 1$ amplitudes. With ZEHNDER 81 $[(I = 0) - (I = 1)]$ result, assert nonexistence of standard $A^0$.

[6] VUILLEUMIER 81 is at Grenoble reactor. Set limit $m_{A^0}$ <280 keV.

### $A^0$ (Axion) and Other Light Boson ($X^0$) Searches in Nuclear Transitions

Limits are for branching ratio.

[1] DERBIN 02 looked for the axion emission in an M1 transition in $^{125m}$Te decay. They looked for a possible presence of a shifted energy spectrum in gamma rays due to the undetected axion.

[2] DEBOER 97C reanalyzed the existent data on Nuclear M1 transitions and find that a 9 MeV boson decaying into $e^+e^-$ would explain the excess of events with large opening angles. See also DEBOER 01 for follow-up experiments.

[3] TSUNODA 95 looked for axion emission when $^{252}$Cf undergoes a spontaneous fission, with the axion decaying into $e^+e^-$. The bound is for $m_{A^0}$=40 MeV. It improves to $2.5 \times 10^{-5}$ for $m_{A^0}$=200 MeV.

[4] MINOWA 93 studied chain process, $^{139}$Ce $\to$ $^{139}$La* by electron capture and M1 transition of $^{139}$La* to the ground state. It does not assume decay modes of $A^0$. The bound applies for $m_{A^0} < 166$ keV.

[5] HICKS 92 bound is applicable for $\tau_{X^0} < 4 \times 10^{-11}$ sec.

[6] The ASANUMA 90 limit is for the branching fraction of $X^0$ emission per $^{241}$Am $\alpha$ decay and valid for $\tau_{X^0} < 3 \times 10^{-11}$ s.

[7] The DEBOER 90 limit is for the branching ratio $^8$Be* (18.15 MeV, $1^+$) $\to$ $^8$Be$A^0$, $A^0 \to e^+e^-$ for the mass range $m_{A^0}$ = 4–15 MeV.

[8] The BINI 89 limit is for the branching fraction of $^{16}$O*(6.05 MeV, $0^+$) $\to$ $^{16}$O$X^0$, $X^0 \to e^+e^-$ for $m_X$ = 1.5–3.1 MeV. $\tau_{X^0} \lesssim 10^{-11}$ s is assumed. The spin-parity of $X$ is restricted to $0^+$ or $1^-$.

[9] AVIGNONE 88 looked for the 1115 keV transition C* $\to$ Cu$A^0$, either from $A^0 \to 2\gamma$ in-flight decay or from the secondary $A^0$ interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for $m_{A^0} < 1.1$ MeV.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[10] DATAR 88 rule out light pseudoscalar particle emission through its decay $A^0 \to e^+e^-$ in the mass range 1.02–2.5 MeV and lifetime range $10^{-13}$–$10^{-8}$ s. The above limit is for $\tau = 5 \times 10^{-13}$ s and $m = 1.7$ MeV; see the paper for the $\tau$-$m$ dependence of the limit.

[11] The limit is for the branching fraction of $^{16}O^*(6.05\ \text{MeV}, 0^+) \to {}^{16}O X^0$, $X^0 \to e^+e^-$ against internal pair conversion for $m_{X^0} = 1.7$ MeV and $\tau_{X^0} < 10^{-11}$ s. Similar limits are obtained for $m_{X^0} = 1.3$–3.2 MeV. The spin parity of $X^0$ must be either $0^+$ or $1^-$. The limit at 1.7 MeV is translated into a limit for the $X^0$-nucleon coupling constant: $g^2_{X^0 NN}/4\pi < 2.3 \times 10^{-9}$.

[12] The DOEHNER 88 limit is for $m_{A^0} = 1.7$ MeV, $\tau(A^0) < 10^{-10}$ s. Limits less than $10^{-4}$ are obtained for $m_{A^0} = 1.2$–2.2 MeV.

[13] SAVAGE 88 looked for $A^0$ that decays into $e^+e^-$ in the decay of the 9.17 MeV $J^P = 2^+$ state in $^{14}N$, 17.64 MeV state $J^P = 1^+$ in $^8Be$, and the 18.15 MeV state $J^P = 1^+$ in $^8Be$. This experiment constrains the isovector coupling of $A^0$ to hadrons, if $m_{A^0} = (1.1 \to 2.2)$ MeV and the isoscalar coupling of $A^0$ to hadrons, if $m_{A^0} = (1.1 \to 2.6)$ MeV. Both limits are valid only if $\tau(A^0) \lesssim 1 \times 10^{-11}$ s.

[14] Limits are for $\Gamma(A^0(1.8\ \text{MeV}))/\Gamma(\pi\text{M1})$; i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of $e^+e^-$ pairs. Valid for $\tau_{A^0} < 2 \times 10^{-11}$s. $^6$Li isovector decay data strongly disfavor PECCEI 86 model I, whereas the $^{10}$B and $^{14}$N isoscalar decay data strongly reject PECCEI 86 model II and III.

[15] SAVAGE 86B looked for $A^0$ that decays into $e^+e^-$ in the decay of the 9.17 MeV $J^P = 2^+$ state in $^{14}N$. Limit on the branching fraction is valid if $\tau_{A^0} \lesssim 1. \times 10^{-11}$s for $m_{A^0} = (1.1$–$1.7)$ MeV. This experiment constrains the iso-vector coupling of $A^0$ to hadrons.

[16] ANANEV 85 with IBR-2 pulsed reactor exclude standard $A^0$ at CL = 95% masses below 470 keV (Li* decay) and below $2m_e$ for deuteron* decay.

[17] CAVAIGNAC 83 at Bugey reactor exclude axion at any $m_{^{97}\text{Nb}^*\text{decay}}$ and axion with $m_{A^0}$ between 275 and 288 keV (deuteron* decay).

[18] ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard $A^0$ at CL = 95% mass-ranges $m_{A^0}$ <400 keV (Li* decay) and 330 keV $< m_{A^0}$ <2.2 MeV. (deuteron* decay).

[19] LEHMANN 82 obtained $A^0 \to 2\gamma$ rate $< 6.2 \times 10^{-5}$/s (CL = 95%) excluding $m_{A^0}$ between 100 and 1000 keV.

[20] ZEHNDER 82 used Gosgen 2.8GW light-water reactor to check $A^0$ production. No $2\gamma$ peak in Li*, Nb* decay (both single $p$ transition) nor in $n$ capture (combined with previous Ba* negative result) rules out standard $A^0$. Set limit $m_{A^0}$ <60 keV for any $A^0$.

[21] ZEHNDER 81 looked for $Ba^* \to A^0 Ba$ transition with $A^0 \to 2\gamma$. Obtained $2\gamma$ coincidence rate $< 2.2 \times 10^{-5}$/s (CL = 95%) excluding $m_{A^0}$ >160 keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.

[22] CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

## $A^0$ (Axion) Limits from Its Electron Coupling

Limits are for $\tau(A^0 \to e^+e^-)$.

[1] The listed BROSS 91 limit is for $m_{A^0} = 1.14$ MeV. $B(A^0 \to e^+e^-) = 1$ assumed. Excluded domain in the $\tau_{A^0}$–$m_{A^0}$ plane extends up to $m_{A^0} \approx 7$ MeV (see Fig. 5). Combining with electron $g-2$ constraint, axions coupling only to $e^+e^-$ ruled out for $m_{A^0} < 4.8$ MeV (90% CL).

[2] GUO 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with $g-2$ constraint, axions coupling only to $e^+e^-$ are ruled out for $m_{A^0} < 2.7$ MeV (90% CL).

[3] BJORKEN 88 reports limits on axion parameters ($f_A$, $m_A$, $\tau_A$) for $m_{A^0} < 200$ MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic electrons.

[4] BLINOV 88 assume zero spin, $m = 1.8$ MeV and lifetime $< 5 \times 10^{-12}$ s and find $\Gamma(A^0 \to \gamma\gamma)B(A^0 \to e^+e^-) < 2$ eV (CL=90%).

[5] Assumes $A^0\gamma\gamma$ coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for $m_{A^0} < 15$ MeV.

[6] Uses electrons in hadronic showers from an incident 800 GeV proton beam. Limits for $m_{A^0} < 15$ MeV are shown in their figure 3.

[7] $m_{A^0} = 1.8$ MeV assumed. The excluded domain in the $\tau_{A^0}$–$m_{A^0}$ plane extends up to $m_{A^0} \approx 14$ MeV, see their figure 4.

[8] The limits are obtained from their figure 3. Also given is the limit on the $A^0\gamma\gamma$–$A^0e^+e^-$ coupling plane by assuming Primakoff production.

## Search for $A^0$ (Axion) Resonance in Bhabha Scattering

The limit is for $\Gamma(A^0)[B(A^0 \to e^+e^-)]^2$.

| <2500 | 90 | MILLS | 87 | CNTR | $m_{A^0} = 1.8$ MeV |
| | | [10] VONWIMMER.. | 87 | CNTR | |

[1] HALLIN 92 quote limits on lifetime, $8 \times 10^{-14} - 5 \times 10^{-13}$ sec depending on mass, assuming $B(A^0 \to e^+e^-) = 100\%$. They say that TSERTOS 91 overstated their sensitivity by a factor of 3.

[2] HENDERSON 92C exclude axion with lifetime $\tau_{A^0} = 1.4 \times 10^{-12} - 4.0 \times 10^{-10}$ s, assuming $B(A^0 \to e^+e^-) = 100\%$. HENDERSON 92C also exclude a vector boson with $\tau = 1.4 \times 10^{-12} - 6.0 \times 10^{-10}$ s.

[3] WU 92 quote limits on lifetime $> 3.3 \times 10^{-13}$ s assuming $B(A^0 \to e^+e^-) = 100\%$. They say that TSERTOS 89 overestimate the limit by a factor of $\pi/2$. WU 92 also quote a bound for vector boson, $\tau > 8.2 \times 10^{-13}$ s.

[4] WIDMANN 91 bound applies exclusively to the case $B(A^0 \to e^+e^-) = 1$, since the detection efficiency varies substantially as $\Gamma(A^0)_{\text{total}}$ changes. See their Fig. 6.

[5] JUDGE 90 excludes an elastic pseudoscalar $e^+e^-$ resonance for $4.5 \times 10^{-13}$ s $< \tau(A^0) < 7.5 \times 10^{-12}$ s (95% CL) at $m_{A^0} = 1.832$ MeV. Comparable limits can be set for $m_{A^0} = 1.776$–$1.856$ MeV.

[6] See also TSERTOS 88B in references.

[7] The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88B, footnote 3.

[8] VANKLINKEN 88 looked for relatively long-lived resonance ($\tau = 10^{-10}$–$10^{-12}$ s). The sensitivity is not sufficient to exclude such a narrow resonance.

[9] MAIER 87 obtained limits $R\Gamma \lesssim 60$ eV (100 eV) at $m_{A^0} \simeq 1.64$ MeV (1.83 MeV) for energy resolution $\Delta E_{\text{cm}} \simeq 3$ keV, where $R$ is the resonance cross section normalized to that of Bhabha scattering, and $\Gamma = \Gamma^2_{ee}/\Gamma_{\text{total}}$. For a discussion implying that $\Delta E_{\text{cm}} \simeq 10$ keV, see TSERTOS 89.

[10] VONWIMMERSPERG 87 measured Bhabha scattering for $E_{\text{cm}} = 1.37$–$1.86$ MeV and found a possible peak at 1.73 with $\int \sigma dE_{\text{cm}} = 14.5 \pm 6.8$ keV·b. For a comment and a reply, see VANKLINKEN 88B and VONWIMMERSPERG 88. Also see CONNELL 88.

## Search for $A^0$ (Axion) Resonance in $e^+e^- \to \gamma\gamma$

The limit is for $\Gamma(A^0 \to e^+e^-)\cdot\Gamma(A^0 \to \gamma\gamma)/\Gamma_{\text{total}}$

[1] TRZASKA 91 also give limits in the range (6.6–30) $\times 10^{-3}$ eV (95%CL) for $m_{A^0} = 1.6$–$2.0$ MeV.

[2] FOX 89 measured positron annihilation with an electron in the source material into two photons and found no signal at 1.062 MeV ($< 9 \times 10^{-5}$ of two-photon annihilation at rest).

[3] Similar limits are obtained for $m_{A^0} = 1.045$–$1.085$ MeV.

## Search for $X^0$ (Light Boson) Resonance in $e^+e^- \to \gamma\gamma\gamma$

The limit is for $\Gamma(X^0 \to e^+e^-)\cdot\Gamma(X^0 \to \gamma\gamma\gamma)/\Gamma_{\text{total}}$. $C$ invariance forbids spin-0 $X^0$ coupling to both $e^+e^-$ and $\gamma\gamma\gamma$.

# Gauge & Higgs Boson Particle Listings

## Axions ($A^0$) and Other Very Light Bosons

| | | | | | |
|---|---|---|---|---|---|
| < 0.2 | 95 | [1] VO | 94 | CNTR | $m_{X^0}$=1.1–1.9 MeV |
| < 1.0 | 95 | [2] VO | 94 | CNTR | $m_{X^0}$=1.1 MeV |
| < 2.5 | 95 | [2] VO | 94 | CNTR | $m_{X^0}$=1.4 MeV |
| <120 | 95 | [2] VO | 94 | CNTR | $m_{X^0}$=1.7 MeV |
| < 3.8 | 95 | [3] SKALSEY | 92 | CNTR | $m_{X^0}$= 1.5 MeV |

[1] VO 94 looked for $X^0 \to \gamma\gamma\gamma$ decaying at rest. The precise limits depend on $m_{X^0}$. See Fig. 2(b) in paper.
[2] VO 94 looked for $X^0 \to \gamma\gamma\gamma$ decaying in flight.
[3] SKALSEY 92 also give limits 4.3 for $m_{X^0}$ = 1.54 and 7.5 for 1.64 MeV. The spin of $X^0$ is assumed to be one.

### Light Boson ($X^0$) Search in Nonresonant $e^+e^-$ Annihilation at Rest

Limits are for the ratio of $n\gamma + X^0$ production relative to $\gamma\gamma$.

| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| < 4.2 | 90 | [1] MITSUI | 96 | CNTR | $\gamma X^0$ |
| < 4 | 68 | [2] SKALSEY | 95 | CNTR | $\gamma X^0$ |
| <40 | 68 | [3] SKALSEY | 95 | RVUE | $\gamma X^0$ |
| < 0.18 | 90 | [4] ADACHI | 94 | CNTR | $\gamma\gamma X^0$, $X^0 \to \gamma\gamma$ |
| < 0.26 | 90 | [5] ADACHI | 94 | CNTR | $\gamma\gamma X^0$, $X^0 \to \gamma\gamma$ |
| < 0.33 | 90 | [6] ADACHI | 94 | CNTR | $\gamma X^0$, $X^0 \to \gamma\gamma\gamma$ |

[1] MITSUI 96 looked for a monochromatic $\gamma$. The bound applies for a vector $X^0$ with $C$=−1 and $m_{X^0}$ <200 keV. They derive an upper bound on $ee X^0$ coupling and hence on the branching ratio B($o$-Ps $\to \gamma\gamma X^0$)< $6.2\times10^{-6}$. The bounds weaken for heavier $X^0$.
[2] SKALSEY 95 looked for a monochromatic $\gamma$ without an accompanying $\gamma$ in $e^+e^-$ annihilation. The bound applies for scalar and vector $X^0$ with $C=-1$ and $m_{X^0}$ = 100–1000 keV.
[3] SKALSEY 95 reinterpreted the bound on $\gamma A^0$ decay of $o$-Ps by ASAI 91 where 3% of delayed annihilations are not from $^3S_1$ states. The bound applies for scalar and vector $X^0$ with $C=-1$ and $m_{X^0}$ = 0–800 keV.
[4] ADACHI 94 looked for a peak in the $\gamma\gamma$ invariant mass distribution in $\gamma\gamma\gamma\gamma$ production from $e^+e^-$ annihilation. The bound applies for $m_{X^0}$ = 70–800 keV.
[5] ADACHI 94 looked for a peak in the missing-mass mass distribution in $\gamma\gamma$ channel, using $\gamma\gamma\gamma\gamma$ production from $e^+e^-$ annihilation. The bound applies for $m_{X^0}$ <800 keV.
[6] ADACHI 94 looked for a peak in the missing mass distribution in $\gamma\gamma\gamma$ channel, using $\gamma\gamma\gamma\gamma$ production from $e^+e^-$ annihilation. The bound applies for $m_{X^0}$ = 200–900 keV.

### Searches for Goldstone Bosons ($X^0$)

(Including Horizontal Bosons and Majorons.) Limits are for branching ratios.

[1] BAYES 15 limits are the average over $m_{X^0}$ = 13–80 MeV for the isotropic decay distribution of positrons. See their Fig. 4 and Table II for the mass-dependent limits as well as the dependence on the decay anisotropy. In particular, they find a limit $< 58\times10^{-6}$ at 90% CL for massless familons and for the same asymmetry as normal muon decay, a case not covered by JODIDIO 86.
[2] LATTANZI 13 use WMAP 9 year data as well as X-ray and $\gamma$-ray observations to derive limits on decaying majoron dark matter. A limit on the decay width $\Gamma(X^0 \to \nu\overline{\nu}) < 6.4\times10^{-19}$ s$^{-1}$ at 95% CL is found if majorons make up all of the dark matter.
[3] LESSA 07 consider decays of the form Meson $\to \ell\nu$Majoron and $\ell \to \ell'\nu\overline{\nu}$Majoron and use existing data to derive limits on the neutrino-Majoron Yukawa couplings $g_{\alpha\beta}$ ($\alpha,\beta$=$e,\mu,\tau$). Their best limits are $|g_{e\alpha}|^2 < 5.5\times10^{-6}$, $|g_{\mu\alpha}|^2 < 4.5\times10^{-5}$, $|g_{\tau\alpha}|^2 < 5.5\times10^{-2}$ at CL = 90%.
[4] DIAZ 98 studied models of spontaneously broken lepton number with both singlet and triplet Higgses. They obtain limits on the parameter space from invisible decay $Z \to H^0A^0 \to X^0X^0X^0X^0$ and $e^+e^- \to ZH^0$ with $H^0 \to X^0X^0$.
[5] BOBRAKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (arion). A limit $x_e^2 < 2\times10^{-4}$ (95%CL) is found for the effective anomalous magneton parametrized as $x_e(G_F/8\pi\sqrt{2})^{1/2}$.
[6] ALBRECHT 90E limits are for B($\tau \to \ell X^0$)/B($\tau \to \ell\nu\overline{\nu}$). Valid for $m_{X^0} < 100$ MeV. The limits rise to 7.1% (for $\mu$), 5.0% (for $e$) for $m_{X^0}$ = 500 MeV.
[7] ATIYA 90 limit is for $m_{X^0}$ = 0. The limit B $< 1\times10^{-8}$ holds for $m_{X^0} < 95$ MeV. For the reduction of the limit due to finite lifetime of $X^0$, see their Fig. 3.
[8] BALKE 88 limits are for B($\mu^+ \to e^+X^0$). Valid for $m_{X^0} < 80$ MeV and $\tau_{X^0} > 10^{-8}$ sec.
[9] BOLTON 88 limit corresponds to $F > 3.1\times10^9$ GeV, which does not depend on the chirality property of the coupling.
[10] CHANDA 88 find $v_T < 10$ MeV for the weak-triplet Higgs vacuum expectation value in Gelmini-Roncadelli model, and $v_S > 5.8\times10^6$ GeV in the singlet Majoron model.
[11] CHOI 88 used the observed neutrino flux from the supernova SN1987A to exclude the neutrino Majoron Yukawa coupling $h$ in the range $2\times10^{-5} < h < 3\times10^{-4}$ for the interaction $L_{\rm int} = \frac{1}{2}ih\overline{\psi}^c_\nu\gamma_5\psi_\nu\phi_X$. For several families of neutrinos, the limit applies for $(\Sigma h_i^4)^{1/4}$.
[12] PICCIOTTO 88 limit applies when $m_{X^0} < 55$ MeV and $\tau_{X^0} > 2$ns, and it decreases to $4\times10^{-7}$ at $m_{X^0}$ = 125 MeV, beyond which no limit is obtained.
[13] GOLDMAN 87 limit corresponds to $F > 2.9\times10^9$ GeV for the family symmetry breaking scale from the Lagrangian $L_{\rm int} = (1/F)\overline{\psi}_\mu\gamma^\mu(a+b\gamma_5)\psi_e\partial_\mu\phi_{X^0}$ with $a^2+b^2=1$. This is not as sensitive as the limit $F > 9.9\times10^9$ GeV derived from the search for $\mu^+ \to e^+X^0$ by JODIDIO 86, but does not depend on the chirality property of the coupling.
[14] Limits are for $\Gamma(\mu \to eX^0)/\Gamma(\mu \to e\nu\overline{\nu})$. Valid when $m_{X^0}$ = 0–93.4, 98.1–103.5 MeV.
[15] EICHLER 86 looked for $\mu^+ \to e^+X^0$ followed by $X^0 \to e^+e^-$. Limits on the branching fraction depend on the mass and and lifetime of $X^0$. The quoted limits are valid when $\tau_{X^0} \lesssim 3.\times10^{-10}$ s if the decays are kinematically allowed.
[16] JODIDIO 86 corresponds to $F > 9.9\times10^9$ GeV for the family symmetry breaking scale with the parity-conserving effective Lagrangian $L_{\rm int} = (1/F)\overline{\psi}_\mu\gamma^\mu\psi_e\partial^\mu\phi_{X^0}$.
[17] BALTRUSAITIS 85 search for light Goldstone boson($X^0$) of broken U(1). CL = 95% limits are B($\tau \to \mu^+X^0$)/B($\tau \to \mu^+\nu\nu$) <0.125 and B($\tau \to e^+X^0$)/B($\tau \to e^+\nu\nu$) <0.04. Inferred limit for the symmetry breaking scale is $m$ >3000 TeV.
[18] The primordial heavy neutrino must decay into $\nu$ and familon, $f_A$, early so that the red-shifted decay products are below critical density, see their table. In addition, $K \to \pi f_A$ and $\mu \to e f_A$ are unseen. Combining these excludes $m_{{\rm heavy}\nu}$ between $5\times10^{-5}$ and $5\times10^{-4}$ MeV ($\mu$ decay) and $m_{{\rm heavy}\nu}$ between $5\times10^{-5}$ and 0.1 MeV ($K$-decay).

### Majoron Searches in Neutrinoless Double $\beta$ Decay

Limits are for the half-life of neutrinoless $\beta\beta$ decay with a Majoron emission. No experiment currently claims any such evidence. Only the best or comparable limits for each isotope are reported.

[1] BERNATOWICZ 92 studied double-$\beta$ decays of $^{128}$Te and $^{130}$Te, and found the ratio $\tau(^{130}\text{Te})/\tau(^{128}\text{Te}) = (3.52\pm0.11)\times10^{-4}$ in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of $^{128}$Te of $(7.7\pm0.4)\times10^{24}$ year. We calculated 90% CL limit as $(7.7–1.28\times0.4=7.2)\times10^{24}$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[2] ARNOLD 19 uses the NEMO-3 tracking calorimeter to determine limits for the Majoron emitting double beta decay, with spectral index n = 3. The limit corresponds to the range of the $g_{ee}$ coupling of 0.013–0.035; dependimg on the nuclear matrix elements used.

[3] ARNOLD 18 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{ee} \rangle <$ 3.2–8.0 $\times 10^{-5}$; the range corresponds to different nuclear matrix element calculations.

[4] AGOSTINI 15A analyze a 20.3 kg yr of data set of the GERDA calorimeter to determine $g_{\nu\chi} <$ 3.4–8.7 $\times 10^{-5}$ on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.

[5] ARNOLD 15 use the NEMO-3 tracking calorimeter with 3.43 kg yr exposure to determine the limit on Majoron emission. The limit corresponds to $g_{\nu\chi} <$ 1.6–3.0 $\times 10^{-4}$. The spread reflects different nuclear matrix elements. Supersedes ARNOLD 06.

[6] ALBERT 14A utilize 100 kg yr of exposure of the EXO-200 tracking calorimeter to place a limit on the $g_{\nu\chi} <$ 0.8–1.7 $\times 10^{-5}$ on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.

[7] GANDO 12 use the KamLAND-Zen detector to obtain the limit on the $0\nu\chi$ decay with Majoron emission. It implies that the coupling constant $g_{\nu\chi} <$ 0.8–1.6 $\times 10^{-5}$ depending on the nuclear matrix elements used.

[8] ARNOLD 11 use the NEMO-3 detector to obtain the reported limit on Majoron emission. It implies that the coupling constant $g_{\nu\chi} <$ 0.6–1.6 $\times 10^{-4}$ depending on the nuclear matrix element used. Supercedes ARNABOLDI 03.

[9] ARGYRIADES 10 use the NEMO-3 tracking detector and $^{96}$Zr to derive the reported limit. No limit for the Majoron electron coupling is given.

[10] ARGYRIADES 09 use $^{150}$Nd data taken with the NEMO-3 tracking detector. The reported limit corresponds to $\langle g_{\nu\chi} \rangle <$ 1.7–3.0 $\times 10^{-4}$ using a range of nuclear matrix elements that include the effect of nuclear deformation.

[11] ARNOLD 06 use $^{100}$Mo data taken with the NEMO-3 tracking detector. The reported limit corresponds to $\langle g_{\nu\chi} \rangle <$ (0.4–1.8) $\times 10^{-4}$ using a range of matrix element calculations. Superseded by ARNOLD 15.

[12] NEMO-3 tracking calorimeter is used in ARNOLD 06 . Reported half-life limit for $^{82}$Se corresponds to $\langle g_{\nu\chi} \rangle <$ (0.66–1.9) $\times 10^{-4}$ using a range of matrix element calculations. Supersedes ARNOLD 04.

[13] ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{\nu\chi} \rangle <$ (0.5–0.9)$10^{-4}$ using the matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03. Superseded by ARNOLD 06.

[14] ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{\nu\chi} \rangle <$ (0.7–1.6)$10^{-4}$ using the matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03.

[15] Supersedes ALESSANDRELLO 00. Array of $TeO_2$ crystals in high resolution cryogenic calorimeter. Some enriched in $^{130}$Te. Derive $\langle g_{\nu\chi} \rangle <$ 17–33 $\times 10^{-5}$ depending on matrix element.

[16] Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search.

[17] Limit for the $0\nu\chi$ decay with Majoron emission of $^{116}$Cd using enriched $CdWO_4$ scintillators. $\langle g_{\nu\chi} \rangle <$ 4.6–8.1 $\times 10^{-5}$ depending on the matrix element. Supersedes DANEVICH 00.

[18] Limit for the $0\nu2\chi$ decay of $^{116}$Cd. Supersedes DANEVICH 00.

[19] BERNABEI 02D obtain limit for $0\nu\chi$ decay with Majoron emission of $^{136}$Xe using liquid Xe scintillation detector. They derive $\langle g_{\nu\chi} \rangle <$ 2.0–3.0 $\times 10^{-5}$ with several nuclear matrix elements.

[20] Replaces TANAKA 93. FUSHIMI 02 derive half-life limit for the $0\nu\chi$ decay by means of tracking calorimeter ELEGANT V. Considering various matrix element calculations, a range of limits for the Majoron-neutrino coupling is given: $\langle g_{\nu\chi} \rangle <$(6.3–360) $\times 10^{-5}$.

[21] ASHITKOV 01 result for $0\nu\chi$ of $^{100}$Mo is less stringent than ARNOLD 00.

[22] DANEVICH 01 obtain limit for the $0\nu\chi$ decay with Majoron emission of $^{160}$Gd using $Gd_2SiO_5$:Ce crystal scintillators.

[23] DANEVICH 01 obtain limit for the $0\nu2\chi$ decay with 2 Majoron emission of $^{160}$Gd.

[24] ARNOLD 00 reports limit for the $0\nu\chi$ decay with Majoron emission derived from tracking calorimeter NEMO 2. Using $^{82}$Se source: $\langle g_{\nu\chi} \rangle < 1.6 \times 10^{-4}$. Matrix element from GUENTHER 96.

[25] Using $^{96}$Zr source: $\langle g_{\nu\chi} \rangle < 2.6 \times 10^{-4}$. Matrix element from ARNOLD 99.

[26] ARNOLD 00 reports limit for the $0\nu2\chi$ decay with two Majoron emission derived from tracking calorimeter NEMO 2.

[27] ARNOLD 98 determine the limit for $0\nu_\chi$ decay with Majoron emission of $^{82}$Se using the NEMO-2 tracking detector. They derive $\langle g_{\nu_\chi} \rangle <$ 2.3–4.3 $\times 10^{-4}$ with several nuclear matrix elements.

[28] LUESCHER 98 report a limit for the $0\nu$ decay with Majoron emission of $^{136}$Xe using Xe TPC. This result is more stringent than BARABASH 89. Using the matrix elements of ENGEL 88, they obtain a limit on $\langle g_{\nu\chi} \rangle$ of 2.0 $\times 10^{-4}$.

[29] See Table 1 in GUENTHER 96 for limits on the Majoron coupling in different models.

## Invisible $A^0$ (Axion) MASS LIMITS from Astrophysics and Cosmology

$v_1 = v_2$ is usually assumed ($v_i$ = vacuum expectation values). For a review of these limits, see RAFFELT 91 and TURNER 90. In the comment lines below, D and K refer to DFSZ and KSVZ axion types, discussed in the above minireview.

[1] PALOMBA 19 used the LIGO O2 dataset to derive limits on nearly monochromatic gravitational waves emitted by boson clouds formed around a stellar-mass black hole. They exclude boson masses in a range of $1.1 \times 10^{-13}$ and $4 \times 10^{-13}$ eV for high initial black hole spin, and $1.2 \times 10^{-13}$ and $1.8 \times 10^{-13}$ eV for moderate spin. See their Figs. 2 and 3 for limits based on various values of black hole initial spin, boson cloud age, and distance.

[2] CHANG 18 update axion bremsstrahlung emission rates in nucleon-nucleon collisions, shifting the excluded mass range to higher values. They rule out the hadronic axion with mass up to a few hundred eV, closing the hadronic axion window. See their Fig. 11 for results based on several different choices of the temperature and density profile of the proto-neutron star.

[3] ARCHIDIACONO 13A is analogous to HANNESTAD 05A. The limit is based on the CMB temperature power spectrum of the Planck data, the CMB polarization from the WMAP 9-yr data, the matter power spectrum from SDSS-DR7, and the local Hubble parameter measurement by the Carnegie Hubble program.

[4] CADAMURO 11 use the deuterium abundance to show that the $m_{A^0}$ range 0.7eV – 300 keV is excluded for axions, complementing HANNESTAD 10.

[5] DERBIN 11A look for solar axions produced by Compton and bremsstrahlung processes, in the resonant excitation of $^{169}$Tm, constraining the axion-electron × axion nucleon couplings.

[6] ANDRIAMONJE 10 search for solar axions produced from $^7$Li (478 keV) and D$(p,\gamma)^3$He (5.5 MeV) nuclear transitions. They show limits on the axion-photon coupling for two reference values of the axion-nucleon coupling for $m_A < 100$ eV.

[7] This is an update of HANNESTAD 08 including 7 years of WMAP data.

[8] ANDRIAMONJE 09 look for solar axions produced from the thermally excited 14.4 keV level of $^{57}$Fe. They show limits on the axion-nucleon × axion-photon coupling assuming $m_A < 0.03$ eV.

[9] DERBIN 09A look for Primakoff-produced solar axions in the resonant excitation of $^{169}$Tm, constraining the axion-photon × axion-nucleon couplings.

[10] KEKEZ 09 look at axio-electric effect of solar axions in HPGe detectors. The one-loop axion-electron coupling for hadronic axions is used.

[11] This is an update of HANNESTAD 07 including 5 years of WMAP data.

[12] This is an update of HANNESTAD 05A with new cosmological data, notably WMAP (3 years) and baryon acoustic oscillations (BAO). Lyman-$\alpha$ data are left out, in contrast to HANNESTAD 05A and MELCHIORRI 07A, because it is argued that systematic errors are large. It uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component.

[13] MELCHIORRI 07A is analogous to HANNESTAD 05A, with updated cosmological data, notably WMAP (3 years). Uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component. Leaving out Lyman-$\alpha$ data, a conservative limit is 1.4 eV.

[14] HANNESTAD 05A puts an upper limit on the mass of hadronic axion because in this mass range it would have been thermalized and contribute to the hot dark matter component of the universe. The limit is based on the CMB anisotropy from WMAP, SDSS large

# Gauge & Higgs Boson Particle Listings

## Axions ($A^0$) and Other Very Light Bosons

scale structure, Lyman $\alpha$, and the prior Hubble parameter from HST Key Project. A $\chi^2$ statistic is used. Neutrinos are assumed not to contribute to hot dark matter.

[15] MOROI 98 points out that a KSVZ axion of this mass range (see CHANG 93) can be a viable hot dark matter of Universe, as long as the model-dependent $g_{A\gamma}$ is accidentally small enough as originally emphasized by KAPLAN 85; see Fig. 1.

[16] BORISOV 97 bound is on the axion-electron coupling $g_{ae} < 1\times10^{-13}$ from the photo-production of axions off of magnetic fields in the outer layers of neutron stars.

[17] KACHELRIESS 97 bound is on the axion-electron coupling $g_{ae} < 1\times10^{-10}$ from the production of axions in strongly magnetized neutron stars. The authors also quote a stronger limit, $g_{ae} < 9\times10^{-13}$ which is strongly dependent on the strength of the magnetic field in white dwarfs.

[18] KEIL 97 uses new measurements of the axial-vector coupling strength of nucleons, as well as a reanalysis of many-body effects and pion-emission processes in the core of the neutron star, to update limits on the invisible-axion mass.

[19] RAFFELT 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red giant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).

[20] ALTHERR 94 bound is on the axion-electron coupling $g_{ae} < 1.5\times10^{-13}$, from energy loss via axion emission.

[21] CHANG 93 updates ENGEL 90 bound with the Kaplan-Manohar ambiguity in $z=m_u/m_d$ (see the Note on the Quark Masses in the Quark Particle Listings). It leaves the window $f_A=3\times10^5$–$3\times10^6$ GeV open. The constraint from Big-Bang Nucleosynthesis is satisfied in this window as well.

[22] BERSHADY 91 searched for a line at wave length from 3100–8300 Å expected from $2\gamma$ decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.

[23] KIM 91C argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an *upperbound* rather than a lowerbound.

[24] RAFFELT 91B argue that previous SN 1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.

[25] RESSELL 91 uses absence of any intracluster line emission to set limit.

[26] ENGEL 90 rule out $10^{-10} \lesssim g_{AN} \lesssim 10^{-3}$, which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to $2.5\times10^{-3}$ eV $\lesssim m_{A^0} \lesssim 2.5\times10^4$ eV. The constraint is loose in the middle of the range, i.e. for $g_{AN} \sim 10^{-6}$.

[27] RAFFELT 90D is a re-analysis of DEARBORN 86.

[28] The region $m_{A^0} \gtrsim 2$ eV is also allowed.

[29] ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.

[30] MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2–4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 88B.

[31] RAFFELT 88B derives a limit for the energy generation rate by exotic processes in helium-burning stars $\epsilon < 100$ erg g$^{-1}$ s$^{-1}$, which gives a firmer basis for the axion limits based on red giant cooling.

[32] RAFFELT 87 also gives a limit $g_{A\gamma} < 1\times10^{-10}$ GeV$^{-1}$.

[33] DEARBORN 86 also gives a limit $g_{A\gamma} < 1.4\times10^{-11}$ GeV$^{-1}$.

[34] RAFFELT 86 gives a limit $g_{A\gamma} < 1.1\times10^{-10}$ GeV$^{-1}$ from red giants and $< 2.4\times10^{-9}$ GeV$^{-1}$ from the sun.

[35] KAPLAN 85 says $m_{A^0} < 23$ eV is allowed for a special choice of model parameters.

[36] FUKUGITA 82 gives a limit $g_{A\gamma} < 2.3\times10^{-10}$ GeV$^{-1}$.

### Search for Relic Invisible Axions

Limits are for $[G_{A\gamma\gamma}/m_{A^0}]^2\rho_A$ where $G_{A\gamma\gamma}$ denotes the axion two-photon coupling, $L_{\rm int} = -\frac{G_{A\gamma\gamma}}{4}\phi_A F_{\mu\nu}\tilde{F}^{\mu\nu} = G_{A\gamma\gamma}\phi_A \mathbf{E}\cdot\mathbf{B}$, and $\rho_A$ is the axion energy density near the earth.

[1] ALESINI 19 used a superconducting resonant cavity made of NbTi to increase the quality factor. The limit applies to a mass range of 0.2 neV around $m_{A^0} = 37.5$ $\mu$eV.

[2] FUJITA 19 look for photon birefringence under the oscillating axion background using the polarimetric imaging observation of a protoplanetary disk, AB Aur. See their Fig. 2 for a more conservative limit taking account of possible systematic effects.

[3] OUELLET 19A look for the axion-induced oscillating magnetic field generated by a toroidal magnetic field. The quoted limit applies at $m_{A^0} = 8$ neV. See their Fig. 3 for the mass-dependent limits.

[4] BOUTAN 18 use a small high frequency cavity installed above the main ADMX cavity to look for heavier axion dark matter. See their Fig. 4 for mass-dependent limits.

[5] DU 18 is analogous to DUFFY 06. They upgraded a dilution refrigerator to reduce the system noise. The quoted limit is around $m_{A^0} = 2.69$ $\mu$eV for the boosted Maxwellian axion line shape. See Fig. 4 for their mass-dependent limits.

[6] ZHONG 18 is analogous to BRUBAKER 17. The quoted limit applies at $m_{A^0} = 23.76$ $\mu$eV. See Fig. 4 for their mass-dependent limits.

[7] BRANCA 17 look for modulations of the fine-structure constant and the electron mass due to moduli dark matter by using the cryogenic resonant-mass AURIGA detector. The limit on the assumed dilatonic coupling implies $G_{S\gamma\gamma} < 1.5\times10^{-24}$ GeV$^{-1}$ for the scalar to two-photon coupling. See Fig. 5 for the mass-dependent limits.

[8] BRUBAKER 17 used a microwave cavity detector at the Yale Wright Laboratory to search for dark matter axions. See Fig. 3 for the mass-dependent limits.

[9] CHOI 17 used a microwave cavity detector with toroidal geometry. See Fig. 4 for their mass-dependent limits.

[10] HOSKINS 16 is analogous to DUFFY 06. See Fig. 12 for mass-dependent limits in terms of the local dark matter density.

[11] BECK 13 argues that dark-matter axions passing through Earth may generate a small observable signal in resonant S/N/S Josephson junctions. A measurement by HOFFMANN 04 [Physical Review **B70** 180503 (2004)] is interpreted in terms of subdominant dark matter axions with $m_{A^0} = 0.11$ meV.

[12] HOSKINS 11 is analogous to DUFFY 06. See Fig. 4 for the mass-dependent limit in terms of the local density.

[13] ASZTALOS 10 used the upgraded detector of ASZTALOS 04 to search for halo axions. See their Fig. 5 for the $m_{A^0}$ dependence of the limit.

[14] DUFFY 06 used the upgraded detector of ASZTALOS 04, while assuming a smaller velocity dispersion than the isothermal model as in Eq. (8) of their paper. See Fig. 10 of their paper on the axion mass dependence of the limit.

[15] ASZTALOS 04 looked for a conversion of halo axions to microwave photons in magnetic field. At 90% CL, the KSVZ axion cannot have a local halo density more than 0.45 GeV/cm$^3$ in the quoted mass range. See Fig. 7 of their paper on the axion mass dependence of the limit.

[16] KIM 98 calculated the axion-to-photon couplings for various axion models and compared them to the HAGMANN 90 bounds. This analysis demonstrates a strong model dependence of $G_{A\gamma\gamma}$ and hence the bound from relic axion search.

[17] HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.

[18] WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagnetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with $[G_{A\gamma\gamma}/m_{A^0}]^2 = 2\times10^{-14}$ MeV$^{-4}$ (the three generation DFSZ model) and $\rho_A = 300$ MeV/cm$^3$ that makes up galactic halos gives $(G_{A\gamma\gamma}/m_{A^0})^2\,\rho_A = 4\times10^{-44}$. Note that our definition of $G_{A\gamma\gamma}$ is $(1/4\pi)$ smaller than that of WUENSCH 89.

### Invisible $A^0$ (Axion) Limits from Photon Coupling

Limits are for the modulus of the axion-two-photon coupling $G_{A\gamma\gamma}$ defined by $L = -G_{A\gamma\gamma}\phi_A \mathbf{E}\cdot\mathbf{B}$. For scalars $S^0$ the limit is on the coupling constant in $L = G_{S\gamma\gamma}\phi_S(\mathbf{E}^2-\mathbf{B}^2)$. The relation between $G_{A\gamma\gamma}$ and $m_{A^0}$ is not used unless stated otherwise, i.e., many of these bounds apply to low-mass axion-like particles (ALPs), not to QCD axions.

[1] ALONI 19 used the data collected by the PRIMEX experiment to derive a limit based on a data-driven method. See their Fig. 2 for mass-dependent limits.

[2] CAPUTO 19 look for an oscillating variation of the polarization angle of the pulsar J0437-4715, where they assume the local axion energy density $\rho_A=0.3$ GeV/cm$^3$. See their Fig. 2 for mass-dependent limits for $5\times10^{-24}$ eV $\leq m_{A^0}\leq 2\times10^{-19}$ eV.

[3] FEDDERKE 19 look for a uniform reduction of the CMB polarization at large scales, which is induced by the oscillating axion background during CMB decoupling. The quoted limit is based on the assumption that axions make up all of the dark matter. See their Fig. 3 for mass-dependent limits for $m_{A^0}=10^{-22}$–$10^{-19}$ eV.

[4] IVANOV 19 look for the axion-induced periodic changes in the polarization angle of parsec-scale jets in active galactic nuclei observed by the MOJAVE program, where they use the axion energy density $\rho_A=20$ GeV/cm$^3$. See their Fig. 6 for mass-dependent limits for $5\times10^{-23}$ eV $\leq m_{A^0}\leq 1.2\times10^{-21}$ eV.

[5] LIANG 19 look for spectral irregularities in the spectrum of 10 bright H.E.S.S. sources in the Galactic plane, assuming photon-ALP mixing in the Galactic magnetic fields. See their Fig. 2 for mass-dependent limits with different Galactic magnetic field models.

[6] FORTIN 18 studied the conversion of axion-like particles produced in the core of a magnetar to hard X-rays in the magnetosphere. See their Fig. 5 for mass-dependent limits with different values of the magnetar core temperature.

[7] YAMAJI 18 search for axions with an x-ray LSW at Spring-8, using the Laue-case conversion in a silicon crystal. They also obtain $G_{A\gamma\gamma}<4.2\times10^{-3}$ GeV$^{-1}$ for $m_{A^0}<10$ eV. See their Fig. 5 for mass-dependent limits.

[8] ZHANG 18 look for spectral irregularities in the spectrum of PKS 2155-304 measured by Fermi LAT, assuming photon-ALP mixing in the intercluster and Galactic magnetic fields. See their Figs. 2 and 3 for mass-dependent limits with different values of the intercluster magnetic field parameters.

[9] ADE 17 look for cosmic birefringence from axion-like particles using CMB polarization data taken by the BICEP2 and Keck Array experiments. They set a limit $G_{A\gamma\gamma}H_I<7.2\times10^{-2}$ at 95 %CL for $m_{A^0}<10^{-28}$ eV, where $H_I$ is the Hubble parameter during inflation.

[10] ANASTASSOPOULOS 17 looked for solar axions by the CAST axion helioscope in the vacuum phase, and supersedes ANDRIAMONJE 07.

[11] DOLAN 17 update existing limits on $G_{A\gamma\gamma}$ for axion-like particles. See their Fig. 2 for mass-dependent limits.

[12] INADA 17 search for axions with an x-ray LSW at Spring-8. See their Fig. 4 for mass-dependent limits.

[13] KOHRI 17 attributed to axion-photon oscillations the excess of cosmic infrared background observed by the CIBER experiment. See their Fig. 5 for the region preferred by their scenario.

[14] MARSH 17 is similar to WOUTERS 13, using Chandra observations of M87. See their Fig. 6 for mass-dependent limits.

[15] TIWARI 17 use observed limits of the cosmic distance-duality relation to constrain the photon-ALP mixing based on 3D simulations of the magnetic field configuration. The quoted value is for the averaged magnetic field of 1nG with a coherent length of 1 Mpc. See their Fig. 5 for mass-dependent limits.

[16] AJELLO 16 look for irregularities in the energy spectrum of the NGC1275 measured by Fermi LAT, assuming photon-ALP mixing in the intra-cluster and Galactic magnetic felds. See their Fig. 2 for mass-dependent limits.

[17] DELLA-VALLE 16 look for the birefringence induced by axion-like particles. See their Fig. 14 for mass-dependent limits.

[18] DELLA-VALLE 16 look for the dichroism induced by axion-like particles. See their Fig. 14 for mass-dependent limits.

[19] JAECKEL 16 use the LEP data of $Z\to2\gamma$ and $Z\to3\gamma$ to constrain the ALP production via $e^+e^-\to Z\to A^0\gamma$ ($A^0\to\gamma\gamma$), assuming the ALP coupling with two hypercharge bosons. See their Fig. 4 for mass-dependent limits.

[20] LEEFER 16 derived limits by using radio-frequency spectroscopy of dysprosium and atomic clock measurements. See their Fig. 1 for mass-dependent limits as well as limits on Yukawa-type couplings of the scalar to the electron and nucleons.

[21] ANASTASSOPOULOS 15 search for solar chameleons with CAST and derived limits on the chameleon coupling to photons and matter. See their Fig. 12 for the exclusion region.

[22] ARIK 15 is analogous to ARIK 09, and search for solar axions for $m_{A^0}$ around 0.2 and 0.4 eV. See their Figs. 1 and 3 for the mass-dependent limits.

[23] Based on OSQAR photon regeneration experiment. See their Fig. 6 for mass-dependent limits on scalar and pseudoscalar bosons.

[24] BRAX 15 derived limits on conformal and disformal couplings of a scalar to photons by searching for a chaotic absorption pattern in the X-ray and UV bands of the Hydra A galaxy cluster and a BL lac object, respectively. See their Fig. 8.

[25] HASEBE 15 look for an axion via a four-wave mixing process at quasi-parallel colliding laser beams. They also derived limits on a scalar coupling to photons $G_{S\gamma\gamma}<2.62\times10^{-4}$ GeV$^{-1}$ at $m_{S^0}=0.15$ eV. See their Figs. 11 and 12 for mass-dependent limits.

[26] MILLEA 15 is similar to CADAMURO 12, including the Planck data and the latest inferences of primordial deuterium abundance. See their Fig. 3 for mass-dependent limits.

[27] VANTILBURG 15 look for harmonic variations in the dyprosium transition frequency data, induced by coherent oscillations of the fine-structure constant due to dilaton-like dark matter, and set the limits, $G_{S\gamma\gamma}<6\times10^{-27}$ GeV$^{-1}$ at $m_{S^0}=6\times10^{-23}$ eV. See their Fig. 4 for mass-dependent limits between $1\times10^{-24}<m_{S^0}<1\times10^{-15}$ eV.

[28] VINYOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations. See their Fig. 9.

[29] ARIK 14 is similar to ARIK 11. See their Fig. 2 for mass-dependent limits.

[30] AYALA 14 derived the limit from the helium-burning lifetime of horizontal-branch stars based on number counts in globular clusters.

[31] DELLA-VALLE 14 use the new PVLAS apparatus to set a limit on vacuum magnetic birefringence induced by axion-like particles. See their Fig. 6 for the mass-dependent limits.

[32] EJLLI 14 set limits on a product of primordial magnetic field and the axion mass using CMB distortion induced by resonant axion production from CMB photons. See their Fig. 1 for limits applying specifically to the DFSZ and KSVZ axion models.

[33] PUGNAT 14 is analogous to EHRET 10. See their Fig. 5 for mass-dependent limits on scalar and pseudoscalar bosons.

[34] REESMAN 14 derive limits by requiring effects of axion-photon interconversion on gamma-ray spectra from distant blazars to be no larger than errors in the best-fit optical depth based on a certain extragalactic background light model. See their Fig. 5 for mass-dependent limits.

[35] ABRAMOWSKI 13A look for irregularities in the energy spectrum of the BL Lac object PKS 2155–304 measured by H.E.S.S. The limits depend on assumed magnetic field around the source. See their Fig. 7 for mass-dependent limits.

[36] ARMENGAUD 13 is analogous to AVIGNONE 98. See Fig. 6 for the limit.

[37] BETZ 13 performed a microwave-based light shining through the wall experiment. See their Fig. 13 for mass-dependent limits.

[38] FRIEDLAND 13 derived the limit by considering blue-loop suppression of the evolution of red giants with 7–12 solar masses.

[39] MEYER 13 attributed to axion-photon oscillations the observed excess of very high-energy $\gamma$-rays with respect to predictions based on extragalactic background light models. See their Fig.4 for mass-dependent lower limits for various magnetic field configurations.

[40] WOUTERS 13 look for irregularities in the X-ray spectrum of the Hydra cluster observed by Chandra. See their Fig. 4 for mass-dependent limits.

[41] CADAMURO 12 derived cosmological limits on $G_{A\gamma\gamma}$ for axion-like particles. See their Fig. 1 for mass-dependent limits.

[42] PAYEZ 12 derive limits from polarization measurements of quasar light (see their Fig. 3). The limits depend on assumed magnetic field strength in galaxy clusters. The limits depend on assumed magnetic field and electron density in the local galaxy supercluster.

[43] ARIK 11 search for solar axions using $^3$He buffer gas in CAST, continuing from the $^4$He version of ARIK 09. See Fig. 2 for the exact mass-dependent limits.

[44] ALPS is a photon regeneration experiment. See their Fig. 4 for mass-dependent limits on scalar and pseudoscalar bosons.

[45] AHMED 09A is analogous to AVIGNONE 98.

[46] ARIK 09 is the $^4$He filling version of the CAST axion helioscope in analogy to INOUE 02 and INOUE 08. See their Fig. 7 for mass-dependent limits.

[47] CHOU 09 use the GammeV apparatus in the afterglow mode to search for chameleons, (pseudo)scalar bosons with a mass depending on the environment. For pseudoscalars they exclude at $3\sigma$ the range $2.6\times10^{-7}$ GeV$^{-1}<G_{A\gamma\gamma}<4.2\times10^{-6}$ GeV$^{-1}$ for vacuum $m_{A^0}$ roughly below 6 meV for density scaling index exceeding 0.8.

# Gauge & Higgs Boson Particle Listings

## Axions ($A^0$) and Other Very Light Bosons

[48] GONDOLO 09 use the all-flavor measured solar neutrino flux to constrain solar interior temperature and thus energy losses.
[49] LIPSS photon regeneration experiment, assuming scalar particle $S^0$. See Fig. 4 for mass-dependent limits.
[50] CHOU 08 perform a variable-baseline photon regeneration experiment. See their Fig. 3 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06.
[51] FOUCHE 08 is an update of ROBILLIARD 07. See their Fig. 12 for mass-dependent limits.
[52] INOUE 08 is an extension of INOUE 02 to larger axion masses, using the Tokyo axion helioscope. See their Fig. 4 for mass-dependent limits.
[53] ZAVATTINI 08 is an upgrade of ZAVATTINI 06, see their Fig. 8 for mass-dependent limits. They now exclude the parameter range where ZAVATTINI 06 had seen a positive signature.
[54] ANDRIAMONJE 07 looked for Primakoff conversion of solar axions in 9T superconducting magnet into X-rays. Supersedes ZIOUTAS 05.
[55] ROBILLIARD 07 perform a photon regeneration experiment with a pulsed laser and pulsed magnetic field. See their Fig. 4 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06 with a CL exceeding 99.9%.
[56] ZAVATTINI 06 propagate a laser beam in a magnetic field and observe dichroism and birefringence effects that could be attributed to an axion-like particle. This result is now excluded by ROBILLIARD 07, ZAVATTINI 08, and CHOU 08.
[57] INOUE 02 looked for Primakoff conversion of solar axions in 4T superconducting magnet into X ray.
[58] MORALES 02B looked for the coherent conversion of solar axions to photons via the Primakoff effect in Germanium detector.
[59] BERNABEI 01B looked for Primakoff coherent conversion of solar axions into photons via Bragg scattering in NaI crystal in DAMA dark matter detector.
[60] ASTIER 00B looked for production of axions from the interaction of high-energy photons with the horn magnetic field and their subsequent re-conversion to photons via the interaction with the NOMAD dipole magnetic field.
[61] MASSO 00 studied limits on axion-proton coupling using the induced axion-photon coupling through the proton loop and CAMERON 93 bound on the axion-photon coupling using optical rotation. They obtained the bound $g_p^2/4\pi < 1.7\times10^{-9}$ for the coupling $g_p\overline{p}\gamma_5 p\phi_A$.
[62] AVIGNONE 98 result is based on the coherent conversion of solar axions to photons via the Primakoff effect in a single crystal germanium detector.
[63] Based on the conversion of solar axions to $X$-rays in a strong laboratory magnetic field.
[64] Experiment based on proposal by MAIANI 86.
[65] Experiment based on proposal by VANBIBBER 87.
[66] LAZARUS 92 experiment is based on proposal found in VANBIBBER 89.
[67] RUOSO 92 experiment is based on the proposal by VANBIBBER 87.
[68] SEMERTZIDIS 90 experiment is based on the proposal of MAIANI 86. The limit is obtained by taking the noise amplitude as the upper limit. Limits extend to $m_{A^0} = 4\times10^{-3}$ where $G_{A\gamma\gamma} < 1\times10^{-4}$ GeV$^{-1}$.

### Limit on Invisible $A^0$ (Axion) Electron Coupling

The limit is for $g_{Aee}\,\phi_A\,\overline{e}(i\gamma_5)e$, or equivalently, the dipole-dipole potential $-\frac{g^2_{Aee}}{16\pi m^2_e}((\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2) - 3(\boldsymbol{\sigma}_1\cdot\boldsymbol{n})(\boldsymbol{\sigma}_2\cdot\boldsymbol{n}))/r^3$ where $\boldsymbol{n}=\boldsymbol{r}/r$ and the sign of the potential was corrected based on DAIDO 17.

[1] ADHIKARI 19B is analogous to LIU 17A.
[2] APRILE 19D is analogous to APRILE 17B, but they use only ionization signals. The quoted limit applies to $m_{A^0} = 0.7$ keV. See their Fig. 5(e) for mass-dependent limits.
[3] DESSERT 19 used the Suzaku observations of a magnetic white dwarf (RE J0317-853) to look for X-ray signatures converted from axions in the surrounding magnetic fields. They obtained the limit, $g_{Aee}\cdot G_{A\gamma\gamma} < 1.6\times10^{-24}$ GeV$^{-1}$ at 95%CL for $m_{A^0} \lesssim 10^{-5}$ eV. See their Fig. 2 for mass-dependent limits.
[4] TERRANO 19 look for the axion-induced oscillating magnetic field acting on the electron spin, using data taken with a rotating torsion pendulum containing polarized electrons. The quoted limit applies to $m_{A^0} = 10^{-23}$–$10^{-18}$ eV and assumes a local axion dark matter density, $\rho_A = 0.45$ GeV/cm$^3$. See their Fig. 5 for mass-dependent limits.
[5] ABE 18F is an update of ABE 14F. The quoted limit applies to $m_{A^0} = 60$ keV. See their Fig. 5 for mass-dependent limits.
[6] ARMENGAUD 18 is analogous to LIU 17A.
[7] ARMENGAUD 18 is analogous to AHMED 09A. See the left panel of Fig. 5 for mass-dependent limits.
[8] CRESCINI 18 look for collective excitations of the electron spins caused by dark matter axions. The quoted limit assumes the local dark matter density, $\rho_A = 0.45$ GeV/c$^3$.
[9] FICEK 18 use the measurements of the hyperfine structure of antiprotonic helium to constrain a dipole-dipole potential between electron and antiproton. See their Fig. 3 for limits on various spin- and velocity-dependent potentials.
[10] ABGRALL 17 is analogous to AHMED 09A using the MAJORANA DEMONSTRATOR. See their Fig. 2 for limits between 6 keV $< m_{A^0} <$ 97 keV.
[11] AKERIB 17B is analogous to LIU 17A.
[12] AKERIB 17B is analogous to AHMED 09A. See their Fig. 7 for mass-dependent limits.
[13] APRILE 17B is analogous to AHMED 09A. They found a bug in their code and needed to correct the limits in Fig. 7 of APRILE 14B. See their Fig. 1 for the corrected limits between 1 keV $< m_{A^0} <$ 40 keV.
[14] FICEK 17 look for spin-dependent interactions between electrons by comparing precision spectroscopic measurements in $^4$He with theoretical calculations. See their Fig. 1 for limits up to $m_{A^0} = 10$ keV.
[15] FU 17A is analogous to LIU 17A. See their Fig. 3 for mass-dependent limits.
[16] FU 17A is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.
[17] LIU 17A is analogous to AHMED 09A. See their Fig. 9 for limits between 0.25 keV $< m_{A^0} <$ 20 keV.
[18] LIU 17A look for solar axions produced from Compton, bremsstrahlung, atomic-recombination and deexcitation channels, and set a limit for $m_{A^0} < 1$ keV.
[19] LUO 17 use a recent measurement of the dipole-dipole interaction between two iron atoms at the nanometer scale and set a limit for $m_{A^0} < 1$ keV. See their Fig. 3 for mass-dependent limits.
[20] BATTICH 16 is analogous to CORSICO 16 and used the pulsating DB white dwarf PG 1351+489.
[21] CORSICO 16 studied the cooling rate of the pulsating DA white dwarf L19-2 based on an asteroseismic model.
[22] YOON 16 look for solar axions with the axio-electric effect in CsI(Tl) crystals and set a limit for $m_{A^0} < 1$ keV.
[23] TERRANO 15 used a torsion pendulum and rotating attractor with 20-pole electron-spin distributions. See their Fig. 4 for a mass-dependent limit up to $m_{A^0} = 500\ \mu$eV.
[24] ABE 14F set limits on the axioelectric effect in the XMASS detector assuming the pseudoscalar constitutes all the local dark matter. See their Fig. 3 for limits between $m_{A^0}$ = 40–120 keV.
[25] APRILE 14B look for solar axions using the XENON100 detector.
[26] APRILE 14B is analogous to AHMED 09A. Their Fig. 7 was later found to be incorrect due to a bug in their code. See Fig. 1 in APRILE 17B for the corrected limits.
[27] DERBIN 14 is an update of DERBIN 13 with a BGO scintillating bolometer. See their Fig. 3 for mass-dependent limits.
[28] MILLER-BERTOLAMI 14 studied the impact of axion emission on white dwarf cooling in a self-consistent way.
[29] ABE 13D is analogous to DERBIN 12, using the XMASS detector.
[30] ARMENGAUD 13 is similar to AALSETH 11. See their Fig. 10 for limits between 3 keV $< m_{A^0} <$ 100 keV.
[31] ARMENGAUD 13 is similar to DERBIN 12, and take account of axio-recombination and axio-deexcitation effects. See their Fig. 12 for mass-dependent limits.
[32] BARTH 13 search for solar axions produced by axion-electron coupling, and obtained the limit, $g_{Aee}\cdot G_{A\gamma\gamma} < 8.1\times10^{-23}$ GeV$^{-1}$ at 95%CL.
[33] DERBIN 13 looked for 5.5 MeV solar axions produced in $pd \to {}^3\mathrm{He}\,A^0$ in a BGO detector through the axioelectric effect. See their Fig. 4 for mass-dependent limits.
[34] HECKEL 13 studied the influence of 2 or 4 stationary sources each containing $6.0\times10^{24}$ polarized electrons, on a rotating torsion pendulum containing $9.8\times10^{24}$ polarized electrons. See their Fig. 4 for mass-dependent limits.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

[35] VIAUX 13A constrain axion emission using the observed brightness of the tip of the red-giant branch in the globular cluster M5.

[36] CORSICO 12 attributed the excessive cooling rate of the pulsating white dwarf R548 to emission of axions with $g_{Aee} \simeq 4.8 \times 10^{-13}$.

[37] DERBIN 12 look for solar axions with the axio-electric effect in a Si(Li) detector. The solar production is based on Compton and bremsstrahlung processes.

[38] AALSETH 11 is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.

[39] AHMED 09A assume keV-mass pseudoscalars are the local dark matter and constrain the axio-electric effect in the CDMS detector. See their Fig. 5 for mass-dependent limits.

[40] DAVOUDIASL 09 use geophysical constraints on Earth cooling by axion emission.

[41] These experiments measured induced magnetization of a bulk material by the spin-dependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor. The sign of the limit set by CHUI 93 is opposite to that of the axion-mediated dipole-dipole potential.

[42] These experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either of them. The limits reflect the corrected sign of the dipole-dipole potential.

[43] WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.

## Invisible $A^0$ (Axion) Limits from Nucleon Coupling

Limits are for the axion mass in eV.

[1] LEINSON 19 is analogous to BEZNOGOV 18, but estimating the axion luminosity based on the Tolman's analytic solution to the Einstein equations of spherical fluids in hydrostatic equilibrium. The dimensionless axion-neutron coupling is constrained as $g_{Ann} < 1.0 \times 10^{-10}$.

[2] LLOYD 19 is analogous to BERENJI 16. They highlight that the limit obtained with this technique strongly depends on the assumed NS core temperature.

[3] SMORRA 19 look for spin-precession effects from ultra-light axion dark matter in the $\overline{p}$ spin-flip resonance data. Assuming $\rho_A = 0.4$ GeV/cm$^3$, they constrain the dimensionless axion-antiproton coupling as $g_{A\overline{p}\overline{p}} < 2$–$9$ at 95% CL for $m_{A^0} = 2\times10^{-23}$–$4\times10^{-17}$ eV. See the right panel of their Fig. 3.

[4] WU 19 look for axion-induced time-oscillating features of the NMR spectrum of acetonitrile-2-$^{13}$C. Assuming $C_p = C_n$ and $\rho_A = 0.4$ GeV/cm$^3$, they constrain the dimensionless axion-nucleon coupling as $g_{ANN} < 6 \times 10^{-5}$ for $m_{A^0} = 10^{-21}$–$1.3 \times 10^{-17}$ eV. Note that the limits for $m_{A^0} < 10^{-21}$ eV in their Fig. 3(a) should be weaker than those for heavier masses. See ADELBERGER 19 and WU 19C on this issue.

[5] AKHMATOV 18 is an update of GAVRILYUK 15.

[6] ARMENGAUD 18 is analogous to ALESSANDRIA 13. The quoted limit assumes the DFSZ axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.

[7] BEZNOGOV 18 constrain the axion–neutron coupling by assuming that thermal evolution of the hot neutron star HESS J1731-347 is dominated by the lowest possible neutrino emission. The quoted limit assumes the KSVZ axion with the effective Peccei-Quinn charge of the neutron $C_n = -0.02$. The dimensionless axion-neutron couling is constrained as $g_{Ann} < 2.8 \times 10^{-10}$.

[8] GAVRILYUK 18 look for the resonant excitation of $^{83}$Kr (9.4 keV) by solar axions produced via the Primakoff effect. The mass bound assumes $m_u/m_d = 0.56$ and $S = 0.5$.

[9] HAMAGUCHI 18 studied the axion emission from the neutron star in Cassiopeia A based on the minimal cooling scenario which explains the observed rapid cooling rate. The quoted limit corresponds to $f_A > 5 \times 10^8$ GeV obtained for the KSVZ axion with $C_p = -0.47$ and $C_n = -0.02$.

[10] ABEL 17 look for a time-oscillating neutron EDM and an axion-wind spin-precession effect respectively induced by axion dark matter couplings to gluons and nucleons. See their Fig. 4 for limits in the range of $m_{A^0} = 10^{-24}$–$10^{-17}$ eV.

[11] ABGRALL 17 limit assumes the hadronic axion model used in ALESSANDRIA 13. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.

[12] FU 17A look for the 14.4 keV $^{57}$Fe solar axions. The limit assumes the DFSZ axion model. See their Fig. 3 for mass-dependent limits on the axion-electron coupling. Notice that in this figure the DFSZ and KSVZ lines should be interchanged.

[13] KLIMCHITSKAYA 17A use the differential measurement of the Casimir force between a Ni-coated sphere and Au and Ni sectors of the structured disc to constrain the axion coupling to nucleons for 2.61 meV $< m_{A^0} <$ 0.9 eV. See their Figs. 1 and 2 for mass dependent limits.

[14] LIU 17 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 6(b) for the limit on product of axion couplings to electrons and nucleons.

[15] BERENJI 16 used the Fermi LAT observations of neutron stars to look for photons from axion decay. They assume the effective Peccei-Quinn charge of the neutron $C_n = 0.1$ and a neutron-star core temperature of 20 MeV.

[16] GAVRILYUK 15 look for solar axions emitted by the M1 transition of $^{83}$Kr (9.4 keV). The mass bound assumes $m_u/m_d = 0.56$ and $S = 0.5$.

[17] KLIMCHITSKAYA 15 use the measurement of differential forces between a test mass and rotating source masses of Au and Si to constrain the force due to two-axion exchange for $1.7 \times 10^{-3} < m_{A^0} <$ 0.9 eV. See their Figs. 1 and 2 for mass dependent limits.

[18] BEZERRA 14 use the measurement of the thermal Casimir-Polder force between a Bose-Einstein condensate of $^{87}$Rb atoms and a $SiO_2$ plate to constrain the force mediated by exchange of two pseudoscalars for 0.1 meV $< m_{A^0} <$ 0.3 eV. See their Fig. 2 for the mass-dependent limit on pseudoscalar coupling to nucleons.

[19] BEZERRA 14A is analogous to BEZERRA 14. They use the measurement of the Casimir pressure between two Au-coated plates to constrain pseudoscalar coupling to nucleons for $1 \times 10^{-3}$ eV $< m_{A^0} <$ 15 eV. See their Figs. 1 and 2 for the mass-dependent limit.

[20] BEZERRA 14B is analogous to BEZERRA 14. BEZERRA 14B use the measurement of the normal and lateral Casimir forces between sinusoidally corrugated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for 1 eV $< m_{A^0} <$ 20 eV. See their Figs. 1–3 for mass-dependent limits.

[21] BEZERRA 14C is analogous to BEZERRA 14. They use the measurement of the gradient of the Casimir force between Au- and Ni-coated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for $3 \times 10^{-5}$ eV $< m_{A_0} <$ 1 eV. See their Figs. 1, 3, and 4 for the mass-dependent limits.

[22] BLUM 14 studied effects of an oscillating strong $CP$ phase induced by axion dark matter on the primordial $^4$He abundance. See their Fig. 1 for mass-dependent limits.

[23] LEINSON 14 attributes the excessive cooling rate of the neutron star in Cassiopeia A to axion emission from the superfluid core, and found $C_n^2\, m_{A^0}^2 \simeq 5.7 \times 10^{-6}$ eV$^2$, where $C_n$ is the effective Peccei-Quinn charge of the neutron.

[24] ALESSANDRIA 13 used the CUORE experiment to look for 14.4 keV solar axions produced from the M1 transition of thermally excited $^{57}$Fe nuclei in the solar core, using the axio-electric effect. The limit assumes the hadronic axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.

[25] ARMENGAUD 13 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 8 for the limit on product of axion couplings to electrons and nucleons.

[26] BELLI 12 looked for solar axions emitted by the M1 transition of $^7$Li* (478 keV) after the electron capture of $^7$Be, using the resonant excitation $^7$Li in the LiF crystal. The mass bound assumes $m_u/m_d = 0.55$, $m_u/m_s = 0.029$, and the flavor-singlet axial vector matrix element $S = 0.4$.

[27] BELLINI 12B looked for 5.5 MeV solar axions produced in the $pd \to {}^3\mathrm{He}\, A^0$. The limit assumes the hadronic axion model. See their Figs. 6 and 7 for mass-dependent limits on productsof axion couplings to photons, electrons, and nucleons.

[28] DERBIN 11 looked for solar axions emitted by the M1 transition of thermally excited $^{57}$Fe nuclei in the Sun, using their possible resonant capture on $^{57}$Fe in the laboratory. The mass bound assumes $m_u/m_d = 0.56$ and the flavor-singlet axial vector matrix element $S = 3F - D \simeq 0.5$.

[29] BELLINI 08 consider solar axions emitted in the M1 transition of $^7$Li* (478 keV) and look for a peak at 478 keV in the energy spectra of the Counting Test Facility (CTF), a Borexino prototype. For $m_{A^0} <$ 450 keV they find mass-dependent limits on products of axion couplings to photons, electrons, and nucleons.

[30] ADELBERGER 07 use precision tests of Newton's law to constrain a force contribution from the exchange of two pseudoscalars. See their Fig. 5 for limits on the pseudoscalar coupling to nucleons, relevant for $m_{A^0}$ below about 1 meV.

## Axion Limits from $T$-violating Medium-Range Forces

The limit is for the coupling $g = g_p\, g_s$ in a $T$-violating potential between nucleons or nucleon and electron of the form $V = \frac{g\hbar^2}{8\pi m_p}(\boldsymbol{\sigma}\cdot\hat{\boldsymbol{r}})\,(\frac{1}{r^2} + \frac{1}{\lambda r})\, e^{-r/\lambda}$, where $g_p$ and $g_s$ are dimensionless scalar and pseudoscalar coupling constants and $\lambda = \hbar/(m_A c)$ is the range of the force.

[1] DZUBA 18 used atomic EDM measurements to derive limits on the product of the pseudoscalar coupling to nucleon and the scalar coupling to electron, which improved on the laboratory bounds for $m_{A^0} > 0.01$ eV. See their Fig. 1 for mass-dependent limits.

[2] STADNIK 18 used atomic and molecular EDM experiments to derive limits on the product of the pseudoscalar couplings to electron and the scalar coupling to nucleon and electron. See their Fig. 2 for mass-dependent limits, which improved on the laboratory bounds for $m_{A^0} > 0.01$ eV.

[3] CRESCINI 17 use the QUAX-$g_p g_s$ experiment to look for variation of a paramagnetic GSO crystal magnetization when rotating lead disks are positioned near the crystal, and find $g = g_p^e g_s^N < 4.3\times10^{-30}$ for $\lambda = 0.1$–$0.2$ m at 95% CL. See their Fig. 6 for limits as a function of $\lambda$.

[4] AFACH 15 look for a change of spin precession frequency of ultracold neutrons when a magnetic field with opposite directions is applied, and find $g < 2.2\times10^{-27}\ (\mathrm{m}/\lambda)^2$ at 95% CL for $1\ \mu\mathrm{m} < \lambda < 5$ mm. See their Fig. 3 for their limits.

[5] STADNIK 15 studied proton and neutron spin contributions for nuclei and derive the limits $g < 10^{-28}$–$10^{-23}$ for $\lambda > 3\times10^{-4}$ m using the data of TULLNEY 13. See their Figs. 1 and 2 for $\lambda$-dependent limits.

[6] TERRANO 15 used a torsion pendulum and rotating attractor, and derived a restrictive limit on the product of the pseudoscalar coupling to electron and the scalar coupling to nucleons, $g < 9\times10^{-29}$–$5\times10^{-26}$ for $m_{A^0} < 1.5$–$400\ \mu$eV. See their Fig. 5 for mass-dependent limits.

[7] BULATOWICZ 13 looked for NMR frequency shifts in polarized $^{129}$Xe and $^{131}$Xe when a zirconia rod is positioned near the NMR cell, and find $g < 1\times10^{-19}$–$1\times10^{-24}$ for $\lambda = 0.01$–$1$ cm. See their Fig. 4 for their limits.

[8] CHU 13 look for a shift of the spin precession frequency of polarized $^3$He in the presence of an unpolarized mass, in analogy to YOUDIN 96. See Fig. 3 for limits on $g$ in the approximate $m_{A^0}$ range 0.02–2 meV.

[9] TULLNEY 13 look for a shift of the precession frequency difference between the colocated $^3$He and $^{129}$Xe in the presence an unpolarized mass, and derive limits $g < 3\times10^{-29}$–$2\times10^{-22}$ for $\lambda > 3\times10^{-4}$ m. See their Fig. 3 for $\lambda$-dependent limits.

[10] RAFFELT 12 show that the pseudoscalar couplings to electron and nucleon and the scalar coupling to nucleon are individually constrained by stellar energy-loss arguments and searches for anomalous monopole-monopole forces, together providing restrictive constraints on $g$. See their Figs. 2 and 3 for results.

[11] HOEDL 11 use a novel torsion pendulum to study the force by the polarized electrons of an external magnet. In their Fig. 3 they show restrictive limits on $g$ in the approximate $m_{A^0}$ range 0.03–10 meV.

[12] PETUKHOV 10 use spin relaxation of polarized $^3$He and find $g < 3\times10^{-23}\ (\mathrm{cm}/\lambda)^2$ at 95% CL for the force range $\lambda = 10^{-4}$–$1$ cm.

[13] SEREBROV 10 use spin precession of ultracold neutrons close to bulk matter and find $g < 2\times10^{-21}\ (\mathrm{cm}/\lambda)^2$ at 95% CL for the force range $\lambda = 10^{-4}$–$1$ cm.

[14] IGNATOVICH 09 use data on depolarization of ultracold neutrons in material traps. They show $\lambda$-dependent limits in their Fig. 1.

[15] SEREBROV 09 uses data on depolarization of ultracold neutrons stored in material traps and finds $g < 2.96\times10^{-21}\ (\mathrm{cm}/\lambda)^2$ for the force range $\lambda = 10^{-3}$–$1$ cm and $g < 3.9\times10^{-22}\ (\mathrm{cm}/\lambda)^2$ for $\lambda = 10^{-4}$–$10^{-3}$ cm, each time at 95% CL, significantly improving on BAESSLER 07.

[16] BAESSLER 07 use the observation of quantum states of ultracold neutrons in the Earth's gravitational field to constrain $g$ for an interaction range $1\ \mu$m–a few mm. See their Fig. 3 for results.

[17] HECKEL 06 studied the influence of unpolarized bulk matter, including the laboratory's surroundings or the Sun, on a torsion pendulum containing about $9\times10^{22}$ polarized electrons. See their Fig. 4 for limits on $g$ as a function of interaction range.

[18] NI 99 searched for a $T$-violating medium-range force acting on paramagnetic Tb $F_3$ salt. See their Fig. 1 for the result.

[19] POSPELOV 98 studied the possible contribution of $T$-violating Medium-Range Force to the neutron electric dipole moment, which is possible when axion interactions violate $CP$. The size of the force among nucleons must be smaller than gravity by a factor of $2\times10^{-10}\ (1\ \mathrm{cm}/\lambda_A)$, where $\lambda_A = \hbar/m_A c$.

[20] YOUDIN 96 compared the precession frequencies of atomic $^{199}$Hg and Cs when a large mass is positioned near the cells, relative to an applied magnetic field. See Fig. 3 for their limits.

[21] RITTER 93 studied the influence of bulk mass with polarized electrons on an unpolarized torsion pendulum, providing limits in the interaction range from 1 to 100 cm.

[22] VENEMA 92 looked for an effect of Earth's gravity on nuclear spin-precession frequencies of $^{199}$Hg and $^{201}$Hg atoms.

[23] WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine resonances in stored $^9$Be$^+$ ions using nuclear magnetic resonance.

### Hidden Photons: Kinetic Mixing Parameter Limits

Limits are on the kinetic mixing parameter $\chi$ which is defined by the Lagrangian

$$L = -\tfrac{1}{4} F_{\mu\nu}F^{\mu\nu} - \tfrac{1}{4} F'_{\mu\nu}F'^{\mu\nu} - \tfrac{\chi}{2} F_{\mu\nu}F'^{\mu\nu} + \frac{m^2_{\gamma'}}{2} A'_\mu A'^\mu,$$

where $A_\mu$ and $A'_\mu$ are the photon and hidden-photon fields with field strengths $F_{\mu\nu}$ and $F'_{\mu\nu}$, respectively, and $m_{\gamma'}$ is the hidden-photon mass.

[1] AAIJ 20C look for hidden photons produced from the $pp$ collision in the decay channel $\gamma' \to \mu^+\mu^-$. For prompt decaying hidden photons, limits at the level of $10^{-4}$–$10^{-3}$ are obtained for $m_{\gamma'} = 0.214$–30 GeV. See their Fig. 2 for mass-dependent limits.

[2] AAIJ 20C look for hidden photons produced from the $pp$ collision in the decay channel $\gamma' \to \mu^+\mu^-$. For hidden photons with lifetimes of order ps, limits at the level of $10^{-5}$ are obtained for $m_{\gamma'} = 218$–315 MeV. See their Fig. 4 for mass-dependent limits.

[3] AABOUD 19G look for $h \to \gamma'\gamma'$ ($\gamma' \to \mu^+\mu^-$) and exclude a kinetic mixing around $10^{-9}$–$10^{-8}$ for B($h \to \gamma'\gamma'$) = 0.01 and 0.1. See their Fig. 9 for mass-dependent limits.

[4] ABLIKIM 19A look for $J/\psi \to \gamma'\eta$ ($\gamma' \to e^+e^-$). Limits between $6 \times 10^{-3}$ and $5 \times 10^{-2}$ are obtained (see their Fig. 8).

[5] ABLIKIM 19H look for $J/\psi \to \gamma'\eta'$ ($\gamma' \to e^+e^-$). Limits between $3.4 \times 10^{-3}$ and $2.6 \times 10^{-2}$ are obtained. See their Fig. 5 for mass-dependent limits.

[6] AGUILAR-AREVALO 19A look for the absorption signal of hidden photon dark matter by using a CCD. The quoted limit applies to $m_{\gamma'} = 17$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm$^3$ is assumed. See their Fig. 4 for mass-dependent limits.

[7] APRILE 19D is analogous to ABE 14F. The quoted limit applies to $m_{\gamma'} = 0.7$ keV. See their Fig. 5(f) for mass-dependent limits.

[8] BANERJEE 19 is an update of BANERJEE 18A. The quoted limit is at $m_{\gamma'} = 1$ MeV. See their Fig. 3 for mass-dependent limits.

[9] BHOONAH 19 examine heating of Galactic Center gas clouds by hidden photon dark matter. The quoted limit applies to $m_{\gamma'} \simeq 10^{-12}$ eV. See their Fig. 2 for mass-dependent limits.

[10] BRUN 19 is analogous to SUZUKI 15. The limit is derived under an assumption that hidden photons constitute the local dark matter density $\rho_{\gamma'} = 0.3$ GeV/cm$^3$.

[11] CORTINA-GIL 19 look for an invisible hidden photon in the reaction $K^+ \to \pi^+\pi^0$ ($\pi^0 \to \gamma\gamma'$). The quoted limit applies to $m_{\gamma'} = 62.5$–65 MeV. See their Figs. 6 and 7 for mass-dependent limits.

[12] DANILOV 19 examined the hidden photon production in nuclear reactors, correctly taking account of the effective photon mass in the reactor and detector. The limit gets weaker for $m_{\gamma'}$ less than the effective photon mass in proportion to $1/m^2_{\gamma'}$. See their Fig. 1 for mass-dependent limits.

[13] HOCHBERG 19 look for the absorption signal of hidden photon dark matter by using superconducting-nanowire single-photon detectors. The quoted limit applies to $m_{\gamma'} \simeq 1$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm$^3$ is assumed. See their Fig. 4 for mass-dependent limits.

[14] KOPYLOV 19 look for hidden-photon dark matter using a counter with an aluminum cathode and derive limits assuming it constitute all the local dark matter. The quoted limit applies to $m_{\gamma'} = 12$ eV. See their Fig. 7 for mass-dependent limits.

[15] KOVETZ 19 examine heating of the early Universe plasma by hidden photon dark matter, and derive the limits by requiring that the cosmic mean 21 cm brightness temperature relative to the CMB temperature satisfy $T_{21} > -100$ mK. The quoted limit applies to $m_{\gamma'} \simeq 2 \times 10^{-14}$ eV. See their Fig. 3 for mass-dependent limits.

[16] NGUYEN 19 look for hidden photon dark matter with a resonant cavity, and set limits $\sim 10^{-12}$ for $m_{\gamma'} = 0.2$–2.07$\mu$eV. The quoted limit applies to $m_{\gamma'} = 1.3$ $\mu$eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm$^3$ is assumed. See their Fig. 19 for mass-dependent limits.

[17] ABE 18F is an update of ABE 14F. The quoted limit applies to $m_{\gamma'} \simeq 40$ keV. See their Fig. 5 for mass-dependent limits.

[18] ADRIAN 18 look for a hidden photon resonance in the reaction $e^- Z \to e^- Z\gamma'$ ($\gamma' \to e^+e^-$). The quoted limit applies to $m_{\gamma'} = 40$ MeV. See their Fig. 4 for mass-dependent limits.

[19] ANASTASI 18B look for a hidden photon resonance in the reaction $e^+e^- \to \gamma'\gamma$ ($\gamma' \to \mu^+\mu^-$). The quoted limit is obtained by combining the result of ANASTASI 16 and it applies to $m_{\gamma'} \simeq 519$–987 MeV. See their Fig. 9 for mass-dependent limits.

[20] ARMENGAUD 18 is analogous to ABE 14F. The quoted limits applies to $m_{\gamma'} = 1.6$ keV. See the right panel of Fig. 5 for mass-dependent limits.

[21] BANERJEE 18 look for hidden photons produced in the reaction $e^- Z \to e^- Z\gamma'$ ($\gamma' \to e^+e^-$), and exclude $9.2\times10^{-5} \lesssim \chi \lesssim 1\times10^{-2}$ for $m_{\gamma'} = 1$–23 MeV. They also set a limit on the electron coupling to a 16.7 MeV gauge boson suggested by the ATOMKI (KRASZNAHORKAY 16) experiment. See their Fig. 3 for mass-dependent limits.

[22] BANERJEE 18A look for invisible decays of hidden photons produced in the reaction $e^- Z \to e^- Z\gamma'$. The quoted limit is at $m_{\gamma'} = 1$ MeV. See their Fig. 15 for mass-dependent limits.

[23] KNIRCK 18 is analogous to SUZUKI 15. See their Fig. 5 for mass-dependent limits.

[24] ABGRALL 17 is analogous to ABE 14F using the MAJORANA DEMONSTRATOR. See their Fig. 3 for limits between 6 keV $< m_{\gamma'} <$ 97 keV.

[25] ABLIKIM 17AA look for $e^+e^- \to \gamma\gamma'$ ($\gamma' \to e^+e^-$ or $\mu^+\mu^-$). Limits between $10^{-3}$ and $10^{-4}$ are obtained (see their Fig. 3).

[26] ANGLOHER 17 is analogous to ABE 14F. The quoted limit is at $m_{\gamma'} = 0.7$ keV. See their Fig. 8 for mass-dependent limits.

[27] BANERJEE 17 look for invisible decays of hidden photons produced in the reaction $e^- Z \to e^- Z\gamma'$. The quoted limit applies to $m_{\gamma'} = 2$ MeV. See their Fig. 3 for mass-dependent limits.

[28] CHANG 17 examine the hidden photon emission from SN1987A, including the effects of finite temperature and density on $\chi$ and obtain limits $\chi$ ($m_{\gamma'}$/MeV) $\lesssim 3 \times 10^{-9}$ for $m_{\gamma'} < 15$ MeV and $\chi \lesssim 10^{-9}$ for $m_{\gamma'} = 15$–120 MeV.

[29] DUBININA 17 look for $\mu^+ \to e^+\overline{\nu}_\mu\nu_e\gamma'$ ($\gamma' \to e^+e^-$) in a nuclear photoemulsion. The quoted limit applies to $m_{\gamma'} = 1.1$ MeV. Limits between $4.5 \times 10^{-3}$ and $10^{-2}$ are obtained (see their Fig. 3).

[30] LEES 17E look for invisible decays of hidden photons produced in the reaction $e^+e^- \to \gamma\gamma'$. See their Fig. 5 for limits in the mass range $m_{\gamma'} \leq 8$ GeV.

[31] AAD 16AG look for hidden photons promptly decaying into collimated electrons and/or muons, assuming that they are produced in the cascade decays of squarks or the Higgs boson. See their Fig. 10 and Fig.13 for their limits on the cross section times branching fractions.

[32] ANASTASI 16 look for the decay $\gamma' \to \pi^+\pi^-$ in the reaction $e^+e^- \to \gamma\gamma'$. Limits between $4.3\times10^{-3}$ and $4.4\times10^{-4}$ are obtained for $527 < m_{\gamma'} < 987$ MeV (see their Fig. 9).

[33] KHACHATRYAN 16 look for $\gamma' \to \mu^+\mu^-$ in a dark SUSY scenario where the SM-like Higgs boson decays into a pair of the visible lightest neutralinos with mass 10 GeV, both of which decay into $\gamma'$ and a hidden neutralino with mass 1 GeV. See the right panel in their Fig. 2.

[34] AAD 15CD look for $H \to Z\gamma' \to 4\ell$ with the ATLAS detector at LHC and find $\chi < 4$–$17 \times 10^{-2}$ for $m_{\gamma'} = 15$–55 GeV. See their Fig. 6.

[35] ADARE 15 look for a hidden photon in $\pi^0, \eta^0 \to \gamma e^+e^-$ at the PHENIX experiment. See their Fig. 4 for mass-dependent limits.

[36] AN 15A derived limits from the absence of ionization signals in the XENON10 and XENON100 experiments, assuming hidden photons constitute all the local dark matter. Their best limit is $\chi < 1.3\times10^{-15}$ at $m_{\gamma'} = 18$ eV. See their Fig. 1 for mass-dependent limits.

[37] ANASTASI 15 look for a production of a hidden photon and a hidden Higgs boson with the KLOE detector at DAΦNE, where the hidden photon decays into a pair of muons and the hidden Higgs boson lighter than $m_{\gamma'}$ escape detection. See their Figs. 6 and 7 for mass-dependent limits on a product of the hidden fine structure constant and the kinetic mixing.

[38] ANASTASI 15A look for the decay $\gamma' \to e^+e^-$ in the reaction $e^+e^- \to e^+e^-\gamma$. Limits between $1.7\times10^{-3}$ and $1\times10^{-2}$ are obtained for $m_{\gamma'} = 5$–320 MeV (see their Fig. 7).

[39] BATLEY 15A look for $\pi^0 \to \gamma\gamma'$ ($\gamma' \to e^+e^-$) at the NA48/2 experiment. Limits between $4.2\times10^{-4}$ and $8.8\times10^{-3}$ are obtained for $m_{\gamma'} = 9$–120 MeV (see their Fig. 4).

[40] JAEGLE 15 look for the decay $\gamma' \to e^+e^-$, $\mu^+\mu^-$, or $\pi^+\pi^-$ in the dark Higgstrahlung channel, $e^+e^- \to \gamma' H'$ ($H' \to \gamma'\gamma'$) at the BELLE experiment. They set limits on a product of the branching fraction and the Born cross section as well as a product of the hidden fine structure constant and the kinetic mixing. See their Figs. 3 and 4.

[41] KAZANAS 15 set limits by studying the decay of hidden photons $\gamma' \to e^+e^-$ inside and near the progenitor star of SN1987A. See their Fig. 6 for mass-dependent limits.

[42] SUZUKI 15 looked for hidden-photon dark matter with a dish antenna and derived limits assuming they constitute all the local dark matter. Their limits are $\chi < 6\times10^{-12}$ for $m_{\gamma'} = 1.9$–4.3 eV. See their Fig. 7 for mass-dependent limits.

[43] VINYOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations, and set the limits $\chi m_{\gamma'} < 1.8\times10^{-12}$ eV for $m_{\gamma'} = 3\times10^{-5}$–8 eV. See their Fig. 11.

[44] ABE 14F look for the photoelectric-like interaction in the XMASS detector assuming the hidden photon constitutes all the local dark matter. Limits between $2\times10^{-13}$ and $1\times10^{-12}$ are obtained, where the relation $\chi^2 = \alpha'/\alpha$ is used to translate the original bound on the ratio of the hidden and EM fine-structure constants. See their Fig. 3 for mass-dependent limits.

[45] AGAKISHIEV 14 look for hidden photons $\gamma' \to e^+e^-$ at the HADES experiment, and set limits on $\chi$ for $m_{\gamma'} = 0.02$–0.6 GeV. See their Fig. 5 for mass-dependent limits.

[46] BABUSCI 14 look for the decay $\gamma' \to \mu^+\mu^-$ in the reaction $e^+e^- \to \mu^+\mu^-\gamma$. Limits between $4\times10^{-3}$ and $9.0\times10^{-4}$ are obtained for 520 MeV $< m_{\gamma'} <$ 980 MeV (see their Fig. 7).

[47] BATELL 14 derived limits from the electron beam dump experiment at SLAC (E-137) by searching for events with recoil electrons by sub-GeV dark matter produced from the decay of the hidden photon. Limits at the level of $10^{-4}$–$10^{-1}$ are obtained for $m_{\gamma'} = 10^{-3}$–1 GeV, depending on the dark matter mass and the hidden gauge coupling (see their Fig. 2).

[48] BLUEMLEIN 14 analyzed the beam dump data taken at the U-70 accelerator to look for $\gamma'$-bremsstrahlung and the subsequent decay into muon pairs and hadrons. See their Fig. 4 for mass-dependent excluded region.

[49] FRADETTE 14 studied effects of decay of relic hidden photons on BBN and CMB to set constraints on very small values of the kinetic mixing. See their Figs. 4 and 7 for mass-dependent excluded regions.

[50] LEES 14J look for hidden photons in the reaction $e^+e^- \to \gamma\gamma'$ ($\gamma' \to e^+e^-, \mu^+\mu^-$). Limits at the level of $10^{-4}$–$10^{-3}$ are obtained for 0.02 GeV $< m_{\gamma'} <$ 10.2 GeV. See their Fig. 4 for mass-dependent limits.

[51] MERKEL 14 look for $\gamma' \to e^+e^-$ at the A1 experiment at the Mainz Microtron (MAMI). See their Fig. 3 for mass-dependent limits.

[52] AN 13B examined the stellar production of hidden photons, correcting an important error of the production rate of the longitudinal mode which now dominates. See their Fig. 2 for mass-dependent limits based on solar energy loss.

[53] AN 13C use the solar flux of hidden photons to set a limit on the atomic ionization rate in the XENON10 experiment. They find $\chi\, m_{\gamma'} < 3\times10^{-12}$ eV for $m_{\gamma'} < 1$ eV. See their Fig. 2 for mass-dependent limits.

[54] DIAMOND 13 analyzed the beam dump data taken at the SLAC millicharge experiment to constrain a hidden photon invisibly decaying into lighter long-lived particles, which undergo elastic scattering off nuclei in the detector. Limits between $8\times10^{-4}$–$2\times10^{-2}$

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

are obtained. The quoted limit is applied when the dark gauge coupling is set equal to the electromagnetic coupling. See their Fig.4 for mass-dependent limits.

[55] GNINENKO 13 used the data taken at the SINDRUM experiment to constrain the decay, $\pi^0 \to \gamma\gamma'$ ($\gamma' \to e^+e^-$) to derive limits. See their Fig. 2 for their mass-dependent excluded region.

[56] HORVAT 13 look for hidden-photo-electric effect in HPGe detectors induced by solar hidden photons. See their Fig. 3 for mass-dependent limits.

[57] INADA 13 search for hidden photons using an intense X-ray beamline at SPring-8. See their Fig. 4 for mass-dependent limits.

[58] MIZUMOTO 13 look for solar hidden photons. See their Fig. 5 for mass-dependent limits.

[59] PARKER 13 look for hidden photons using a cryogenic resonant microwave cavity. See their Fig.5 for mass-dependent limits.

[60] PARKER 13 derived a limit for the hidden photon CDM with a randomly oriented hidden photon field.

[61] REDONDO 13 examined the solar emission of hidden photons including the enhancement factor for the longitudinal mode pointed out by AN 13B, and also updated stellar-energy loss arguments. See their Fig.3 for mass-dependent limits, including a review of the currently best limits from other arguments.

[62] GNINENKO 12A obtained bounds on $B(\pi^0 \to \gamma\gamma') \cdot B(\gamma' \to e^+e^-)$ from the NOMAD and PS191 neutrino experiments, and derived limits between $8 \times 10^{-8}$–$2 \times 10^{-4}$. See their Fig.4 for mass-dependent excluded regions.

[63] GNINENKO 12B used the data taken at the CHARM experiment to constrain the decay, $\eta(\eta') \to \gamma\gamma'$ ($\gamma' \to e^+e^-$), and derived limits between $1 \times 10^{-7}$–$1 \times 10^{-4}$. See their Fig.4 for mass-dependent excluded region.

[64] ABRAHAMYAN 11 look for $\gamma' \to e^+e^-$ in the electron-nucelon fixed-target experiment at the Jefferson Laboratory (APEX). See their Fig. 5 for mass-dependent limits.

[65] BLUEMLEIN 11 analyzed the beam dump data taken at the U-70 accelerator to look for $\pi^0 \to \gamma\gamma'$ ($\gamma' \to e^+e^-$). See their Fig. 5 for mass-dependent limits.

[66] BJORKEN 09 analyzed the beam dump data taken at E137, E141, and E774 to constrain a hidden photon produced by bremsstrahlung, subsequently decaying into $e^+e^-$, and derived limits between $10^{-7}$ and $10^{-2}$. See their Fig. 1 for mass-dependent excluded region.

[67] BJORKEN 09 required the energy loss in the $\gamma'$ emission from the core of SN1987A not to exceed $10^{53}$ erg/s, and derived limits between $5 \times 10^{-9}$ and $2 \times 10^{-6}$. See their Fig. 1 for mass-dependent excluded region.

## e

$J = \frac{1}{2}$

### e MASS (atomic mass units u)

The primary determination of an electron's mass comes from measuring the ratio of the mass to that of a nucleus, so that the result is obtained in u (atomic mass units). The conversion factor to MeV is more uncertain than the mass of the electron in u; indeed, the recent improvements in the mass determination are not evident when the result is given in MeV. In this datablock we give the result in u, and in the following datablock in MeV.

| VALUE ($10^{-6}$ u) | | DOCUMENT ID | | TECN | COMMENT |

[1] BEIER 02 compares Larmor frequency of the electron bound in a $^{12}C^{5+}$ ion with the cyclotron frequency of a single trapped $^{12}C^{5+}$ ion.
[2] FARNHAM 95 compares cyclotron frequency of trapped electrons with that of a single trapped $^{12}C^{6+}$ ion.

### e MASS

2010 CODATA (MOHR 12) gives the conversion factor from u (atomic mass units, see the above datablock) to MeV as 931.494 061 (21). Earlier values use the then-current conversion factor. The conversion error dominates the uncertainty of the masses given below.

| VALUE (MeV) | | DOCUMENT ID | | TECN | COMMENT |

| **$<8\times10^{-9}$** | 90 | [1] FEE | 93 | CNTR | Positronium spectroscopy |
| • • • We do not use the following data for averages, fits, limits, etc. • • • | | | | | |
| $<4\times10^{-23}$ | 90 | [2] DOLGOV | 14 | | From photon mass limit |
| $<4\times10^{-8}$ | 90 | CHU | 84 | CNTR | Positronium spectroscopy |

[1] FEE 93 value is obtained under the assumption that the positronium Rydberg constant is exactly half the hydrogen one.
[2] DOLGOV 14 result is obtained under the assumption that any mass difference between electron and positron would lead to a non-zero photon mass. The PDG 12 limit of $1\times10^{-18}$ eV on the photon mass is in turn used to derive the value quoted here.

### $|q_{e^+} + q_{e^-}|/e$

A test of $CPT$ invariance. See also similar tests involving the proton.

| VALUE | DOCUMENT ID | | TECN | COMMENT |

[1] ANDREEV 18 gives a measurement corresponding to this limit as $(4.3 \pm 3.1 \pm 2.6)\times10^{-30}$ ecm.
[2] CAIRNCROSS 17 gives a measurement corresponding to this limit as $(0.09 \pm 0.77 \pm 0.17)\times10^{-28}$ ecm.
[3] BARON 14 gives a measurement corresponding to this limit as $(-0.21 \pm 0.37 \pm 0.25)\times10^{-28}$ ecm.
[4] ECKEL 12 gives a measurement corresponding to this limit as $(-1.07 \pm 3.06 \pm 1.74)\times10^{-25}$ ecm.
[5] HUDSON 11 gives a measurement corresponding to this limit as $(-2.4 \pm 5.7 \pm 1.5)\times10^{-28}$ ecm.
[6] ABDULLAH 90, COMMINS 94, and REGAN 02 use the relativistic enhancement of a valence electron's electric dipole moment in a high-Z atom.

### $e^-$ MEAN LIFE / BRANCHING FRACTION

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review **D45** S1 (1992), p. VI.10).

Most of these experiments are one of three kinds: Attempts to observe (a) the 255.5 keV gamma ray produced in $e^- \to \nu_e\gamma$, (b) the (K) shell x ray produced when an electron decays without additional energy deposit, e.g., $e^- \to \nu_e\bar{\nu}_e\nu_e$ ("disappearance" experiments), and (c) nuclear de-excitation gamma rays after the electron disappears from an atomic shell and the nucleus is left in an excited state. The last can include both weak boson and photon mediating processes. We use the best $e^- \to \nu_e\gamma$ limit for the Summary Tables.

Note that we use the mean life rather than the half life, which is often reported.

## $\mu$

$J = \frac{1}{2}$

### $\mu$ MASS (atomic mass units u)

The muon's mass is obtained from the muon-electron mass ratio as determined from the measurement of Zeeman transition frequencies in muonium ($\mu^+e^-$ atom). Since the electron's mass is most accurately known in u, the muon's mass is also most accurately known in u. The conversion factor to MeV has approximately the same relative uncertainty as the mass of the muon in u. In this datablock we give the result in u, and in the following datablock in MeV.

| VALUE (u) | DOCUMENT ID | | TECN | COMMENT |
|---|---|---|---|---|
| **0.1134289257±0.0000000025** | MOHR | 16 | RVUE | 2014 CODATA value |

• • • We do not use the following data for averages, fits, limits, etc. • • •

[1] MOHR 99 make use of other 1998 CODATA entries below.
[2] COHEN 87 make use of other 1986 CODATA entries below.

### $\mu$ MASS

2010 CODATA (MOHR 12) gives the conversion factor from u (atomic mass units, see the above datablock) to MeV as 931.494 061 (21). Earlier values use the then-current conversion factor. The conversion error contributes significantly to the uncertainty of the masses given below.

| VALUE (MeV) | DOCUMENT ID | | TECN | CHG | COMMENT |
|---|---|---|---|---|---|
| **105.6583745±0.0000024** | MOHR | 16 | RVUE | | 2014 CODATA value |

• • • We do not use the following data for averages, fits, limits, etc. • • •

| | | | | | |
|---|---|---|---|---|---|

Muon Anomalous Magnetic Moment

### $\mu$ MAGNETIC MOMENT ANOMALY

The parity-violating decay of muons in a storage ring is observed. The difference frequency $\omega_a$ between the muon spin precision and the orbital angular frequency $(e/m_\mu c)\langle B\rangle$ is measured, as is the free proton NMR frequency $\omega_p$, thus determining the ratio $R=\omega_a/\omega_p$. Given the magnetic moment ratio $\lambda=\mu_\mu/\mu_p$ (from hyperfine structure in muonium), $(g-2)/2 = R/(\lambda-R)$.

#### $\mu_\mu/(e\hbar/2m_\mu)-1 = (g_\mu-2)/2$

[1] BENNETT 06 reports $(g_\mu-2)/2 = (11659208.0 \pm 5.4 \pm 3.3) \times 10^{-10}$. We rescaled this value using $\mu/p$ magnetic moment ratio of 3.183345137(85) from MOHR 08.
[2] BAILEY 79 values recalculated by HUGHES 99 using the COHEN 87 $\mu/p$ magnetic moment. The improved MOHR 99 value does not change the result.

### $(g_{\mu^+} - g_{\mu^-})/g_{\text{average}}$

| 0.8±4.3 | | BAILEY | 78 | CNTR | − | Storage ring |

[1] This is the combination of the two BENNETT 09 measurements quoted here separately for $\mu^+$ and $\mu^-$. The result is also presented as a measurement of $(0.0 \pm 0.9) \times 10^{-19}$ e cm.
[2] Also reported as the limit of $|d(\mu^+)| < 2.1 \times 10^{-19}$ e cm at 95% CL.
[3] Also reported as the limit of $|d(\mu^-)| < 1.5 \times 10^{-19}$ e cm at 95% CL.
[4] This is the combination of the two BAILEY 78 results quoted here separately for $\mu^+$ and $\mu^-$. BAILEY 78 uses the convention $d = 1/2 \cdot (d_{\mu^+} - d_{\mu^-})$ and reports 3.7 ± 3.4. We convert their result to use the same convention as BENNETT 09.

### MUON-ELECTRON CHARGE RATIO ANOMALY $q_{\mu^+}/q_{e^-} + 1$

| VALUE | DOCUMENT ID | | TECN | CHG | COMMENT |
|---|---|---|---|---|---|
| **(1.1±2.1) × 10$^{-9}$** | [1] MEYER | 00 | CNTR | + | 1s–2s muonium interval |

[1] MEYER 00 measure the 1s–2s muonium interval, and then interpret the result in terms of muon-electron charge ratio $q_{\mu^+}/q_{e^-}$.

### $\mu^-$ DECAY MODES

$\mu^+$ modes are charge conjugates of the modes below.

| | Mode | | Fraction ($\Gamma_i/\Gamma$) | | Confidence level |
|---|---|---|---|---|---|
| $\Gamma_1$ | $e^-\overline{\nu}_e\nu_\mu$ | | ≈ 100% | | |
| $\Gamma_2$ | $e^-\overline{\nu}_e\nu_\mu\gamma$ | | [a] $(6.0\pm0.5)\times10^{-8}$ | | |
| $\Gamma_3$ | $e^-\overline{\nu}_e\nu_\mu e^+e^-$ | | [b] $(3.4\pm0.4)\times10^{-5}$ | | |
| | **Lepton Family number (*LF*) violating modes** | | | | |
| $\Gamma_4$ | $e^-\nu_e\overline{\nu}_\mu$ | *LF* | [c] < 1.2 | % | 90% |
| $\Gamma_5$ | $e^-\gamma$ | *LF* | < 4.2 | $\times10^{-13}$ | 90% |
| $\Gamma_6$ | $e^-e^+e^-$ | *LF* | < 1.0 | $\times10^{-12}$ | 90% |
| $\Gamma_7$ | $e^-2\gamma$ | *LF* | < 7.2 | $\times10^{-11}$ | 90% |

[a] This only includes events with energy of $e > 45$ MeV and energy of $\gamma > 40$ MeV. Since the $e^-\overline{\nu}_e\nu_\mu$ and $e^-\overline{\nu}_e\nu_\mu\gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.
[b] See the Particle Listings below for the energy limits used in this measurement.
[c] A test of additive vs. multiplicative lepton family number conservation.

### $\mu^-$ BRANCHING RATIOS

#### $\Gamma(e^-\overline{\nu}_e\nu_\mu\gamma)/\Gamma_{\text{total}}$ $\Gamma_2/\Gamma$

| VALUE | EVTS | DOCUMENT ID | | TECN | COMMENT |

[1] This limit assumes a giant resonance excitation of the daughter Ca nucleus (mean energy and width both 20 MeV).
[2] KAULARD 98 obtained these same limits using the unified classical analysis of FELDMAN 98.
[3] This limit assumes the daughter Ca nucleus is left in the ground state. However, the probability of this is unknown.
[4] Assuming a giant-resonance-excitation model.

## LIMIT ON MUONIUM → ANTIMUONIUM CONVERSION

Forbidden by lepton family number conservation.

### $R_g = G_C / G_F$

The effective Lagrangian for the $\mu^+ e^- \to \mu^- e^+$ conversion is assumed to be

$$\mathcal{L} = 2^{-1/2}\, G_C\, [\overline{\psi}_\mu \gamma_\lambda (1-\gamma_5)\, \psi_e]\, [\overline{\psi}_\mu \gamma_\lambda (1-\gamma_5)\, \psi_e] + \text{h.c.}$$

The experimental result is then an upper limit on $G_C/G_F$, where $G_F$ is the Fermi coupling constant.

[1] Previously we used the global fit result from BURKARD 85B in OUR AVERAGE, we now only include their actual measurement. BURKARD 85B measure $e^+$ polarizations $P_{T_1}$ and $P_{T_2}$ versus $e^+$ energy.
[2] $\alpha = \alpha' = 0$ assumed.
[3] Global fit to all measured parameters. The fit correlation coefficients are given in BURKARD 85B.

## $\tau$

$J = \frac{1}{2}$

$\tau$ discovery paper was PERL 75. $e^+e^- \to \tau^+\tau^-$ cross-section threshold behavior and magnitude are consistent with pointlike spin-1/2 Dirac particle. BRANDELIK 78 ruled out pointlike spin-0 or spin-1 particle. FELDMAN 78 ruled out $J = 3/2$. KIRKBY 79 also ruled out $J$=integer, $J = 3/2$.

[1] ABLIKIM 14D fit $\sigma(e^+e^- \to \tau^+\tau^-)$ at different energies near threshold.

[2] AUBERT 09AK and BELOUS 07 fit $\tau$ pseudomass spectrum in $\tau \to \pi\pi^+\pi^-\nu_\tau$ decays. Result assumes $m_{\nu_\tau} = 0$.

[3] ABBIENDI 00A fit $\tau$ pseudomass spectrum in $\tau \to \pi^\pm \leq 2\pi^0\nu_\tau$ and $\tau \to \pi^\pm\pi^+\pi^- \leq 1\pi^0\nu_\tau$ decays. Result assumes $m_{\nu_\tau}$=0.

[4] BAI 96 fit $\sigma(e^+e^- \to \tau^+\tau^-)$ at different energies near threshold.

[5] ALBRECHT 92M fit $\tau$ pseudomass spectrum in $\tau^- \to 2\pi^-\pi^+\nu_\tau$ decays. Result assumes $m_{\nu_\tau}$=0.

[6] BACINO 78B value comes from $e^\pm X^\mp$ threshold. Published mass 1782 MeV increased by 1 MeV using the high precision $\psi(2S)$ mass measurement of ZHOLENTZ 80 to eliminate the absolute SPEAR energy calibration uncertainty.

[7] BALEST 93 fit spectra of minimum kinematically allowed $\tau$ mass in events of the type $e^+e^- \to \tau^+\tau^- \to (\pi^+ n\pi^0\nu_\tau)(\pi^- m\pi^0\nu_\tau)$ $n \leq 2$, $m \leq 2$, $1 \leq n+m \leq 3$. If $m_{\nu_\tau} \neq 0$, result increases by $(m^2_{\nu_\tau}/1100$ MeV).

[8] BAI 92 fit $\sigma(e^+e^- \to \tau^+\tau^-)$ near threshold using $e\mu$ events.

## $(m_{\tau^+} - m_{\tau^-})/m_{\text{average}}$

A test of $CPT$ invariance.

| $< 0.023$ | 95 | [8] SILVERMAN | 83 | RVUE | $e^+e^- \to \tau^+\tau^-$ at PETRA |

[1] ABDALLAH 04K limit is derived from $e^+e^- \to e^+e^-\tau^+\tau^-$ total cross-section measurements at $\sqrt{s}$ between 183 and 208 GeV. In addition to the limits, the authors also quote a value of $-0.018 \pm 0.017$.

[2] ACHARD 04G limit is derived from $e^+e^- \to e^+e^-\tau^+\tau^-$ total cross-section measurements at $\sqrt{s}$ between 189 and 206 GeV, and is on the absolute value of the magnetic moment anomaly.

[3] GONZALEZ-SPRINBERG 00 use data on tau lepton production at LEP1, SLC, and LEP2, and data from colliders and LEP2 to determine limits. Assume imaginary component is zero.

[4] ACCIARRI 98E use $Z \to \tau^+\tau^-\gamma$ events. In addition to the limits, the authors also quote a value of $0.004 \pm 0.027 \pm 0.023$.

[5] ACKERSTAFF 98N use $Z \to \tau^+\tau^-\gamma$ events. The limit applies to an average of the form factor for off-shell $\tau$'s having $p^2$ ranging from $m_\tau^2$ to $(M_Z - m_\tau)^2$.

[6] ESCRIBANO 97 use preliminary experimental results.

[7] ESCRIBANO 93 limit derived from $\Gamma(Z \to \tau^+\tau^-)$, and is on the absolute value of the magnetic moment anomaly.

[8] SILVERMAN 83 limit is derived from $e^+e^- \to \tau^+\tau^-$ total cross-section measurements for $q^2$ up to (37 GeV)$^2$.

## $\tau$ ELECTRIC DIPOLE MOMENT ($d_\tau$)

A nonzero value is forbidden by both $T$ invariance and $P$ invariance.

The $q^2$ dependence is expected to be small providing no thresholds are nearby.

[1] INAMI 03 use $e^+e^- \to \tau^+\tau^-$ events.

[2] GROZIN 09A calculate the contribution to the electron electric dipole moment from the $\tau$ electric dipole moment appearing in loops, which is $\Delta d_e = 6.9 \times 10^{-12}\ d_\tau$. Dividing the REGAN 02 upper limit $|d_e| \leq 1.6 \times 10^{-27}$ e cm at CL=90% by $6.9 \times 10^{-12}$ gives this limit.

[3] ABDALLAH 04K limit is derived from $e^+e^- \to e^+e^-\tau^+\tau^-$ total cross-section measurements at $\sqrt{s}$ between 183 and 208 GeV and is on the absolute value of $d_\tau$.

[4] ACHARD 04G limit is derived from $e^+e^- \to e^+e^-\tau^+\tau^-$ total cross-section measurements at $\sqrt{s}$ between 189 and 206 GeV, and is on the absolute value of $d_\tau$.

[5] ALBRECHT 00 use $e^+e^- \to \tau^+\tau^-$ events. Limit is on the absolute value of Re($d_\tau$).

[6] ACKERSTAFF 98N use $Z \to \tau^+\tau^-\gamma$ events. The limit applies to an average of the form factor for off-shell $\tau$'s having $p^2$ ranging from $m_\tau^2$ to $(M_Z - m_\tau)^2$.

[7] ESCRIBANO 97 derive the relationship $|d_\tau| = \cot\theta_W |d_\tau^W|$ using effective Lagrangian methods, and use a conference result $|d_\tau^W| < 5.8 \times 10^{-18}$ e cm at 95% CL (L. Silvestris, ICHEP96) to obtain this result.

[8] ESCRIBANO 97 use preliminary experimental results.

[9] ESCRIBANO 93 limit derived from $\Gamma(Z \to \tau^+\tau^-)$, and is on the absolute value of the electric dipole moment.

### Lepton Family number ($LF$), Lepton number ($L$), or Baryon number ($B$) violating modes

$L$ means lepton number violation (*e.g.* $\tau^- \to e^+\pi^-\pi^-$). Following common usage, $LF$ means lepton family violation *and not* lepton number violation (*e.g.* $\tau^- \to e^-\pi^+\pi^-$). $B$ means baryon number violation.

| | | | | | | |
|---|---|---|---|---|---|---|
| $\Gamma_{186}$ | $e^-\gamma$ | $LF$ | $<$ | 3.3 | $\times 10^{-8}$ | CL=90% |
| $\Gamma_{187}$ | $\mu^-\gamma$ | $LF$ | $<$ | 4.4 | $\times 10^{-8}$ | CL=90% |
| $\Gamma_{188}$ | $e^-\pi^0$ | $LF$ | $<$ | 8.0 | $\times 10^{-8}$ | CL=90% |

[*a*] Basis mode for the $\tau$.

[*b*] See the Particle Listings below for the energy limits used in this measurement.

### CONSTRAINED FIT INFORMATION

An overall fit to 87 branching ratios uses 170 measurements and one constraint to determine 46 parameters. The overall fit has a $\chi^2 = 135$ for 125 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$.

## $\tau^-$ BRANCHING RATIOS

**$\Gamma(\text{particle}^- \geq 0 \text{ neutrals} \geq 0K^0\nu_\tau(\text{"1-prong"}))/\Gamma_{total}$ $\Gamma_1/\Gamma$**

$\Gamma_1/\Gamma = (\Gamma_3+\Gamma_5+\Gamma_9+\Gamma_{10}+\Gamma_{14}+\Gamma_{16}+\Gamma_{20}+\Gamma_{23}+\Gamma_{27}+\Gamma_{28}+\Gamma_{30}+\Gamma_{36}+\Gamma_{38}+\Gamma_{41}+\Gamma_{43}+\Gamma_{45}+\Gamma_{48}+\Gamma_{49}+\Gamma_{50}+\Gamma_{52}+\Gamma_{56}+\Gamma_{57}+0.7212\Gamma_{150}+0.7212\Gamma_{152}+0.7212\Gamma_{154}+0.7212\Gamma_{156}+0.340\Gamma_{170}+0.0840\Gamma_{178}+0.0840\Gamma_{179}+0.0840\Gamma_{180})/\Gamma$

The charged particle here can be $e$, $\mu$, or hadron. In many analyses, the sum of the topological branching fractions (1, 3, and 5 prongs) is constrained to be unity. Since the 5-prong fraction is very small, the measured 1-prong and 3-prong fractions are highly correlated and cannot be treated as independent quantities in our overall fit. We arbitrarily choose to use the 3-prong fraction in our fit, and leave the 1-prong fraction out. We do, however, use these 1-prong measurements in our average below.

[1] SHIMIZU 18A impose requirements on detected $\gamma$'s corresponding to a $\tau$-rest-frame energy cutoff $E^*_\gamma > 10$ MeV.

[2] LEES 15G impose requirements on detected $\gamma$'s corresponding to a $\tau$-rest-frame energy cutoff $E^*_\gamma > 10$ MeV.

[3] BERGFELD 00 impose requirements on detected $\gamma$'s corresponding to a $\tau$-rest-frame energy cutoff $E^*_\gamma > 10$ MeV. For $E^*_\gamma > 20$ MeV, they quote $(3.04 \pm 0.14 \pm 0.30) \times 10^{-3}$.

[4] ALEXANDER 96S impose requirements on detected $\gamma$'s corresponding to a $\tau$-rest-frame energy cutoff $E_\gamma >$20 MeV.

[5] WU 90 reports $\Gamma(\mu^-\overline{\nu}_\mu\nu_\tau\gamma)/\Gamma(\mu^-\overline{\nu}_\mu\nu_\tau) = 0.013 \pm 0.006$, which is converted to $\Gamma(\mu^-\overline{\nu}_\mu\nu_\tau\gamma)/\Gamma_{\text{total}}$ using $\Gamma(\mu^-\overline{\nu}_\mu\nu_\tau\gamma)/\Gamma_{\text{total}} = 17.35\%$. Requirements on detected $\gamma$'s correspond to a $\tau$ rest frame energy cutoff $E_\gamma > 37$ MeV.

## $\Gamma(e^-\overline{\nu}_e\nu_\tau)/\Gamma_{\text{total}}$ $\Gamma_5/\Gamma$

To minimize the effect of experiments with large systematic errors, we exclude experiments which together would contribute 5% of the weight in the average.
