Photons propagating through a transverse magnetic field, with incident \mathbf{E}_γ and magnetic field \mathbf{B} parallel, may convert into axions. For $m_A^2 L / 2\omega \ll 2\pi$, where L is the length of the B field region and ω the photon energy, the resultant axion beam is coherent with the incident photon beam and the conversion probability is $\Pi \sim (1/4)(g_{A\gamma\gamma} B L)^2$. A practical realization uses a laser beam propagating down the bore of a superconducting dipole magnet (like the bending magnets in high-energy accelerators). If another magnet is in line with the first, but shielded by an optical barrier, then photons may be regenerated from the pure axion beam [39, 40]. The overall probability is $P(\gamma \rightarrow A \rightarrow \gamma) = \Pi^2$.

The first such Light-Shining-through-Walls (LSW) experiment was performed by the BFRT collaboration. It utilized two magnets of length $L = 4.4$ m and $B = 3.7$ T and found $|g_{A\gamma\gamma}| < 6.7 \times 10^{-7} \text{ GeV}^{-1}$ at 95% CL for $m_A < 1$ meV [41]. More recently, several such experiments were performed (see Listings) [42–48]. The current best limit, $|g_{A\gamma\gamma}| < 3.5 \times 10^{-8} \text{ GeV}^{-1}$ at 95% CL for $m_A \lesssim 0.3$ meV (see Fig. 91.1), has been achieved by the OSQAR (Optical Search for QED Vacuum Birefringence, Axions, and Photon Regeneration) experiment, which exploited two 9 T LHC dipole magnets and an 18.5 W continuous wave laser emitting at the wavelength of 532 nm [48]. Some of these experiments have also reported limits for scalar bosons where the photon \mathbf{E}_γ must be chosen perpendicular to the magnetic field \mathbf{B} .

The concept of resonantly enhanced photon regeneration may open unexplored regions of coupling strength [49, 50]. In this scheme, both the production and detection magnets are within Fabry-Perot optical cavities and actively locked in frequency. The $\gamma \rightarrow A \rightarrow \gamma$ rate is enhanced by a factor $\mathcal{F}\mathcal{F}'/\pi^2$ relative to a single-pass experiment, where \mathcal{F} and \mathcal{F}' are the finesses of the two cavities. The resonant enhancement could be of order $10^{(10-12)}$, improving the $g_{A\gamma\gamma}$ sensitivity by $10^{(2.5-3)}$. The experiment ALPS II (Any Light Particle Search II) is based on this concept and aims at an improvement of the current laboratory bound on $g_{A\gamma\gamma}$ by a factor $\sim 10^3$ in the year 2020 [51].

Resonantly enhanced photon regeneration has already been exploited in experiments searching for ‘radiowaves shining through a shielding’ [52–55]. For $m_A \lesssim 10^{-5}$ eV, the upper bound on $g_{A\gamma\gamma}$ established by the CROWS (CERN Resonant Weakly Interacting sub-eV Particle Search) experiment [56] is slightly less stringent than the one set by OSQAR.

91.3.2 Photon polarization

An alternative to regenerating the lost photons is to use the beam itself to detect conversion: the polarization of light propagating through a transverse B field suffers dichroism and birefringence [57]. Dichroism: The E_{\parallel} component, but not E_{\perp} , is depleted by axion production, causing a small rotation of linearly polarized light. For $m_A^2 L / 2\omega \ll 2\pi$, the effect is independent of m_A . For heavier axions, it oscillates and diminishes as m_A increases, and it vanishes for $m_A > \omega$. Birefringence: This effect occurs because there is mixing of virtual axions in the E_{\parallel} state, but not for E_{\perp} . Hence, linearly polarized light will develop elliptical polarization. Higher-order QED also induces vacuum magnetic birefringence (VMB). A search for these effects was performed in the same dipole magnets of the BFRT experiment mentioned before [58]. The dichroic rotation gave a stronger limit than the ellipticity rotation: $|g_{A\gamma\gamma}| < 3.6 \times 10^{-7} \text{ GeV}^{-1}$ at 95% CL, for $m_A < 5 \times 10^{-4}$ eV. The ellipticity limits are better at higher masses, as they fall off smoothly and do not terminate at m_A .

In 2006, the PVLAS collaboration reported a signature of magnetically induced vacuum dichroism that could be interpreted as the effect of a pseudoscalar with $m_A = 1\text{--}1.5$ meV and $|g_{A\gamma\gamma}| = (1.6\text{--}5) \times 10^{-6} \text{ GeV}^{-1}$ [59]. Later, it turned out that these findings are due to instrumental artifacts [60]. This particle interpretation is also excluded by the above photon regeneration searches that were inspired by the original PVLAS result. The fourth generation setup of the PVLAS experiment has published results on searches for VMB (see Fig. 91.1) and dichroism [61].

The bounds from the non-observation of the latter on $g_{A\gamma\gamma}$ are slightly weaker than the ones from OSQAR.

91.3.3 Long-range forces

New bosons would mediate long-range forces, which are severely constrained by “fifth force” experiments [62]. Those looking for new mass-spin couplings provide significant constraints on pseudoscalar bosons [63]. Presently, the most restrictive limits are obtained from combining long-range force measurements with stellar cooling arguments [64]. For the moment, any of these limits are far from realistic values expected for axions. Still, these efforts provide constraints on more general low-mass bosons.

In Ref. [65], a method was proposed that can extend the search for axion-mediated spin-dependent forces by several orders of magnitude. By combining techniques used in nuclear magnetic resonance and short-distance tests of gravity, this method appears to be sensitive to axions in the $\mu\text{eV} - \text{meV}$ mass range, independent of the cosmic axion abundance, if axions have a CP-violating interaction with nuclei as large as the current experimental bound on the electric dipole moment of the neutron allows. Experimental tests to demonstrate the requirements of ARIADNE (Axion Resonant InterAction DetectioN Experiment) are under way [66].

91.4 Axions from Astrophysical Sources

91.4.1 Stellar energy-loss limits

Low-mass weakly-interacting particles (neutrinos, gravitons, axions, baryonic or leptonic gauge bosons, *etc.*) are produced in hot astrophysical plasmas, and can thus transport energy out of stars. The coupling strength of these particles with normal matter and radiation is bounded by the constraint that stellar lifetimes or energy-loss rates are not in conflict with observation [67, 68].

We begin this discussion with our Sun and concentrate on hadronic axions. They are produced predominantly by the Primakoff process $\gamma + Ze \rightarrow Ze + A$. Integrating over a standard solar model yields the axion luminosity [69]

$$L_A = g_{10}^2 \times 1.85 \times 10^{-3} L_\odot, \quad (91.12)$$

where $g_{10} = |g_{A\gamma\gamma}| \times 10^{10} \text{ GeV}$. The maximum of the spectrum is at 3.0 keV, the average at 4.2 keV, and the number flux at Earth is $g_{10}^2 \times 3.75 \times 10^{11} \text{ cm}^{-2} \text{ s}^{-1}$. The solar photon luminosity is fixed, so energy losses due to the Primakoff process require enhanced nuclear energy production and thus enhanced neutrino fluxes. The all-flavor measurements by SNO (Solar Neutrino Observatory), together with a standard solar model, imply $L_A \lesssim 0.10 L_\odot$, corresponding to $g_{10} \lesssim 7$ [70], mildly superseding a similar limit from helioseismology [71]. In Ref. [72], this limit was improved to $g_{10} < 4.1$ (at 3σ), exploiting a new statistical analysis that combined helioseismology (sound speed, surface helium and convective radius) and solar neutrino observations, including theoretical and observational errors, and accounting for tensions between input parameters of solar models, in particular the solar element abundances.

A more restrictive limit derives from globular-cluster (GC) stars that allow for detailed tests of stellar-evolution theory. The stars on the horizontal branch (HB) in the color-magnitude diagram have reached helium burning with a core-averaged energy release of about $80 \text{ erg g}^{-1} \text{ s}^{-1}$, compared to Primakoff axion losses of $g_{10}^2 30 \text{ erg g}^{-1} \text{ s}^{-1}$. The accelerated consumption of helium reduces the HB lifetime by about $80/(80+30 g_{10}^2)$. Number counts of HB stars in a large sample of 39 Galactic GCs compared with the number of red giants (that are not much affected by Primakoff losses) give a weak indication of non-standard losses which may be accounted by Primakoff-like axion emission, if the photon coupling is in the range $|g_{A\gamma\gamma}| = (2.9 \pm 1.8) \times 10^{-11} \text{ GeV}^{-1}$ [73, 74]. Still, the upper bound found in this analysis,

$$|g_{A\gamma\gamma}| < 6.6 \times 10^{-11} \text{ GeV}^{-1} \quad (95\% \text{ CL}), \quad (91.13)$$

represents the strongest limit on $g_{A\gamma\gamma}$ for a wide mass range, see Fig. 91.1. The conservative constraint, Eq. (91.13), on $g_{A\gamma\gamma}$ may be translated to $f_A > 3.4 \times 10^7 \text{ GeV}$ ($m_A < 0.2 \text{ eV}$), using $E/N = 0$ as in the KSVZ model, or to $f_A > 1.3 \times 10^7 \text{ GeV}$ ($m_A < 0.5 \text{ eV}$), for the DFSZ axion model, with $E/N = 8/3$, see Fig. 91.1.

If axions couple directly to electrons, the dominant emission processes are atomic axio-recombination and axio-deexcitation, axio-bremsstrahlung in electron-ion or electron-electron collisions, and Compton scattering [75]. Stars in the red giant (RG) branch of the color-magnitude diagram of GCs are particularly sensitive to these processes. In fact, they would lead to an extension of the latter to larger brightness. Reference [76] provided high-precision photometry for the Galactic globular cluster M5 (NGC 5904), allowing for a detailed comparison between the observed tip of the RG branch with predictions based on state-of-the-art stellar evolution theory. It was found that, within the uncertainties, the observed and predicted tip of the RG branch brightness agree reasonably well, leading to the bound

$$|g_{Aee}| < 4.3 \times 10^{-13} \quad (95\% \text{ CL}), \quad (91.14)$$

implying an upper bound on the axion mass in the DFSZ model,

$$m_A \sin^2 \beta < 15 \text{ meV} \quad (95\% \text{ CL}), \quad (91.15)$$

see Fig. 91.2 (left panel). Intriguingly, the agreement would improve with a small amount of extra cooling that slightly postpones helium ignition, preferring an electron coupling around $|g_{Aee}| \sim 1.9 \times 10^{-13}$, corresponding to $m_A \sin^2 \beta \sim 7 \text{ meV}$.

Bremsstrahlung is also efficient in white dwarfs (WDs), where the Primakoff and Compton processes are suppressed by the large plasma frequency. A comparison of the predicted and observed luminosity function of WDs can be used to put limits on $|g_{Aee}|$ [78]. A recent analysis, based on detailed WD cooling treatment and new data on the WD luminosity function (WDLF) of the Galactic Disk, found that electron couplings above $|g_{Aee}| \gtrsim 3 \times 10^{-13}$, corresponding to a DFSZ axion mass $m_A \sin^2 \beta \gtrsim 10 \text{ meV}$, are disfavoured [79], see Fig. 91.2 (left panel). Lower couplings cannot be discarded from the current knowledge of the WDLF of the Galactic Disk. On the contrary, features in some WDLFs can be interpreted as suggestions for electron couplings in the range $7.2 \times 10^{-14} \lesssim |g_{Aee}| \lesssim 2.2 \times 10^{-13}$, corresponding to $2.5 \text{ meV} \lesssim m_A \sin^2 \beta \lesssim 7.5 \text{ meV}$ [79, 80]. This hypothesis will be further scrutinized by the Large Synoptic Survey Telescope (LSST) which is expected to increase the sample of WDs in the Galactic halo to hundreds of thousands [81]. This will allow for the determination of independent WDLFs from different Galactic populations, greatly reducing the uncertainties related to star formation histories. For pulsationally unstable WDs (ZZ Ceti stars), the period decrease \dot{P}/P is a measure of the cooling speed. The corresponding observations of the pulsating WDs G117-B15A and R548 imply additional cooling that can be interpreted also in terms of similar axion losses [82, 83].

Recently, it has been pointed out that the hints of excessive cooling of WDs, RGs and HB stars can be explained at one stroke by an ALP coupling to electrons and photons, with couplings $|g_{Aee}| \sim 1.5 \times 10^{-13}$ and $|g_{A\gamma\gamma}| \sim 1.4 \times 10^{-11} \text{ GeV}^{-1}$, respectively [84, 85]. Intriguingly, good fits to the data can be obtained employing the DFSZ axion with a mass in the range $4 \text{ meV} \lesssim m_A \lesssim 250 \text{ meV}$ [84].

Similar constraints derive from the measured duration of the neutrino signal of the supernova SN 1987A. Numerical simulations for a variety of cases, including axions and Kaluza-Klein gravitons, reveal that the energy-loss rate of a nuclear medium at the density $3 \times 10^{14} \text{ g cm}^{-3}$ and temperature 30 MeV should not exceed about $1 \times 10^{19} \text{ erg g}^{-1} \text{ s}^{-1}$ [86]. The energy-loss rate from nucleon bremsstrahlung, $N+N \rightarrow N+N+A$, is $(C_N/2f_A)^2 (T^4/\pi^2 m_N) F$. Here F is a numerical factor that represents an integral over the dynamical spin-density structure function because axions couple to the nucleon spin. For realistic conditions, even after considerable effort, one is limited to a heuristic estimate leading to $F \approx 1$ [68]. The SN 1987A limits are of particular interest for hadronic axions where the bounds on $|g_{Aee}|$ are moot. Using a proton fraction of 0.3, $g_{Ann} = 0$, $F = 1$, and $T = 30 \text{ MeV}$, one finds $f_A \gtrsim 4 \times 10^8 \text{ GeV}$ and $m_A \lesssim 16 \text{ meV}$ [68], see Fig. 91.2 (right panel). A more detailed numerical calculation [87] with state of the art SN models, again assuming $g_{Ann} = 0$, found that a coupling larger than $|g_{App}| \gtrsim 6 \times 10^{-10}$, would shorten significantly the timescale of the neutrino emission. This result is, not surprisingly, rather close to the estimate in Ref. [68]. Improving the

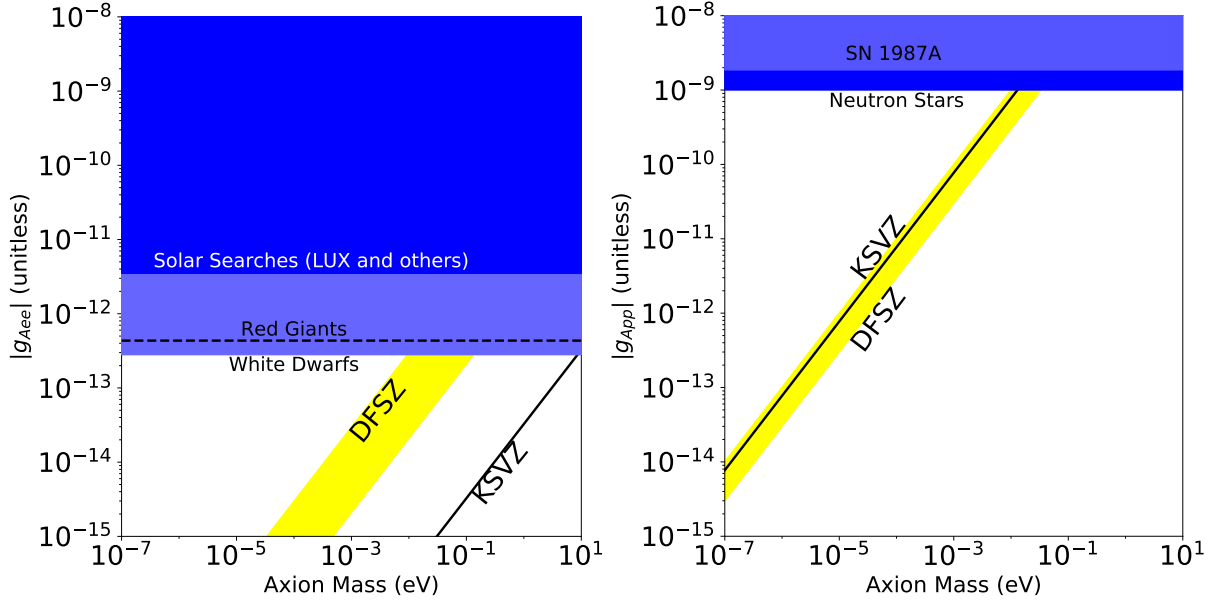

Figure 91.2: Exclusion plots for ALPs as described in the text. For the DFSZ range we have taken into account the constraint $0.28 \lesssim \tan \beta \lesssim 140$ [77] arising from the requirement of perturbative unitarity of the Yukawa couplings of Standard Model fermions.

calculation of axion emission via nucleon-nucleon bremsstrahlung beyond the basic one-pion exchange approximation appears to loosen the bound [88, 89]. The latter analysis finds a reduction of the axion emissivity by an order of magnitude if one takes into account the non-vanishing mass of the exchanged pion, the contribution from two-pion exchange, effective in-medium nucleon masses and multiple nucleon scattering, leading to a looser bound (Maurizio Giannotti and Alessandro Mirizzi, private communication)

$$g_{Ann}^2 + 0.29 g_{App}^2 + 0.27 g_{Ann} g_{App} < 3.25 \times 10^{-18}. \quad (91.16)$$

However, with the present understanding of SNe (current lack of self-consistent 3D SN simulations) and the sparse data from SN 1987A, the constraint on the axion-nucleon couplings from SN 1987A should be considered more as indicative than as a sharp bound [87].

If axions interact sufficiently strongly they are trapped. Only about three orders of magnitude in g_{ANN} or m_A are excluded. For even larger couplings, the axion flux would have been negligible, yet it would have triggered additional events in the detectors, excluding a further range [90]. A possible gap between these two SN 1987A arguments was discussed as the “hadronic axion window” under the assumption that $g_{A\gamma\gamma}$ was anomalously small [91]. This range is now excluded by hot dark matter (HDM) bounds (see below).

There is another hint for excessive stellar energy losses from the neutron star (NS) in the supernova remnant Cassiopeia A (Cas A): its surface temperature measured over 10 years reveals an unusually fast cooling rate. This rapid cooling of the Cas A NS may be explained by NS minimal cooling with neutron superfluidity and proton superconductivity [92, 93]. The rapid cooling may also arise from a phase transition of the neutron condensate into a multicomponent state [94]. Recently, Ref. [95] analyzed Cas A NS cooling in the presence of axion emission and obtained

$$g_{App}^2 + 1.6g_{Ann}^2 < 1 \times 10^{-18}, \quad (91.17)$$

which is comparable to the SN 1987A bound. Refs. [96] put a more conservative bound without an attempt to fit a transient behavior of Cas A,

$$g_{App}^2 < (1 - 6) \times 10^{-17} \text{ (or } f_A > (5 - 10) \times 10^7 \text{ GeV)}, \quad (91.18)$$

from the temperatures of Cas A and other NSs. The Cas A NS cooling may also be interpreted as a hint for extra cooling caused

by the emission of axions from the breaking and re-formation of neutron triplet Cooper pairs [97], requiring a coupling to the neutron of

$$g_{Ann}^2 = (1.4 \pm 0.5) \times 10^{-19}, \quad (91.19)$$

corresponding to an axion mass

$$m_A = (2.3 \pm 0.4) \text{ meV}/C_n. \quad (91.20)$$

On the other hand, Ref. [98] considered another hot young NS in the supernova remnant HESS J1731-347. Its high temperature implies that all the neutrino emission processes except neutron-neutron bremsstrahlung must be strongly suppressed, which can be realized with a negligible neutron triplet gap and a large proton singlet gap. In this setup, the bremsstrahlung from neutrons is the dominant channel for axion emission, from which one obtains a limit

$$g_{Ann}^2 < 7.7 \times 10^{-20}, \quad (91.21)$$

see Fig. 91.3 (left panel).

Finally, let us note that if the interpretation of the various hints for additional cooling of stars reported in this section in terms of emission of axions with $m_A \sim \text{meV}$ were correct, SNe would lose a large fraction of their energy as axions. This would lead to a diffuse SN axion background in the universe with an energy density comparable to the extra-galactic background light [99]. However, there is no apparent way of detecting it or the axion burst from the next nearby SN. On the other hand, neutrino detectors such as IceCube, Super-Kamiokande or a future mega-ton water Cherenkov detector will probe exactly the mass region of interest by measuring the neutrino pulse duration of the next galactic SN [87].

91.4.2 Searches for solar axions and ALPs

Instead of using stellar energy losses to derive axion limits, one can also search directly for these fluxes, notably from the Sun. The main focus has been on ALPs with a two-photon vertex. They are produced by the Primakoff process with a flux given by Eq. (91.12) and an average energy of 4.2 keV, and can be detected at Earth with the reverse process in a macroscopic B -field (“axion helioscope”) [6]. In order to extend the sensitivity in mass towards larger values, one can endow the photon with an effective mass in a gas, $m_\gamma = \omega_{\text{plas}}$, thus matching the axion and photon dispersion relations [100].

An early implementation of these ideas used a conventional dipole magnet, with a conversion volume of variable-pressure gas with a xenon proportional chamber as x-ray detector [101]. The

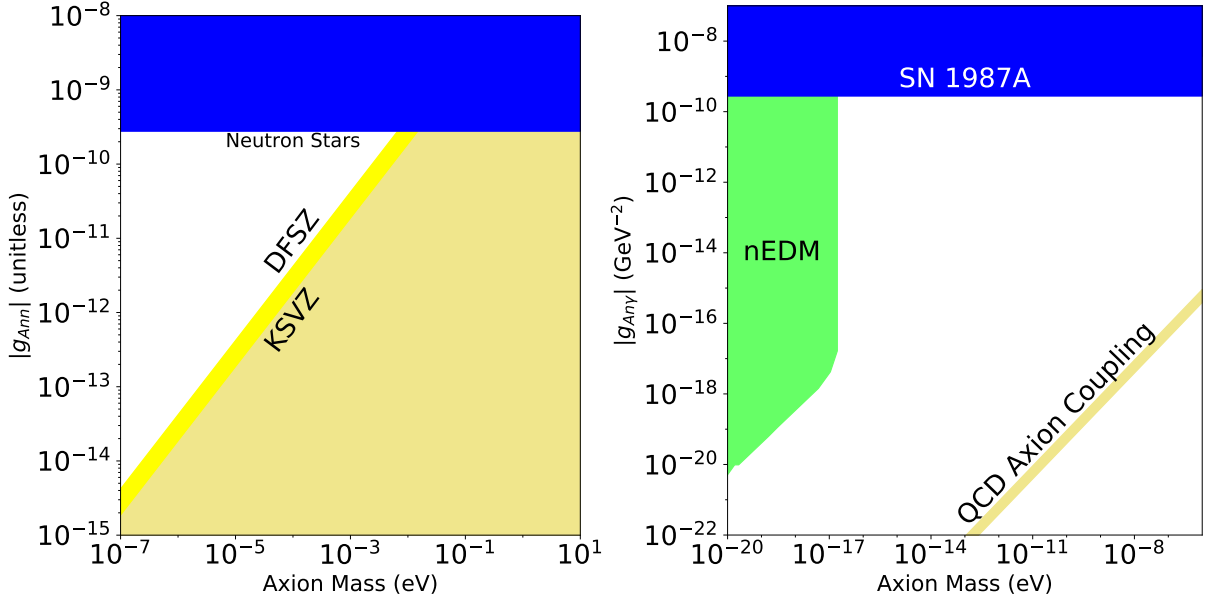

Figure 91.3: Exclusion plots for ALPs as described in the text.

conversion magnet was fixed in orientation and collected data for about 1000 s/day. Axions were excluded for $|g_{A\gamma\gamma}| < 3.6 \times 10^{-9} \text{ GeV}^{-1}$ for $m_A < 0.03 \text{ eV}$, and $|g_{A\gamma\gamma}| < 7.7 \times 10^{-9} \text{ GeV}^{-1}$ for $0.03 < m_A < 0.11 \text{ eV}$ at 95% CL.

Later, the Tokyo axion helioscope used a superconducting magnet on a tracking mount, viewing the Sun continuously. They reported $|g_{A\gamma\gamma}| < 6 \times 10^{-10} \text{ GeV}^{-1}$ for $m_A < 0.3 \text{ eV}$ [102]. This experiment was recommissioned and a similar limit for masses around 1 eV was reported [103].

The most recent helioscope CAST (CERN Axion Solar Telescope) uses a decommissioned LHC dipole magnet on a tracking mount. The hardware includes grazing-incidence x-ray optics with solid-state x-ray detectors, as well as novel x-ray Micromegas position-sensitive gaseous detectors. Exploiting a IAXO (see below) pathfinder system, CAST has established the limit

$$|g_{A\gamma\gamma}| < 6.6 \times 10^{-11} \text{ GeV}^{-1} \quad (95\% \text{ CL}), \quad (91.22)$$

for $m_A < 0.02 \text{ eV}$ [104]. To cover larger masses, the magnet bores are filled with a gas at varying pressure. The runs with ^4He cover masses up to about 0.4 eV [105], providing the ^4He limits shown in Fig. 91.1. To cover yet larger masses, ^3He was used to achieve a larger pressure at cryogenic temperatures. Limits up to 1.17 eV allowed CAST to “cross the axion line” for the KSVZ model [106], see Fig. 91.1.

Going to yet larger masses in a helioscope search is not well motivated because of the cosmic HDM bound of $m_A \lesssim 1 \text{ eV}$ (see below). Sensitivity to significantly smaller values of $g_{A\gamma\gamma}$ can be achieved with a next-generation axion helioscope with a much larger magnetic-field cross section. Realistic design options for this “International Axion Observatory” (IAXO) have been studied in some detail [107] and its physics potential has been reviewed recently [108]. Such a next-generation axion helioscope may also push the sensitivity in the product of couplings to photons and to electrons, $g_{A\gamma\gamma}g_{Aee}$, into a range beyond stellar energy-loss limits and test the hypothesis that WD, RG, and HB cooling is dominated by axion emission [84, 109]. As a first step towards IAXO, an intermediate experimental stage called BabyIAXO is currently under preparation at DESY (for a short introduction, see Ref. [108]).

Other Primakoff searches for solar axions and ALPs have been carried out using crystal detectors, exploiting the coherent conversion of axions into photons when the axion angle of incidence satisfies a Bragg condition with a crystal plane [110]. However, none of these limits is more restrictive than the one derived from the constraint on the solar axion luminosity ($L_A \lesssim 0.10 L_\odot$) discussed earlier.

Another idea is to look at the Sun with an x-ray satellite when the Earth is in between. Solar axions and ALPs would convert in the Earth magnetic field on the far side and could be detected [111]. The sensitivity to $g_{A\gamma\gamma}$ could be comparable to CAST, but only for much smaller m_A . Deep solar x-ray measurements with existing satellites, using the solar magnetosphere as conversion region, have reported preliminary limits on $g_{A\gamma\gamma}$ [112].

Direct detection experiments searching for dark matter (DM) consisting of weakly interacting massive particles, such as EDELWEISS-II, LUX, and XENON100, have also the capability to search for solar axions and ALPs [113, 114]. Recently, the LUX experiment [114] has put a bound on the axion-electron coupling constant by exploiting the axio-electric effect in liquid xenon,

$$|g_{Aee}| < 3.5 \times 10^{-12} \quad (90\% \text{ CL}), \quad (91.23)$$

excluding the DFSZ model with $m_A \sin^2 \beta > 0.12 \text{ eV}$, cf. see Fig. 91.2 (left panel). However, as obvious from the same figure, this technique has not reached the sensitivity of energy-loss considerations in stars (RGs and WDs).

91.4.3 Conversion of astrophysical photon fluxes

Large-scale B fields exist in astrophysics that can induce axion-photon oscillations. In practical cases, B is much smaller than in the laboratory, whereas the conversion region L is much larger. Therefore, while the product BL can be large, realistic sensitivities are usually restricted to very low-mass particles, far away from the “axion band” in a plot like Fig. 91.1.

One example is SN 1987A, which would have emitted a burst of ALPs due to the Primakoff production in its core. They would have partially converted into γ -rays in the galactic B -field. The lack of a gamma-ray signal in the GRS instrument of the SMM satellite in coincidence with the observation of the neutrinos emitted from SN 1987A therefore provides a strong bound on their coupling to photons [115]. This bound has been revisited and the underlying physics has been brought to the current state-of-the-art, as far as modelling of the supernova and the Milky-Way magnetic field are concerned, resulting in the limit [116]

$$|g_{A\gamma\gamma}| < 5.3 \times 10^{-12} \text{ GeV}^{-1}, \text{ for } m_A \lesssim 4.4 \times 10^{-10} \text{ eV}, \quad (91.24)$$

see Fig. 91.1. Magnetically induced oscillations between photons and ALPs can modify the photon fluxes from distant sources in various ways, featuring (i) frequency-dependent dimming, (ii) modified polarization, and (iii) avoiding absorption by propagation in the form of axions.

For example, dimming of SNe Ia could influence the interpretation in terms of cosmic acceleration [117], although it has become

clear that photon-ALP conversion could only be a subdominant effect [118]. Searches for linearly polarised emission from magnetised white dwarfs [119] and changes of the linear polarisation from radio galaxies (see, e.g., Ref. [120]) provide limits close to $g_{A\gamma\gamma} \sim 10^{-11} \text{ GeV}^{-1}$, for masses $m_A \lesssim 10^{-7} \text{ eV}$ and $m_A \lesssim 10^{-15} \text{ eV}$, respectively, albeit with uncertainties related to the underlying assumptions. Even stronger limits, $g_{A\gamma\gamma} \lesssim 2 \times 10^{-13} \text{ GeV}^{-1}$, for $m_A \lesssim 10^{-14} \text{ eV}$, have been obtained by exploiting high-precision measurements of quasar polarisations [121].

Remarkably, it appears that the universe could be too transparent to TeV γ -rays that should be absorbed by pair production on the extra-galactic background light [122–126]. The situation is not conclusive at present [127–129], but the possible role of photon-ALP oscillations in TeV γ -ray astronomy is tantalizing [130]. Fortunately, the region in ALP parameter space, $g_{A\gamma\gamma} \sim 10^{-12} - 10^{-10} \text{ GeV}^{-1}$ for $m_A \lesssim 10^{-7} \text{ eV}$ [131], required to explain the anomalous TeV transparency of the universe, could be conceivably probed by the next generation of laboratory experiments (ALPS II) and helioscopes (IAXO) mentioned above. This parameter region can also be probed by searching for an irregular behavior of the gamma ray spectrum of distant active galactic nuclei (AGN), expected to arise from photon-ALP mixing in a limited energy range. The H.E.S.S. collaboration has set a limit of $|g_{A\gamma\gamma}| \lesssim 2.1 \times 10^{-11} \text{ GeV}^{-1}$, for $1.5 \times 10^{-8} \text{ eV} \lesssim m_A \lesssim 6.0 \times 10^{-8} \text{ eV}$, from the non-observation of an irregular behavior of the spectrum of the AGN PKS 2155-304 [132], see Fig. 91.1. The Fermi-LAT collaboration has put an even more stringent limit on the ALP-photon coupling [133] from observations of the gamma ray spectrum of NGC 1275, the central galaxy of the Perseus cluster, see Fig. 91.1. A similar analysis has been carried out in Ref. [134] using Fermi-LAT data of PKS 2155-304.

Evidence for spectral irregularities has been reported in Galactic sources, such as pulsars and supernova remnants, and has been interpreted as hints for ALPs [135, 136]. However, the inferred ALP parameters are in tension with the CAST helioscope bounds. It should also be noted that the high signal-to-noise spectra of Galactic gamma-ray sources are dominated by uncertainties of the instrumental systematics rather than statistical errors. Furthermore, it has been shown that additional care has to be taken when deriving confidence intervals on ALP parameters based on Wilks' theorem [137], since it has been shown that it does not apply for testing the ALP hypothesis [133].

At smaller masses, $m_A \lesssim 10^{-12} \text{ eV}$, galaxy clusters become highly efficient at interconverting ALPs and photons at x-ray energies. Constraints on spectral irregularities in the spectra of luminous x-ray sources (Hydra A, M87, NGC 1275, NGC 3862, Seyfert galaxy 2E3140; taken by Chandra and XMM-Newton) located in or behind galaxy clusters then lead to stringent upper limits on the ALP-photon coupling [138–143]. In this type of studies, the uncertainty in the cluster magnetic field needs to be taken into account. This typically leads to a range of limits on the ALP-photon coupling that depend on the modelling assumptions. Reference [143] recently performed the most sensitive x-ray searches for ALPs to date by employing Chandra's High-Energy Transmission Gratings that allow for an unsurpassed spectral resolution. New observations of the AGN NGC 1275 then led to the bound

$$|g_{A\gamma\gamma}| < 8 \times 10^{-13} \text{ GeV}^{-1} \quad (99.7\% \text{ CL}) \quad (91.25)$$

for light ALPs, see Fig. 91.1.

91.4.4 Superradiance of black holes

Light bosonic fields such as axions or ALPs can affect the dynamics and gravitational wave emission of rapidly rotating astrophysical black holes through the superradiance mechanism. When their Compton wavelength is of order of the black hole size, they form gravitational bound states around the black hole. Their occupation number grows exponentially by extracting energy and angular momentum from the black hole, forming a coherent axion or ALP bound state emitting gravitational waves. When accretion cannot replenish the spin of the black hole, superradiance dominates the black hole spin evolution; this is true for both su-

permassive and stellar mass black holes. The existence of destabilizing light bosonic fields thus leads to gaps in the mass vs. spin plot of rotating black holes. Stellar black hole spin measurements – exploiting well-studied binaries and two independent techniques – exclude a mass range $6 \times 10^{-13} \text{ eV} < m_A < 2 \times 10^{-11} \text{ eV}$ at 2σ , which for the axion excludes $3 \times 10^{17} \text{ GeV} < f_A < 1 \times 10^{19} \text{ GeV}$ [11, 144, 145]. These bounds apply when gravitational interactions dominate over the axion self-interaction, which is true for the QCD axion in this mass range. Long lasting, monochromatic gravitational wave signals, which can be distinguished from ordinary astrophysical sources by their clustering in a narrow frequency range, are expected to be produced by axions or ALPs annihilating to gravitons. Gravitational waves could also be sourced by axions/ALPs transitioning between gravitationally bound levels. Accordingly, the gravitational wave detector Advanced LIGO should be sensitive to the axion in the $m_A \lesssim 10^{-10} \text{ eV}$ region. LIGO measurements of black hole spins in binary merger events could also provide statistical evidence for the presence of an axion [146, 147]. Similar signatures could arise for supermassive black holes for particle with masses $\lesssim 10^{-15} \text{ eV}$. Gravitational waves from such sources could be detected at lower-frequency observatories such as LISA.

91.5 Cosmic Axions

91.5.1 Cosmic axion populations

In the early universe, axions are produced by processes involving quarks and gluons [148]. After color confinement, the dominant thermalization process is $\pi + \pi \leftrightarrow \pi + A$ [34]. The resulting axion population would contribute an HDM component in analogy to massive neutrinos. Cosmological precision data provide restrictive constraints on a possible HDM fraction that translate into $m_A \lesssim 1 \text{ eV}$ [149], but in detail depend on the used data set and assumed cosmological model. In the future, data from a EUCLID-like survey combined with Planck CMB data can detect HDM axions with a mass $m_A \gtrsim 0.15 \text{ eV}$ at very high significance [150].

For $m_A \gtrsim 20 \text{ eV}$, axions decay fast on a cosmic time scale, removing the axion population while injecting photons. This excess radiation provides additional limits up to very large axion masses [151]. An anomalously small $g_{A\gamma\gamma}$ provides no loophole because suppressing decays leads to thermal axions overdominating the mass density of the universe.

The main cosmological interest in axions derives from their possible role as CDM. In addition to thermal processes, axions are abundantly produced by the vacuum re-alignment (VR) mechanism [152].

The axion DM abundance crucially depends on the cosmological history. Let us first consider the so called *pre-inflationary PQ symmetry breaking scenario*, in which the PQ symmetry is broken before and during inflation and not restored afterwards. After the breakdown of the PQ symmetry, the axion field relaxes somewhere in the bottom of the “wine-bottle-bottom” potential. Near the QCD epoch, topological fluctuations of the gluon fields such as instantons explicitly break the PQ symmetry. This tilting of the “wine-bottle-bottom” drives the axion field toward the CP-conserving minimum, thereby exciting coherent oscillations of the axion field that ultimately represent a condensate of CDM. The fractional cosmic mass density in this homogeneous field mode, created by the VR mechanism, is [23, 153–155],

$$\begin{aligned} \Omega_A^{\text{VR}} h^2 &\approx 0.12 \left(\frac{f_A}{9 \times 10^{11} \text{ GeV}} \right)^{1.165} F \Theta_i^2 \\ &\approx 0.12 \left(\frac{6 \mu\text{eV}}{m_A} \right)^{1.165} F \Theta_i^2, \end{aligned} \quad (91.26)$$

where h is the present-day Hubble expansion parameter in units of $100 \text{ km s}^{-1} \text{ Mpc}^{-1}$, and $-\pi \leq \Theta_i \leq \pi$ is the initial “misalignment angle” relative to the CP-conserving position attained in the causally connected region which evolved into today's observable universe. $F = F(\Theta_i, f_A)$ is a factor accounting for anharmonicities in the axion potential. For $F \Theta_i^2 = \mathcal{O}(1)$, m_A should be above $\sim 6 \mu\text{eV}$ in order that the cosmic axion density does not exceed the observed CDM density, $\Omega_{\text{CDM}} h^2 = 0.12$. However, much smaller

axion masses (much higher PQ scales) are still possible if the initial value Θ_i just happens to be small enough in today's observable universe ("anthropic axion window" [156]). In this cosmological scenario, however, quantum fluctuations of the axion field during inflation are expected to lead to isocurvature density fluctuations which get imprinted to the temperature fluctuations of the CMB [157, 158]. Their non-observation puts severe constraints on the Hubble expansion rate H_I during inflation [159–163], which read, in the simplest cosmological inflationary scenario,

$$H_I \lesssim 5.7 \times 10^8 \text{ GeV} \left(\frac{5 \text{ neV}}{m_a} \right)^{0.4175}, \quad (91.27)$$

if axions represent all of DM.

In the *post-inflationary PQ symmetry breaking scenario*, on the other hand, Θ_i will take on different values in different patches of the present universe. The average contribution is [23, 153–155]

$$\Omega_A^{\text{VR}} h^2 \approx 0.12 \left(\frac{30 \text{ } \mu\text{eV}}{m_A} \right)^{1.165}. \quad (91.28)$$

The decay of cosmic strings and domain walls gives rise to a further population of CDM axions, whose abundance suffers from significant uncertainties [154, 155, 164–172] which arise from the difficulty in understanding the energy loss process of topological defects and the generated axion spectrum in a quantitative way. In fact, in the present state-of-the-art it is still possible that the CDM contribution from the decay of topological defects is subdominant or overwhelmingly large in comparison to the one from the VR mechanism. Correspondingly, the plausible range of axion masses providing all of CDM in scenarios with postinflationary PQ symmetry breaking is still rather large, namely

$$m_A \approx 25 \text{ } \mu\text{eV} - 4.4 \text{ meV}, \quad (91.29)$$

for models with short-lived (requiring unit color anomaly $N = 1$) domain walls, such as the KSVZ model. For models with long-lived ($N > 1$) domain walls, such as an accidental DFSZ model [173], where the PQ symmetry is broken by higher dimensional Planck suppressed operators, the mass is predicted to be significantly higher [168, 173, 174],

$$m_A \approx (0.58 - 130) \text{ meV}. \quad (91.30)$$

However, the upper part of the predicted range is in conflict with stellar energy-loss limits on the axion, cf. Fig. 91.2 (right panel) and Fig. 91.3 (left panel).

In this post-inflationary PQ symmetry breakdown scenario, the spatial axion density variations are large at the QCD transition and they are not erased by free streaming. Gravitationally bound "axion miniclusters" form before and around matter-radiation equality [175–177]. A significant fraction of CDM axions can reside in these bound objects [171, 178]. Remarkably, the minicluster fraction can be bounded by gravitational lensing [179–181].

In the above predictions of the fractional cosmic mass density in axions, the exponent, 1.165, arises from the non-trivial temperature dependence of the topological susceptibility $\chi(T) = m_A^2(T) f_A^2$ at temperatures slightly above the QCD quark-hadron phase transition. Lattice QCD calculations of this exponent [23, 182–186], but also Ref. [187], found it to be remarkably close to the prediction of the dilute instanton gas approximation [188] which was previously exploited. Therefore, the state-of-the-art prediction of the axion mass relevant for DM for a fixed initial misalignment angle Θ_i differs from the previous prediction by just a factor of order one.

The non-thermal production mechanisms attributed to axions are generic to light bosonic weakly interacting particles such as ALPs [189]. The relic abundance is set by the epoch when the axion mass becomes significant, $3H(t) \approx m_A(t)$, and ALP field oscillations begin. For ALPs to contribute to the DM density this epoch must precede that of matter radiation equality. For a temperature independent ALP mass this leads to the bound:

$$m_A \gtrsim 7 \times 10^{-28} \text{ eV} \left(\frac{\Omega_m h^2}{0.15} \right)^{1/2} \left(\frac{1 + z_{\text{eq}}}{3.4 \times 10^3} \right)^{3/2}. \quad (91.31)$$

ALPs lighter than this bound are allowed if their cosmic energy density is small, but they are quite distinct from other forms of DM [190]. Ignoring anharmonicities in the ALP potential, and taking the ALP mass to be temperature independent, the relic density in DM ALPs due to the VR mechanism is given by

$$\Omega_{\text{ALP}}^{\text{VR}} h^2 = 0.12 \left(\frac{m_A}{4.7 \times 10^{-19} \text{ eV}} \right)^{1/2} \left(\frac{f_A}{10^{16} \text{ GeV}} \right)^2 \times \left(\frac{\Omega_m h^2}{0.15} \right)^{3/4} \left(\frac{1 + z_{\text{eq}}}{3.4 \times 10^3} \right)^{-3/4} \Theta_i^2. \quad (91.32)$$

An ALP decay constant near the GUT scale gives the correct relic abundance for *ultralight ALPs* (ULAs), which we now define. Extended discussions of ULAs can be found in Refs. [191, 192].

The standard CDM model treats DM as a distribution of cold, collisionless particles interacting only via gravity. Below the Compton wavelength, $\lambda_c = 2\pi/m_A$, the particle description of ALPs breaks down. For large occupation numbers we can model ALPs below the Compton wavelength as a coherent classical field. Taking as a reference length scale the Earth radius, $R_{\oplus} = 6371 \text{ km}$, we define ULAs to be those axions with $\lambda_c > R_{\oplus}$, leading to the defining bound

$$m_{\text{ULA}} < 2 \times 10^{-13} \text{ eV}. \quad (91.33)$$

ULAs encompass the entire Earth in a single coherent field. The coherence time of the ULA field on Earth can be estimated from the crossing time of the de Broglie wavelength at the virial velocity in the Milky Way, $\tau_{\text{coh}} \sim 1/m_{\text{ULA}} v_{\text{vir}}^2$.

We notice that by the definition, Eq. (91.33), an ultralight QCD axion must have a super-Planckian decay constant, $f_A > 3 \times 10^{19} \text{ GeV}$ and would require fine tuning of θ_i to provide the relic abundance. Natural models for ULAs can be found in string and M-theory compactifications [7–14], in field theory with accidental symmetries [193], or new hidden strongly coupled sectors [194].

In addition to the gravitational potential energy, the ULA field also carries gradient energy. On scales where the gradient energy is non-negligible, ULAs acquire an effective pressure and do not behave as CDM. The gradient energy opposes gravitational collapse, leading to a Jeans scale below which perturbations are stable [195]. The Jeans scale suppresses linear cosmological structure formation relative to CDM [196]. The Jeans scale at matter-radiation equality in the case that ULAs make up all of CDM is:

$$k_{\text{J,eq}} = 8.7 \text{ Mpc}^{-1} \left(\frac{1 + z_{\text{eq}}}{3.4 \times 10^3} \right)^{-1/4} \left(\frac{\Omega_{\text{ALP}}^{\text{VR}}}{0.12} \right)^{1/4} \times \left(\frac{m_{\text{ULA}}}{10^{-22} \text{ eV}} \right)^{1/2}. \quad (91.34)$$

On non-linear scales the gradient energy leads to the existence of a class of pseudo-solitons known as oscillatons, or axion stars [197].

Cosmological and astrophysical observations are consistent with the CDM model, and departures from it are only allowed on the scales of the smallest observed DM structures with $M \sim 10^{6-8} M_{\odot}$. The CMB power spectrum and galaxy auto-correlation power spectrum limit the ULA mass to $m_{\text{ULA}} > 10^{-24} \text{ eV}$ from linear theory of structure formation [190, 198]. Analytic models [199] and N -body simulations [200] for non-linear structures show that halo formation is suppressed in ULA models relative to CDM. This leads to constraints on the ULA mass of $m_{\text{ULA}} > 10^{-22} \text{ eV}$ from observations of high- z galaxies [200, 201], and $m_{\text{ULA}} > 10^{-21} \text{ eV}$ from the Lyman-alpha forest flux power spectrum [202]. Including the effects of anharmonicities on structure formation with ALPs can weaken these bounds if the misalignment angle $\Theta_i \approx \pi$ [203]. Cosmological simulations that treat gradient energy in the ULA field beyond the N -body approximation have just recently become available [204, 205], and show, among other things, evidence for the formation of axion stars in the centres of ULA halos (various consequences of axion stars are considered in Refs. [206]). These central axion stars have been conjectured to play a role in the apparently cored density

profiles of dwarf spheroidal galaxies, and other central galactic regions [204, 207–209]. However, the relationship between the halo mass and the axion star mass [210] leads to problems with this scenario in some galaxies [211–213]. It should be emphasised that many of the conclusions about the role of ULA axion stars in galactic dynamics are based on use of simulation results that do not contain baryons (however, see Ref. [214]), and feedback [215] could be important.

Inside DM halos the axion gradient energy causes coherence on the de Broglie wavelength and fluctuations on the coherence time [204, 216]. These fluctuations can be thought of as short-lived quasiparticles and lead to relaxation processes that can be described statistically [192, 217] (this relaxation processes also leads to the gravitational condensation of axion stars [218]). The typical relaxation time is:

$$t \sim 10^{10} \text{ years} \left(\frac{m_{\text{ULA}}}{10^{-22} \text{ eV}} \right)^3 \left(\frac{v}{100 \text{ km s}^{-1}} \right)^2 \left(\frac{r}{5 \text{ kpc}} \right)^4, \quad (91.35)$$

where v and r are the velocity and radius of the orbit in the host DM halo.

Relaxation processes such as these are not observed in galaxies, though there are some circumstances where they may be desirable [192]. An absence of observed relaxation can be used to set limits on the ULA mass. An absence of observed Milky Way disk thickening excludes $m_{\text{ULA}} > 0.6 \times 10^{-22} \text{ eV}$ [219], while stellar streams give the stronger bound $m_{\text{ULA}} > 1.5 \times 10^{-22} \text{ eV}$ [220]. The survival of the old star cluster in Eridanus II [221] excludes the range of masses $10^{-21} \text{ eV} \lesssim m_{\text{ULA}} \lesssim 10^{-19} \text{ eV}$ [222]. As in the case of ULA axion stars, current constraints from heating do not fully account for the possible role of baryons.

Finally, one should note that the beyond-CDM physics of ULAs (Jeans scale, relaxation, axion star formation) of course also applies to the QCD axion on smaller length scales. This is of particular interest inside axion miniclusters [175, 176, 218, 223].

91.5.2 Telescope searches

The two-photon decay is extremely slow for axions with masses in the CDM regime, but could be detectable for eV masses. The signature would be a quasi-monochromatic emission line from galaxies and galaxy clusters. The expected optical line intensity for DFSZ axions is similar to the continuum night emission. An early search in three rich Abell clusters [224] and a recent search in two rich Abell clusters [225] exclude the ‘‘Telescope’’ range in Fig. 91.1. Of course, axions in this mass range would anyway provide an excessive hot DM contribution.

Very low-mass axions in halos produce a weak quasi-monochromatic radio line. Virial velocities in undisrupted dwarf galaxies are very low, and the axion decay line would therefore be extremely narrow. A search with the Haystack radio telescope on three nearby dwarf galaxies provided a limit $|g_{A\gamma\gamma}| < 1.0 \times 10^{-9} \text{ GeV}^{-1}$ at 96% CL for $298 < m_A < 363 \mu\text{eV}$ [226]. However, this combination of m_A and $g_{A\gamma\gamma}$ does not exclude plausible axion models.

A monochromatic signal is also produced in the conversion of DM axions in the background of slowly varying galactic B -fields [227]. The signal is, however, sensitive to magnetic field power on the scale of the axion mass [228]. Present and future radio telescopes appear to be able to probe ALP DM in the mass range $0.1 - 100 \mu\text{eV}$ for couplings $g_{A\gamma\gamma} \gtrsim 10^{-13} \text{ GeV}^{-1}$ [228] – unfortunately not reaching down to the benchmark QCD axion sensitivity.

Resonant conversion of QCD axion DM in neutron star magnetospheres may give a detectable signal from individual neutron stars for axion masses in the μeV range [229]. Furthermore, stimulated ALP decays in high radiation environments may be detectable, by next-generation radio telescopes such as the Square Kilometer Array, down to $g_{A\gamma\gamma} \gtrsim 10^{-11} \text{ GeV}^{-1}$, for masses between μeV and 0.1 meV [230].

Photon propagation on an ULA DM background can induce birefringence that can be compared with upper limits from the CMB [231] and may also be probed with other sources such as pulsars [232].

91.5.3 Microwave cavity experiments

In a big part of the plausible m_A range for CDM, galactic halo axions may be detected by their resonant conversion into a quasi-monochromatic microwave signal in a high-Q electromagnetic cavity permeated by a strong static B field [6, 233, 234]. The cavity frequency is tunable, and the signal is maximized when the frequency is the total axion energy, rest mass plus kinetic energy, of $\nu = (m_A/2\pi) [1 + \mathcal{O}(10^{-6})]$, the width above the rest mass representing the virial distribution in the galaxy. The frequency spectrum may also contain finer structure from axions more recently fallen into the galactic potential and not yet completely virialized [235, 236].

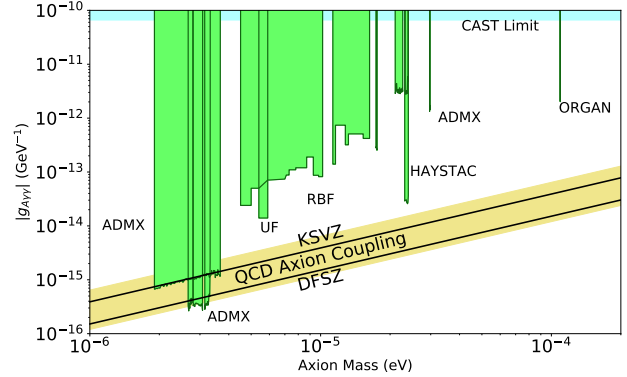

Figure 91.4: Exclusion plot for ALPs as described in the text.

The feasibility of this technique was established in early experiments (RBF and UF) of relatively small sensitive volume, $\mathcal{O}(1)$ liter), with HFET-based amplifiers, setting limits in the range $4.5 < m_A < 16.3 \mu\text{eV}$ [237], but lacking by 2–3 orders of magnitude the sensitivity required to detect realistic axions, see Fig. 91.4. Later, ADMX ($B \sim 8 \text{ T}$, $V \sim 200$ liters) has achieved sensitivity to KSVZ axions, assuming they saturate the local DM density and are well virialized, over the mass range $1.9 - 3.3 \mu\text{eV}$ [238]. Should halo axions have a significant component not yet virialized, ADMX is sensitive to DFSZ axions over the entire mass range [239]. The corresponding 90% CL exclusion regions shown in Fig. 91.4 are normalized to an assumed local CDM density of $7.5 \times 10^{-25} \text{ g cm}^{-3}$ (450 MeV cm^{-3}). More recently, the ADMX experiment commissioned an upgrade [240] that replaces the microwave HFET amplifiers by near quantum-limited low-noise dc SQUID microwave amplifiers [241]. It has reached an unprecedented axion DM sensitivity in the mass range between 2.66 and $3.31 \mu\text{eV}$ [242, 243], down to the DFSZ benchmark axion-photon coupling, see Fig. 91.4. This apparatus is also sensitive to other hypothetical light bosons, such as hidden photons or chameleons, over a limited parameter space [189, 244, 245]. ADMX has also done a testbed experiment to probe higher masses. This experiment lives inside of and operates in tandem with the main ADMX experiment, searches in three widely spaced frequency ranges (4202–4249 MHz, 5086–5799 MHz and 7173–7203 MHz), uses both the TM_{010} and TM_{020} cavity modes, and demonstrates the successful use of a piezoelectric actuator for cavity tuning [246]. Recently, the HAYSTAC experiment reported on first results from a new microwave cavity search for DM axions with masses above $20 \mu\text{eV}$. They exclude axions with two-photon coupling $|g_{A\gamma\gamma}| \gtrsim 2 \times 10^{-14} \text{ GeV}^{-1}$ over the range $23.15 \mu\text{eV} < m_A < 24.0 \mu\text{eV}$ [247, 248], a factor of 2.7 above the KSVZ benchmark, see Fig. 91.4. Exploiting a Josephson parametric amplifier, this experiment has demonstrated total noise approaching the standard quantum limit for the first time in an axion search. A Rydberg atom single-photon detector [249], like any photon counter, can in principle evade the standard quantum limit for coherent photon detection. The ORGAN experiment is designed to probe axions in the mass range $60 \mu\text{eV} < m_A < 210 \mu\text{eV}$. In a pathfinding run, it has set the limit $|g_{A\gamma\gamma}| < 2 \times 10^{-12} \text{ GeV}^{-1}$ at $110 \mu\text{eV}$, in a span of 2.5 neV [250]. There are further microwave cavity axion DM experiments recently in operation (CULTASK [251]), under construction (RADES [252]) or proposed (KLASH [253]).

91.5.4 New concepts for axion DM direct detection

Other new concepts for searching for axion DM are also being investigated. An alternative to the microwave cavity technique is based on a novel detector architecture consisting of an open, Fabry-Perot resonator and a series of current-carrying wire planes [254]. The Orpheus detector has demonstrated this new technique, excluding DM ALPs with masses between 68.2 and 76.5 μeV and axion-photon couplings greater than $4 \times 10^{-7} \text{ GeV}^{-1}$. This technique may be able to probe DM axions in the mass range from 40 to 700 μeV . Another detector concept exploits the fact that a magnetized mirror would radiate photons in the background of axion DM, which could be collected like in a dish antenna [255]. Searches for hidden photon DM exploiting this technique are already underway [256]. The proposed MADMAX experiment will place a stack of dielectric layers in a magnetic field in order to resonantly enhance the photon signal, aiming a sensitivity to probe the mass range $40 \mu\text{eV} \lesssim m_A \lesssim 200 \mu\text{eV}$ [257, 258]. Optical dielectric haloscopes with single photon signal detection have been proposed to search for axions in the 50 meV – 10 eV mass range [259]. Absorption of axions on molecular transitions can be sensitive to the axion pseudoscalar coupling g_{ANN} to nucleons or the pseudoscalar coupling g_{Aee} to electrons in the 0.5 – 20 eV range [260]. Another proposed axion DM search method sensitive in the 100 μeV mass range is to cool a kilogram-sized sample to mK temperatures and count axion induced atomic transitions using laser techniques [261].

The oscillating galactic DM axion field induces oscillating nuclear electric dipole moments (EDMs) [262],

$$d_N(t) = g_{AN\gamma} \sqrt{2\rho_{\text{ADM}}} \cos(m_A t) / m_A, \quad (91.36)$$

where $g_{AN\gamma}$ is the coupling of the axion to the nucleon EDM operator,

$$\mathcal{L}_A \supset -\frac{i}{2} g_{AN\gamma} A \bar{\Psi}_N \sigma_{\mu\nu} \gamma_5 \Psi_N F^{\mu\nu}. \quad (91.37)$$

For the QCD axion, this coupling is predicted as [263]

$$\begin{aligned} g_{AN\gamma} = -g_{Ap\gamma} &= (3.7 \pm 1.5) \times 10^{-3} \left(\frac{1}{f_A} \right) \frac{1}{\text{GeV}} = \\ &= (6.5 \pm 2.6) \times 10^{-13} \left(\frac{m_A}{\text{meV}} \right) \frac{1}{\text{GeV}^2} \end{aligned} \quad (91.38)$$

and plotted as a yellow diagonal band in Fig. 91.3 (right panel). An analysis of the ratio of spin-precession frequencies of stored ultracold neutrons and ^{199}Hg atoms measured by neutron EDM experiments for an axion-induced oscillating neutron EDM revealed no signal consistent with axion DM, excluding a sizeable region of parameter space in the mass region $10^{-24} \text{ eV} \leq m_A \leq 10^{-17} \text{ eV}$ [264], which surpass the limits on anomalous energy loss of SN 1987A [262] by more than seven orders of magnitude, but are still a few orders of magnitude above the QCD axion expectations, see Fig. 91.3 (right panel). The oscillating EDMs cause also the precession of nuclear spins in a nucleon spin polarized sample in the presence of an electric field. The resulting transverse magnetization can be searched for by exploiting magnetic-resonance (MR) techniques, which are most sensitive in the range of low oscillation frequencies corresponding to sub-neV axion masses. The aim of the corresponding Cosmic Axion Spin Precession Experiment (CASPER) [265] is to probe axion DM in the anthropic window, $f_A \gtrsim 10^{15} \text{ GeV}$ ($m_A \lesssim \text{neV}$), motivated from Grand Unification [266–269]. Sub- μeV ALP masses can also be probed by using the storage ring EDM method proposed in Ref. [270] which exploits a combination of B and E-fields to produce a resonance between the $g - 2$ spin precession frequency and the DM ALP field oscillation frequency. This method, however, does not reach the sensitivity to probe the QCD axion prediction for $g_{AN\gamma}$.

In the intermediate mass region, $\text{neV} \lesssim m_A \lesssim 0.1 \mu\text{eV}$, one may exploit a cooled LC circuit and precision magnetometry to search for the oscillating electric current induced by DM axions in a strong magnetic field [271]. A similar approach is followed by the proposed ABRACADABRA [272] and DM-Radio Pathfinder [273] experiments. Recently, ABRACADABRA-10 cm – a small-scale prototype for a future detector that could be sensitive to the QCD

axion – established upper limits on the axion-photon coupling in the mass range $3.1 \times 10^{-10} \text{ eV} - 8.3 \times 10^{-9} \text{ eV}$ [274], which are, however, not competitive yet with other limits in this mass range, see Fig. 91.1.

An eventually non-zero axion electron coupling g_{Aee} will lead to an electron spin precession about the axion DM wind [275]. The QUAX (QUAerere AXions) experiment aims at exploiting MR inside a magnetized material [276]. Because of the higher Larmor frequency of the electron, it is sensitive in the classic window.

91.6 Conclusions

There is a strengthening physics case for very weakly coupled light particles beyond the Standard Model. The elegant solution of the strong CP problem proposed by Peccei and Quinn yields a particularly strong motivation for the axion. In many theoretically appealing ultraviolet completions of the Standard Model axions and ALPs occur automatically. Moreover, they are natural CDM candidates. Perhaps the first hints of their existence have already been seen in the anomalous excessive cooling of stars and the anomalous transparency of the Universe for VHE gamma rays. Interestingly, a significant portion of previously unexplored, but phenomenologically very interesting and theoretically very well motivated axion and ALP parameter space can be tackled in the foreseeable future by a number of terrestrial experiments searching for axion/ALP DM, for solar axions/ALPs, and for light apparently shining through a wall.

92. Searches for Quark and Lepton Compositeness

Revised 2019 by K. Hikasa (Tohoku University), M. Tanabashi (Nagoya University), K. Terashi (ICEPP, University of Tokyo), and N. Varelas (University of Illinois at Chicago)

92.1. Limits on contact interactions

If quarks and leptons are made of constituents, then at the scale of constituent binding energies (compositeness scale) there should appear new interactions among them. At energies much below the compositeness scale (Λ), these interactions are suppressed by inverse powers of Λ . The dominant effect of the compositeness of fermion ψ should come from the lowest dimensional interactions with four fermions (contact terms), whose most general flavor-diagonal color-singlet chirally invariant form reads [1,2]

$$\mathcal{L} = \mathcal{L}_{LL} + \mathcal{L}_{RR} + \mathcal{L}_{LR} + \mathcal{L}_{RL},$$

with

$$\begin{aligned} \mathcal{L}_{LL} &= \frac{g_{\text{contact}}^2}{2\Lambda^2} \sum_{i,j} \eta_{LL}^{ij} (\bar{\psi}_L^i \gamma_\mu \psi_L^i) (\bar{\psi}_L^j \gamma^\mu \psi_L^j), \\ \mathcal{L}_{RR} &= \frac{g_{\text{contact}}^2}{2\Lambda^2} \sum_{i,j} \eta_{RR}^{ij} (\bar{\psi}_R^i \gamma_\mu \psi_R^i) (\bar{\psi}_R^j \gamma^\mu \psi_R^j), \\ \mathcal{L}_{LR} &= \frac{g_{\text{contact}}^2}{2\Lambda^2} \sum_{i,j} \eta_{LR}^{ij} (\bar{\psi}_L^i \gamma_\mu \psi_L^i) (\bar{\psi}_R^j \gamma^\mu \psi_R^j), \\ \mathcal{L}_{RL} &= \frac{g_{\text{contact}}^2}{2\Lambda^2} \sum_{i,j} \eta_{RL}^{ij} (\bar{\psi}_R^i \gamma_\mu \psi_R^i) (\bar{\psi}_L^j \gamma^\mu \psi_L^j), \end{aligned} \quad (92.1)$$

where i, j are the indices of fermion species. Color and other indices are suppressed in Eq. (92.1). Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size Λ . Note $\eta_{\alpha\beta}^{ij} = \eta_{\beta\alpha}^{ji}$, therefore, in order to specify the contact interaction among the same fermion species $i = j$, it is enough to use η_{LL} , η_{RR} and η_{LR} . We will suppress the indices of fermion species hereafter. We may determine the scale Λ unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting $g_{\text{contact}}^2/4\pi = g_{\text{contact}}^2(\Lambda)/4\pi = 1$ for the new strong interaction coupling and by setting the largest magnitude of the coefficients $\eta_{\alpha\beta}$ to be unity. In the following, we denote

$$\begin{aligned} \Lambda &= \Lambda_{LL}^\pm \text{ for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, 0, 0), \\ \Lambda &= \Lambda_{RR}^\pm \text{ for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0, \pm 1, 0), \\ \Lambda &= \Lambda_{VV}^\pm \text{ for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, \pm 1, \pm 1), \\ \Lambda &= \Lambda_{AA}^\pm \text{ for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, \pm 1, \mp 1), \\ \Lambda &= \Lambda_{V-A}^\pm \text{ for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0, 0, \pm 1). \end{aligned} \quad (92.2)$$

Such interactions can arise by interchanging constituents (when the fermions have common constituents), and/or by exchanging the binding quanta (whenever binding quanta couple to constituents of both particles).

Fermion scattering amplitude induced from the contact interaction in Eq. (92.1) interferes with the Standard Model (SM) amplitude destructively or constructively [2]. The sign of interference depends on the sign of $\eta_{\alpha\beta}$ ($\alpha, \beta = L, R$). For instance, in the parton level $qq \rightarrow qq$ scattering cross section in the Λ_{LL}^\pm model, the contact interaction amplitude and the SM gluon exchange amplitude interfere destructively for $\eta_{LL} = +1$, while they interfere constructively for $\eta_{LL} = -1$. In models of quark compositeness, the quark scattering cross sections induced from the contact interactions receive sizable QCD radiative corrections. Ref. 3 provides the exact next-to-leading order (NLO) QCD corrections to the contact interaction induced quark scattering cross sections.

Over the last three decades experiments at the CERN SpS [4,5], the Fermilab Tevatron [6,7], and the CERN LHC [8–12] have searched for quark contact interactions, characterized by the four-fermion effective Lagrangian in Eq. (92.1), using jet final states. These searches have been performed primarily by studying the angular distribution of the two highest transverse momentum, p_T , jets (dijets), and the inclusive jet p_T spectrum. The variable $\chi = \exp(|(y_1 - y_2)|)$ is used to measure the dijet angular distribution, where y_1 and y_2 are the rapidities of the two jets with the highest transverse momenta. For collinear massless parton scattering, χ is related to the polar scattering angle θ^* in the partonic center-of-mass frame by $\chi = (1 + |\cos\theta^*|)/(1 - |\cos\theta^*|)$. The choice of χ is motivated by the fact that the angular distribution for Rutherford scattering, which is proportional to $1/(1 - \cos\theta^*)^2$, is independent of χ . In perturbative QCD the χ distributions are relatively uniform and only mildly modified by higher-order QCD or electroweak corrections. Signatures of quark contact interactions exhibit more isotropic angular distribution than QCD and they can be identified as an excess at low values of χ . In the inclusive jet cross section measurement, quark contact interaction effects are searched for as deviations from the predictions of perturbative QCD in the tails of the high- p_T jet spectrum [11].

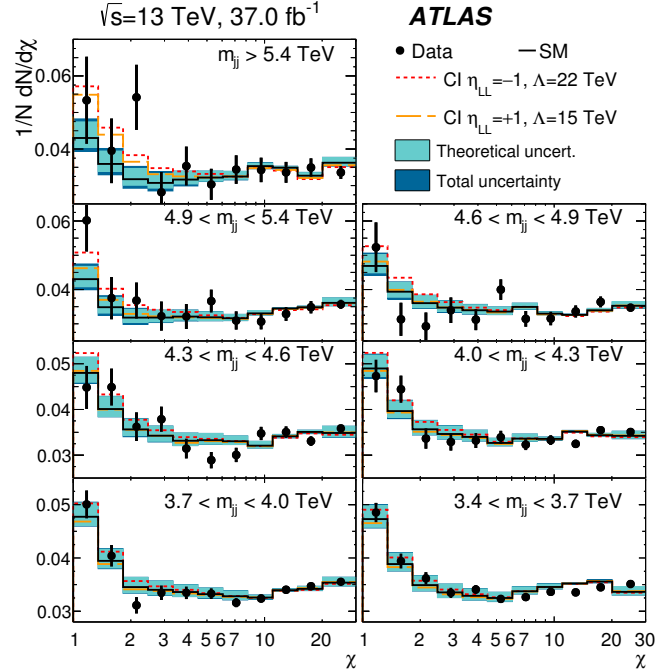

Figure 92.1: Normalized dijet angular distributions in several dijet mass (m_{jj}) ranges. The data distributions are compared to PYTHIA8 predictions with NLO and electroweak corrections applied (solid line) and with the predictions including a contact interaction (CI) term in which only left-handed quarks participate of compositeness scale $\Lambda_{LL}^+ = 15$ TeV (dashed line) and $\Lambda_{LL}^- = 22$ TeV (dotted line). The theoretical uncertainties and the total theoretical and experimental uncertainties in the predictions are displayed as shaded bands around the SM prediction. Figure adopted from Ref. 9.

Recent results from the LHC, using data collected at proton-proton center-of-mass energy of $\sqrt{s} = 13$ TeV, extend previous limits on quark contact interactions. Figure 92.1 shows the normalized dijet angular distributions for several dijet mass ranges measured in ATLAS [9] at $\sqrt{s} = 13$ TeV. The data distributions are compared with SM predictions, estimated using PYTHIA8 [13] with GEANT4-based [14] ATLAS detector simulation and corrected to NLO QCD calculation provided by NLO Jet++ [15] including electroweak corrections [16], and with predictions including a contact interaction term in which only

left-handed quarks participate at compositeness scale $\Lambda_{LL}^+ = 15$ TeV ($\Lambda_{LL}^- = 22$ TeV) with destructive (constructive) interference. Over a wide range of χ and dijet mass the data are well described by the SM predictions. Using the dijet angular distributions measured at high dijet masses and $\sqrt{s} = 13$ TeV, the ATLAS [9] and CMS [12] Collaborations have set 95% confidence level (C.L.) lower limits on the contact interaction scale Λ , ranging from 9.2 to 29.5 TeV for different quark contact interaction models that correspond to various combinations of $(\eta_{LL}, \eta_{RR}, \eta_{LR})$, as summarized in Figure 92.2. The contact interaction scale limits extracted using the dijet angular distributions include the exact NLO QCD corrections to dijet production induced by contact interactions [3]. In proton-proton collisions, the Λ_{LL}^\pm and Λ_{RR}^\pm contact interaction models result in identical tree-level cross sections and NLO QCD corrections and yield the same exclusion limits. For Λ_{VV}^\pm and Λ_{AA}^\pm , the contact interaction predictions are identical at tree level, but exhibit different NLO QCD corrections and yield different exclusion limits.

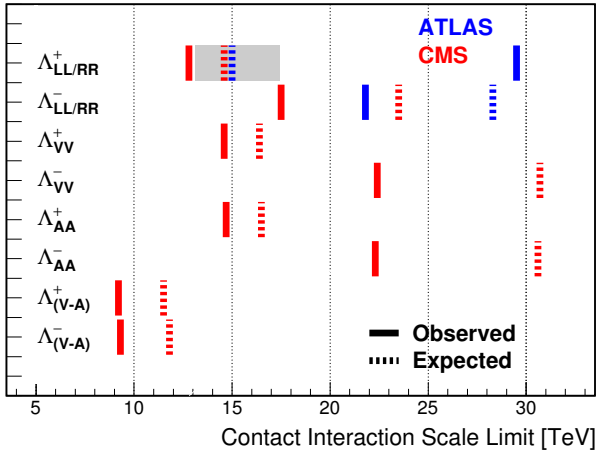

Figure 92.2: Observed (solid lines) and expected (dashed lines) 95% C.L. lower limits on the contact interaction scale Λ for different contact interaction models from ATLAS [9] and CMS [12] using the dijet angular distributions. The contact interaction models used for the dijet angular distributions include the exact NLO QCD corrections to dijet production. The shaded band for the $\Lambda_{LL/RR}^+$ model indicates the range of contact interaction scale that was not excluded in ATLAS [9] due to statistical fluctuation of observed data.

If leptons (l) and quarks (q) are composite with common constituents, the interaction of these constituents will manifest itself in the form of a $llqq$ -type four-fermion contact interaction Lagrangian at energies below the compositeness scale Λ . The $llqq$ terms in the contact interaction Lagrangian can be expressed as

$$\begin{aligned}\mathcal{L}_{LL} &= \frac{g_{\text{contact}}^2}{\Lambda^2} \sum_{i,j} \eta_{LL}^{ij} (\bar{q}_L^i \gamma_\mu q_L^i) (\bar{l}_L^j \gamma^\mu l_L^j), \\ \mathcal{L}_{RR} &= \frac{g_{\text{contact}}^2}{\Lambda^2} \sum_{i,j} \eta_{RR}^{ij} (\bar{q}_R^i \gamma_\mu q_R^i) (\bar{l}_R^j \gamma^\mu l_R^j), \\ \mathcal{L}_{LR} &= \frac{g_{\text{contact}}^2}{\Lambda^2} \sum_{i,j} \eta_{LR}^{ij} (\bar{q}_L^i \gamma_\mu q_L^i) (\bar{l}_R^j \gamma^\mu l_R^j), \\ \mathcal{L}_{RL} &= \frac{g_{\text{contact}}^2}{\Lambda^2} \sum_{i,j} \eta_{RL}^{ij} (\bar{q}_R^i \gamma_\mu q_R^i) (\bar{l}_L^j \gamma^\mu l_L^j).\end{aligned}\quad (92.3)$$

Searches on quark-lepton compositeness have been reported from experiments at LEP [17–20], HERA [21,22], the Tevatron [23,24], and recently from the ATLAS [25,26] and CMS [27–29] experiments at

the LHC. The most stringent searches for $llqq$ contact interactions are performed by the LHC experiments using high-mass oppositely-charged lepton pairs produced through the $q\bar{q} \rightarrow l^+l^-$ Drell-Yan process. The contact interaction amplitude of the $u\bar{u} \rightarrow l^+l^-$ process ($l = e$ or μ) interferes with the corresponding SM amplitude constructively (destructively) for $\eta_{\alpha\beta}^{ul} = -1$ ($\eta_{\alpha\beta}^{ul} = +1$). The ATLAS Collaboration has extracted limits on the $llqq$ contact interaction at $\sqrt{s} = 13$ TeV for the right-right ($\eta_{RR} = \pm 1$, $\eta_{LL} = \eta_{LR} = \eta_{RL} = 0$), left-left ($\eta_{LL} = \pm 1$, $\eta_{RR} = \eta_{LR} = \eta_{RL} = 0$), and left-right ($\eta_{LR} = \eta_{RL} = \pm 1$, $\eta_{RR} = \eta_{LL} = 0$) models. Combining the dielectron and dimuon channels, the 95% C.L. lower limits on the $llqq$ contact interaction scale Λ are 35 TeV (28 TeV) for the right-right model, 40 TeV (25 TeV) for the left-left model, and 36 TeV (28 TeV) for the left-right model, each with constructive (destructive) interference [26]. The CMS Collaboration, using a 36 fb^{-1} dataset at 13 TeV, has set 95% C.L. exclusion limits on the $llqq$ contact interaction scale that range from $\Lambda_{LL} > 20$ TeV for the destructive interference to $\Lambda_{RR} > 32$ TeV for the constructive interference, for the left-left and the right-right models, respectively [29].

Note that the contact interactions arising from the compositeness of quarks and leptons in Eq. (92.1) can also be regarded as a part of more general dimension six operators in the context of low energy standard model effective theory. For a complete list of these dimension six operators, see [30,31].

Interactions of hypothetical dark matter candidate particles with SM particles through mediators can also be described as contact interactions at low energy. See “Searches for WIMPs and Other Particles” in this volume for limits on the interactions involving dark matter candidate particles.

92.2. Limits on excited fermions

Another typical consequence of compositeness is the appearance of excited leptons and quarks (l^* and q^*). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares a leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron e^* is characterized by a nonzero transition-magnetic coupling with electrons. Smallness of the lepton mass and the success of QED prediction for $g - 2$ suggest chirality conservation, *i.e.*, an excited lepton should not couple to both left- and right-handed components of the corresponding lepton [32–34].

Excited leptons may be classified by $SU(2) \times U(1)$ quantum numbers. Typical examples are:

1. Sequential type

$$\begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_L, \quad [\nu_R^*], \quad l_R^*.$$

ν_R^* is necessary unless ν^* has a Majorana mass.

2. Mirror type

$$[\nu_L^*], \quad l_L^*, \quad \begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_R.$$

3. Homodoublet type

$$\begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_L, \quad \begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_R.$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their minimal gauge couplings. The couplings of excited leptons with Z are given by

$$\begin{aligned}& \frac{e}{2 \sin \theta_W \cos \theta_W} (-1 + 2 \sin^2 \theta_W) \bar{l}^* \gamma^\mu l^* Z_\mu \\ & + \frac{e}{2 \sin \theta_W \cos \theta_W} \bar{\nu}^* \gamma^\mu \nu^* Z_\mu\end{aligned}$$

in the homodoublet model. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at $q^2 \neq 0$, they are usually neglected.

Excited fermions may also be produced via the contact interactions with ordinary quarks and leptons [35]

$$\mathcal{L} = \frac{g_{\text{contact}}^2}{\Lambda^2} [\eta'_{LL}(\bar{\psi}_L \gamma_\mu \psi_L)(\bar{\psi}_L^* \gamma^\mu \psi_L^*) + (\eta''_{LL}(\bar{\psi}_L \gamma_\mu \psi_L)(\bar{\psi}_L^* \gamma^\mu \psi_L) + \text{h.c.}) + \dots]. \quad (92.4)$$

Again, the coefficient is conventionally taken $g_{\text{contact}}^2 = 4\pi$. It is widely assumed $\eta'_{LL} = \eta''_{LL} = 1$, $\eta'_{LR} = \eta''_{LR} = \eta'_{RL} = \eta''_{RL} = \eta'_{RR} = \eta''_{RR} = 0$ in experimental analyses for simplicity.

In addition, transition-magnetic type couplings with a gauge boson are expected. These couplings can be generally parameterized as follows:

$$\begin{aligned} \mathcal{L} = & \frac{\lambda_\gamma^{(\psi^*)} e}{2m_{\psi^*}} \bar{\psi}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) \psi F_{\mu\nu} \\ & + \frac{\lambda_Z^{(\psi^*)} e}{2m_{\psi^*}} \bar{\psi}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) \psi Z_{\mu\nu} \\ & + \frac{\lambda_W^{(l^*)} g}{2m_{l^*}} \bar{l}^* \sigma^{\mu\nu} \frac{1-\gamma_5}{2} \nu W_{\mu\nu} \\ & + \frac{\lambda_W^{(\nu^*)} g}{2m_{\nu^*}} \bar{\nu}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) l W_{\mu\nu}^\dagger \\ & + \text{h.c.}, \end{aligned} \quad (92.5)$$

where $g = e/\sin\theta_W$, $\psi = \nu$ or l , $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ is the photon field strength, $Z_{\mu\nu} = \partial_\mu Z_\nu - \partial_\nu Z_\mu$, etc.. The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1.$$

Chirality conservation requires

$$\eta_L \eta_R = 0. \quad (92.6)$$

These couplings in Eq. (92.5) can arise from $SU(2) \times U(1)$ -invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type l^* with the Lagrangian (see [36,37])

$$\mathcal{L} = \frac{1}{2\Lambda} \bar{L}^* \sigma^{\mu\nu} (g f \frac{\tau^a}{2} W_{\mu\nu}^a + g' f' Y B_{\mu\nu}) \frac{1-\gamma_5}{2} L + \text{h.c.}, \quad (92.7)$$

where L denotes the lepton doublet (ν, l) , Λ is the compositeness scale, g, g' are $SU(2)$ and $U(1)_Y$ gauge couplings, and $W_{\mu\nu}^a$ and $B_{\mu\nu}$ are the field strengths for $SU(2)$ and $U(1)_Y$ gauge fields. These couplings satisfy the relation

$$\lambda_W = -\sqrt{2} \sin^2 \theta_W (\lambda_Z \cot \theta_W + \lambda_\gamma), \quad (92.8)$$

with $\lambda_{W,Z,\gamma}$ being defined in Eq. (92.5) with $\lambda_{W,Z,\gamma} = \lambda_{W,Z,\gamma}^{(l^*)}$ or $\lambda_{W,Z,\gamma} = \lambda_{W,Z,\gamma}^{(\nu^*)}$. Here $(\eta_L, \eta_R) = (1, 0)$ is assumed. It should be noted that the electromagnetic radiative decay of l^* (ν^*) is forbidden if $f = -f'$ ($f = f'$).

Additional coupling with gluons is possible for excited quarks:

$$\begin{aligned} \mathcal{L} = & \frac{1}{2\Lambda} \bar{Q}^* \sigma^{\mu\nu} \left(g_s f_s \frac{\lambda^a}{2} G_{\mu\nu}^a + g f \frac{\tau^a}{2} W_{\mu\nu}^a + g' f' Y B_{\mu\nu} \right) \\ & \times \frac{1-\gamma_5}{2} Q + \text{h.c.}, \end{aligned} \quad (92.9)$$

where Q denotes a quark doublet, g_s is the QCD gauge coupling, and $G_{\mu\nu}^a$ the gluon field strength.

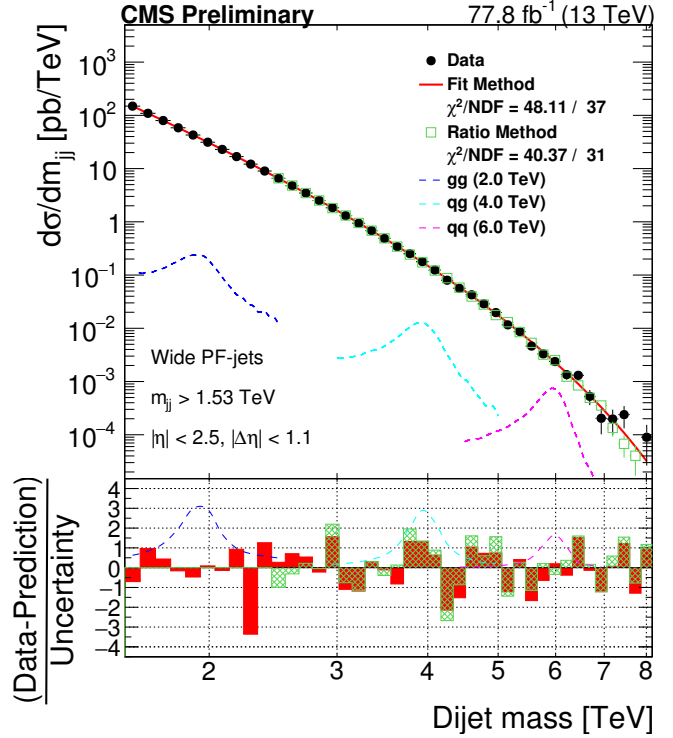

Figure 92.3: Dijet mass distribution measured by CMS using wide jets reconstructed from two highest transverse momentum jets by adding nearby jets within $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2} < 1.1$. The data distribution is compared to a fit representing a smooth background spectrum (solid curve). The excited quark signal with mass of 4.0 TeV (labeled as qq) is shown together with other benchmark signals. Shown at the bottom panel is the difference between the data and the fitted parametrization divided by the statistical uncertainty of the data. Figure adopted from Ref. 62.

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons (l_8) and the ordinary lepton (l) may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda} \sum_l \{ \bar{l}_8^\alpha g_S F_{\mu\nu}^\alpha \sigma^{\mu\nu} (\eta_L l_L + \eta_R l_R) + \text{h.c.} \} \quad (92.10)$$

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies $\eta_L \eta_R = 0$ as before.

Searches for the excited quarks and leptons have been performed over the last decades in experiments at the LEP [38–41], HERA [42,43], Tevatron [44,45], and LHC [46–71]. Most stringent constraints, which are described below at 95% confidence level, come from the LHC experiments.

The signature of excited quarks q^* at hadron colliders is characterized by a narrow resonant peak in the reconstructed invariant mass distribution of the q^* decay products. The decays via the transition-magnetic type operator in Eq. (92.9) are considered for excited quarks in LHC searches, and the final states to search for are dijet (qq) [46, 47, 59–62] or a jet in association with a photon ($q\gamma$) [48, 49, 63, 64] or a weak gauge boson (qW, qZ) [65, 66]. All analyses consider only spin-1/2 excited states of first generation quarks (u^*, d^*) with degenerate masses, expected to be predominantly produced in proton-proton collisions except for the excited b quark searches described below. Only the minimal gauge interactions and the transition-magnetic couplings with the form given in Eq. (92.9) are considered in the production process, and hence the contact interactions in Eq. (92.4) are not considered. The compositeness scale Λ is taken to be the same as the excited quark mass m_{q^*} . The transition-magnetic coupling coefficients f_s, f and f' are assumed to be equal to 1 (denoted by f).

With proton-proton collision data recorded at $\sqrt{s} = 13$ TeV at the LHC, the excited quark masses are excluded in dijet resonance searches up to 6.7 TeV in ATLAS using 140 fb^{-1} [47] and 6.0 TeV in CMS using 77.8 fb^{-1} [62]. Figure 92.3 shows the dijet mass distribution measured in CMS [62] by using the two highest p_T jets reconstructed with the anti- k_T algorithm [72] of a distance parameter of 0.4, and by combining nearby jets within $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2} < 1.1$ around the leading two jets. The measured dijet mass spectrum is compared to a fit with smoothly falling background shape (solid curve) to look for a narrow resonance; an excited quark signal with mass of 4.0 TeV is shown in the figure (denoted by qg) as one of the benchmark signals considered in the analysis.

The photon + jet resonance searches, targeting excited quarks decaying into a quark and a photon ($q^* \rightarrow q + \gamma$), have excluded q^* masses up to 5.3 TeV in ATLAS [49] and 5.5 TeV in CMS [64] using collision data at $\sqrt{s} = 13$ TeV. The W/Z boson + jet final states are examined to look for the $q^* \rightarrow q + W$ and $q + Z$ signal in CMS [66], exploiting jet substructure technique designed to provide sensitivity for highly-boosted hadronically decaying W and Z bosons. The lower mass limit of 5.0 (4.8) TeV is obtained from the $W + \text{jet}$ ($Z + \text{jet}$) search using dataset recorded at $\sqrt{s} = 13$ TeV.

The excited b quarks (b^*) are also considered in the present searches at the LHC. Assuming the similar production processes to the first-generation excited quarks, the b^* has been searched for in final states containing at least one jet identified as originating from a b quark (b -tagging). The searches using two jets including at least one b -tagged jet have been performed at 8 and 13 TeV [50, 51, 60], resulting in b^* lower mass limits of 2.6 TeV in ATLAS using 36.1 fb^{-1} at $\sqrt{s} = 13$ TeV [50] and 1.6 TeV in CMS using 19.7 fb^{-1} at $\sqrt{s} = 8$ TeV [60]. The CMS Collaboration also performed a search for $b^* \rightarrow b + \gamma$ in events with a b -tagged jet in association with a photon using data at $\sqrt{s} = 13$ TeV [64], and excluded b^* masses up to 1.8 TeV. Excited b quarks with charged-current decay into a W -boson and a top quark ($b^* \rightarrow t + W$) were looked for in both ATLAS and CMS using the full 8 TeV data [52, 67]. ATLAS excluded b^* masses below 1.5 TeV for the b^* with left- and right-handed couplings [52] while CMS excluded the masses below 1.39(1.43) TeV for the left(right)-handed couplings [67].

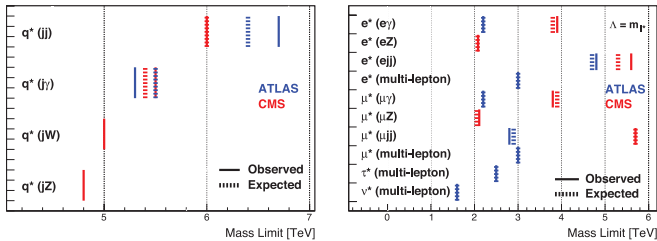

Figure 92.4: 95% C.L. lower mass limits for the excited quarks (left) and excited leptons (right) at ATLAS [47,49,55–57] and CMS [62,64,66] [69–71] experiments. Shown are the most stringent limits for each final state (denoted in parentheses) of the excited fermions from both experiments. Only first generation quarks (u, d) with transition-magnetic type interactions with $f_s = f = f' = 1$ are considered for the excited quarks. The excited lepton limits are given for the production via contact interactions with $\Lambda = m_{l^*}$.

Searches for excited leptons l^* are also performed at the LHC using proton-proton collision data recorded at $\sqrt{s} = 7$ and 8 TeV [54–58, 68, 69] as well as at 13 TeV [70]. Considering single l^* production in contact interactions (Eq. (92.4)) and electromagnetic radiative decay to a SM lepton and a photon ($l^* \rightarrow l + \gamma$ where $l = e, \mu$), the excited electron and muon masses are excluded for $\Lambda = m_{l^*}$ up to 3.9 and 3.8 TeV, respectively, using 35.9 fb^{-1} at $\sqrt{s} = 13$ TeV in CMS [70] and 2.2 TeV using 13 fb^{-1} at $\sqrt{s} = 8$ TeV in ATLAS [55].

With the full 20.3 fb^{-1} data at $\sqrt{s} = 8$ TeV, the inclusive search on multi-lepton signatures with 3 or more charged leptons

in ATLAS [56] further constrains the excited charged leptons and neutrinos. Considering both the transition-magnetic (Eq. (92.7)) and contact interaction (Eq. (92.4)) processes, the lower mass limits for the e^* , μ^* , τ^* and ν_i^* (for every excited neutrino flavor) are obtained to be 3.0, 3.0, 2.5 and 1.6 TeV, respectively, for $\Lambda = m_{e^*}$, m_{μ^*} , m_{τ^*} and $m_{\nu_i^*}$. The rate of pair-produced excited leptons is independent of Λ for the minimal gauge interaction processes, and it allows to improve search sensitivity with multi-lepton signatures at high Λ , especially for excited neutrinos because the predominant $\nu_i^* \rightarrow l + W$ decays result in a higher acceptance for ≥ 3 charged lepton final states.

Both ATLAS and CMS Collaborations performed searches for singly produced excited leptons. The single excited leptons, both produced and decayed in contact interaction processes (Eq. (92.4)), were searched for in CMS using 77.4 fb^{-1} at 13 TeV [71] and in ATLAS using 20.3 fb^{-1} at 8 TeV [57] using the final states with two leptons and two jets ($q\bar{q} \rightarrow ll^* \rightarrow llq\bar{q}$). The CMS search [71] considered both excited electrons and excited muons, using the invariant mass of the combination of the two leptons and two jets as a discriminating variable to separate signal from background. The ATLAS search [57] considered only excited muons. The single excited electrons, produced in contact interactions and decayed either in contact interaction or charged-current processes, were considered in ATLAS using 36.1 fb^{-1} at 13 TeV [58] in the final states with two electrons and two jets ($q\bar{q} \rightarrow ee^* \rightarrow eeq\bar{q}$) or an electron, missing transverse momentum and a hadronically decaying W -boson candidate ($q\bar{q} \rightarrow ee^* \rightarrow e\nu W$). The excited electron (muon) mass was excluded up to 5.6 (5.7) TeV in CMS [71] at $\Lambda = m_{e^*}$ ($\Lambda = m_{\mu^*}$), which is the best limit to date on the excited electrons (muons).

The CMS Collaboration also performed an excited lepton search in the final states containing a Z boson [69], probing the excited leptons produced in contact interactions and decayed in neutral-current processes ($l^* \rightarrow l + Z$) with $f = f' = 1$ or $f = -f' = 1$. The leptonic and hadronic decays of Z bosons have been considered in the search, and the most stringent limits are obtained from the hadronic Z decay to be 2.08 (2.34) TeV and 2.11 (2.37) TeV for the e^* and μ^* , respectively, with $f = f' = 1$ ($f = -f' = 1$) at $\Lambda = m_{l^*}$.

Figure 92.4 summarizes the most stringent 95% C.L. lower mass limits for excited quarks and leptons obtained from the LHC experiments.

93. Dynamical Electroweak Symmetry Breaking: Implications of the H^0

Revised August 2019 by K.M. Black (Wisconsin U.), R.Sekhar Chivukula (UC San Diego) and M. Narain (Brown U.).

93.1 Introduction and Phenomenology

In theories of dynamical electroweak symmetry breaking, the electroweak interactions are broken to electromagnetism by the vacuum expectation value of a composite operator, typically a fermion bilinear. In these theories, the longitudinal components of the massive weak bosons are identified with composite Nambu-Goldstone bosons arising from dynamical symmetry breaking in a strongly-coupled extension of the standard model. Viable theories of dynamical electroweak symmetry breaking must also explain (or at least accommodate) the presence of an additional composite scalar state to be identified with the H^0 scalar boson [1,2] – a state unlike any other observed previously.

Theories of dynamical electroweak symmetry breaking can be classified by the nature of the composite singlet state to be associated with the H^0 and the corresponding dimensional scales f , the analog of the pion decay-constant in QCD, and Λ , the scale of the underlying strong dynamics.¹ Of particular importance is the ratio v/f , where $v^2 = 1/(\sqrt{2}G_F) \approx (246 \text{ GeV})^2$, since this ratio measures the expected size of the deviations of the couplings of a composite Higgs boson from those expected in the standard model. The basic possibilities, and the additional states that they predict, are described below.

93.1.1 Technicolor, $v/f \simeq 1$, $\Lambda \simeq 1 \text{ TeV}$

Technicolor models [7–9] provided the first examples of theories of dynamical electroweak symmetry breaking. These theories incorporate a new asymptotically free gauge theory (“technicolor”) and additional massless fermions (“technifermions” transforming under a vectorial representation of the gauge group). The global chiral symmetry of the fermions is spontaneously broken by the formation of a technifermion condensate, just as the approximate chiral symmetry in QCD is broken down to isospin by the formation of a quark condensate. The $SU(2)_W \times U(1)_Y$ interactions are embedded in the global technifermion chiral symmetries in such a way that the only unbroken gauge symmetry after chiral symmetry breaking is $U(1)_{em}$.² The theories naturally provide the Nambu-Goldstone bosons “eaten” by the W and Z boson. There would also typically be additional heavy states (e.g. vector mesons, analogous to the ρ and ω mesons in QCD) with TeV masses [13,14], and the WW and ZZ scattering amplitudes would be expected to be strong at energies of order 1 TeV.

There are various possibilities for the scalar H^0 in technicolor models. First, the H^0 could be identified as a singlet scalar resonance, analogous to the σ particle expected in pion-scattering in QCD [15,16]. Alternatively, the H^0 could be identified as a dilaton, a (pseudo-)Goldstone boson of scale invariance in theories of “walking technicolor” [17–21].³ Finally, the H^0 could be identified as an additional isosinglet state if the chiral symmetry breaking pattern of the technicolor theory provides for such a state.⁴ In all of these cases, however, one expects large deviations in the couplings of this particle from those of the standard model Higgs boson. Since the couplings observed for the H^0 approximate those of the Higgs boson to the 10% level, models of this kind are very highly constrained.

¹In a strongly interacting theory “Naive Dimensional Analysis” [3,4] implies that, in the absence of fine-tuning, $\Lambda \simeq g^* f$ where $g^* \simeq 4\pi$ is the typical size of a strong coupling in the low-energy theory [5,6]. This estimate is modified in the presence of multiple flavors or colors [7].

²For a review of technicolor models, see [10–12].

³If both the electroweak symmetry and the approximate scale symmetry are broken only by electroweak doublet condensate(s), then the decay-constants for scale and electroweak symmetry breaking may be approximately equal – differing only by terms formally proportional to the amount of explicit scale-symmetry breaking.

⁴In this case, however, the coupling strength of the singlet state to WW and ZZ pairs would be comparable to the couplings to gluon and photon pairs, and these would all arise from loop-level couplings in the underlying technicolor theory [22].

93.1.2 The Higgs doublet as a pseudo-Nambu-Goldstone Boson, $v/f < 1$, $\Lambda > 1 \text{ TeV}$

In technicolor models, the symmetry-breaking properties of the underlying strong dynamics necessarily breaks the electroweak gauge symmetries. An alternative possibility is that the underlying strong dynamics itself does not break the electroweak interactions, and that the entire quartet of bosons in the Higgs doublet (including the state associated with the H^0) are composite (pseudo-) Nambu-Goldstone particles [23,24]. In this case, the underlying dynamics can occur at energies exceeding 1 TeV and additional interactions with the top-quark mass generating sector (and possibly with additional weakly-coupled gauge bosons) cause the vacuum energy to be minimized when the composite Higgs doublet gains a vacuum expectation value [25,26]. In these theories, the couplings of the remaining singlet scalar state would naturally be equal to that of the standard model Higgs boson up to corrections of order $(v/f)^2$ and, therefore, constraints on the size of deviations of the H^0 couplings from that of the standard model Higgs [27] give rise to lower bounds on the scales f and Λ .⁵

The electroweak gauge interactions, as well as the interactions responsible for the top-quark mass, explicitly break the chiral symmetries of the composite Higgs model and lead generically to sizable corrections to the mass-squared of the Higgs-doublet – the so-called “Little Hierarchy Problem” [28]. “Little Higgs” theories [29–32] are examples of composite Higgs models in which the (collective) symmetry-breaking structure is selected so as to suppress these contributions to the Higgs mass-squared.

Composite Higgs models typically require a larger global symmetry of the underlying theory, and hence additional relatively light (compared to Λ) scalar particles, extra electroweak vector bosons (e.g. an additional $SU(2) \times U(1)$ gauge group), and vector-like partners of the top-quark of charge $+2/3$ and possibly also $+5/3$ [33]. In addition to these states, one would expect the underlying dynamics to yield additional scalar and vector resonances with masses of order Λ . If the theory respects a custodial symmetry [34], the couplings of these additional states to the electroweak and Higgs boson will be related – and, for example, one might expect a charged vector resonance to have similar branching ratios to WZ and WH . Different composite Higgs models utilize different mechanisms for arranging for the hierarchy of scales $v < f$ and arranging for a scalar Higgs self-coupling small enough to produce an H^0 of mass of order 125 GeV, for a review see [35]. If the additional states in these models carry color, they can provide additional contributions to Higgs production via gluon fusion [36]. The extent to which Higgs production at the LHC conforms with standard model predictions provides additional constraints (typically lower bounds on the masses of the additional colored states of order 0.7 TeV) on these models.

In addition, if the larger symmetry of the underlying composite Higgs theory does not commute with the standard model gauge group, then the additional states found in those models – especially those related to the top-quark, which tend to have the largest couplings to the electroweak sector – may be *colorless*. For example, in twin Higgs models [37], the top-partners carry no standard model charges. The phenomenology of the additional states in twin Higgs theories is rather different, since lacking color the production of these particles at the LHC will be suppressed – and, their decays may occur only via the electroweak symmetry breaking sector, leading to their being long-lived.

93.1.3 Top-Condensate, Top-Color, Top-Seesaw and related theories, $v/f < 1$, $\Lambda > 1 \text{ TeV}$

A final alternative is to consider a strongly interacting theory with a high (compared to a TeV) underlying dynamical scale that would naturally break the electroweak interactions, but whose

⁵In these models v/f is an adjustable parameter, and in the limit $v/f \rightarrow 1$ they reduce, essentially, to the technicolor models discussed in the previous subsection. Our discussion here is consistent with that given there, since we expect corrections to the SM Higgs couplings to be large for $v/f \simeq 1$. Current measurements constrain the couplings of the H^0 to equal those predicted for the Higgs in the standard model to about the 10% level [27], suggesting that f must have values of order a TeV or higher and, therefore, a dynamical scale Λ of at least several TeV.

strength is adjusted (“fine-tuned”) to produce electroweak symmetry breaking at 1 TeV. This alternative is possible if the electroweak (quantum) phase transition is continuous (second order) in the strength of the strong dynamics [38]. If the fine tuning can be achieved, the underlying strong interactions will produce a light composite Higgs bound state with couplings equal to that of the standard model Higgs boson up to corrections of order $(1 \text{ TeV}/\Lambda)^2$. As in theories in which electroweak symmetry breaking occurs through vacuum alignment, therefore, constraints on the size of deviations of the H^0 couplings from that of the standard model Higgs give rise to lower bounds on the scale Λ . Formally, in the limit $\Lambda \rightarrow \infty$ (a limit which requires arbitrarily fine adjustment of the strength of the high-energy interactions), these theories are equivalent to a theory with a fundamental Higgs boson – and the fine adjustment of the coupling strength is a manifestation of the hierarchy problem of theories with a fundamental scalar particle.

In many of these theories the top-quark itself interacts strongly (at high energies), potentially through an extended color gauge sector [39, 39–43]. In these theories, top-quark condensation (or the condensation of an admixture of the top with additional vector-like quarks) is responsible for electroweak symmetry breaking, and the H^0 is identified with a bound state involving the third generation of quarks. These theories typically include an extra set of massive color-octet vector bosons (top-gluons), and an extra $U(1)$ interaction (giving rise to a top-color Z') which couple preferentially to the third generation and whose masses define the scale Λ of the underlying physics.

93.1.4 Flavor

In addition to the electroweak symmetry breaking dynamics described above, which gives rise to the masses of the W and Z particles, additional interactions must be introduced to produce the masses of the standard model fermions. Two general avenues have been suggested for these new interactions. In “extended technicolor” (ETC) theories [44, 45], the gauge interactions in the underlying strongly interacting theory are extended to incorporate flavor. This extended gauge symmetry is broken down (possibly sequentially, at several different mass scales) to the residual strong interaction responsible for electroweak symmetry breaking. The massive gauge-bosons corresponding to the broken symmetries then mediate interactions between mass operators for the quarks/leptons and the corresponding bilinears of the strongly-interacting fermions, giving rise to the masses of the ordinary fermions after electroweak symmetry breaking.

In the case of “partial compositeness” [46], the additional flavor-dependent interactions arise from mixing between the ordinary quarks and leptons and massive composite fermions in the strongly-interacting underlying theory. Theories incorporating partial compositeness include additional vector-like partners of the ordinary quarks and leptons, typically with masses of order a TeV or less.

In both cases, the effects of flavor interactions on the electroweak properties of the ordinary quarks and leptons are likely to be most pronounced in the third generation of fermions.⁶ The additional particles present in these theories, especially the additional scalars, often couple more strongly to heavier fermions.

Moreover, since the flavor interactions must give rise to quark mixing, we expect that a generic theory of this kind could give rise to large flavor-changing neutral-currents [45]. In ETC theories, these constraints are typically somewhat relaxed if the theory incorporates approximate generational flavor symmetries [47], the theory has a slowly running coupling constant or “walks” [17–21], or if $\Lambda > 1 \text{ TeV}$ [48]. In theories of partial compositeness, the masses of the ordinary fermions depend on the scaling-dimension of the operators corresponding to the composite fermions with which they mix. This leads to a new mechanism for generating the mass-hierarchy of the observed quarks and leptons that, potentially, ameliorates flavor-changing neutral current problems and can provide new contributions to the composite Higgs poten-

tial which allow for $v/f < 1$ [49–53].

Alternatively, one can assume that the underlying flavor dynamics respect flavor symmetries (“minimal” [54, 55] or “next-to-minimal” [56] flavor violation) that suppress flavor-changing neutral currents in the two light generations. Additional considerations apply when extending these arguments to potential explanation of neutrino masses (see, for example, [57, 58]).

Since the underlying high-energy dynamics in these theories are strongly coupled, there are no reliable calculation techniques that can be applied to analyze their properties. Instead, most phenomenological studies depend on the construction of a “low-energy” effective theory describing additional scalar, fermion, or vector boson degrees of freedom, which incorporates the relevant symmetries and, when available, dynamical principles. In some cases, motivated by the AdS/CFT correspondence [59], the strongly-interacting theories described above have been investigated by analyzing a dual compactified five-dimensional gauge theory. In these cases, the AdS/CFT “dictionary” is used to map the features of the underlying strongly coupled high-energy dynamics onto the low-energy weakly coupled dual theory [60].

More recently, progress has been made in investigating strongly-coupled models using lattice gauge theory [61]. These calculations offer the prospect of establishing which strongly coupled theories of electroweak symmetry breaking have a particle with properties consistent with those observed for the H^0 – and for establishing concrete predictions for these theories at the LHC [62].

93.2 Experimental Searches

As discussed above, the extent to which the couplings of the H^0 conform to the expectations for a standard model Higgs boson constrains the viability of each of these models. Measurements of the H^0 couplings, and their interpretation in terms of effective field theory, are summarized in the H^0 review in this volume. In what follows, we will focus on searches for the additional particles that might be expected to accompany the singlet scalar: extra scalars, fermions, and vector bosons. In some cases, detailed model-specific searches have been made for the particles described above (though generally not yet taking account of the demonstrated existence of the H^0 boson).

In most cases, however, generic searches (e.g. for extra W' or Z' particles, extra scalars in the context of multi-Higgs models, or for fourth-generation quarks) are quoted that can be used – when appropriately translated – to derive bounds on a specific model of interest.

The mass scale of the new particles implied by the interpretations of the low mass of H^0 discussed above, and existing studies from the Tevatron and lower-energy colliders, suggests that only the Large Hadron Collider has any real sensitivity. A number of analyses already carried out by ATLAS and CMS use relevant final states and might have been expected to observe a deviation from standard model expectations – in no case so far has any such deviation been reported. The detailed implications of these searches in various model frameworks are described below.

Except where otherwise noted, all limits in this section are quoted at a confidence level of 95%. The searches at $\sqrt{s} = 8 \text{ TeV}$ (Run 1) are based on 20.3 fb^{-1} of data recorded by ATLAS, and an integrated luminosity of 19.7 fb^{-1} analyzed by CMS. The datasets collected at $\sqrt{s} = 13 \text{ TeV}$ during Run 2 of the LHC since 2015 are based on analyses with varied integrated luminosities ranging from $\sim 2\text{--}140 \text{ fb}^{-1}$.

93.2.1 Searches for Z' or W' Bosons

Massive vector bosons or particles with similar decay channels would be expected to arise in Little Higgs theories, in theories of Technicolor, or models involving a dilaton, adjusted to produce a light Higgs boson, consistent with the observed H^0 . These particles would be expected to decay to pairs of vector bosons, or to third generation quarks, or to leptons. The generic searches for W' and Z' vector bosons listed below can, therefore, be used to constrain models incorporating a composite Higgs-like boson.

A general review of searches for Z' and W' bosons is also included in this volume [63, 64]. In the context of the dynamical electroweak symmetry breaking models, we emphasize their decays to third generation fermions by including a detailed overview,

⁶Indeed, from this point of view, the vector-like partners of the top-quark in top-seesaw and little Higgs models can be viewed as incorporating partial compositeness to explain the origin of the top quark’s large mass.

while also briefly summarizing the other searches.

$Z' \rightarrow \ell\ell$:

ATLAS [65] and CMS [66] have both searched for Z' production with $Z' \rightarrow ee$ or $\mu\mu$. No deviation from the standard model prediction was seen in the dielectron and dimuon invariant mass spectra, by either the ATLAS or the CMS analysis, and lower limits on possible Z' boson masses were set. A Z'_{SSM} with couplings equal to the standard model Z' (a “sequential standard model” Z') and a mass below 5.1 TeV was excluded by ATLAS, while CMS set a lower mass limit of 5.15 TeV. The experiments also place limits on the parameters of extra dimension models and in the case of ATLAS on the parameters of a minimal walking technicolor model [17–21], consistent with a 125 GeV Higgs boson [67]. For a general review of searches in these channels see the PDG review of Z prime in this volume [63].

In addition, both experiments have also searched for Z' decaying to a ditau final state [68, 69]. An excess in $\tau^+\tau^-$ could have interesting implications for models in which lepton universality is not a requirement and enhanced couplings to the third generation are allowed. This analysis led to lower limits on the mass of a Z'_{SSM} of 2.4 and 2.1 TeV from ATLAS and CMS respectively.

$Z' \rightarrow q\bar{q}$:

The ability to relatively cleanly select $t\bar{t}$ pairs at the LHC together with the existence of enhanced couplings to the third generation in many models makes it worthwhile to search for new particles decaying in this channel. Both ATLAS [70] and CMS [71] have carried out searches for new particles decaying into $t\bar{t}$.

Both the ATLAS and CMS collaborations searched for $t\bar{t}$ in the all hadronic mode [72] [73] in both the resolved and boosted regions. No evidence of resonance production were seen and limits were produced for various models including the Z' boson in topcolor-assisted technicolor which excludes masses less than 3.1 to 3.6 TeV (ATLAS) depending on the details of the model and 3.3, 5.25, and 6.65 TeV for widths of 1, 10 and 30 percent relative to the mass of the resonance.

ATLAS also presented results on the lepton plus jets final state, where the top quark pair decays as $t\bar{t} \rightarrow WbWb$ with one W boson decaying leptonically and the other hadronically; CMS used final states where both, one or neither W decays leptonically and then combined the results. The $t\bar{t}$ invariant mass spectrum was analyzed for any excess, and no evidence for any resonance was seen. ATLAS excluded a narrow ($\Gamma/m = 1.2\%$) leptophobic topcolor Z' boson with masses between 0.7 and 2.1 TeV and with $\Gamma/m = 3\%$ between 0.7 and 3.2 TeV. CMS set limits on leptophobic Z' bosons for three different assumed widths $\Gamma/m = 1.0\%$, $\Gamma/m = 10.0\%$, and $\Gamma/m = 30.0\%$ of 3.9 TeV to 4.0 TeV and exclude RS KK gluons up to 3.3 TeV.

Both ATLAS [74] and CMS [75] have also searched for resonances decaying into $q\bar{q}$, qg or gg using the dijet invariant mass spectrum. Excited quarks are excluded up to masses of 6.7 TeV and model-independent upper limits on cross sections with a gaussian signal shape were set. CMS excluded string resonances with masses below 7.9 TeV, scalar diquarks below 7.5 TeV, axigluons and colorons below 6.6 TeV, excited quarks below 6.3 TeV, color-octet scalars below 3.7 TeV, W' bosons below 3.6 TeV, Z' bosons with SM-like couplings below 2.9 TeV and between 3.1 TeV and 3.3 TeV, Randall–Sundrum Gravitons below 2.6 TeV.

$W' \rightarrow \ell\nu$:

Both LHC experiments have also searched for massive charged vector bosons. In this section we include a summary of the results, with emphasis on final states with third generation fermions, while the details on other decays are discussed in the mini-review of W' [64]. ATLAS searched for a heavy W' decaying to $e\nu$ or $\mu\nu$ and find no excess over the standard model expectation. A sequential standard model (SSM) W' boson (assuming zero branching ratio to WZ) with mass less than 7 TeV was excluded [76] using 139 fb^{-1} dataset at $\sqrt{s} = 13$ TeV, as well as setting model independent cross-section limits as a function of mass. Based on a smaller dataset, the CMS experiment excluded a SSM W' boson with mass up to 4.1 TeV [77] and presented the upper limits on the production of generic W' bosons decaying into this final state using a model-independent approach.

CMS [78] has carried out a complementary search in the $\tau\nu$ final state. As noted above, such searches place limits on models with enhanced couplings to the third generation. No excess was observed and limits between 2.0 and 2.7 TeV were set on the mass of a W' decaying preferentially to the third generation; a W' with universal fermion couplings was also excluded for masses less than 2.7 TeV.

$W' \rightarrow t\bar{b}$:

Heavy new gauge bosons can couple to left-handed fermions like the SM W boson or to right-handed fermions. W' bosons that couple only to right-handed fermions (W'_R) may not have leptonic decay modes, depending on the mass of the right-handed neutrino. For these W' bosons, the $t\bar{b}$ ($\bar{t}b + \bar{t}b$) decay mode is especially important because in many models the W' boson is expected to have enhanced couplings to the third generation of quarks relative to those in the first and second generations. It is also the hadronic decay mode with the best signal-to-background. ATLAS and CMS have performed searches for W' bosons via the $W' \rightarrow t\bar{b}$ decay channel in the lepton+jets and all-hadronic final state.

The CMS lepton+jets search [79–82], $W' \rightarrow t\bar{b} \rightarrow Wbb \rightarrow \ell\nu b\bar{b}$, proceeded via selecting events with an isolated lepton (electron or muon), and at least two jets, one of which is identified to originate from a b-quark. The mass of the W' boson ($M_{t\bar{b}}$) was reconstructed using the four-momentum vectors of the final state objects ($b\bar{b}\ell\nu$). The distribution of $M_{t\bar{b}}$ is used as the search discriminant. A search [82] using 35.9 fb^{-1} of data, collected at $\sqrt{s} = 13$ TeV, led to an exclusion of W'_R bosons with masses below 3.4 TeV (3.6 TeV) if $M_{W'_R} \gg M_{\nu_R}$ ($M_{W'_R} < M_{\nu_R}$), where M_{ν_R} is the mass of the right-handed neutrino.

The CMS search for $W' \rightarrow t\bar{b}$ decays using the all-hadronic final state focused on W' masses above 1 TeV [81]. In this region, the top quark gets a large Lorentz boost and hence the three hadronic products from its decay merge into a single large-radius jet. Techniques which rely on substructure information of the jets [83] are employed to identify boosted all hadronic W boson and top quark jets and compute the mass of the jet. W' candidate mass was computed from back-to-back boosted top-tagged jet and a low mass b-tagged jet. From this all-hadronic search, W' bosons were excluded for masses up to 2.02 TeV.

ATLAS has searched for W'_R bosons in the $t\bar{b}$ final state both for lepton+jets [84] and all-hadronic [85] decays of the top. No significant deviations from the standard model were seen in either analysis and limits were set on the $W' \rightarrow t\bar{b}$ cross section times branching ratio and W' bosons with purely right-handed couplings to fermions were excluded for masses below 3.15 TeV when the two channels are combined.

In addition, the above studies also provided upper limits on the W' effective couplings to right- and left-handed fermions. In Fig. 93.1 (bottom) the upper limits on W' couplings normalized to the SM W boson couplings derived by ATLAS [86] are shown. The top panel of Fig. 93.1 shows the upper limits for arbitrary combinations of left- and right-handed couplings of the W' boson to fermions set using a model independent approach by CMS [82].

93.2.2 Searches for Resonances decaying to Vector Bosons and/or Higgs Bosons

Both the ATLAS and CMS experiments have used the data collected at $\sqrt{s} = 13$ TeV to search for resonances decaying to pairs of bosons. Overall no significant excesses were seen in the full datasets that were analyzed and the results are interpreted in models with heavy vector triplets (HVT) [87], models with strong gravity and extra spatial dimensions, as well as setting model independent limits as a function of mass. For a full review of models including extra spatial dimensions including the interpretation of many of these results in that context please see the review of extra dimensions in this volume [60].

Utilizing data collected at $\sqrt{s} = 13$ TeV, ATLAS [88] and CMS [89], have both looked for a resonant state decaying into VV (with $V = W$ or Z), VH (with H representing the SM Higgs boson), and HH. Both collaborations have analyzed bosonic decay modes. ATLAS searches in the $qqqq$, $\nu\nu qq$, $\nu\nu qq$, $llqq$, $l\nu l\nu$, $ll\nu l$, $ll\nu l$, $llll$, $qqbb$, $\nu\nu bb$, $l\nu bb$, and $llbb$ final states and combined the results

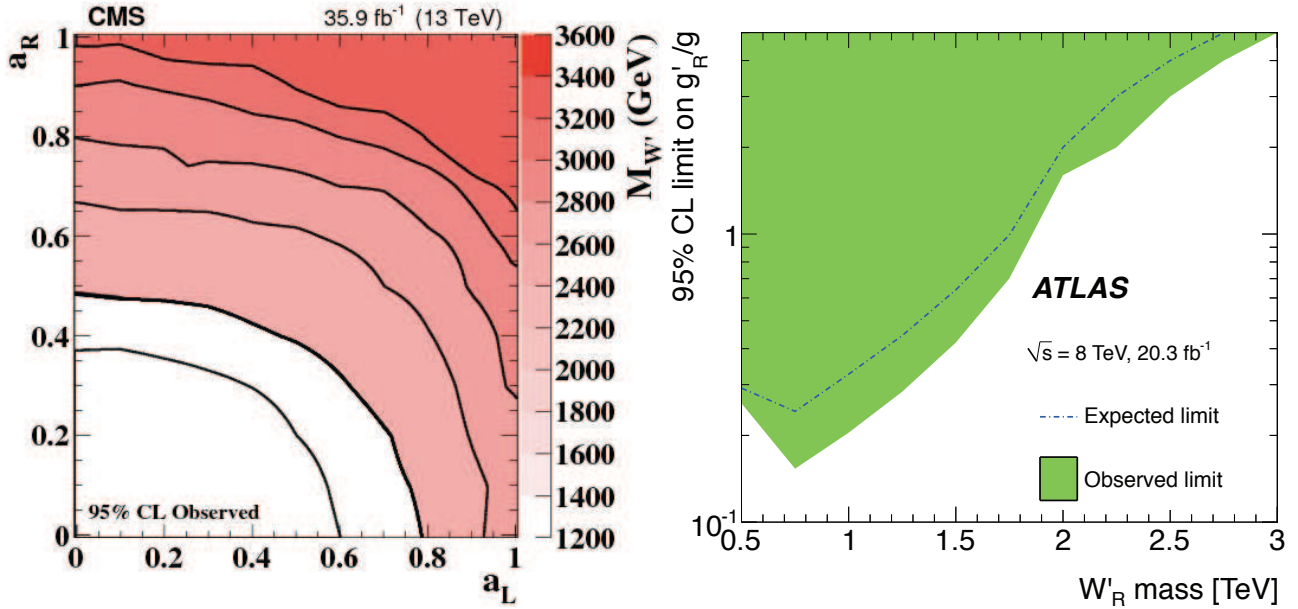

Figure 93.1: Left panel: Observed limits on the W' boson mass as function of the left-handed (a_L) and right-handed (a_R) couplings. Black lines represent contours of equal W' boson mass [82]. Right panel: Observed and expected regions, on the g'/g vs mass of the W' boson plane, that are excluded at 95% CL, for right-handed W' bosons [86].

(separately within each experiment) . While CMS analyzes the $qqqq$, $\nu\nu qq$, $lvqq$, $llqq$, $ll\nu\nu$, $\nu\nu bb$, $lvbb$, $llbb$, $bbbb$, $\tau\tau bb$, and $qq\tau\tau$ final states.

The combined limits are expressed both as limits on the cross-section as a function resonance mass as well as constraints on the coupling of the heavy boson triplet to quarks, leptons, and the Higgs boson.

$X \rightarrow WZ$:

ATLAS searches for new heavy resonances decaying into WZ in the channels $WZ \rightarrow qqqq$ [90], $lvqq$ [91], and $lvll$ [92]. In the fully leptonic channel, the invariant mass of the WZ pair is obtained by considering all possible four lepton permutations in each event. The dominant background is Standard Model continuum WZ production, ZZ production where one lepton is not identified or falls outside the detector acceptance, and top quark plus vector boson production. No resonant production is seen in data and lower limits on the mass of a HVT decaying into WZ are set at 2260 (2460) GeV assuming a coupling constant of $g_V = 1$ ($g_V = 3$). In the $WZ \rightarrow lvqq$ mode, ATLAS searches in both the cases that the quarks are observed as individual jets (resolved) and where they merge into one jet in the detector (boosted) which probe the low and high p_T regime of the Z boson. No significant excess is seen in either channel and combined lower mass limits are placed at 2900 (3000) GeV for $g_V = 1$ ($g_V = 3$) in the HVT model. In the all hadronic decay mode, ATLAS searches for two high p_T hadronically decaying vector bosons looking for a resonant structure. No excess is seen and limits are placed excluding 1200-3000 (1200-3300) GeV for $g_V = 1$ ($g_V = 3$) in the HVT model.

The CMS collaboration searches for $VV \rightarrow qqqq$ [93] in the large R dijet search. The W and Z boson are identified through the mass of the large R jet and substructure variables. No excess is seen and limits are set for charged HVT bosons with masses lower than 3200 (3800) GeV for $g_V = 1$ ($g_V = 3$). Cross-section limits as function of mass are reported for the charged spin-1 resonance interpretation and are placed at 44.4 fb at 1.4 TeV to 0.7 pb at 4 TeV. In the $\nu\nu qq$ final state [94], the CMS collaboration searches for a charged spin 1 resonance decaying into a VZ final state with a Z boson decaying into a pair of neutrinos and the other boson decaying into two collimated quarks reconstructed as a large R-jet. The transverse mass of the VZ candidate is reconstructed and utilized to search for evidence of resonant VZ production. No excess is seen and lower mass limits are placed on the charged resonance at 3100 (3400) GeV for $g_V = 1$ ($g_V = 3$) .

In the $2l2q$ final state, the CMS collaboration searches for a heavy resonance decaying into ZV [95] looking for events with one large R-jet consistent with the hadronic decay of a vector boson and a Z boson reconstructed in the charged lepton decay channel (e or μ). Limits are set for a HVT W' with a lower mass of 2270 (2330) for $g_V = 1$ ($g_V = 3$) .

$X \rightarrow WW$:

The ATLAS collaboration searches for a new heavy resonance decaying into WW in the channels $WW \rightarrow qqqq$ [90], $lvqq$ [91], and $lv\nu\nu$ [96]. In the case where both W 's decay leptonically, ATLAS utilizes the transverse of the two lepton and two neutrino final state and searches for an excess in this distribution between 200 GeV and 5 TeV. No excess is seen and the mass of a HVT is excluded below 1300 GeV. Further vector boson fusion is also considered and cross-section limits as a function of mass are placed ranging from 1.3 pb to 0.006 pb at 200 GeV to 3 TeV, respectively. In the $lvqq$ mode, ATLAS completed a companion analysis to the $WZ \rightarrow$ analysis discussed above and places lower mass limits of 2850 (3150) GeV for $g_V = 1$ ($g_V = 3$) in the HVT model. ATLAS also interprets the all hadronic mode analysis in the hypothesis that $WW \rightarrow qqqq$ and places limits on a HVT boson decaying into WW in the all hadronic mode between 1200 to 2200 (1200 to 2800) GeV for $g_V = 1$ ($g_V = 3$).

The CMS collaboration searches for $VV \rightarrow qqqq$ [93] in the large R dijet search. The W and Z boson are identified through the mass of the large R jet and substructure variables. No excess is seen and limits are set for charged HVT bosons with masses lower than 2700 (2800) GeV for $g_V = 1$ ($g_V = 3$). Cross-section limits as function of mass are reported for the uncharged spin-1 resonance interpretation and are placed at 41.6 fb at 1.4 TeV to 0.6 pb at 4 TeV.

$X \rightarrow VH$:

The ATLAS Collaboration searches for a new heavy resonance decaying into WH and ZH in the $qbbb$ (WH and ZH) [97], $lvbb$ (WH), $\nu\nu bb$ (ZH), $llbb$ (ZH) [98]. In the all hadronic mode, ATLAS searches for boosted VH production looking for two large R jets where the larger invariant mass large R jet is interpreted as the Higgs boson decay products while the lesser the hadronically decaying vector boson requiring b tagging on the Higgs boson subjects. The invariant mass is reconstructed and a search is done for resonant production of ZH . None is found and limits from

1100 to 2500 (1300 to 3800 GeV) are placed for $g_V = 1$ ($g_V = 3$). ATLAS also searches for ZH where the W or Z boson decays into $\nu\nu$, $l\nu$, and ll . The analysis searches for both resolved and merged (boosted) b jets from the decay of the Higgs boson as well as defining signal regions based on the number of reconstructed charged leptons (0,1,or 2). In the dilepton channel the invariant mass is explicitly reconstructed of the entire diboson system, the single lepton channel reconstructs the diboson final state constraining the lepton and missing transverse momentum utilizing the known W boson mass, while the 0 charged lepton channel reconstructs the transverse mass of the diboson system. No excess is seen in any channel and limits on the production of a HVT are placed at 2800 GeV (2930) GeV for $g_V = 1$ ($g_V = 3$).

The CMS Collaboration searches for a heavy resonance decaying into VH [99] searching for resonances decaying into a Higgs boson and either a hadronically decaying W or Z boson. The search identifies events with two large-R jets using substructure variables and requires one large-R jets is tagged with a pair of b -hadrons clustered in a single jet. The invariant mass of the VH bosons is reconstructed and evidence for resonance production is sought. No excess is seen and limits are placed. With $g_V = 1$ (3) a narrow W' resonance with $m_{W'} < 2470(3150)$ GeV and $m_{Z'} < 1150(1190)$ GeV. Summary of Searches with Diboson Final States:

Both ATLAS [88] and CMS [89] provide plots summarizing the various searches results and limits combining. The results are shown in the context of HVT models and models of strong gravity with extra spatial dimensions. No excess is seen in any search and limits on the 4.3 (4.5) TeV (ATLAS) and (CMS). Inclusion of decays directly to fermions increase these limits to 5.3 (5.5) TeV and 5.0 (5.2) TeV from the ATLAS and CMS combinations, respectively. Both collaborations also place varying limits on the coupling strength as a function of HVT boson mass as well.

93.2.3 Vector-like third generation quarks

Vector-like quarks (VLQ) have non-chiral couplings to W bosons, i.e. their left- and right-handed components couple in the same way. They therefore have vectorial couplings to W bosons. Vector-like quarks arise in Little Higgs theories, top-coloron-models, and theories of a composite Higgs boson with partial compositeness. In the following, the notation T quark refers to a vector-like quark with charge $2/3$ and the notation B quark refers to a vector-like quark with charge $-1/3$, the same charges as the SM top and b quarks respectively. The exotic vector-like quarks $X_{5/3}$ and $Y_{-4/3}$ have charges $5/3$, and $-4/3$ respectively. Vector-like quarks couple with SM quarks with Yukawa interactions and may exist as $SU(2)$ singlets (T , and B), doublets $[(X_{5/3}, T), (T, B), (B, Y_{-4/3})]$, or triplets $[(X_{5/3}, T, B), (T, B, Y_{-4/3})]$. At the LHC, VLQs can be pair produced via the dominant gluon-gluon fusion. VLQs can also be produced singly by their electroweak effective couplings to a weak boson and a standard model quark. Single production rate is expected to dominate over the rate of pair production at large VLQ masses. T quarks can decay to bW , tZ , or tH^0 . Weak isospin singlets are expected to decay to all three final states with (asymptotic) branching fractions of 50%, 25%, 25%, respectively. Weak isospin doublets are expected to decay exclusively to tZ and to tH^0 [100] with equal branching ratios. Analogously, B quarks can decay to tW , bZ , or bH^0 . The $Y_{-4/3}$ and $X_{5/3}$ quarks decay exclusively to bW and to tW . While these are taken as the benchmark scenarios, other representations are possible and hence the final results are interpreted for many allowed branching fraction combinations.

Given the multiple decay modes of the VLQs, the final state signatures of both pair produced and the singly produced VLQs are fairly rich with leptons, jets, b jets, and missing energy. Depending on the mass of the VLQ, the top quarks and $W/Z/H^0$ bosons may be Lorentz boosted and identified using jet substructure techniques. Thus the searches are performed using lepton+jets signatures, multi-lepton and all-hadronic decays. In addition, T or B quarks with their antiparticles can result in events with same-sign leptons, for example if the decay $T \rightarrow tH \rightarrow bWW^+W^-$ is present, followed by leptonic decays of two same-sign W bosons. In the following subsections, while we describe the searches for each of the decay modes of the VLQs, the same analysis can be

re-interpreted to obtain the sensitivity to a combination with varied branching fractions to the different decay modes.

In the following sections, the results obtained for T (B) quarks assuming 100% branching ratio to Wb (Wt) are also applicable to heavy vector-like $Y_{-4/3}$ ($X_{5/3}$) with charge $4/3$ ($5/3$).

93.2.3.1 Searches for T quarks that decay to W , Z and H^0 bosons

$T/Y \rightarrow bW$:

CMS has searched for pair production of heavy T quarks that decay exclusively to bW [101–103]. The analysis selected events with exactly one charged lepton, assuming that the W boson from the second T quark decays hadronically. Under this hypothesis, a 2-constraint kinematic fit can be performed to reconstruct the mass of the T quark as a narrow mass peak with a mass resolution of around 7%. In Refs. [102] and [103], the two-dimensional distribution of reconstructed mass vs S_T was used to test for the signal, where S_T is the scalar sum of the missing p_T and the transverse momenta of the lepton and the leading four jets. This analysis, when combined with the search in the fully hadronic final state [104] excluded new quarks that decay 100% to bW for masses below 0.89 TeV [103]. At times the hadronically-decaying W boson is produced with a large Lorentz boost, leading to the W decay products merged into a large-radius jet. Algorithms such as jet pruning [105] were used to remove contributions from soft, wide angle radiation, from large-radius jets, leading to better discrimination between QCD jets and those arising from decays of the heavy particles. If the mass of the boosted jet was compatible with the W boson mass, then the W boson candidate jet and its subjects were used in the kinematic reconstruction of the T quark. No excess over standard model backgrounds was observed. Upper limits on the production cross section as a function of the mass of T quarks were measured. By comparing them with the predicted cross section for vector like quark pair production, the strong pair production of T quarks was excluded for masses below 1.30 TeV (1.28 TeV expected) [101].

Another “cut-based” search for pair produced T quarks in the all-hadronic final state targeting the Wb decay mode [106], relies on mass reconstruction of two highest p_T Wb combinations using boosted W boson candidates with $p_T > 200$ GeV and b -tagged jets. H_T is used as the signal discriminator, with selected events divided into nine categories based on the multiplicity of W and b jets in the event. From this search T quarks with pure Wb decays are excluded for masses below 1.04 TeV (1.07 TeV expected).

An analogous search has been carried out by ATLAS [107, 108] for the pair production of heavy T quarks. It used the lepton+jets final state with an isolated electron or muon and at least four jets, including a b jet and required reconstruction of the T quark mass. Given the mass range of the T quark being explored was from a 0.4 TeV to a couple of TeV, the W boson from the T quark may fall in two categories: those with a high boost leading to merged decay products, and others where the two jets from the W boson were resolved. In addition, the selection was optimized to require large angular separation between the high p_T W bosons and the b jets.

The $T \rightarrow Wb$ candidates were constructed from both the leptonically and hadronically decaying W bosons by pairing them with the two highest p_T b -tagged jets in the event. The pairing of b jets with W bosons which minimizes the difference between the masses of leptonically decaying T ($m_{lep}(T)$) and the hadronic T ($m_{had}(T)$) was chosen. Finally, $m_{lep}(T)$ was used as the discriminating variable in a signal region defined by high S'_T (here S'_T is defined as the scalar sum of the missing p_T , the p_T of the lepton and jets) and the opening angle between the lepton and the neutrino ($\Delta R(e, \nu)$). With the 36.1 fb^{-1} data collected during Run 2 at $\sqrt{s} = 13$ TeV, assuming 100% branching ratio to the Wb decay, the observed lower limit on the T mass was 1.35 TeV, and in the $SU(2)$ singlet scenario, the lower mass limit was obtained to be 1.17 TeV [107].

A targeted search for a T quark, produced singly in association with a light flavor quark and a b quark and decaying into bW , was carried out by CMS at $\sqrt{s}=13$ TeV and a dataset corresponding to 2.3 fb^{-1} [109]. The analysis used lepton+jets events, with at least

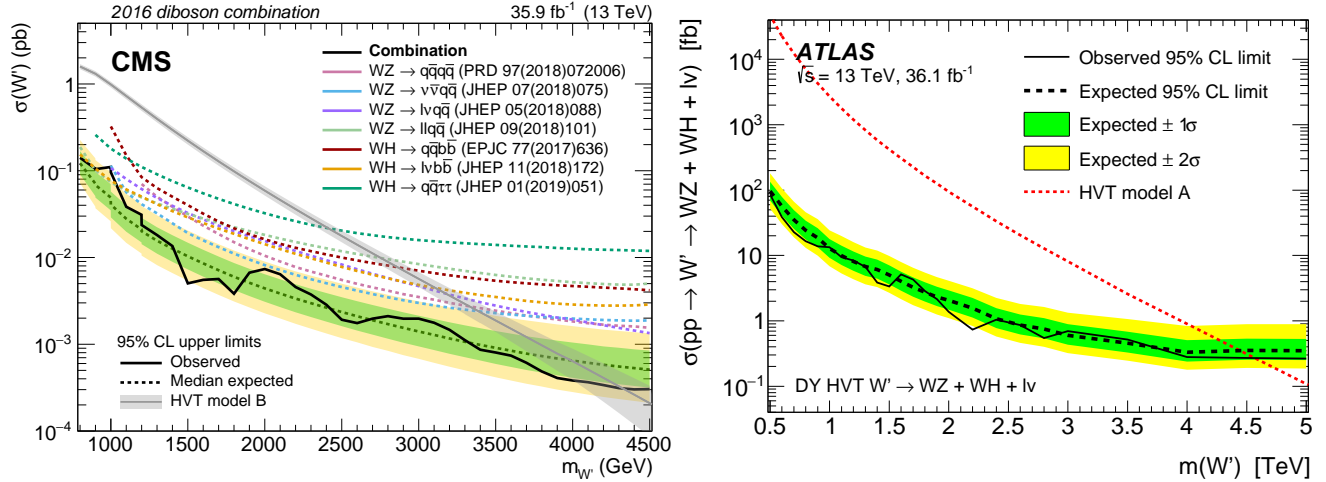

Figure 93.2: Left panel: Observed limits from W' to diboson from CMS [89]. Right panel: Observed limits from W' to diboson decays from ATLAS [88].

one b-tagged jet with large transverse momentum, and a jet in the forward η region. Selected events were required to have $S_T'' > 500$ GeV, where S_T'' is defined as the scalar sum of the transverse momenta of the lepton, the leading central jet, and the missing transverse momentum. The invariant mass of the T candidate was used as the discriminating variable and was reconstructed using the four-vectors of the leptonically decaying W boson and the leading central jet. No excess over the standard model prediction was observed. As the VLQ width is proportional to the square of the coupling, upper limits were set on the production cross section assuming a narrow width VLQ with coupling greater than 0.5. For Y/T quarks with a coupling of 0.5 and a 100% branching fraction for the decay to bW the excluded masses were in the range from 0.85 to 1.40 TeV [109]. A similar search [110, 111] performed by ATLAS singly produced T or $Y_{-4/3}$ quark decaying to Wb using a dataset corresponding to 36.1 fb^{-1} . The search was performed using lepton+jets events with a high p_T b-tagged jet, and at least one forward jet. The reconstructed mass of the $T/Y_{-4/3}$ quark, was used as the discriminating variable and showed no excess above the expectation from SM. Interference effects with the SM background are included in the study. This search led to 95% CL upper limits on the mixing angle $|\sin(\theta_L)|$ (C_L^{Wb}) in the range of 0.18–0.35 (0.25–0.49) for singlet T quark mass between 0.8–1.2 TeV. This search also provided limits as a function of the $Y_{-4/3}$ quark mass, on the coupling of the $Y_{-4/3}$ quark to bW , and the mixing parameter $|\sin\theta_R|$ (C_R^{Wb}) for a $(B, Y_{-4/3})$ doublet model [110]. For VLQ masses between 0.08–1.8 TeV, the limits on $|\sin(\theta_R)|$ (C_R^{Wb}) is in the range 0.17–0.55 (0.24–0.77), where limits on $|\sin\theta_R|$ are around 0.18–0.19 and below the constraints from electroweak precision observables for $Y_{-4/3}$ quark mass between 0.9–1.25 TeV. For $Y_{-4/3}$ quark in the triplets $(T, B, Y_{-4/3})$, limits on $|\sin(\theta_L)|$ (C_L^{Wb}) are between 0.16–0.39 (0.31–0.78) for masses between 0.8 GeV–1.6 TeV [110].

$T \rightarrow tH^0$:

ATLAS has performed a search for $T\bar{T}$ production with $T \rightarrow tH^0$ [108, 112]. Given the dominant decay mode $H^0 \rightarrow b\bar{b}$, these events are characterized by a large number of jets, many of which are b jets. Thus the event selection required one isolated electron or muon and high jet multiplicity (including b-tagged jets). The sample is categorized by the jet multiplicity (5 and ≥ 6 jets in the 1-lepton channel; 6 and ≥ 7 jets in the 0-lepton channel), b tag multiplicity (2, 3 and ≥ 4) and mass-tagged jet multiplicity (0, 1 and ≥ 2). The distribution of m_{eff} , defined as the scalar sum of the lepton and jet p_T and the missing E_T , for each category were used as the discriminant for the final signal and background separation. No excess of events were found. Weak isospin doublet T quarks were excluded below 1.16 TeV.

A search by ATLAS for pair produced VLQs with an all-hadronic final state signature yields an exclusion of pure decays

$T \rightarrow tH^0$ upto a T quark mass of 1.01 TeV [113]. This analysis used a deep neural network technique to identify jets originating from boosted bosons and top-quarks and described further in subsection 93.2.3.2.

The CMS search for $T\bar{T}$ production, with $T \rightarrow tH^0$ decays has been performed in both lepton+jets, multilepton and all-hadronic final states. The lepton+jets analysis [114] emphasizes the presence of large number of b-tagged jets, and combined with other kinematic variables in a Boosted Decision Tree (BDT) for enhancing signal to background discrimination. The multilepton analysis [114] was optimized for the presence of b jets and the large hadronic activity. For $\mathcal{B}(T \rightarrow Wb) = 1$, the combined lepton+jets and multilepton analyses led to a lower limit on T quark masses of 0.71 TeV. A search for $T \rightarrow tH^0$ in all-hadronic decays [115], optimized for a high mass T quark, and based on identifying boosted top quark jets has been carried out by CMS. This search aimed to resolve subjects within the jets arising from boosted top quark decays, including b tagging of the subjects. A likelihood discriminator was defined based on the distributions of H_T , and the invariant mass of the two b jets in the events for signal and background. No excess above background expectations was observed. Assuming 100% branching ratio for $T \rightarrow tH^0$, this analysis led to a lower limit of 0.75 TeV on the mass of the T quark.

Searches for T quarks at $\sqrt{s}=13$ TeV, based on a 2.6 fb^{-1} dataset [116] have been performed by CMS using the lepton+jets final state. This search has been optimized for high mass T quarks by exploiting techniques to identify W or Higgs bosons decaying hadronically with large transverse momenta. The boosted W channel excluded T quarks decaying only to bW with masses below 0.91 TeV, and the boosted tH channel excluded T quarks decaying only to tH for masses below 0.89 TeV.

A CMS search for $T \rightarrow tH^0$ with $H^0 \rightarrow \gamma\gamma$ decays has been performed [117] in pair production of T quarks. To identify the Higgs boson produced in the decay of the heavy T quark, and the subsequent $H^0 \rightarrow \gamma\gamma$ decay, the analysis focused on identification of two photons in events with one or more high p_T lepton+jets or events with no leptons and large hadronic activity. A search for a resonance in the invariant mass distribution of the two photons in events with large hadronic activity defined by the H_T variable showed no excess above the prediction from standard model processes. The analysis resulted in exclusion of T quark masses below 0.54 TeV.

A search for electroweak single production of T quark decaying to tH^0 using boosted topologies in fully hadronic [118] and lepton+jets [119] in the final states has been performed by CMS. The electroweak couplings of the T quarks to the SM third generation quarks are highly model dependent and hence these couplings determine the rates of the single T quark production. In both analyses, T quark candidate invariant mass was reconstructed using the

Implications of the H^0

boosted Higgs boson jets and the top quark. Higgs boson jets were identified using jet substructure techniques and subjet b tagging. For the lepton+jets analysis the top quark was reconstructed from the leptonically decaying W and the b jet, while in the all-hadronic analysis the top quark jet was tagged using substructure analysis. There was no excess of events observed above background. Exclusion limits on the product of the production cross section and the branching fraction ($\sigma(pp \rightarrow Tqt/b) \times \mathcal{B}(T \rightarrow tH^0)$) were derived for the T quark masses in the range 0.70–1.8 TeV. From the lepton+jets analysis, for a mass of 1.0 TeV, values of ($\sigma(pp \rightarrow Tqt/b) \times \mathcal{B}(T \rightarrow tH^0)$) greater than 0.8 and 0.7 pb were excluded assuming left- and right-handed coupling of the T quark to standard model fermions, respectively [119]. For the all-hadronic analysis, upper limits between 0.31 and 0.93 pb were obtained on ($\sigma(pp \rightarrow Tqt/b) \times \mathcal{B}(T \rightarrow tH^0)$) for T quark masses in the range 1.0–1.8 TeV [118].

 $T \rightarrow tZ$:

Both ATLAS and CMS searched for T quarks that decay exclusively into tZ in pp collisions at $\sqrt{s} = 13$ TeV. No excesses were found in either search.

ATLAS performed a search [120] for optimized pair production of vector-like top quarks decaying into tZ where the Z boson subsequently decays into neutrino pairs utilizing 36.1 fb^{-1} of data. The search selected events with one lepton, multiple jets, and significant missing transverse momentum. No significant excesses were found and lower limits on the mass of a vector like top quark were placed, excluding masses below 0.87 TeV (weak-isospin singlet), 1.05 TeV (weak-isospin doublet), and 1.16 TeV (pure tZ mode).

Another search by ATLAS for pair produced T decaying to tZ has been carried out by reconstructing the high transverse momentum Z boson from a pair of opposite-sign same-flavor lepton, using events with two or three charged leptons [121]. The final analysis is based on three final signatures. In the trilepton events, at least one b -tagged jet is required and S_T is used as the discriminating variable. In events with two leptons, at least 2 b jets are requested and those with zero or one high p_T top-tagged jet, use H_T as the discriminator. The second dilepton analysis with two top-tagged high p_T jets focuses on hadronically decaying heavy resonances and the invariant mass of the Z boson and the highest p_T b -tagged jet if found to be a good discriminating variable. No excess was observed over the background expectations. The combined analysis yields a lower limit on T quark mass of 1.03 TeV (1.21 TeV) in the singlet (doublet) model or 100% branching ratio for $T \rightarrow tZ$ a lower limit on the T quark mass of 1.34 TeV is obtained.

ATLAS has subsequently carried out a search [122] for singly produced T quark decaying to tZ where the Z boson decays into neutrino pairs. The search is carried out using 36.1 fb^{-1} of data in events with two different final state signatures: one with jets, and significant missing p_T (0L) and the other with single lepton, jets and missing p_T (1L). Events are divided into signal and dedicated W +jets and $t\bar{t}$ background control regions. The sensitivity to T quark signal is extracted using distributions of missing p_T for 1L and the distributions of transverse mass T quark constructed from missing p_T and the high p_T large-radius top-tagged jet for 0L analysis. The is no excess found over the expected background and lower limits on the production of T singlets is obtained as a function of the left- and right-handed couplings $c_{L,W}$ and $c_{R,W}$ to top quarks and W bosons, where c_W above 0.7 are excluded for T quark mass of 1.4 TeV. The limits on c_W are also recasted into expected and observed 95% CL upper limits for the mixing angle (θ_L) of a singlet T with the top quark.

CMS searched [123] for single production of T quarks decaying into tZ with the Z boson decaying to pairs of charged leptons (electrons and muons) and the top quark decaying hadronically using 35.9 fb^{-1} of data. Limits were placed on T quarks with masses between 0.7 and 1.7 TeV excluding the product of cross section and branching fraction above values of 0.27 to 0.04 pb. Additionally, limits on the product of cross section and branching fractions for a Z' boson decaying into tZ were set between 0.13 and 0.06 pb for Z' boson masses in the range from 1.5 to 2.5 TeV.

Similar searches by ATLAS for singly produced T decaying to

Zt have been performed in final state signatures with two or three charged leptons [121]. The analysis relies on tagging b jets and high p_T large-radius jets originating from top-quarks. Additional selections are devised to reduce the contributions from pair production of T quarks. For events with dilepton analysis, the discriminating variable is the mass of the T quark formed using the invariant mass of the Z boson candidate and the highest p_T top-tagged jet, while for the trilepton analysis, the variable S_T is used to search for an excess of data over the expected SM background. No excess above the SM expectations is observed. The two final states (dilepton and trileptons) are combined to obtain the final results. For the coupling parameter κ_T between 0.1–1.6, the 95% CL upper limits on the production cross section times branching fraction into Zt is between 0.16–0.18 (0.03–0.05) pb at T quark mass of 0.7 (2) TeV.

Combination of $T \rightarrow bW/tZ/tH^0$:

Most of the analyses described above targeted an individual decay mode of the T quark, with 100% branching ratio to either bW , tZ or tH^0 and were optimized accordingly. However, they have varied sensitivity to all three decay modes and the results can be interpreted as a function of branching ratios to each of the three decay modes, with the total adding up to unity ($\mathcal{B}(tH) + \mathcal{B}(tZ) + \mathcal{B}(Wb) = 1$).

Combinations of analyses have been performed by both ATLAS and CMS. The limits set by ATLAS searches in $W(\ell\nu)b = X$, $H(bb)b + X$, $Z(\ell\bar{\nu})$, $Z(\ell\ell)t/b + X$, dileptons with same-sign charge, trileptons, all-hadronic final states have been combined and the results obtained for various sets of branching fractions for T quark decays to bW , tH^0 and tZ are shown in Fig. 93.3 (left). In the combined analysis, ATLAS sets lower T quarks mass limit of 1.31 TeV for all possible values of the branching fractions to the three decay modes [107, 120, 124]. In Fig. 93.3, exclusion is shown in the plane of $\mathcal{B}(T \rightarrow Ht)$ versus $\mathcal{B}(T \rightarrow Wb)$, for different values of the T quark mass. The default branching ratio values for the weak-isospin singlet and doublet cases are also shown in Fig. 93.3 as yellow circle and star symbols respectively. Assuming a weak isospin (T, B) doublet and $|V_{Tb}| \ll |V_{tB}|$, T quark mass below 1.37 TeV is excluded.

CMS analysis for pair production of T , combined three channels with lepton final states: single lepton, two leptons with the same sign of the electric charge (SS), or at least three leptons (trilepton) [125]. For various combinations of branching fractions for T quark decays to bW , tH^0 and tZ , the combined results exclude T quarks with masses below 1.14–1.3 TeV and are shown in Figure 93.3 (right). Single lepton events are classified into 16 signal categories and 6 background control regions based on multiplicity of b -tagged, high p_T H^0 and W -tagged jets. The discriminating variables are H_T for H^0 -tagged and the minimum invariant mass constructed from the lepton and the b jet, $\min[M_{l\bar{b}}]$, for zero H^0 -tagged events. For the same-sign dilepton and trilepton analyses, the non-prompt backgrounds due to misidentified jets and leptons are derived from data control regions. In the trilepton analysis the S_T variable is used as the signal discriminator binned in four categories based on the lepton flavor combinations (eee , $e\mu\mu$, $e\mu\mu$, $\mu\mu\mu$). The single lepton analysis is most sensitive for $tHbW$ and $WbWb$ decay modes, within the the SS dilepton analysis $tHtH$ and $tHtZ$ have the best efficiency and for trileptons the $tZtZ$ and $tHtZ$ decays modes have the highest efficiency. CMS excludes singlet (doublet) T quark masses below 1.2 (1.28) TeV. Masses below 800 GeV were excluded in previous searches. For T quark masses in the range 0.8–1.8 TeV, cross sections smaller than 30.4–9.4 fb (21.2–6.1 fb) are excluded for the singlet (doublet) scenario.

Another inclusive search for pair produced T in all-hadronic final state [106] has been performed by CMS using the boosted event shape tagger (BEST) neural network technique to classify jets in six categories W , Z , H^0 , t , b , and light. This search does not focus on a given VLQ mode, but on various combinations of the boson and quark jets in the final state. Anti- k_T jets with a distance parameter of 0.8 are used. The BEST NN algorithm simultaneously classifies jets according to heavy object type. For each of the six particle hypothesis, it boosts each jet constituent into corresponding frame along jet momentum direction, and cal-

culates event shape and angular variables in the boosted frame, with the expectation that when boosting to the correct rest frame, jet constituents will be isotropic and show the expected N-prong structure of the decaying object in its rest frame. A neural network is trained using the event shape and angular variables in the boosted frame to classify jets according to one of those six possibilities (W, Z, H, t, b , or light). The analysis bins the events into 126 categories depending on the number of W, Z, H, t, b , or light jets in the final state with a maximum of four such objects. For each category H_T^{AK8} , the scalar sum of p_T of all AK8 jets, is used as the signal discriminator. A scan over a combination of various branching fractions is also performed. This search excludes T quark masses in the range 0.74–1.37 TeV for the tH decay mode in the NN analysis.

An inclusive search for VLQs has been carried out by CMS targeted at heavy T quarks decaying to any combination of bW, tZ , or tH^0 is described in [114]. Selected events have at least one isolated charged lepton. Events were categorized according to number and flavour of the leptons, the number of jets, and the presence of hadronic vector boson and top quark decays that are merged into a single jet. The use of jet substructure to identify hadronic decays significantly increases the acceptance for high T quark masses. No excess above standard model backgrounds was observed. Limits on the pair production cross section of the new quarks are set, combining all event categories, for all combinations of branching fractions into the three final states. For T quarks that exclusively decay to $bW/tZ/tH^0$, masses below 0.70/0.78/0.71 TeV are excluded.

93.2.3.2 Searches for B quarks that decay to W, Z and H^0 bosons

ATLAS and CMS have performed searches for pair production of heavy B quarks which subsequently decay to Wt, bZ or bH^0 . The searches have been carried out in final states with single leptons, dileptons (with same charge or opposite charge), multileptons, as well as in fully hadronic final states.

$B \rightarrow bH^0 X$:

Using 36.1 fb^{-1} of data, ATLAS has performed a search for pair produced VLQs with all-hadronic final state signature [113]. While this analysis provides exclusion limits for all third generation VLQs, it provides the strongest results for $B \rightarrow bH^0$ decay mode and excludes pure $B \rightarrow bH^0$ decays for B masses up to 1.01 TeV. The limits are also casted as a two-dimensional plane of branching ratio values of $B \rightarrow bH^0$ vs. $B \rightarrow Wb$. This analysis required the presence of high p_T jets and multiple b tags. It used a multi-class DNN to classify jets arising from W, Z, H^0 bosons and top-quarks. In addition, the matrix element method is used to compute the likelihood for the event to arise from a particular VLQ final state and used to construct the final discriminator. To increase the performance sensitivity, processes with the same number of top quarks, W/Z bosons, and H^0 Higgs bosons are combined into a single hypothesis.

$B \rightarrow WtX$:

A search for $B \rightarrow tW$ in B pair produced events has been performed by the ATLAS experiment [107] using lepton+jets events with one hadronically decaying W and one leptonically decaying W utilizing 36.1 fb^{-1} of data at $\sqrt{s} = 13 \text{ TeV}$. The search was optimized for T production decaying into Wb . Since the analysis was optimized for $T \rightarrow Wb$ rather than Wt decays the analysis does not reconstruct the full B mass. As discussed earlier, the hadronically and leptonically decaying heavy quarks were required to have similar reconstructed masses (within 300 GeV). The interpretation of the $T \rightarrow Wb$ in the context of $B \rightarrow tW$ production led to the exclusion of heavy B like VLQs for masses less than 1.25 TeV and 1.08 TeV, assuming a 100% branching fraction to tW or $SU(2)$ singlet B scenario, respectively.

A similar search by CMS [126], using 19.8 fb^{-1} of $\sqrt{s} = 8 \text{ TeV}$ data, selected events with one lepton and four or more jets, with at least one b -tagged jet, significant missing p_T , and further categorizes them based on the number of jets tagged as arising from the decay of boosted W, Z or H^0 bosons. The S_T distributions of the events in different categories showed no excess of events

above the expected background and yielded a lower limit on the B quark mass of 0.73 TeV for $BR(B \rightarrow Wt) = 1$.

CMS [116] also searched for pair production of both TT and BB with collisions from 2.5 fb^{-1} of $\sqrt{s} = 13 \text{ TeV}$ data. The analysis searches for events with one high p_T lepton, multiple jets, and highly boosted W or Higgs bosons decaying hadronically. The analysis focuses on pair production and selects events with either a boosted W or Higgs candidate and then proceeds to search for anomalous production in excess of standard model production. Seeing no significant excesses CMS then proceeded to set limits in many different interpretations. The strongest was from the the $B \rightarrow Wt$ interpretation leading to excluding heavy vector-like B quark less than 0.73 TeV.

The all-hadronic inclusive analysis [106] performed by CMS using the BEST NN technique to classify $W/Z/H^0/t/b$ light jets also gives exclusion limits on B quark production for various combinations of branching fractions for decays to tW, bZ, bH^0 . By considering categories based on various combinations of the boson and quark jets in the final state it excludes B quarks with masses up to 1230 GeV, for B decays to tW with a 100% branching fraction.

Electroweak production of single heavy $B+b$ productions has been studied by CMS in the decay to tW with lepton+jets final state [127]. Single lepton events with hadronic jets, including a forward jet, missing p_T are selected and divided into 10 different categories based on lepton flavor (e/μ), top-tagged, W -tagged, and $0/1/2$ b -tagged jets. B quark mass m_{reco} is fully reconstructed from lepton, jets, and missing p_T , where the neutrino four-momentum is computed using the missing p_T and the W mass constraint (assuming massless ν). For events within top-tagged category, the high p_T top-tagged hadronic jet and the leptonically decaying W boson is used to compute m_{reco} . The m_{reco} distribution is used as the signal discriminator. In the absence of an excess over the expected SM background, the exclusion limits on the production cross section is for B quark masses between 0.7–2 TeV varies between 0.3 to 0.03 pb. In addition, B quarks with left-handed couplings and a relative width of 10, 20, and 30% are excluded for masses below 1.49, 1.59, and 1.66 TeV respectively.

$B \rightarrow bZX$:

A search by CMS [128] for the pair-production of a heavy B quark and its antiparticle has been performed, where one the heavy B quark decays to bZ . Events with a Z boson decaying to e^+e^- or $\mu^+\mu^-$ and at least one b jet are selected. The signal from $B \rightarrow bZ$ decays are expected to appear as a local enhancement in the bZ mass distribution. No such enhancement was found and B quarks that decay 100% into bZ are excluded below 0.70 TeV. This analysis also set upper limits on the branching fraction for $B \rightarrow bZ$ decays of 30–100% in the B quark mass range 0.45–0.70 TeV. A complementary search has been carried out by ATLAS for new heavy quarks decaying into a Z boson and a b -quark [129]. Selected dilepton events contain a high transverse momentum Z boson that decays leptonically, together with two b jets. If the dilepton events have an extra lepton in addition to those from the Z boson, then only one b -jet is required. No significant excess of events above the standard model expectation was observed, and mass limits were set depending on the assumed branching ratios, as shown in Fig. 93.4. In a weak-isospin singlet scenario, a B quark with mass lower than 0.65 TeV was excluded, while for a particular weak-isospin doublet scenario, a B quark with mass lower than 0.73 TeV was ruled out.

ATLAS has searched for the electroweak production of single B quarks, which is accompanied by a b jet and a light jet [129]. The dilepton selection for double B production was modified for the single B production study by requiring the presence of an additional energetic jet in the forward region. An upper limit of 200 fb was obtained for the process $\sigma(pp \rightarrow B\bar{b}q) \times B(B \rightarrow Zb)$ with a heavy B quark mass at 0.70 TeV. This search indicated that the electroweak mixing parameter X_{Bb} below 0.5 is neither expected or observed to be excluded for any values of B quark mass.

Combination of $B \rightarrow tW/bZ/bH^0$:

The ATLAS experiment has combined the various analyses tar-

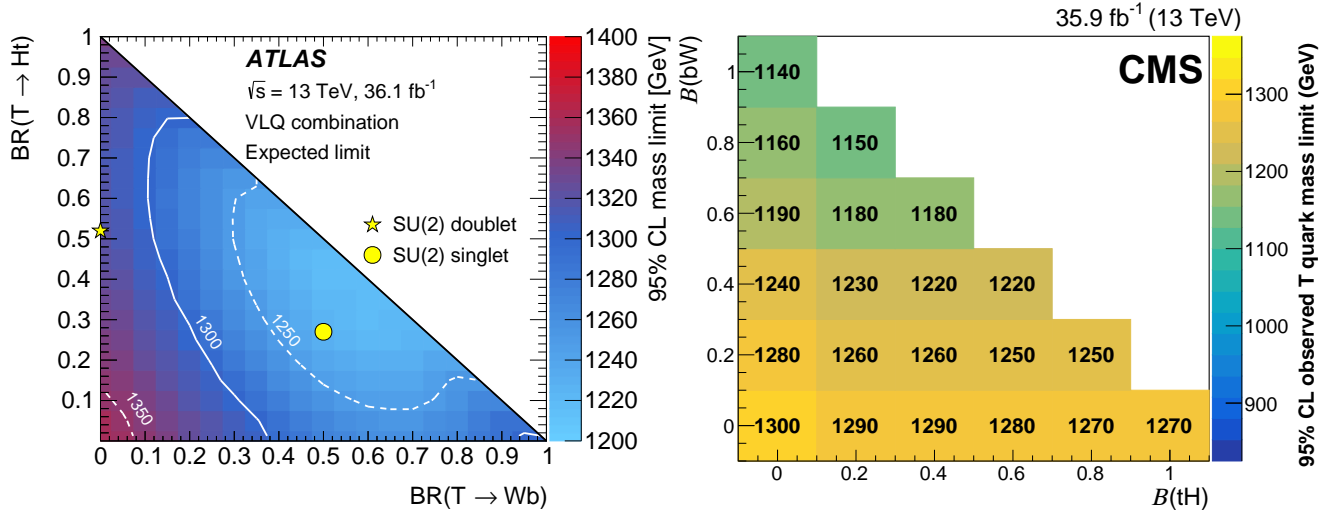

Figure 93.3: Left panel: observed limits on the mass of the T quark in the plane of $\mathcal{B}(T \rightarrow tH^0)$ versus $\mathcal{B}(T \rightarrow bW)$ from a combination [124] of all ATLAS searches for TT production. The markers indicate the default branching ratios for the SU(2) singlet and doublet scenarios. Right panel: the observed lower limits on the T quark mass (in GeV), from CMS searches after combining all lepton channels [125], for various branching fraction scenarios. $\mathcal{B}(T \rightarrow Wb) + \mathcal{B}(T \rightarrow tZ) + \mathcal{B}(T \rightarrow tH^0) = 1$ is assumed.

geted for specific decay modes to obtain the most sensitive limits on the pair production of B quarks [107, 108, 124]. Various searches ($W(\ell\nu)t + X$, $Z(\ell\ell)t/b + X$, same sign charge dilepton events, trilepton events, and all-hadronic) are combined to obtain lower limits on the mass of the B quark in the plane of $BR(B \rightarrow Wt)$ vs $BR(B \rightarrow bH)$. The searches were optimized for 100% branching fractions and hence are most sensitive at large $BR(B \rightarrow Wt)$, and also at large $BR(B \rightarrow bH^0)$. For all possible values of branching ratios in the three decay modes tW , bZ , or bH^0 , the lower limits on the B quark mass was found to be 1.03 TeV and shown in Fig. 93.4 (left) as a function of both B mass and branching ratio.

CMS combined three channels with lepton final states: single lepton, two leptons with the same sign of the electric charge (SS), or at least three leptons (trilepton) [125]. For various combinations of branching fractions for B quark decays to tW , bH^0 and bZ , the combined results exclude b quarks with masses below 0.91–1.24 TeV and are shown in Figure 93.4 (right) the details are provided earlier in subsection 93.2.3.1. The single lepton analysis is most sensitive for $tHbW$ and $WbWb$ decay modes, within the the SS dilepton analysis $tHtH$ and $tHtZ$ have the best efficiency and for trileptons the $tZtZ$ and $tHtZ$ decays modes have the highest efficiency. CMS excludes singlet (doublet) B quark masses below 1.17 (0.94) TeV. Masses below 800 GeV were excluded in previous searches. For B quark masses in the range 0.8–1.8 TeV, cross sections smaller than 40.6–9.4 fb (101–49.0 fb) are excluded for the singlet (doublet) scenario.

93.2.3.3 Searches for top-partner quark $X_{5/3}$

Searches for a heavy top vector-like quark $X_{5/3}$, with exotic charge $\pm 5/3$, such as that proposed in Refs. [131, 132], have been performed by both ATLAS and CMS [107, 133].

The analyses assumed pair-production or single-production of $X_{5/3}$ with $X_{5/3}$ decaying with 100% branching fraction to tW . Searches for $X_{5/3}$ have been performed using two final state signatures: same-sign leptons and lepton+jets.

The analysis based on searching for same-sign leptons, from the two W bosons from one of the $X_{5/3}$, has smaller backgrounds compared to the lepton+jets signature. Requiring same-sign leptons eliminates most of the standard model background processes, leaving those with smaller cross sections: $t\bar{t}$, W , $t\bar{t}Z$, WWW , and same-sign WW . In addition, backgrounds from instrumental effects due to charge misidentification were considered. Assuming pair production of $X_{5/3}$, the analyses by CMS using H_T as the discriminating variable restrict the $X_{5/3}$ mass to be higher than 1.16 (1.10) TeV for a right (left) handed chirality particle [133–135]. The limits obtained by ATLAS, by classifying the signal region by

number of b jets, H_T , and missing p_T in the event, corresponded to a lower mass limit on $X_{5/3}$ of 1.19 TeV [136, 137].

Searches for $X_{5/3}$ using leptons+jets final state signatures are based on either full or partial reconstruction of the T mass from the lepton, jets (including b jets) and missing p_T . The CMS search [133, 138] also utilized jet substructure techniques to identify boosted $X_{5/3}$ topologies. The discriminating variable used was the mass constructed from the lepton and b -tagged jet, $M_{(\ell,b)}$, which corresponds to the visible mass of leptonically decaying top quark. To optimize the search sensitivity, the events were further separated into categories based on lepton flavor (e , μ), the number of b -tagged jets, the number of W -tagged jets, and the number of t -tagged jets. In the absence of a signal, the CMS analysis excluded $X_{5/3}$ quark masses with right-handed (left-handed) couplings below 1.32 (1.30) TeV [138]. Combining the lepton+jets with the same-sign leptons analyses leads to a slight improvement and excludes $X_{5/3}$ quark masses with right-handed (left-handed) couplings below 1.33 (1.30) TeV.

The ATLAS lepton+jets search for $X_{5/3}$ utilized events with high p_T W bosons and b jets. The search described earlier for T pair production, with $T \rightarrow Wb$ decays, can be reinterpreted as a search for $X \rightarrow tW$. This analysis excluded $X_{5/3}$ with masses below 1.25 TeV [107].

The single $X_{5/3}$ production cross section depends on the coupling constant λ of the tWX vertex. ATLAS has performed an analysis of same-sign dileptons which includes both the single and pair production. This analysis led to a lower limit on the mass of the $X_{5/3}$ of 0.75 TeV for both values of $\lambda = 0.5$ and 1.0 [139].

Single heavy $X_{5/3} + t$ production has been studied by CMS in the decay to tW with lepton+jets final state [127]. The description of the analysis is provided earlier in the discussion of $B \rightarrow WtX$ decays, where the reconstructed mass of $X_{5/3}$, m_{reco} distribution is used as the signal discriminator. In the absence of an excess over the expected SM background, the exclusion limits on the production cross section is for $X_{5/3}$ quark masses between 0.7–2 TeV varies between 0.3 to 0.03 pb, depending on the width of $X_{5/3}$ between 1–10%. In addition, $X_{5/3}$ quarks with left-handed couplings and a relative width of 10, 20, and 30% are excluded for masses below 0.92, 1.3, and 1.45 TeV respectively.

93.2.4 Heavy resonances decaying to VLQ

CMS has performed search for VLQ production in the decay of massive resonances such as Z' and W' bosons.

$Z' \rightarrow tT$: Specifically searches are presented by CMS in Refs. [140] and [141] for massive spin-1 Z' resonances decaying to a top quark and heavy VLQ top quark partner T . The results of this search for a heavy spin-1 resonance are interpreted in the

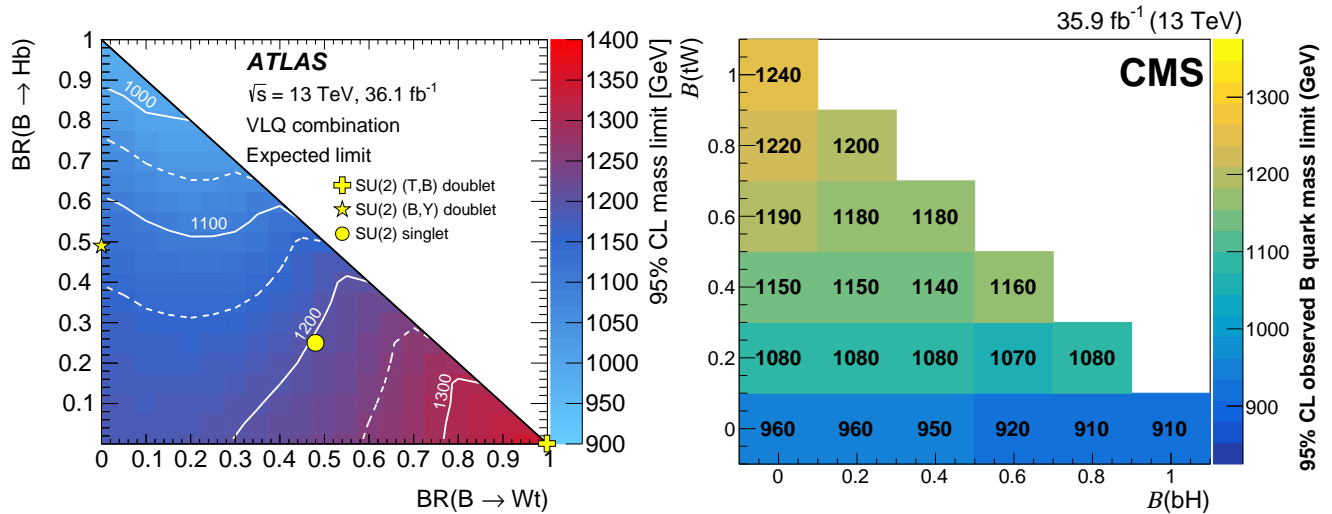

Figure 93.4: Observed limits on the mass of the B quark in the plane of $BR(B \rightarrow bH^0)$ versus $BR(B \rightarrow tW)$ from ATLAS searches [124] on the left panel, and CMS searches [125] on the right panel, for BB production. $B(B \rightarrow \mathcal{H}) + B(B \rightarrow \mathcal{Z}) + B(B \rightarrow \mathcal{W}) = 1$ is assumed. The yellow markers indicate the branching ratios for the SU(2) singlet and doublet scenarios.

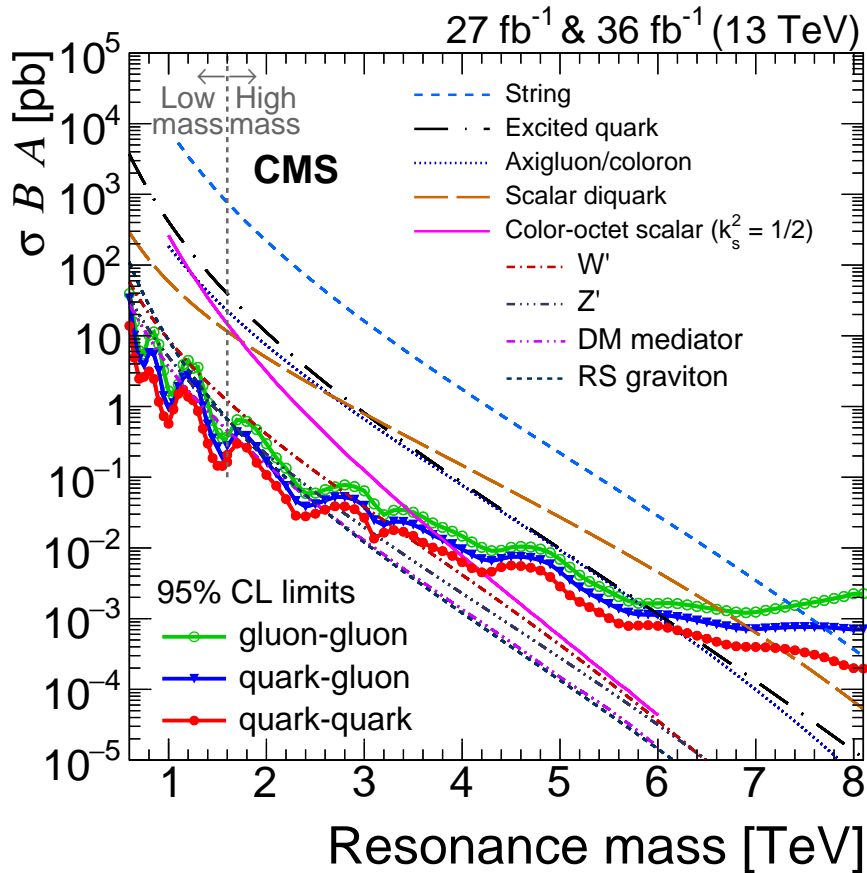

Figure 93.5: Observed 95% C.L. limits on $\sigma \times B \times A$ for string resonances, excited quarks, axigluons, colorons, E6 diquarks, s8 resonances, W' and Z' bosons, and Randall-Sundrum Gravitons g_{KK} from [130].

context of two different models. In the G^* model which predicts ten VLQs ($T, B, \tilde{T}, \tilde{B}, T_{5/3}, T_{2/3}, T', B', B_{-1/3}, B_{-4/3}$) with the mass relationship $M(T_{5/3}) = M(T_{2/3}) = M(T)\cos(\phi_L)$. For the benchmark scenario [142], $\cos(\phi_L)=0.84$ and the branching fractions $T \rightarrow tH^0, tZ, Wb$ are 0.25, 0.25 and 0.5 respectively. The ρ^0 model predicts a multiple of four new VLQs $T, B, X_{2/3}, X_{5/3}$, and in the benchmark scenario [143], the branching fractions $T \rightarrow tH^0, tZ, Wb$ are 0.5, 0.5 and 0 respectively.

Two of the three different decays of the $Z' \rightarrow tT$ with $T \rightarrow$

tH^0, tZ, Wb are characterized by the presence of two top quark decays and a boson (H^0/Z). A search [141] by CMS, optimized for $T \rightarrow tH/Zt$ decays is carried out in the lepton+jets final state using a dataset corresponding to an integrated luminosity of 35.9 fb^{-1} . Jet substructure techniques are used to identify (or tag) the high p_T large-radius jets originating from H^0, Z bosons and merged top quarks. The mass of the Z' boson is used as the signal discriminator and constructed using H^0 or Z -tagged dijet, the hadronic and leptonic top quark four vectors. For the

leptonic top quark reconstruction ($t \rightarrow b\ell\nu_\ell$), the neutrino four vector is obtained from the event missing p_T using the W boson mass constraint. While the high p_T hadronic top quark jets from decays of massive Z' bosons are mostly merged and identified by top tagging techniques, those from T decays maybe resolved. The reconstructed Z' candidate events are classified into six different categories requiring the presence of either H^0 -tagged jet with 2 b-tagged subjets or one b-tagged subjet or a Z -tagged boson, each with either zero or one top-tagged jet. This search does not observe any significant deviation in data over the expectation from standard model backgrounds. Within the context of the G^* model, for a T mass of 1.2 (1.5), this search excludes G^* [142] resonances with masses between 1.5–2.3 (2.0–2.4) TeV.

The search in the all-hadronic final state is based on a 2.6 fb^{-1} dataset [140], and optimized for $T \rightarrow Wb$ decays. Jet substructure techniques are deployed for tagging jets from high p_T W boson and top quarks. Events are categorized into two groups based on the presence of b-tagged subjet in the top-tagged jet. Multijet background estimation is challenging and determined using sidebands defined by inverting the b tagging requirement. Upper limits on cross section for $Z' \rightarrow tT$ are obtained in the range of 0.13–10 pb. With additional data, this search has the potential to exclude scenarios in composite Higgs and extra dimension models.

$W' \rightarrow Tb/Bt$: W' bosons are predicted to decay to VLQ third generation partners T , B quarks within composite Higgs and warped extra dimensional models [144]. In the benchmark scenarios of this framework, W' decays to Tb or Bt are equally distributed and the subsequent VLQ decays $T \rightarrow tH$ and $B \rightarrow bH^0$ each are assumed to have a branching fraction of 0.5. The search for $W' \rightarrow Tb/bH^0 \rightarrow tbH^0$ is performed using a sample of 35.9 fb^{-1} by CMS [145] in the final state with all-hadronic decays of both the Higgs boson ($H^0 \rightarrow b\bar{b}$) and the top quark. Both the H^0 boson and the top quark are expected to be boosted in the decay of a heavy W' , and hence jet substructure techniques, including subjet b-tagging and double b-tagging are deployed to identify the H^0 -tagged and the top-tagged jets. The three particle mass m_{tbH^0} , is used as the signal discriminant to observe the W' resonance. There is no excess observed in data above the expected SM background. This search excludes W' production cross section above 0.01–0.43 pb for masses between 1.5–4.0 TeV.

93.2.5 Colorons and Colored Scalars

These particles are associated with top-condensate and top-seesaw models, which involve an enlarged color gauge group. The new particles decay to dijets, $t\bar{t}$, and $b\bar{b}$.

Direct searches for colorons, color-octet scalars and other heavy objects decaying to $q\bar{q}$, qg , qg , or gg has been performed using LHC data from pp collisions at $\sqrt{s} = 7, 8$ and 13 TeV. Based on the analysis of dijet events from a data sample corresponding to a luminosity of 19.6 fb^{-1} , at $\sqrt{s} = 8$ TeV the CMS experiment excluded pair production of colorons with mass between 1.20–3.60 and 3.90–4.08 TeV [146]. Analyses of inclusive 8- and 10-jet final states with low missing transverse momentum by CMS [147], set limits in several benchmark models. Colorons (axigluons) with masses between 0.6 and 0.75 (up to 1.15) TeV were excluded, and gluinos in R-parity violating supersymmetric scenarios were ruled out from 0.6 up to 1.1 TeV.

A search for pair-produced colorons based on an integrated luminosity of 5.0 fb^{-1} at $\sqrt{s} = 7$ TeV by CMS excluded colorons with masses between 0.25 TeV and 0.74 TeV, assuming colorons decay 100% into $q\bar{q}$ [148]. This analysis was based on events with at least four jets and two dijet combinations with similar dijet mass. Color-octet scalars (s8) with masses between 1.20–2.79 TeV were excluded by CMS [146], and below 2.7 TeV by ATLAS [149].

These studies have now been extended to take advantage of the increased center-of-mass energy during Run 2 of the LHC. Using the 35.9 fb^{-1} of data collected at $\sqrt{s} = 13$ TeV, searches for narrow resonances have been performed by CMS. An analysis of the dijet invariant mass spectrum formed using wide jets [130, 150, 151], separated by $\Delta\eta_{jj} \leq 1.3$, led to limits on new particles decaying to parton pairs ($q\bar{q}$, qg , gg). Specific exclusions on the masses of colorons and color-octet scalars were obtained and are shown in Fig. 93.5. Exclusions have been obtained for axigluons and

colorons below 6.1 TeV, and color-octet scalars below 3.4 TeV.

93.3 Conclusions

As the above analyses have demonstrated, there is already substantial sensitivity to possible new particles predicted to accompany the H^0 in dynamical frameworks of electroweak symmetry breaking. No significant hints of any deviations from the standard model have been observed, and limits typically at the scale of a few hundred GeV to a few TeV are set.

Given the need to better understand the H^0 and to determine in detail how it behaves, such analyses continue to be a major theme of Run 2 the LHC, and we look forward to increased sensitivity as a result of the higher luminosity at the increased center of mass energy of collisions.

94. Grand Unified Theories

Revised August 2019 by A. Hebecker (Heidelberg U.) and J. Hisano (KMI, Nagoya U.).

94.1 The standard model

The Standard Model (SM) may be defined as the renormalizable field theory with gauge group $G_{SM} = SU(3)_C \times SU(2)_L \times U(1)_Y$, with 3 generations of fermions in the representation

$$(3, 2)_{1/3} + (\bar{3}, 1)_{-4/3} + (\bar{3}, 1)_{2/3} + (1, 2)_{-1} + (1, 1)_2, \quad (94.1)$$

and a scalar Higgs doublet H transforming as $(1, 2)_1$. Here and below we use boldface numbers to specify the dimension of representations of non-Abelian groups (in this case fundamental and antifundamental) and lower indices for $U(1)$ charges. The fields of Eq. (94.1) should also be familiar as $[Q, u^c, d^c, L, e^c]$, with $Q = (u, d)$ and $L = (\nu, e)$ being the quark and lepton $SU(2)$ -doublets and u^c, d^c, e^c charge conjugate $SU(2)$ -singlets.¹ Especially after the discovery of the Higgs, this model is remarkably complete and consistent with almost all experimental data.

A notable exception are neutrino masses, which are known to be non-zero but are absent in the SM even after the Higgs acquires its vacuum expectation value (VEV). The minimalist attitude is to allow for the dimension-five operator $(HL)^2$ [1], which induces (Majorana) neutrino masses. In the seesaw mechanism [2–4] this operator is generated by integrating out heavy singlet fermions (right-handed (r.h.) neutrinos). Alternatively, neutrinos can have Dirac masses if light singlet neutrinos are added to the SM spectrum.

Conceptual problems of the SM include the absence of a Dark Matter candidate, of a mechanism for generating the baryon asymmetry of the universe, and of any reason for the observed smallness of the θ parameter of QCD (θ_{QCD}). In addition, the apparently rather complex group-theoretic data of Eq. (94.1) remains unexplained. Together with the abundance of seemingly arbitrary coupling constants, this disfavors the SM as a candidate fundamental theory, even before quantum gravity problems arise at energies near the Planck mass M_P .

To be precise, there are 19 SM parameters which have to be fitted to data: Three gauge couplings² g_3, g_2 and g_1 , 13 parameters associated with the Yukawa couplings (9 charged fermion masses, three mixing angles and one CP phase in the CKM matrix.), the Higgs mass and quartic coupling, and θ_{QCD} . In addition, Majorana neutrinos introduce 3 more masses and 6 mixing angles and phases. As we will see, the paradigm of grand unification addresses mainly the group theoretic data of Eq. (94.1) and the values of the three gauge couplings. In many concrete realizations, it then impacts also the other mentioned issues of the SM, such as the family structure and fermion mass hierarchy.

More specifically, after precision measurements of the Weinberg angle θ_W in the LEP experiments, supersymmetric GUTs (SUSY GUTs) have become the leading candidates in the search for ‘Physics beyond the SM’. Supersymmetry (SUSY) is a symmetry between bosons and fermions which requires the addition of superpartners to the SM spectrum. If SUSY is motivated as a solution to the gauge hierarchy problem (i.e. to the naturalness or fine-tuning problem of the electroweak scale) [5], superpartners have to be present near the weak scale. SUSY GUTs [6] then lead to the prediction of θ_W , in good agreement with subsequent observations [7]. However, the non-discovery of new particles at the LHC puts into question the presence of new physics at the TeV scale in general and in particular of low-scale supersymmetry. Still, SUSY may be present just outside the presently explored energy domain.

The measured Higgs mass (125 GeV) is in principle consistent with this picture, assuming superpartners in the region of roughly 10 TeV. Such heavy superpartners then induce radiative corrections raising the Higgs mass above the Z boson mass m_Z [8, 9]. However, from the vantage point of the hierarchy problem, heavy

superpartners are problematic: They also contribute to SUSY-breaking Higgs mass parameters and thereby to the Higgs potential, tending to raise the Z mass. As a result, the incarnation of SUSY in terms of the minimal supersymmetric SM (MSSM) is becoming questionable. Turning the logic around, one may say that compared to expectations based on the MSSM with superpartner masses below about 1 TeV, the measured Higgs mass value of 125 GeV is somewhat too high [10]. Independently, the LHC has disfavored light colored superpartners (which does not imply that *all* superpartners are heavy). These facts represent new hints for future work on SUSY GUTs or on GUTs without TeV-scale supersymmetry.

94.2 Basic group theory and charge quantization

94.2.1 $SU(4)_C \times SU(2)_L \times SU(2)_R$

Historically, the first attempt at unification was the Pati-Salam model with gauge group $G_{PS} = SU(4)_C \times SU(2)_L \times SU(2)_R$ [11]. It unifies SM fermions in the sense that one generation (plus an extra SM singlet) now comes from the $(4, 2, 1) + (\bar{4}, 1, 2)$ of G_{PS} . This is easy to verify from the breaking pattern $SU(4)_C \rightarrow SU(3)_C \times U(1)_{B-L}$ together with the identification of SM hypercharge as a linear combination between $B-L$ (baryon minus lepton number) and the T_3 generator of $SU(2)_R$. This model explains charge quantization, that is, why all electric charges are integer multiples of some smallest charge in the SM. Concretely, the 4 and $\bar{4}$ of $SU(4)_C$ identify lepton number as the 4th colour and the tracelessness of the diagonal generator implies that quark charges are expressed in terms of $1/N_c$ fractions of lepton charges. However, G_{PS} is not simple (containing three simple factors), and thus it does not predict gauge coupling unification.

94.2.2 $SU(5)$

Since G_{SM} has rank four (two for $SU(3)_C$ and one for $SU(2)_L$ and $U(1)_Y$, respectively), the rank-four group $SU(5)$ is the minimal choice for unification in a simple group [12]. The three SM gauge coupling constants derive from a universal coupling α_G at the GUT scale M_G . Explicitly embedding G_{SM} in $SU(5)$ is straightforward, with $SU(3)_C$ and $SU(2)_L$ corresponding e.g. to the upper-left 3×3 and lower-right 2×2 blocks, respectively, in traceless 5×5 matrices for $SU(5)$ generators of the fundamental representation. The $U(1)_Y$ corresponds to matrices generated by $\text{diag}(-2/3, -2/3, -2/3, 1, 1)$ and hence commutes with $SU(3)_C \times SU(2)_L \subset SU(5)$. It is then easy to derive how one SM generation precisely comes from the $10 + \bar{5}$ of $SU(5)$ (where 10 is the antisymmetric rank-2 tensor):

$$10 : \begin{pmatrix} 0 & u_b^c & -u_g^c & u_r & d_r \\ -u_b^c & 0 & u_r^c & u_g & d_g \\ u_g^c & -u_r^c & 0 & u_b & d_b \\ -u_r & -u_g & -u_b & 0 & e^c \\ -d_r & -d_g & -d_b & -e^c & 0 \end{pmatrix} \quad \text{and} \quad \bar{5} : \begin{pmatrix} d_r^c \\ d_g^c \\ d_b^c \\ e \\ -\nu_e \end{pmatrix}. \quad (94.2)$$

In addition to charge quantisation this structure explains why the l.h. quark and lepton states fall in $SU(2)_L$ doublets while the r.h. states are singlets.

Since $SU(5)$ has 24 generators, $SU(5)$ GUTs have 12 new gauge bosons known as X bosons (or X/Y bosons) in addition to the SM. X bosons form an $SU(3)_C$ -triplet and $SU(2)_L$ -doublet. Their interaction connects quarks and leptons such that baryon and lepton numbers are not conserved and nucleon decay is predicted. Furthermore, $U(1)_Y$ hypercharge is automatically quantized since it is embedded in $SU(5)$.

In order to break the electroweak symmetry at the weak scale and give mass to quarks and leptons, Higgs doublets are needed. In the minimal $SU(5)$ model, they can sit in either a 5_H or $\bar{5}_H$. The three additional states are referred to as color-triplet Higgs scalars. Their couplings also violate baryon and lepton numbers, inducing nucleon decay. In order not to violently disagree with the non-observation of nucleon decay, the triplet mass must be greater than $\sim 10^{11}$ GeV [13]. Moreover, in SUSY GUTs [6], in order to cancel anomalies as well as give mass to both up and down quarks, both Higgs multiplets 5_H and $\bar{5}_H$ are required. As we shall discuss later, nucleon decay now constrains the Higgs triplets to have

¹ In our convention the electric charge is $Q = T_3 + Y/2$ and all our spinor fields are left-handed (l.h.).

² Equivalently, the $SU(2)_L$ and $U(1)_Y$ couplings are denoted as $g = g_2$ and $g' = \sqrt{3/5} g_1$. One also uses $\alpha_s = \alpha_3 = (g_3^2/4\pi)$, $\alpha_{EM} = (e^2/4\pi)$ with $e = g \sin \theta_W$ and $\sin^2 \theta_W = (g')^2/(g^2 + (g')^2)$.

mass significantly greater than M_G in the minimal SUSY $SU(5)$ GUT since integrating out the Higgs triplets generates dimension-five baryon-number-violating operators [14]. The mass splitting between doublet and triplet in the $\mathbf{5}_H$ (and $\bar{\mathbf{5}}_H$) comes from their interaction with the $SU(5)$ breaking sector.

94.2.3 $SO(10)$

While $SU(5)$ allows for the minimal GUT models, unification is not complete: Two independent representations, $\mathbf{10}$ and $\bar{\mathbf{5}}$, are required for one SM generation. A further representation, an $SU(5)$ singlet, has to be added to serve as r.h. neutrino in the seesaw mechanism. In this case, the r.h. neutrino masses are not necessarily related to the GUT scale. By contrast, a single $\mathbf{16}$ -dimensional spinor representation of $SO(10)$ accommodates a full SM generation together with an extra singlet, potentially providing a r.h. neutrino [15]. This is most easily understood from the breaking pattern $SO(10) \rightarrow SU(5) \times U(1)_X$ and the associated branching rule³ $\mathbf{16} = \mathbf{10}_{-1} + \bar{\mathbf{5}}_3 + \mathbf{1}_{-4}$. Here the indices refer to charges under the $U(1)_X$ subgroup, which is orthogonal to $SU(5)$ and reflects the fact that $SO(10)$ has rank five. From the above, it is easy to see that $U(1)_X$ charges can be given as $2Y - 5(B - L)$. Intriguingly, all representations of $SO(10)$ are anomaly free in four dimensions (4d). Thus, the absence of anomalies in an $SU(5)$ -GUT or a SM generation can be viewed as deriving from this feature.

We now describe in more detail how one family of quarks and leptons appears in the $\mathbf{16}$. To understand this, recall that the Γ -matrices of the 10d Clifford algebra give rise to five independent, anticommuting ‘creation-annihilation’ operators $\Gamma^{a\pm} = (\Gamma^{2a-1} \pm i\Gamma^{2a})/2$ with $a = 1, \dots, 5$. These correspond to five fermionic harmonic oscillators or ‘spin’ 1/2 systems. The 32-dimensional tensor product of those is reducible since the 10d rotation generators $M_{mn} = -i[\Gamma^m, \Gamma^n]/4$ ($m, n = 1, \dots, 10$) always flip an even number of ‘spins’. This gives rise to the $\mathbf{16}$ as displayed in Table 94.1. Next, one also recalls that the natural embedding of $SU(5)$ in $SO(10)$ relies on ‘pairing up’ the 10 real dimensions to produce 5 complex dimensions, $\mathbb{R}^{10} \equiv \mathbb{C}^5$, similarly to the pairing up of Γ^m s used above. This makes it clear how to associate one $|\pm\rangle$ system to each complex dimension of $SU(5)$, which explains the labeling of the ‘spin’ columns in Table 94.1: The first three and last two ‘spins’ correspond to $SU(3)_C$ and $SU(2)_L$, respectively. In fact, an $SU(3)_C$ rotation just raises one color index and lowers another, changing colors $\{r, g, b\}$, or changes relative phases between the three spin states. Similarly, an $SU(2)_L$ rotation raises one weak index and lowers another, thereby flipping the weak isospin from up to down or vice versa, or changes the relative phase between the two spin states. In this representation $U(1)_Y$ hypercharge is simply given by $Y = -2/3(\sum \text{color spins}) + (\sum \text{weak spins})$. $SU(5)$ rotations corresponding to X bosons then raise (or lower) a color index, while at the same time lowering (or raising) a weak index. It is easy to see that such rotations can mix the states $\{Q, u^c, e^c\}$ and $\{d^c, L\}$ among themselves and ν^c is a singlet. Since $SO(10)$ has 45 generators, additional 21 gauge bosons are introduced including the $U(1)_X$ above. The 20 new $SO(10)$ rotations not in $SU(5)$ are then given by either raising any two spins or lowering them. With these rotations, $\mathbf{1}$ and $\bar{\mathbf{5}}$ are connected with $\mathbf{10}$. The last $SO(10)$ rotation changes phases of states with weight $2(\sum \text{color spins}) + 2(\sum \text{weak spins})$, which corresponds to $U(1)_X$.

$SO(10)$ has two inequivalent maximal subgroups and hence breaking patterns, $SO(10) \rightarrow SU(5) \times U(1)_X$ and $SO(10) \rightarrow SU(4)_C \times SU(2)_L \times SU(2)_R$. In the first case, one can carry on breaking to $G_{SM} \subset SU(5)$ precisely as in the minimal $SU(5)$ case above. Alternatively, one can identify $U(1)_Y$ as an appropriate linear combination of $U(1)_X$ and the $U(1)$ factor from $SU(5)$, leading to the so-called flipped $SU(5)$ [17] as an intermediate step in breaking $SO(10)$ to G_{SM} . In the second case, we have an intermediate Pati-Salam model thanks to the branching rule $\mathbf{16} = (\mathbf{4}, \mathbf{2}, \mathbf{1}) + (\bar{\mathbf{4}}, \mathbf{1}, \mathbf{2})$. Finally, $SO(10)$ can break directly to the SM at M_G . Gauge coupling unification remains intact in

Table 94.1: Quantum numbers of $\mathbf{16}$ -dimensional representation of $SO(10)$.

state	Y	Color	Weak	$SU(5)$	$SO(10)$
ν^c	0	---	--	1	16
e^c	2	---	++	10	
u_r	1/3	+--	-+		
d_r	1/3	+--	+-		
u_g	1/3	-+-	-+		
d_g	1/3	-+-	+-		
u_b	1/3	--+	-+		
d_b	1/3	--+	+-		
u_r^c	-4/3	-++	--		
u_g^c	-4/3	-++	--		
u_b^c	-4/3	-++	--		
d_r^c	2/3	-++	++		
d_g^c	2/3	-++	++		
d_b^c	2/3	-++	++		
ν	-1	+++	-+		
e	-1	+++	+-		

the case of this ‘direct’ breaking and for the breaking pattern $SO(10) \rightarrow SU(5) \rightarrow G_{SM}$ (with $SU(5)$ broken at M_G). In the case of intermediate-scale Pati-Salam or flipped $SU(5)$ models, gauge coupling predictions are modified. The Higgs multiplets in the minimal $SO(10)$ come from the fundamental representation, $\mathbf{10}_H = \mathbf{5}_H + \bar{\mathbf{5}}_H$. Note, only in $SO(10)$ does the representation type distinguish SM matter from Higgs fields.

94.2.4 Beyond $SO(10)$

Finally, larger symmetry groups can be considered. For example, the exceptional group E_6 has maximal subgroup $SO(10) \times U(1)$ [18]. Its fundamental representation branches as $\mathbf{27} = \mathbf{16}_1 + \mathbf{10}_{-2} + \mathbf{1}_4$. Another maximal subgroup is $SU(3)_C \times SU(3)_L \times SU(3)_R \subset E_6$ with branching rule $\mathbf{27} = (\mathbf{3}, \mathbf{3}, \mathbf{1}) + (\bar{\mathbf{3}}, \mathbf{1}, \bar{\mathbf{3}}) + (\mathbf{1}, \bar{\mathbf{3}}, \mathbf{3})$. Independently of any underlying E_6 , the group $[SU(3)]^3$ with additional permutation symmetry Z_3 interchanging the three factors can be considered. This is known as ‘trinification’ [19]. The $E_6 \rightarrow [SU(3)]^3$ breaking pattern has been used in phenomenological analyses of the heterotic string [20]. However, in larger symmetry groups, such as E_6 , $SU(6)$, etc., there are now many more states which have not been observed and must be removed from the effective low-energy theory.

Intriguingly, the logic by which G_{SM} is a maximal subgroup of $SU(5)$, which together with $U(1)_X$ is a maximal subgroup of $SO(10)$, continues in a very elegant and systematic way up to the largest exceptional group. The resulting famous breaking chain $E_8 \rightarrow E_7 \rightarrow E_6 \rightarrow SO(10) \rightarrow SU(5) \rightarrow G_{SM}$ together with the special role played by E_8 in group and in string theory is a tantalizing hint at deeper structures. However, since all representations of E_8 and E_7 are real and can not lead to 4d chiral fermions, this is necessarily outside the 4d GUT framework.

94.3 GUT breaking and doublet-triplet splitting

In the standard, 4d field-theoretic approach to GUTs, the unified gauge group is broken spontaneously by an appropriate GUT Higgs sector. Scalar potentials (or superpotentials in SUSY GUTs) exist whose vacua spontaneously break $SU(5)$ or $SO(10)$. While these potentials are ad hoc (just like the Higgs potential in the SM), the most naive expectation is that all their dimensional parameters are $O(M_G)$. In the simplest case of $SU(5)$, the $\mathbf{24}$ (adjoint) GUT Higgs develops a VEV along the G_{SM} -singlet direction as $\langle \Phi \rangle \propto \text{diag}(-2/3, -2/3, -2/3, 1, 1)$. In order for $SO(10)$ to break to $SU(5)$, the $\mathbf{16}$ or $\mathbf{126}$, which have a G_{SM} -singlet with non-zero $U(1)_X$ charge, get a VEV.

The masses of doublet and triplet in the $\mathbf{5}_H$ (and $\bar{\mathbf{5}}_H$) generically split due to their coupling to the GUT Higgs. In addition, both the doublet and the triplet masses also get an equal contribution from an $SU(5)$ -invariant GUT-scale mass term. Without any further structure, an extreme fine-tuning between two large effects is then necessary to keep the doublet mass at the electroweak scale. Supersymmetry plays an important role in for-

³ Useful references on group theory in the present context include [16] and refs. therein.

bidding large radiative correction to the doublet mass due to the non-renormalization theorem [5]. However, even in this case we have to fine tune parameters at tree level. This is the doublet-triplet splitting problem which, in the SUSY context, is clearly related the μ -term problem of the MSSM (the smallness of the coefficient of $\mu H_u H_d$).

Several mechanisms for natural doublet-triplet splitting have been suggested under the assumption of supersymmetry, such as the sliding singlet [21], missing partner [22], missing VEV [23], and pseudo-Nambu-Goldstone boson mechanisms [24]. Particular examples of the missing partner mechanism for $SU(5)$ [25], the missing VEV mechanism for $SO(10)$ [26, 27] and the pseudo-Nambu-Goldstone boson mechanism for $SU(6)$ [28] have been shown to be consistent with gauge coupling unification and nucleon decay. From the GUT-scale perspective, one is satisfied if the triplets are naturally heavy and the doublets are massless ($\mu \simeq 0$). There are also several mechanisms for resolving the subsequent issue of why μ is of order the SUSY breaking scale [29].⁴ For a review of the μ problem and some suggested solutions in SUSY GUTs and string theory, see [30–33] and references therein.

In general, GUT-breaking sectors successfully resolving the doublet-triplet splitting problem, dynamically stabilizing all GUT-scale VEVs and allowing for realistic neutrino masses and Yukawa couplings (including the GUT-symmetry violation in the latter) require a number of ingredients. However, for validity of the effective theory, introduction of higher or many representations is limited, otherwise a Landau pole may appear below the Planck scale. In addition, GUTs are only effective theories below the Planck scale in the 4d field-theoretic approach. Since M_G is close to this scale, the effects of higher-dimension operators are not obviously negligible. In particular, operators including the GUT-breaking Higgs may affect low-energy predictions, such as quark and lepton masses.

Thus, especially in the context of GUT breaking and doublet-triplet splitting, models beyond 4d field theory appear attractive. While this is mainly the subject of the next section, some advantages can already be noted: In models with extra dimensions, in particular string constructions, GUT breaking may occur due to boundary conditions in the compactified dimensions [34–37]. No complicated GUT breaking sector is then required. Moreover, boundary conditions can give mass only to the triplet, leaving the doublet massless. This is similar to the ‘missing partner mechanism’ since the effective mass term does not ‘pair up’ the triplets from $\mathbf{5}_H$ and $\bar{\mathbf{5}}_H$ but rather each of them with further fields which are automatically present in the higher-dimensional theory. This can eliminate dimension-five nucleon decay (cf. Sec. 94.6).

94.4 String-theoretic and higher-dimensional unified models

As noted earlier, the GUT scale is dangerously close to the scale of quantum gravity. It may hence be necessary to discuss unified models of particle physics in the latter, more ambitious context. Among the models of quantum gravity, superstring or M-theory stands out as the best-studied and technically most developed proposal, possessing in particular a high level of internal, mathematical consistency. For our purposes, it is sufficient to know that five 10d and one 11d low-energy effective supergravity theories arise in this setting (cf. [38] and refs. therein).

Grand unification is realized most naturally in the context of the two ‘heterotic’ theories with gauge groups $E_8 \times E_8$ and $SO(32)$, respectively [36, 39] (see [40] for some of the more recent results). Justified in part by the intriguing breaking path $E_8 \rightarrow \dots \rightarrow G_{SM}$ mentioned above, the focus has historically largely been on $E_8 \times E_8$. To describe particle physics, solutions of the 10d theory with geometry $\mathbb{R}^{1,3} \times M_6$ are considered, where M_6 is a Calabi-Yau (CY) 3-fold (with 6 real dimensions) [36]. The background solution involves expectation values of higher-dimensional components of the $E_8 \times E_8$ gauge fields. This includes

both Wilson lines [34] and non-vanishing field-strength and leads, in general, to a reduced gauge symmetry and to chirality in the resulting 4d effective theory. The 4d fermions arise from 10d gauginos.

Given an appropriate embedding⁵ of G_{SM} in $E_8 \times E_8$, gauge coupling unification is automatic at leading order. Corrections arise mainly through (string)-loop effects and are similar to the familiar field-theory thresholds of 4d GUTs⁶ [41]. Thus, one may say that coupling unification is a generic prediction in spite of the complete absence⁷ of a 4d GUT at any energy scale. This absence is both an advantage and a weakness. On the up side, GUT breaking and doublet-triplet splitting [43] are more naturally realized and dimension-five nucleon decay is relatively easy to avoid. On the down side, there is no reason to expect full GUT representations in the matter sector and flavor model building is much less tied to the GUT structure than in 4d.

Let us pause to explain the beautiful idea behind the advertised solution of the doublet-triplet splitting problem: One starts with a simply connected CY X and mods out the action of a discrete group G (say \mathbb{Z}_2). In the absence of fixed points, X/G is smooth and has a non-contractible 1-cycle. Furthermore, let G also act on the gauge bundle, according to an embedding $G \rightarrow E_8$. Now the parallel transport around the 1-cycle is tied to a gauge rotation (one says a non-trivial Wilson-line is present). Moreover, this Wilson line can not be continuously turned off since, e.g. in the case of \mathbb{Z}_2 , its square is the unit element of the group. The induced ‘Wilson-line breaking’, which comes on top of the breaking by non-zero field strengths, may remove certain sub-representations (e.g. the triplet of $SU(5) \rightarrow G_{SM}$) while keeping others exactly massless. A simpler and, due to fixed points, singular version of this will appear below in the context of orbifold GUTs.

One technical problem of heterotic constructions is the dependence on the numerous size and shape parameters of M_6 (the so-called moduli), the stabilization of which is poorly understood (see [44] for recent developments). Another is the sheer mathematical complexity of the analysis, involving in particular the study of (non-Abelian) gauge-bundles on CY spaces [45] (see however [46]).

An interesting aspect of heterotic string constructions is represented by orbifold models [35]. Here the internal space is given by a six-torus, modded out by a discrete symmetry group (e.g. T^6/\mathbb{Z}_n). More recent progress is reported in [47, 48], including in particular the systematic exploration of the phenomenological advantages of so-called ‘non-prime’ (referring to n) orbifolds. The symmetry breaking to G_{SM} as well as the survival of Higgs doublets without triplet partners is ensured by the appropriate embedding of the discrete orbifold group in $E_8 \times E_8$. String theory on such spaces, which are locally flat but include singularities, is much more calculable than in the CY case. The orbifold geometries can be viewed as singular limits of CYs.

An even simpler approach to unified models, which includes many of the advantages of full-fledged string constructions, is provided by Orbifold GUTs [37]. These are (mostly) 5d or 6d SUSY field theories with unified gauge group (e.g. $SU(5)$ or $SO(10)$), broken in the process of compactifying to 4d. To give a particularly simple example, consider $SU(5)$ on $\mathbb{R}^{1,3} \times S^1/(\mathbb{Z}_2 \times \mathbb{Z}'_2)$. Here the compact space is an interval of length $\pi R/2$ and the embedding of \mathbb{Z}'_2 in the hypercharge direction of $SU(5)$ realizes the breaking to G_{SM} . Concretely, 5d X bosons are given Dirichlet BCs at one endpoint of the interval and thus have no Kaluza-Klein (KK) zero mode. Their lightest modes have mass $\sim 1/R$, making the KK-scale the effective GUT scale. As an implication, the boundary theory has no $SU(5)$ invariance. Nevertheless, since the $SU(5)$ -symmetric 5d bulk dominates 4d gauge couplings, unification remains a prediction. Many other features but also problems

⁴ The solution of [29] relies on the absence of the fundamental superpotential term $\mu H_u H_d$ (or $\mu \mathbf{5}_H \bar{\mathbf{5}}_H$). This can be ensured either by a discrete R symmetry or by a $U(1)_R$. The latter clashes with typical superpotentials for the GUT breaking sector. However, higher-dimensional or stringy GUTs, where the triplet Higgs is simply projected out, can be consistent with the $U(1)_R$ symmetry.

⁵ All embeddings of G_{SM} in one E_8 factor which are consistent with a breaking-pattern $E_8 \rightarrow SU(5) \rightarrow G_{SM}$ are suitable (cf. for example the natural breaking chain from E_8 to G_{SM} through maximal subgroups mentioned at the end of Sect. 94.3). Other embeddings can change the ratios between the three resulting G_{SM} couplings at the GUT scale by group-theoretic factors. Crucially, due to the single 10d gauge coupling, no continuous tuning is possible.

⁶ Field-theory thresholds of 4d GUTs are discussed in 94.5.

⁷ See however [42].

of 4d GUTs can be circumvented, especially doublet-triplet splitting is easily realized.

With the advent of the string-theory ‘flux landscape’ [49], which is best understood in 10d type-IIB supergravity, the focus in string model building has shifted to this framework. While type II string theories have no gauge group in 10d, brane-stacks support gauge dynamics. A particularly appealing setting (see e.g. [50]) is provided by type IIB models with D7 branes (defining 8d submanifolds). However, in the $SO(10)$ context the **16** is not available and, for $SU(5)$, the top-Yukawa coupling vanishes at leading order [51]. As a crucial insight, this can be overcome on the non-perturbative branch of type IIB, also known as F-theory [52, 53]. This setting allows for more general branes, thus avoiding constraints of the Dp -brane framework. GUT breaking can be realized using hypercharge flux (the VEV of the $U(1)_Y$ field strength), an option not available in heterotic models. The whole framework combines the advantages of the heterotic or higher-dimensional unification approach with the more recent progress in understanding moduli stabilization. It thus represents at this moment the most active and promising branch of theory-driven GUT model building (see e.g. [54] and refs. therein).

As a result of the flux-breaking, a characteristic ‘type IIB’ or ‘F-theoretic’ tree-level correction to gauge unification arises [55]. The fact that this correction can be rather significant numerically is occasionally held against the framework of F-theory GUTs. However, at a parametric level, this correction nevertheless behaves like a 4d threshold, i.e., it provides $\mathcal{O}(1)$ additive contributions to the inverse 4d gauge couplings $\alpha_i^{-1}(M_G)$.

A final important issue in string GUTs is the so-called string-scale/GUT-scale problem [56]. It arises since, in heterotic compactifications, the Planck scale and the high-scale value of the gauge coupling unambiguously fix the string-scale to about 10^{18} GeV. As the compactification radius R is raised above the string length, the GUT scale (identified with $1/R$) goes down and the string coupling goes up. Within the domain of perturbative string theory, a gap of about a factor ~ 20 remains between the lowest GUT scale achievable in this way and the phenomenological goal of 2×10^{16} GeV. The situation can be improved by venturing into the non-perturbative regime [56], by considering ‘anisotropic’ geometries with hierarchically different radii R [56, 57] or by including GUT scale threshold corrections [58, 59].

In F-theory GUTs, the situation is dramatically improved since the gauge theory lives only in four out of the six compact dimensions. This allows for models with a ‘decoupling limit’, where the GUT scale is parametrically below the Planck scale [53]. However, moduli stabilization may not be without problems in such constructions, in part due to a tension between the required large volume and the desirable low SUSY breaking scale.

94.5 Gauge coupling unification

The quantitative unification of the three SM gauge couplings at the energy scale M_G is one of the cornerstones of the GUT paradigm. It is obviously of direct phenomenological relevance. Gauge coupling unification is well understood in the framework of effective field theory (EFT) [60]. In the simplest case, the relevant EFT at energies $\mu \gg M_G$ has a unified gauge symmetry (say $SU(5)$ for definiteness) and a single running gauge coupling $\alpha_G(\mu)$. At energies $\mu \ll M_G$, states with mass $\sim M_G$ (such as X bosons, GUT Higgs, color-triplet Higgs) have to be integrated out. The EFT now has three independent couplings and SM (or SUSY SM) matter content. One-loop renormalization group equations readily allow for an extrapolation to the weak scale,

$$\alpha_i^{-1}(m_Z) = \alpha_G^{-1}(M_G) + \frac{b_i}{2\pi} \log\left(\frac{M_G}{m_Z}\right) + \delta_i, \quad (94.3)$$

($i = 1, 2, 3$). Here we defined δ_i to absorb all sub-leading effects, such as threshold corrections at or near the weak scale (e.g. from superpartners and the additional Higgs bosons in the case of the MSSM) and at the GUT scale, and also higher-order corrections. We will discuss them momentarily.

It is apparent from Eq. (94.3) that the three low-scale couplings can be very different. This is due to the large energy range $m_Z \ll \mu \ll M_G$ and the non-universal β -function coefficients

($b_i^{\text{SM}} = \{41/10, -19/6, -7\}$ or $b_i^{\text{MSSM}} = \{33/5, 1, -3\}$). Incomplete GUT multiplets, such as gauge and Higgs bosons in the SM and also their superpartners and the additional Higgs bosons in the MSSM, contribute to the differences between the β functions. Inverting the argument, one expects that extrapolating the measured couplings to the high scale, we find quantitative unification at $\mu \sim M_G$. While this fails in the SM, it works intriguingly well in the MSSM (cf. Fig. 94.1).

The three equations contained in Eq. (94.3) can be used to determine the three ‘unknowns’ $\alpha_3(m_Z)$, $\alpha_G(M_G)$ and M_G , assuming that all other parameters entering the equations are given. Focusing on the SUSY case and using the $\overline{\text{MS}}$ coupling constants $\alpha_{\text{EM}}^{-1}(m_Z)$ and $\sin^2 \theta_W(m_Z)$ from [62],

$$\alpha_{\text{EM}}^{-1}(m_Z) = 127.955 \pm 0.010, \quad (94.4)$$

$$\sin^2 \theta_W(m_Z) = 0.23122 \pm 0.00003, \quad (94.5)$$

as input, one determines $\alpha_{1,2}^{-1}(m_Z)$, which then gives

$$\alpha_G^{-1}(M_G) \simeq 24.3 \quad \text{and} \quad M_G \simeq 2 \times 10^{16} \text{ GeV}. \quad (94.6)$$

Here we have set $\delta_i = 0$ for simplicity. Crucially, one in addition obtains a prediction for the low-energy observable α_3 ,

$$\alpha_3^{-1}(m_Z) = -\frac{5}{7}\alpha_1^{-1}(m_Z) + \frac{12}{7}\alpha_2^{-1}(m_Z) + \Delta_3, \quad (94.7)$$

where

$$\Delta_3 = \frac{5}{7}\delta_1 - \frac{12}{7}\delta_2 + \delta_3. \quad (94.8)$$

Here we followed the elegant formulation in Ref. [63] of the classical analyses of [7]. Of course, it is a matter of convention which of the three low-energy gauge coupling parameters one ‘predicts’ and indeed, early works on the subject discussed the prediction of $\sin^2 \theta_W$ in terms of α_{EM} and α_3 [64, 65].

Remarkably, the leading order result (i.e. Eq. (94.7) with $\delta_i = 0$) is in excellent agreement with experiments [62]:

$$\alpha_3^{\text{LO}}(m_Z) = 0.117 \quad \text{vs.} \quad \alpha_3^{\text{EXP}}(m_Z) = 0.1181 \pm 0.0011. \quad (94.9)$$

However, this near perfection is to some extent accidental. To see this, we now discuss the various contributions to the δ_i (and hence to Δ_3).

The two-loop running correction from the gauge sector $\Delta_3^{(2)}$ and the low-scale threshold correction $\Delta_3^{(l)}$ from superpartners can be summarized as [63]

$$\Delta_3^{(2)} \simeq -0.82 \quad \text{and} \quad \Delta_3^{(l)} \simeq \frac{19}{28\pi} \log\left(\frac{m_{\text{SUSY}}}{m_Z}\right). \quad (94.10)$$

The relevant scale m_{SUSY} can be estimated as [66]

$$m_{\text{SUSY}} \rightarrow m_H^{3/19} m_{\tilde{H}}^{12/19} m_{\tilde{W}}^{4/19} \times \left(\frac{m_{\tilde{W}}}{m_{\tilde{g}}}\right)^{28/19} \left(\frac{m_{\tilde{t}}}{m_{\tilde{q}}}\right)^{3/19}, \quad (94.11)$$

where m_H stands for the masses of non-SM Higgs states and superpartner masses are given in self-evident notation. Detailed analyses including the above effects are best done using appropriate software packages, such as SOFTSUSY [61] (or alternatively SuSpect [67] or SPheno [68]). See also [61] for references to the underlying theoretical two-loop analyses.

To get a very rough feeling for these effects, let us assume that all superpartners are degenerate at $m_{\text{SUSY}} = 1$ TeV, except for heavier gluinos: $m_{\tilde{W}}/m_{\tilde{g}} \simeq 1/3$. This gives $\Delta_3^{(l)} \simeq -0.35 + 0.22 \ln(m_{\text{SUSY}}/m_Z) \simeq 0.18$. The resulting prediction of $\alpha_3(m_Z) \simeq 0.126$ significantly upsets the perfect one-loop agreement found earlier. Before discussing this issue further, it is useful to introduce yet another important type of correction, the high or GUT scale thresholds.

To discuss high scale thresholds, let us set all other corrections to zero for the moment and write down a version of Eq. (94.3)

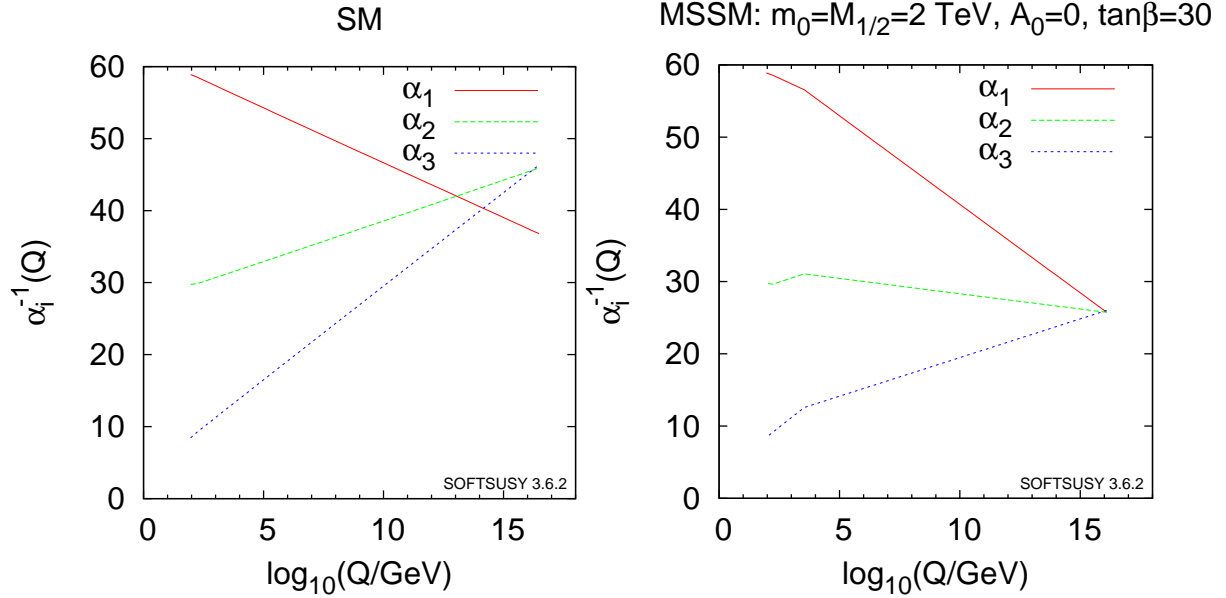

Figure 94.1: Running couplings in SM and MSSM using two-loop RG evolution. The SUSY threshold at 2 TeV is clearly visible on the MSSM side. (We thank Ben Allanach for providing the plots created using SOFTSUSY [61].)

that captures the running near and above the GUT scale more correctly. The threshold correction at one-loop level can be evaluated accurately by the simple step-function approximation for the β functions in the $\overline{\text{DR}}$ scheme⁸ [72],

$$\alpha_i^{-1}(m_Z) = \alpha_G^{-1}(\mu) + \frac{1}{2\pi} \left[b_i \ln \frac{\mu}{m_Z} + b_i^C \ln \frac{\mu}{M_C} + b_i^X \ln \frac{\mu}{M_X} + b_i^\Phi \ln \frac{\mu}{M_\Phi} \right]. \quad (94.12)$$

Here we started the running at some scale $\mu \gg M_G$, including the contribution of the minimal set of states relevant for the transition from the high-scale $SU(5)$ model to the MSSM. These are the color-triplet Higgs multiplets with mass M_C , massive vector multiplets of X -bosons with mass M_X (including GUT Higgs degrees of freedom), and the remaining GUT-Higgs fields and superpartners with mass M_Φ . The coefficients $b_i^{C,X,\Phi}$ can be found in Ref. [73]. Crucially, the b_i in Eq. (94.12) conspire to make the running GUT-universal at high scales, such that the resulting prediction for α_3 does not depend on the value of μ .

To relate this to our previous discussion, we can, for example, define $M_G \equiv M_X$ and then choose $\mu = M_G$ in Eq. (94.12). This gives the high-scale threshold corrections

$$\delta_i^{(h)} = \frac{1}{2\pi} \left[b_i^C \ln \frac{M_G}{M_C} + b_i^\Phi \ln \frac{M_G}{M_\Phi} \right], \quad (94.13)$$

and a corresponding correction $\Delta_3^{(h)}$. To get some intuition for the magnitude, one can furthermore assume $M_\Phi = M_G$, finding (with $b_i^C = \{2/5, 0, 1\}$)

$$\Delta_3^{(h)} = \frac{9}{14\pi} \ln \left(\frac{M_G}{M_C} \right). \quad (94.14)$$

To obtain the desired effect of $-\Delta_3^{(2)} - \Delta_3^{(l)} \simeq +0.64$, the triplet Higgs would have to be by about a factor 20 lighter than the GUT scale. While this is ruled out by nucleon decay in the minimal model [74] as will be discussed Sec. 94.6, it is also clear that threshold corrections of this order of magnitude can, in general, be realized with a certain amount of GUT-scale model building, e.g. in specific $SU(5)$ [25] or $SO(10)$ [26,27] constructions. Corrections

⁸The $\overline{\text{DR}}$ scheme is frequently used in a supersymmetric regularization [69]. The renormalization transformation of the gauge coupling constants from $\overline{\text{MS}}$ to $\overline{\text{DR}}$ scheme is given in Ref. [70]. For an alternative treatment using holomorphic gauge couplings and NSVZ β -functions see e.g. [71].

can also be much larger or of different sign if, as is required in many fully realistic 4d GUT models, many additional (and in particular higher) representations are introduced. Thus, there is considerable model building freedom. Nevertheless, a significant constraint from getting the right GUT threshold corrections while keeping the triplet Higgs heavy remains.

The above analysis implicitly assumes universal soft SUSY breaking masses at the GUT scale, which directly affect the spectrum of SUSY particles at the weak scale. In the simplest case we have a universal gaugino mass $M_{1/2}$, a universal mass for squarks and sleptons m_{16} and a universal Higgs mass m_{10} , as motivated by $SO(10)$. In some cases, threshold corrections to gauge coupling unification can be exchanged for threshold corrections to soft SUSY parameters (see [75] and refs. therein). For example, if gaugino masses were not unified at M_G and, in particular, gluinos were lighter than winos at the weak scale (cf. Eq. (94.11)), then it is possible that, due to weak scale threshold corrections, a much smaller or even slightly negative threshold correction at the GUT scale would be consistent with gauge coupling unification [76].

It is also noteworthy that perfect unification can be realized without significant GUT-scale corrections, simply by slightly raising the (universal) SUSY breaking scale. In this case the dark matter abundance produced by thermal processes in the early universe (if the lightest neutralino is the dark matter particle) is too high. However, even if the gaugino mass in the MSSM is about 1 TeV to explain the dark matter abundance, if the Higgsino and the non-SM Higgs boson masses are about 10-100 TeV, the effective SUSY scale can be raised [77]. This setup is realized in split SUSY [78] or the pure gravity mediation model [79] based on anomaly mediation [80]. Since the squarks and sleptons are much heavier than the gaugino masses in those setups, a gauge hierarchy problem is reintroduced. The facts that no superpartners have so far been seen at the LHC and that the observed Higgs mass favors heavier stop masses than about 1 TeV force one to accept a certain amount of fine-tuning anyway.

For non-SUSY GUTs or GUTs with a very high SUSY breaking scale to fit the data, new light states in incomplete GUT multiplets or multiple GUT breaking scales are required. For example, non-SUSY models $SO(10) \rightarrow SU(4)_C \times SU(2)_L \times SU(2)_R \rightarrow \text{SM}$, with the second breaking scale of order an intermediate scale, determined by light neutrino masses using the see-saw mechanism, can fit the low-energy data for gauge couplings [81] and at the same time survive nucleon decay bounds [82]. Alternatively, one can appeal to string-theoretic corrections discussed in Sec. 94.4 to compensate for a high SUSY breaking scale. This has, for ex-

ample, been concretely analyzed in the context of F-theory GUTs in [83]. Similarly, one may even wonder whether particularly large GUT threshold corrections could be sufficient to ensure non-SUSY precision unification. Notice here that the gauge coupling unification predicts just one parameter. When introducing new states, typically one can fit the data by choice of their masses. This is not the case in SUSY GUTs with low-scale SUSY breaking scale where the masses are constrained by fine tuning.

In 5d or 6d orbifold GUTs, certain “GUT scale” threshold corrections come from the Kaluza-Klein modes between the compactification scale, $M_c \sim 1/R$, and the effective cutoff scale M_* . In string theory, this cutoff scale is the string scale. Gauge coupling unification at two loops then constrains the values of M_c and M_* .⁹ Often, one finds M_c to be lower than the 4d GUT scale. Since the X -bosons, responsible for nucleon decay, get mass at the compactification scale, this has significant consequences for nucleon decay.

Finally, it has been shown that non-supersymmetric GUTs in warped 5d orbifolds can be consistent with gauge coupling unification. This assumes (in 4d language) that the r.h. top quark and the Higgs doublets are composite-like objects with a compositeness scale in the TeV range [85].

94.6 Nucleon decay

Quarks and leptons are indistinguishable in any 4d GUT, and both the baryon (B) and lepton number (L) are not conserved. This leads to baryon-number-violating nucleon decay. In addition to baryon-number violation, lepton-number violation is also required for nucleon decay since, in the SM, leptons are the only free fermions which are lighter than nucleons. The lowest-dimension operators relevant for nucleon decay are $(B+L)$ violating dimension-six four-fermion-terms in the SM, and all baryon-violating operators with dimension less than seven preserve $(B-L)$ [1, 86].

In $SU(5)$ GUTs, the dimension-six operators are induced by X boson exchange. These operators are suppressed by $(1/M_X^2)$ (M_X is the X boson mass), and the nucleon lifetime is given by $\tau_N \propto M_X^4/(\alpha_G^2 m_p^5)$ (m_p is proton mass). The dominant decay mode of the proton (and the baryon-violating decay mode of the neutron), via X boson exchange, is $p \rightarrow e^+ \pi^0$ ($n \rightarrow e^+ \pi^-$). In any simple gauge symmetry, with one universal GUT coupling α_G and scale M_X , the nucleon lifetime from gauge boson exchange is calculable. Hence, the GUT scale may be directly observed via the extremely rare decay of the nucleon. Experimental searches for nucleon decay began with the Kolar Gold Mine, Homestake, Soudan, NUSEX, Frejus, HPW, IMB, and Kamiokande detectors [64]. The present experimental bounds on the modes come from Super-Kamiokande. With 306 kton-years of data they find $\tau_p/\text{Br}(p \rightarrow e^+ \pi^0) > 1.67 \times 10^{34}$ years at 90% CL [87]. In addition, Hyper-Kamiokande [88] is planned to reach to $\tau_p/\text{Br}(p \rightarrow e^+ \pi^0) \sim 10^{35}$ years. The hadronic matrix elements for baryon-number-violating operators are evaluated with lattice QCD simulations [89]. In SUSY $SU(5)$ GUTs, the lower bound on the X boson mass from null results in nucleon decay searches is approaching 10^{16} GeV [90], which is close to the GUT scale suggested by gauge coupling unification. On the other hand, the prediction for nucleon decay in non-SUSY GUTs is hard to quantify. The reason is that gauge couplings do not unify with just the SM particle content. Once extra states or large thresholds are included to ensure precision unification, a certain range of unification scales is allowed.

In SUSY GUTs there are additional sources for baryon and/or lepton-number violation – dimension-four and five operators [14]. These arise since, in the SUSY SM, quarks and leptons have scalar partners (squarks and sleptons). Although our notation does not change, when discussing SUSY models our fields are chiral superfields and both fermionic and bosonic matter is implicitly represented by those. In this language, baryon- and/or lepton-number-violating dimension-four and five operators are given as so-called F terms of products of chiral superfields, which con-

tain two fermionic components and the rest scalars or products of scalars. Within the context of $SU(5)$ the dimension-four and five operators have the form

$$(10 \bar{5} \bar{5}) \supset (u^c d^c d^c) + (Q L d^c) + (e^c L L),$$

$$(10 10 10 \bar{5}) \supset (Q Q Q L) + (u^c u^c d^c e^c) \\ + B\text{- and }L\text{-conserving terms,}$$

respectively.

The dimension-four operators in $(10 \bar{5} \bar{5})$ violate either baryon number or lepton number. The nucleon lifetime is extremely short if both types of dimension-four operators are present in the SUSY SM since squark or slepton exchange induces the dangerous dimension-six SM operators. Even in the case that they violate baryon number or lepton number only but not both, they are constrained by various phenomena [91]. For example, the primordial baryon number in the universe is washed out unless the dimensionless coupling constants are less than 10^{-7} . Both types of operators can be eliminated by requiring R parity, which distinguishes Higgs from ordinary matter multiplets. R parity [92] or its cousin, matter parity [6, 93], act as $F \rightarrow -F$, $H \rightarrow H$ with $F = \{10, \bar{5}\}$, $H = \{\bar{5}_H, 5_H\}$ in $SU(5)$.¹⁰ In $SU(5)$, the Higgs multiplet $\bar{5}_H$ and the matter multiplets $\bar{5}$ have identical gauge quantum numbers. In E_6 , Higgs and matter multiplets could be unified within the fundamental 27 representation. Only in $SO(10)$ are Higgs and matter multiplets distinguished by their gauge quantum numbers. The Z_4 center of $SO(10)$ distinguishes 10_s from 16_s and can be associated with R parity [94].

The baryon-number violating dimension-five operators have a dimensionful coupling. They are generated by integrating out the color-triplet Higgs with GUT-scale mass in SUSY GUTs such that the coefficient is suppressed by $1/M_G$. Note that both triplet Higgsinos (due to their fermionic nature) and Higgs scalars (due to their mass-enhanced trilinear coupling with matter) contribute to the operators. The dimension-five operators include squarks and/or sleptons. To allow for nucleon decay, these must be converted to light quarks or leptons by exchange of a gaugino or Higgsino in the SUSY SM. The nucleon lifetime is proportional to $M_G^2 m_{\text{SUSY}}^2/m_p^5$, where m_{SUSY} is the SUSY breaking scale. Thus, dimension-five operators may predict a shorter nucleon lifetime than dimension-six operators. Unless accidental cancellations are present, the dominant decay modes from dimension-five operators include a K meson, such as $p \rightarrow K^+ \bar{\nu}$ ($n \rightarrow K^0 \bar{\nu}$). This is due to a simple symmetry argument: The operators are given as $(Q_i Q_j Q_k L_l)$ and $(u_i^c u_j^c d_k^c e_l^c)$, where $i, j, k, l (= 1, 2, 3)$ are family indices and color and weak indices are implicit. They must be invariant under $SU(3)_C$ and $SU(2)_L$ so that their color and weak doublet indices must be anti-symmetrized. Since these operators are given by bosonic superfields, they must be totally symmetric under interchange of all indices. Thus the first operator vanishes for $i = j = k$ and the second vanishes for $i = j$. Hence a second or third generation member exists in the dominant modes of nucleon decay unless these modes are accidentally suppressed [93].

The Super-Kamiokande bounds on the proton lifetime severely constrain the dimension-five operators. With 306 kton-years of data they find $\tau_p/\text{Br}(p \rightarrow K^+ \bar{\nu}) > 6.61 \times 10^{33}$ years at 90% CL [87]. In the minimal SUSY $SU(5)$, $\tau_p/\text{Br}(p \rightarrow K^+ \bar{\nu})$ is smaller than about 10^{31} years if the triplet Higgs mass is 10^{16} GeV and $m_{\text{SUSY}} = 1$ TeV [95]. The triplet Higgs mass bound from nucleon decay is then in conflict with gauge coupling unification so that this model is considered to be ruled out [74].

Since nucleon decay induced by the triplet Higgs is a severe problem in SUSY GUTs, various proposals for its suppression have been made. First, some accidental symmetry or accidental structure in non-minimal Higgs sectors in $SU(5)$ or $SO(10)$ theories may suppress the dimension-five operators [22, 26, 27, 96].

⁹ It is interesting to note that a ratio $M_*/M_c \sim 100$, needed for gauge coupling unification to work in orbifold GUTs, is typically the maximum value for this ratio consistent with perturbativity [84].

¹⁰ This forbids the dimension-four operator $(10 \bar{5} \bar{5})$, but allows the Yukawa couplings for quark and lepton masses of the form $(10 \bar{5} \bar{5}_H)$ and $(10 10 \bar{5}_H)$. It also forbids the dimension-three, lepton-number-violating operator $(\bar{5} 5_H) \supset (L H_u)$ as well as the dimension-five, baryon-number-violating operator $(10 10 10 \bar{5}_H) \supset (Q Q Q H_d) + \dots$

Symmetries to suppress the dimension-five operators are typically broken by the VEVs responsible for the color-triplet Higgs masses. Consequently the dimension-five operators are generically generated via the triplet Higgs exchange in SUSY $SU(5)$ GUTs, as mentioned above. In other words, the nucleon decay is suppressed if the Higgs triplets in $\bar{\mathbf{5}}_H$ and $\mathbf{5}_H$ do not have a common mass term but, instead, their mass terms involve partners from other $SU(5)$ multiplets. Second, the SUSY breaking scale may be around $\mathcal{O}(10\text{--}100)$ TeV in order to explain the observed Higgs boson mass at the LHC. In this case, nucleon decay is automatically suppressed [78, 97, 98]. Third, accidental cancellations among diagrams due to a fine-tuned structure of squark and slepton flavor mixing might suppress nucleon decay [99]. Last, we have also implicitly assumed a hierarchical structure for Yukawa matrices in the analysis. It is however possible to fine-tune a hierarchical structure for quarks and leptons which baffles the family structure so that the nucleon decay is suppressed [100]. The upper bound on the proton lifetime from some of these theories is approximately a factor of 10 above the experimental bounds. Future experiments with larger neutrino detectors, such as JUNO [101], Hyper-Kamiokande [88] and DUNE [102], are planned and will have higher sensitivities to nucleon decay.

Are there ways to avoid the stringent predictions for proton decay discussed above? Orbifold GUTs and string theories, see Sec. 94.4, contain grand unified symmetries realized in higher dimensions. In the process of compactification and GUT symmetry breaking, the triplet Higgs states may be removed (projected out of the massless sector of the theory). In such models, the nucleon decay due to dimension-five operators can be severely suppressed or eliminated completely. However, nucleon decay due to dimension-six operators may be enhanced, since the gauge-bosons mediating proton decay obtain mass at the compactification scale, M_c , which is typically less than the 4d GUT scale (cf. Sec. 94.5). Alternatively, the same projections which eliminate the triplet Higgs may rearrange the quark and lepton states such that the massless states of one family come from different higher-dimensional GUT multiplets. This can suppress or completely eliminate even dimension-six proton decay. Thus, enhancement or suppression of dimension-six proton decay is model-dependent. In some complete 5d orbifold GUT models [63, 103] the lifetime for the decay $\tau_p/\text{Br}(p \rightarrow e^+\pi^0)$ can be near the bound of 1×10^{34} years with, however, large model-dependence and/or theoretical uncertainties. In other cases, the modes $p \rightarrow K^+\bar{\nu}$ and $p \rightarrow K^0\mu^+$ may be dominant [63]. Thus, interestingly, the observation of nucleon decay may distinguish string or higher-dimensional GUTs from 4d ones.

In orbifold GUTs or string theory, new discrete symmetries consistent with SUSY GUTs can forbid all dimension-three and four baryon- and lepton-number-violating operators. Even the μ term and dimension-five baryon- and lepton-number-violating operators can be forbidden to all orders in perturbation theory [33]. The μ term and dimension-five baryon- and lepton-number-violating operators may then be generated, albeit sufficiently suppressed, via non-perturbative effects. The simplest example of this is a Z_4^R symmetry which is the unique discrete R symmetry consistent with $SO(10)$ [33]. Even though it forbids the dimension-five proton decay operator to the desired level, it allows the required dimension-five neutrino mass term. In this case, proton decay is dominated by dimension-six operators, leading to decays such as $p \rightarrow e^+\pi^0$.

94.7 Yukawa coupling unification

In the SM, masses and mixings for quarks and leptons come from the Yukawa couplings with the Higgs doublet, but the values of these couplings remain a mystery. GUTs provide at least a partial understanding since each generation is embedded in unified multiplet(s). Specifically, since quarks and leptons are two sides of the same coin, the GUT symmetry relates the Yukawa couplings (and hence the masses) of quarks and leptons.

In $SU(5)$, there are two types of independent renormalizable Yukawa interactions given by $\lambda_{ij}(\mathbf{10}_i \mathbf{10}_j \mathbf{5}_H) + \lambda'_{ij}(\mathbf{10}_i \bar{\mathbf{5}}_j \bar{\mathbf{5}}_H)$. These contain the SM interactions $\lambda_{ij}(Q_i u_j^c H_u) + \lambda'_{ij}(Q_i d_j^c H_d + e_i^c L_j H_d)$. Here $i, j (= 1, 2, 3)$

are, as before, family indices. Hence, at the GUT scale we have tree-level relations between Yukawa coupling constants for charged lepton and down quark masses, such as $\lambda_b = \lambda_\tau$ in which $\lambda_{b/\tau}$ are the bottom quark / τ lepton Yukawa coupling constants [104, 105]. In $SO(10)$, there is only one type of independent renormalizable Yukawa interaction given by $\lambda_{ij}(\mathbf{16}_i \mathbf{16}_j \mathbf{10}_H)$, leading to relations among all Yukawa coupling constants and quark and lepton masses within one generation [106, 107] (such as $\lambda_t = \lambda_b = \lambda_\tau$, with λ_t the top quark Yukawa coupling constant).

In addition to gauge coupling unification, the ratio of bottom quark and τ lepton mass has been a central target in the study of GUTs since it was found that this ratio was almost consistent with observations after including the QCD correction [104]. Today the quark masses and the gauge coupling constants are known precisely such that, as discussed below, the ratio of bottom quark and τ lepton mass has become a target of precision analyses in the GUT context.

94.7.1 The third generation, $b\text{--}\tau$ or $t\text{--}b\text{--}\tau$ unification

Third generation Yukawa couplings are larger than those of the first two generations. Hence, the fermion mass relations predicted from renormalizable GUT interactions which we introduced above are expected to be more reliable. In order to compare them with data, we have to include the radiative correction to these relations from the RG evolution between GUT and fermion mass scale, from integrating out heavy particles at the GUT scale, and from weak scale thresholds.

Since testing Yukawa coupling unification is only possible in models with successful gauge coupling unification, we here focus on SUSY GUTs. In the MSSM, top and bottom quark and τ lepton masses are related to the Yukawa coupling constants at the scale m_Z as

$$\begin{aligned} m_t(m_Z) &= \lambda_t(m_Z) v_u(1 + \delta m_t/m_t), \\ m_{b/\tau}(m_Z) &= \lambda_{b/\tau}(m_Z) v_d(1 + \delta m_{b/\tau}/m_{b/\tau}), \end{aligned}$$

where $\langle H_u^0 \rangle \equiv v_u = \sin\beta v/\sqrt{2}$, $\langle H_d^0 \rangle \equiv v_d = \cos\beta v/\sqrt{2}$, $v_u/v_d \equiv \tan\beta$ and $v \sim 246$ GeV is fixed by the Fermi constant, G_μ . Here, $\delta m_f/m_f$ ($f = t, b, \tau$) represents the threshold correction due to integrating out SUSY partners. For the bottom quark mass, it is found [108] that the dominant corrections come from the gluino-sbottom and from the Higgsino-stop loops,

$$\begin{aligned} \left(\frac{\delta m_b}{m_b}\right)_{g_3} &\sim \frac{g_3^2}{6\pi^2} \frac{m_{\tilde{g}}\mu}{m_{\text{SUSY}}^2} \tan\beta \quad \text{and} \\ \left(\frac{\delta m_b}{m_b}\right)_{\lambda_t} &\sim \frac{\lambda_t^2}{16\pi^2} \frac{A_t\mu}{m_{\text{SUSY}}^2} \tan\beta, \end{aligned} \quad (94.16)$$

where $m_{\tilde{g}}$, μ , and A_t stand for gluino and Higgsino masses and trilinear stop coupling, respectively. Note that Eq. (94.16) only illustrates the structure of the corrections – non-trivial functional dependences on several soft parameters $\sim m_{\text{SUSY}}$ have been suppressed. For the full one-loop correction to the bottom quark mass see, for example, Ref. [109].

Note also that the corrections do not go to zero as SUSY particles become much heavier than m_Z . They may change the bottom quark mass at the $\mathcal{O}(10)\%$ level for $\tan\beta = \mathcal{O}(10)$. The total effect is sensitive to the relative phase between gluino and Higgsino masses since $A_t \sim -m_{\tilde{g}}$ due to the infrared fixed point nature of the RG equation for A_t [110] in settings where SUSY breaking terms come from Planck scale dynamics, such as gravity mediation. The τ lepton mass also receives a similar correction, though only at the few % level. The top quark mass correction, not being proportional to $\tan\beta$, is at most 10% [111].

Including one loop threshold corrections at m_Z and additional RG running, one finds the top, bottom and τ pole masses. In SUSY GUTs, $b\text{--}\tau$ unification has two possible solutions with $\tan\beta \sim 1$ or $\mathcal{O}(10)$. The small $\tan\beta$ solution may be realized in the MSSM if superpartner masses are $\mathcal{O}(10)$ TeV, as suggested by the observed Higgs mass [97]. The large $\tan\beta$ limit such as $\tan\beta \sim 40\text{--}50$ overlaps the $SO(10)$ symmetry relation [111, 112]. When $\tan\beta$ is large, there are significant threshold corrections to

down quark masses as mentioned above, and Yukawa unification is only consistent with low-energy data in a restricted region of SUSY parameter space, with important consequences for SUSY searches [111, 113]. More recent analyses of Yukawa unification after LHC Run-I are found in Ref. [114].

Gauge coupling unification is also successful in the scenario of split supersymmetry [78], in which squarks and sleptons have mass at a scale $\tilde{m} \gg m_Z$, while gauginos and/or Higgsinos have masses of order the weak scale. Unification of b - τ Yukawa couplings requires $\tan\beta$ to be fine-tuned close to 1 [97]. If by contrast, $\tan\beta \gtrsim 1.5$, b - τ Yukawa unification only works for $\tilde{m} \lesssim 10^4$ GeV. This is because the effective theory between the gaugino mass scale and \tilde{m} includes only one Higgs doublet, as in the standard model. As a result, the large top quark Yukawa coupling tends to increase the ratio λ_b/λ_τ due to the vertex correction, which is absent in supersymmetric theories, as one runs down in energy below \tilde{m} . This is opposite to what happens in the MSSM where the large top quark Yukawa coupling lowers the ratio λ_b/λ_τ [105].

94.7.2 Beyond leading order: three-family models

Simple Yukawa unification is not possible for the first two generations. Indeed, the simplest implementation of $SU(5)$ implies $\lambda_s = \lambda_\mu$, $\lambda_d = \lambda_e$ and hence $\lambda_s/\lambda_d = \lambda_\mu/\lambda_e$. This is an RG-invariant relation which extrapolates to $m_s/m_d = m_\mu/m_e$ at the weak scale, in serious disagreement with data ($m_s/m_d \sim 20$ and $m_\mu/m_e \sim 200$). An elegant solution to this problem was given by Georgi and Jarlskog [115] (for a recent analysis in the SUSY context see [116]).

More generally, we have to recall that in all of the previous discussion of Yukawa couplings, we assumed renormalizable interactions as well as the minimal matter and Higgs content. Since the GUT scale is close to the Planck scale, higher-dimension operators involving the GUT-breaking Higgs may modify the predictions, especially for lower generations. An example is provided by the operators $\mathbf{10} \bar{\mathbf{5}} \bar{\mathbf{5}}_H \mathbf{24}_H$ with $\mathbf{24}_H$ the GUT-breaking Higgs of $SU(5)$. We can fit parameters to the observed fermion masses with these operators, though some fine-tuning is introduced in doing so. The SM Higgs doublet may come in part from higher representations of the GUT group. For example, the $\mathbf{45}$ of $SU(5)$ includes an $SU(2)_L$ doublet with appropriate $U(1)_Y$ charge [115]. This $\mathbf{45}$ can, in turn, come from the $\mathbf{120}$ or $\mathbf{126}$ of $SO(10)$ after its breaking to $SU(5)$ [117, 118]. These fields may also have renormalizable couplings with quarks and leptons. The relations among the Yukawa coupling constants in the SM are modified if the SM Higgs doublet is a linear combination of several such doublets from different $SU(5)$ multiplets. Finally, the SM fermions may not be embedded in GUT multiplets in the minimal way. Indeed, if all quarks and leptons are embedded in $\mathbf{16}$ s of $SO(10)$, the renormalizable interactions with $\mathbf{10}_H$ cannot explain the observed CKM mixing angles. This situation improves when extra matter multiplets, such as $\mathbf{10}$, are introduced: After $U(1)_X$, which distinguishes the $\bar{\mathbf{5}}$ s coming from the $\mathbf{16}$ and the $\mathbf{10}$ of $SO(10)$, is broken (e.g. by a VEV of $\mathbf{16}_H$ or $\mathbf{126}_H$), the r.h. down quarks and l.h. leptons in the SM can be linear combinations of components in $\mathbf{16}$ s and $\mathbf{10}$ s. As a result, $\lambda \neq \lambda'$ in $SU(5)$ [119].

To construct realistic three-family models, some or all of the above effects can be used. Even so, to achieve significant predictions for fermion masses and mixing angles grand unification alone is not sufficient. Other ingredients, for example additional global family symmetries are needed (in particular, non-Abelian symmetries can strongly reduce the number of free parameters). These family symmetries constrain the set of effective higher-dimensional fermion mass operators discussed above. In addition, sequential breaking of the family symmetry can be correlated with the hierarchy of fermion masses [120]. One simple, widely known idea in this context is to ensure that each $\mathbf{10}_i$ enters Yukawa interactions together with a suppression factor ϵ^{3-i} (ϵ being a small parameter). This way one automatically generates a stronger hierarchy in up-type quark Yukawas as compared to down-type quark and lepton Yukawas and no hierarchy for neutrinos, which agrees with observations at the $\mathcal{O}(1)$ -level. Three-family models exist which fit all the data, including neutrino masses and mixing [27, 121].

Finally, a particularly ambitious variant of unification is to re-

quire that the fermions of all three generations come from a single representation of a large gauge group. A somewhat weaker assumption is that the flavor group (e.g. $SU(3)$) unifies with the SM gauge group in a simple gauge group at some energy scale $M \geq M_G$. Early work on such ‘flavor-unified GUTs’, see e.g. [119, 122], has been reviewed in [123, 124]. For a selection of more recent papers see [125]. In such settings, Yukawa couplings are generally determined by gauge couplings together with symmetry breaking VEVs. This is reminiscent of heterotic string GUTs, where all couplings come from the 10d gauge coupling. However, while the $E_8 \rightarrow SU(3) \times E_6$ branching rule $\mathbf{248} = (\mathbf{8}, \mathbf{1}) + (\mathbf{1}, \mathbf{78}) + (\mathbf{3}, \mathbf{27}) + (\bar{\mathbf{3}}, \mathbf{27})$ looks very suggestive in this context, the way in which most modern heterotic models arrive at three generations is actually more complicated.

94.8 Neutrino masses

We see from atmospheric and solar neutrino oscillation observations, along with long baseline accelerator and reactor experiments, that neutrinos have finite masses. By adding three ‘sterile’ neutrinos ν_i^c with Yukawa couplings $\lambda_{\nu,ij} (\nu_i^c L_j H_u)$ ($i, j = 1, 2, 3$), one easily obtains three massive Dirac neutrinos with mass $m_\nu = \lambda_\nu v_u$, analogously to quark and charged lepton masses. However, in order to obtain a τ neutrino with mass of order 0.1 eV, one requires the exceedingly small coupling ratio $\lambda_{\nu\tau}/\lambda_\tau \lesssim 10^{-10}$. By contrast, in GUTs the seesaw mechanism *naturally* explains such tiny neutrino masses as follows [2–4]: The sterile neutrinos have no SM gauge quantum numbers so that there is no symmetry other than global lepton number which forbids the Majorana mass term $\frac{1}{2} M_{ij} \nu_i^c \nu_j^c$. Note also that sterile neutrinos can be identified with the r.h. neutrinos necessarily contained in complete families of $SO(10)$ or Pati-Salam models. Since the Majorana mass term violates $U(1)_X$ in $SO(10)$, one might expect $M_{ij} \sim M_G$. The heavy sterile neutrinos can be integrated out, defining an effective low-energy theory with only three light active Majorana neutrinos with the effective dimension-five operator

$$- \mathcal{L}_{eff} = \frac{1}{2} c_{ij} (L_i H_u) (L_j H_u), \tag{94.17}$$

where $c = \lambda_\nu^T M^{-1} \lambda_\nu$. This then leads to a 3×3 Majorana neutrino mass matrix $m = m_\nu^T M^{-1} m_\nu$.

The seesaw mechanism implemented by r.h. neutrinos is sometimes called the type-I seesaw model. There are variant models in which the dimension-five operator for neutrino masses is induced in different ways: In the type-II model, an $SU(2)_L$ triplet Higgs boson Σ is introduced to have couplings ΣL^2 and also ΣH_u^2 [117, 126]. In the type-III model, an $SU(2)_L$ triplet of fermions $\tilde{\Sigma}$ with a Yukawa coupling $\tilde{\Sigma} L H_u$ is introduced [127]. In these models, the dimension-five operator is induced by integrating out the triplet Higgs boson or fermions. Such models can also be implemented in GUTs by introducing Higgs bosons in the $\mathbf{15}$ or fermions in the $\mathbf{24}$ in $SU(5)$ GUTs or the $\mathbf{126}$ in $SO(10)$ GUTs. Notice that the gauge non-singlet fields in the type-II and III models have masses at the intermediate scale. Thus, gauge coupling unification is not automatic if these variant mechanisms are implemented in SUSY GUTs.

Atmospheric neutrino oscillations discovered by Super-Kamiokande [128] require neutrino masses with $\Delta m_\nu^2 \sim 2.5 \times 10^{-3}$ eV² with maximal mixing [62], in the simplest scenario of two neutrino dominance. With hierarchical neutrino masses this implies $m_{\nu\tau} = \sqrt{\Delta m_\nu^2} \sim 0.05$ eV. Next, we can try to relate the neutrino Yukawa coupling to the top quark Yukawa coupling, $\lambda_{\nu\tau} = \lambda_t$ at the GUT scale, as in $SO(10)$ or $SU(4) \times SU(2)_L \times SU(2)_R$ models. This gives $M \sim 10^{14}$ GeV, which is remarkably close to the GUT scale.

Neutrinos pose a special problem for GUTs. The question is why the quark mixing angles in the CKM matrix are small while there are two large lepton mixing angles in the PMNS matrix. Global fits of neutrino masses and mixing angles can, for example, be found in Refs. [129] and [130]. For SUSY GUT models which fit quark and lepton masses, see Ref. [131] for reviews. Finally, for a compilation of the range of SUSY GUT predictions for neutrino mixing, see [132].

94.9 Selected topics

94.9.1 Global symmetries

As we discussed, global symmetries are frequently introduced to control higher-dimension operators in GUT models. This is particularly important in the context of nucleon decay but also plays a role in GUT-based flavor model building and cosmological applications, such as baryogenesis and inflation. However, we should note that appealing to global symmetries to suppress specific interactions may not be as straightforward as it naively seems. Indeed, there are two possibilities: On the one hand, the relevant symmetry might be gauged at a higher scale. Effects of the VEVs responsible for the spontaneous breaking are then in principle dangerous and need to be quantified. On the other hand, the symmetry might be truly only global. This must e.g. be the case for anomalous symmetries, which are then also violated by field-theoretic non-perturbative effects. The latter can in principle be exponentially small. It is, however, widely believed that global symmetries are always broken in quantum gravity (see e.g. [133]). One then needs to understand which power or functional form the Planck scale suppression of the relevant interaction has. For example, dimension-five baryon number violating operators suppressed by just one unit of the Planck or string scale are completely excluded.

In view of the above, it is also useful to recall that in string models 4d global symmetries generally originate in higher-dimensional gauge symmetries [38, 134]. Here ‘global’ implies that the gauge boson has acquired a Stückelberg-mass. This is a necessity in the anomalous case (Green-Schwarz mechanism [135]) but can also happen to non-anomalous symmetries. One expects no symmetry violation beyond the well-understood non-perturbative effects. Discrete symmetries arise as subgroups of continuous gauge symmetries, such as $\mathbb{Z}_N \subset U(1)$. In particular, non-anomalous subgroups of Stückelberg-massive $U(1)$ s represent unbroken discrete gauge symmetries and as such are non-perturbatively exact (see e.g. [136]). Of course, such discrete gauge symmetries may also arise as remnants of continuous gauge symmetries after conventional 4d spontaneous breaking.

94.9.2 Anomaly constraints vs. GUT paradigm

As emphasized at the very beginning, the fact that the SM fermions of one generation fill out the $\mathbf{10} + \bar{\mathbf{5}}$ of $SU(5)$ appears to provide overwhelming evidence for some form of GUT embedding. However, one should be aware that a counterargument can be made which is related to the issue of ‘charge quantization by anomaly cancellation’ (see [137, 138] for some early papers and [139] for a more detailed reference list): Imagine we only knew that the low-energy gauge group were G_{SM} and the matter content included the $(\mathbf{3}, \mathbf{2})_Y$, i.e. a ‘quark doublet’ with $U(1)$ -charge Y . One can then ask which possibilities exist of adding further matter to ensure the cancellation of all triangle anomalies. It turns out that this problem has only three different, minimal¹¹ solutions [138]. One of those is precisely a single SM generation, with the apparent ‘ $SU(5)$ -ness’ emerging accidentally. Thus, if one randomly picks models from the set of consistent gauge theories, preconditioning on G_{SM} and $(\mathbf{3}, \mathbf{2})_Y$, one may easily end up with ‘ $\mathbf{10} + \bar{\mathbf{5}}$ ’ of an $SU(5)$ that is in no way dynamically present. This is precisely what happens in the context of non-GUT string model building [140].

94.9.3 Magnetic monopoles

In the broken phase of a GUT there are typically localized classical solutions carrying magnetic charge under an unbroken $U(1)$ symmetry [141]. These magnetic monopoles with mass of order M_G/α_G can be produced during a possible GUT phase transition in the early universe. The flux of magnetic monopoles is experimentally found to be less than $\sim 10^{-16} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ [142]. Many more are however predicted, hence the GUT monopole problem. In fact, one of the original motivations for inflation was to solve the monopole problem by exponential expansion after the GUT phase transition [143] and hence dilution of the

monopole density. Other possible solutions to the monopole problem include: sweeping them away by domain walls [144], $U(1)$ electromagnetic symmetry breaking at high temperature [145] or GUT symmetry non-restoration [146]. Parenthetically, it was also shown that GUT monopoles can catalyze nucleon decay [147]. A significantly stronger bound on the monopole flux can then be obtained by considering X-ray emission from radio pulsars due to monopole capture and the subsequent nucleon decay catalysis [148].

Note that the present upper bound on the inflationary vacuum energy density is very close to the GUT scale, $V_{inf}^{1/4} = (1.88 \times 10^{16} \text{ GeV}) \times (r/0.10)^{1/4}$, with the scalar-to-tensor ratio constrained to $r < 0.07$ [149]. This guarantees that reheating does not lead to temperatures above M_G and hence the monopole problem is solved by inflation (unless M_G is unexpectedly low).

94.9.4 Flavor violation

Yukawa interactions of GUT-scale particles with quarks and leptons may leave imprints on the flavor violation induced by SUSY breaking parameters [150]. To understand this, focus first on the MSSM with universal Planck-scale boundary conditions (as e.g. in gravity mediation). Working in a basis where up-quark and lepton Yukawas are diagonal, one finds that the large top-quark Yukawa coupling reduces the l.h. squark mass squareds in the third generation radiatively. It turns out that only the l.h. down-type squark mass matrix has sizable off-diagonal terms in the flavor basis after CKM-rotation. However, in GUTs the color-triplet Higgs has flavor violating interactions from the Yukawa coupling $\lambda_{ij}(\mathbf{10}_i \mathbf{10}_j \mathbf{5}_H)$, such that flavor-violating r.h. slepton mass terms are radiatively generated in addition [151]. In $SU(5)$ extension of the type-I seesaw model, where r.h. neutrinos are introduced as $SU(5)$ singlets with interactions $\lambda''_{ij}(\mathbf{1}_i \bar{\mathbf{5}}_j \mathbf{5}_H)$, the doublet and color-triplet Higgses acquire another type of Yukawa coupling, respectively. They then radiatively generate flavor-violating l.h. slepton [152] and r.h. down squark masses [153]. These flavor-violating SUSY breaking terms induce new contributions to FCNC processes in quark and lepton sectors, such as $\mu \rightarrow e\gamma$ and $K^0-\bar{K}^0$ and $B^0-\bar{B}^0$ mixing. Note that even if the SUSY breaking terms are generated at M_G , the r.h. neutrino Yukawa coupling may induce sizable flavor violation in l.h. slepton masses due to the running between M_G and the right-handed-neutrino mass scale.

EDMs are also induced when both l.h. and r.h. squarks/sleptons have flavor-violating mass terms with relative phases, as discussed for $SO(10)$ in [154] or for $SU(5)$ with r.h. neutrinos in [155]. Thus, such low-energy observables constrain GUT-scale interactions.

94.9.5 From GUT baryogenesis to leptogenesis and B/L-violating transitions

During inflation, any conserved quantum number is extremely diluted. Thus, one expects the observed baryon asymmetry of the universe to originate at reheating or in the subsequent cosmological evolution. In detail, the situation is slightly more involved: Both baryon number B and lepton number L are global symmetries of the SM. However, $(B+L)$ is anomalous and violated by thermal fluctuations in the early universe, via so-called sphaleron processes. Moreover, it is violated in GUT models, as is most apparent in proton decay. By contrast, $(B-L)$ is anomaly free and preserved by both the SM as well as $SU(5)$ or $SO(10)$ gauge interactions.

Now, the old idea of GUT baryogenesis [156, 157] is to generate a $(B+L)$ and hence a baryon asymmetry by the out-of-equilibrium decay of the color-triplet Higgs. However such an asymmetry, generated at GUT temperatures, is washed out by sphalerons¹². This can be overcome [159] using lepton-number violating interaction of neutrinos to create a $(B-L)$ from the $(B+L)$ asymmetry, before sphaleron processes become sufficiently fast at $T < 10^{12}$ GeV. This $(B-L)$ asymmetry can then survive the subsequent sphaleron dominated phase. Note that this does not work in the minimal SUSY GUT setting, with the triplet Higgs above the

¹¹ Adding extra vector-like sets of fields, e.g. two fermions which only transform under $U(1)$ and have charges Y and $-Y$, is considered to violate minimality.

¹² To be precise, if lepton flavor numbers L_i ($i = 1-3$) are nonzero and $(L_i - L_j) \neq 0$ ($i \neq j$), one may obtain nonzero values for B and L even if $(B-L) = 0$ [158].

GUT scale. The reason is that a correspondingly high reheating temperature would be required which, as explained above, is ruled out by Planck data.

However, the most widely accepted simple way out of the dilemma is to directly generate a net $(B-L)$ asymmetry dynamically in the early universe, also using r.h. neutrinos. Indeed, we have seen that neutrino oscillations suggest a new scale of physics of order 10^{14} GeV. This scale is associated with heavy Majorana neutrinos in the seesaw mechanism. If in the early universe, the decay of the heavy neutrinos is out of equilibrium and violates both lepton number and CP, then a net lepton number may be generated. This lepton number will then be partially converted into baryon number via electroweak processes [160]. This mechanism is called leptogenesis.

If the three heavy Majorana neutrino masses are hierarchical, the net lepton number is produced by decay of the lightest one, and it is proportional to the CP asymmetry in the decay. The CP asymmetry is bounded from above, and the lightest neutrino mass is required to be larger than 10^9 GeV in order to explain the observed baryon asymmetry [161]. This implies that the reheating temperature after inflation should be larger than 10^9 GeV so that the heavy neutrinos are thermally produced¹³. In supersymmetric models, there is a tension between leptogenesis and Big Bang Nucleosynthesis (BBN) if gravitinos decay in the BBN era. The gravitino problem gives a constraint on the reheating temperature $\lesssim 10^{6-10}$ GeV though the precise value depends on the SUSY breaking parameters [163]. Recent reviews of leptogenesis can be found in Ref. [164].

One of the important tests of leptogenesis are searches for neutrinoless double- β ($0\nu\beta\beta$) decays¹⁴. In a $0\nu\beta\beta$ decay, only two electrons but no (anti-)neutrinos are emitted by the decaying nucleus. This is in contrast to ordinary double- β decay. Thus, $0\nu\beta\beta$ decays are lepton-number-violating with $\Delta L = 2$. At the nucleon level, this is described by dimension-nine effective operators for $nn \rightarrow ppee$. These operators may in turn come from SM operators of with dimension less than nine, in combination with SM weak interactions. The lowest one is the dimension-five operator generating the Majorana neutrino mass terms (Eq. (94.17)). Thus, if the lepton-number violating effective interactions come from physics at energies much above the weak scale, the $0\nu\beta\beta$ decay rates are proportional to the Majorana neutrino masses. The latest experimental results are reviewed in [62]. For recent studies of the $0\nu\beta\beta$ decay including SM operators up to mass dimension nine, see [165] and refs. therein.

In addition to L -violation, one can consider $(B-L)$ and B violating phenomena. They are interesting in their own right and may also be relevant to baryogenesis. The relevant operators have higher mass dimension than the familiar dimension-six $(B+L)$ -violating operators (cf. Sec. 94.6). They may be predicted in $SO(10)$ GUTs with an intermediate scale, at which baryogenesis is realized, such as in [166]. First, one may have nucleon decays with $\Delta(B-L) = 2$, such as $n \rightarrow e^-\pi^+$. This is induced by dimension-seven effective operators in the SM, which are suppressed by the SM Higgs VEV or derivatives. Second, there are neutron-antineutron ($n-\bar{n}$) oscillations, which are induced by $\Delta B = 2$ dimension-nine effective operators in the SM. The upper bound on the mean time for $n-\bar{n}$ transitions is directly derived using free neutrons [167]. It is also constrained from the lower limit on the lifetime for neutrons bound in ^{16}O , derived by Super-Kamiokande [168]. Their results are very similar. Super-Kamiokande also searches for dinucleon decays with $\Delta B = 2$, such as $pp \rightarrow \pi^+\pi^+$ and $nn \rightarrow \pi^+\pi^-$ [169].

94.10 Conclusion

Most conservatively, grand unification means that (some of) the SM gauge interactions of $U(1)_Y$, $SU(2)_L$ and $SU(3)_C$ become

¹³ This constraint may be avoided in resonant leptogenesis [162], in which the right-handed neutrinos are required to be almost degenerate in mass.

¹⁴ Another important test of leptogenesis would be the observation of CP violation in neutrino oscillations. Strictly speaking, the CP phase in the PMNS matrix does not contribute to ϵ_1 in the seesaw model. Nevertheless, the observation of CP violation in neutrino oscillations would suggest that the seesaw mechanism is associated with a large CP violation, similarly to the quark sector.

part of a larger, unifying gauge symmetry at a high energy scale. In most models, especially in the simplest and most appealing variants of $SU(5)$ and $SO(10)$ unification, the statement is much stronger: One expects the three gauge couplings to unify (up to small threshold corrections) at a unique scale, M_G , and the proton to be unstable due to exchange of gauge bosons of the larger symmetry group. Supersymmetric grand unified theories provide, by far, the most predictive and economical framework allowing for perturbative unification. Many more details than could be discussed in the present article can be found in some of the classic reviews [123,170] and the two books [171] (see also [172] for two recent overviews).

Thus, the three classical pillars of GUTs are gauge coupling unification at $M_G \sim 2 \times 10^{16}$ GeV, low-energy supersymmetry (with a large SUSY desert), and nucleon decay. The first of these may be viewed as predicting the value of the strong coupling – a prediction which has already been verified (see Fig. 94.1). Numerically, this prediction remains intact even if SUSY partner masses are somewhat above the weak scale. However, at the conceptual level a continuously increasing lower bound on the SUSY scale is nevertheless problematic for the GUT paradigm: Indeed, if the independent, gauge-hierarchy-based motivation for SUSY is completely abandoned, the SUSY scale and hence α_3 become simply free parameters and the first two pillars crumble. Thus, it is important to keep pushing bounds on proton decay which, although again not completely universal in all GUT constructions, is arguably a more generic part of the GUT paradigm than low-energy SUSY.

Whether or not Yukawa couplings unify is more model dependent. However, irrespective of possible (partial) Yukawa unification, there certainly exists a very interesting and potentially fruitful interplay between flavor model building and grand unification. Especially in the neutrino sector this is strongly influenced by the developing experimental situation.

Another phenomenological signature of grand unification is the strength of the direct coupling of the QCD axion to photons, relative to its coupling to gluons. It is quantified by the predicted anomaly ratio $E/N = 8/3$ (see [173,174]). This arises in field-theoretic axion models consistent with GUT symmetry (such as DFSZ [175]) and in string-theoretic GUTs [174,176]. In the latter, the axion does not come from the phase of a complex scalar but is a fundamental shift-symmetric real field, coupling through a higher-dimension operator directly to the product of the GUT field-strength and its dual.

It is probably fair to say that, due to limitations of the 4d approach, including especially remaining ambiguities (free parameters or ad hoc assumptions) in models of flavor and GUT breaking, the string theoretic approach has become more important in GUT model building. In this framework, challenges include learning how to deal with the many vacua of the ‘landscape’ as well as, for each vacuum, developing the tools for reliably calculating detailed, phenomenological observables. Finally, due to limitations of space, the present article has barely touched on the interesting cosmological implications of GUTs. They may become more important in the future, especially in the case that a high inflationary energy scale is established observationally.

95. Leptoquarks

Updated August 2019 by S. Rolli (US Department of Energy) and M. Tanabashi (Nagoya U.)

Leptoquarks are hypothetical particles carrying both baryon number (B) and lepton number (L). The possible quantum numbers of leptoquark states can be restricted by assuming that their direct interactions with the ordinary standard model (SM) fermions are dimensionless and invariant under the SM gauge group. Table 95.1 shows the list of all possible quantum numbers with this assumption [1]. The columns of $SU(3)_C$, $SU(2)_W$, and $U(1)_Y$ in Table 95.1 indicate the QCD representation, the weak isospin representation, and the weak hypercharge, respectively. The spin of a leptoquark state is taken to be 1 (vector leptoquark) or 0 (scalar leptoquark).

Table 95.1: Possible leptoquarks and their quantum numbers.

Spin	$3B + L$	$SU(3)_c$	$SU(2)_W$	$U(1)_Y$	Allowed coupling
0	-2	$\bar{3}$	1	1/3	$\bar{q}_L^c \ell_L$ or $\bar{u}_R^c e_R$
0	-2	$\bar{3}$	1	4/3	$\bar{d}_R^c e_R$
0	-2	$\bar{3}$	3	1/3	$\bar{q}_L^c \ell_L$
1	-2	$\bar{3}$	2	5/6	$\bar{q}_L^c \gamma^\mu e_R$ or $\bar{d}_R^c \gamma^\mu \ell_L$
1	-2	$\bar{3}$	2	-1/6	$\bar{u}_R^c \gamma^\mu \ell_L$
0	0	3	2	7/6	$\bar{q}_L e_R$ or $\bar{u}_R \ell_L$
0	0	3	2	1/6	$\bar{d}_R \ell_L$
1	0	3	1	2/3	$\bar{q}_L \gamma^\mu \ell_L$ or $\bar{d}_R \gamma^\mu e_R$
1	0	3	1	5/3	$\bar{u}_R \gamma^\mu e_R$
1	0	3	3	2/3	$\bar{q}_L \gamma^\mu \ell_L$

If we do not require leptoquark states to couple directly with SM fermions, different assignments of quantum numbers become possible [2,3].

Leptoquark states are expected to exist in various extensions of the SM. The Pati-Salam model [4] is an example predicting the existence of a leptoquark state. Leptoquark states also exist in grand unification theories based on $SU(5)$ [5], $SO(10)$ [6], which includes Pati-Salam color $SU(4)$, and larger gauge groups. Scalar quarks in supersymmetric models with R-parity violation may also have leptoquark-type Yukawa couplings. The bounds on the leptoquark states can therefore be applied to constrain R-parity-violating supersymmetric models. Scalar leptoquarks are expected to exist at the TeV scale in extended technicolor models [7,8] where leptoquark states appear as the bound states of techni-fermions. Compositeness of quarks and leptons also provides examples of models which may have light leptoquark states [9].

Bounds on leptoquark states are obtained both directly and indirectly. Direct limits are from their production cross sections at colliders, while indirect limits are calculated from bounds on leptoquark-induced four-fermion interactions, which are obtained from low-energy experiments, or from collider experiments below threshold. These four-fermion interactions often cause lepton-flavor non-universalities in heavy quark decays. Anomalies observed recently in the R_K and R_D ratios [10,11] in the semi-leptonic B decays may be explained in models with TeV scale leptoquarks.

If a leptoquark couples to quarks (leptons) belonging to more than a single generation in the mass eigenbasis, it can induce four-fermion interactions causing flavor-changing neutral currents (lepton-family-number violations). The quantum number assignment of Table 1 allows several leptoquark states to couple to both left- and right-handed quarks simultaneously. Such leptoquark states are called non-chiral and may cause four-fermion interactions affecting the $(\pi \rightarrow e\nu)/(\pi \rightarrow \mu\nu)$ ratio [12]. Non-chiral scalar leptoquarks also contribute to the muon anomalous magnetic moment [13,14]. Since indirect limits provide more stringent constraints on these types of leptoquarks, it is often assumed that a leptoquark state couples only to a single generation of quarks and a single generation of leptons in a chiral interaction, for which indirect limits become much weaker.

Additionally, this assumption gives strong constraints on models of leptoquarks.

Refs. [15,16,17] give extensive lists of the bounds on the leptoquark-induced four-fermion interactions. For the isoscalar scalar and vector leptoquarks S_0 and V_0 , for example, which couple with the first- (second-) generation left-handed quark, and the first-generation left-handed lepton, the bounds $\lambda^2 < 0.07 \times (M_{LQ}/1 \text{ TeV})^2$ for S_0 , and $\lambda^2 < 0.4 \times (M_{LQ}/1 \text{ TeV})^2$ for V_0 ($\lambda^2 < 0.7 \times (M_{LQ}/1 \text{ TeV})^2$ for S_0 , and $\lambda^2 < 0.5 \times (M_{LQ}/1 \text{ TeV})^2$ for V_0) with λ being the leptoquark coupling strength, can be derived from the limits listed in Ref. [17]. The e^+e^- experiments are sensitive to the indirect effects coming from t - and u -channel exchanges of leptoquarks in the $e^+e^- \rightarrow q\bar{q}$ process. The HERA experiments give bounds on the leptoquark-induced four-fermion interaction. For detailed bounds obtained in this way, see the Boson Particle Listings for ‘‘Indirect Limits for Leptoquarks’’ and its references.

Collider experiments provide direct limits on the leptoquark states through limits on the pair- and single-production cross sections. The leading-order cross sections of the parton processes

$$\begin{aligned}
 q + \bar{q} &\rightarrow LQ + \bar{LQ} \\
 g + g &\rightarrow LQ + \bar{LQ} \\
 e + q &\rightarrow LQ
 \end{aligned}
 \tag{95.1}$$

may be written as [21]

$$\begin{aligned}
 \hat{\sigma}_{LO} [q\bar{q} \rightarrow LQ + \bar{LQ}] &= \frac{2\alpha_s^2 \pi}{27\hat{s}} \beta^3, \\
 \hat{\sigma}_{LO} [gg \rightarrow LQ + \bar{LQ}] &= \frac{\alpha_s^2 \pi}{96\hat{s}} \\
 &\times \left[\beta(41 - 31\beta^2) + (18\beta^2 - \beta^4 - 17) \log \frac{1+\beta}{1-\beta} \right], \\
 \hat{\sigma}_{LO} [eq \rightarrow LQ] &= \frac{\pi\lambda^2}{4} \delta(\hat{s} - M_{LQ}^2)
 \end{aligned}
 \tag{95.2}$$

for a scalar leptoquark. Here $\sqrt{\hat{s}}$ is the invariant energy of the parton subprocess, and $\beta \equiv \sqrt{1 - 4M_{LQ}^2/\hat{s}}$. The leptoquark Yukawa coupling is given by λ . Leptoquarks are also produced singly at hadron colliders through $g + q \rightarrow LQ + \ell$ [22], which allows extending to higher masses the collider reach in the leptoquark search [23], depending on the leptoquark Yukawa coupling. See also Ref. [24] for a comprehensive review on the leptoquark phenomenology in precision experiments and particle colliders.

Leptoquark states which couple only to left- or right-handed quarks are called chiral leptoquarks. Leptoquark states which couple only to the first (second, third) generation are referred as the first- (second-, third-) generation leptoquarks.

The LHC, Tevatron and LEP experiments have been searching for pair production of the leptoquark states, which arises from the leptoquark gauge interaction. Due to the typical decay of the leptoquark into charged and neutral leptons and quarks, the searches are carried on in signatures including high P_T charged leptons, high E_T jets and large missing transverse energy. Additionally searches for pair produced LQs are often organized by the decay mode of the pair of LQs, via the decay parameter β , which represents the branching fraction into a charge lepton vs a neutrino: $\beta = 1$ for both LQs decaying into a charged lepton, $\beta = 0.5$ for one LQ decaying into a charged lepton and one into a neutrino. The gauge couplings of a scalar leptoquark are determined uniquely according to its quantum numbers in Table 95.1. Since all of the leptoquark states belong to color-triplet representation, the scalar leptoquark pair-production cross section at the Tevatron and LHC can be determined solely as a function of the leptoquark mass without making further assumptions. This is in contrast to the indirect or single-production limits, which give constraints in the leptoquark mass-coupling plane.

Older results from the Tevatron run can be found here: [26], [27], [28] and [29].

Since the previous version of this review, both ATLAS and CMS have updated their results concerning searches for first, second, and third generation LQs and leptoquark states which couple only with the i -th generation quarks and the j -th generation leptons ($i \neq j$) without causing conflicts with severe indirect constraints. The datasets were almost all collected at center of mass energy of 13 TeV and corresponding to the latest integrated luminosity collected before the shutdown of the LHC occurring in 2019 and 2020.

It is worthy to note that organizing LQs by flavor quantum number first before organizing them by gauge quantum number is becoming more common and advantageous because it relates more closely to some of the experimental searches being performed. The traditional nomenclature for 1st, 2nd, and 3rd generation LQ encourages only looking for the diagonal elements in a flavor matrix of possibilities, which has been the traditional experimental search strategy.

Current results extend previous mass limits for scalar leptoquarks to > 1435 GeV (first generation, CMS, $\beta = 1, \sqrt{s} = 13$ TeV) and > 1270 GeV (first generation, CMS, $\beta = 0.5, \sqrt{s} = 13$ TeV) [30]; > 1400 GeV (first generation, ATLAS, $\beta = 1, \sqrt{s} = 13$ TeV) and > 1290 GeV (first generation, ATLAS, $\beta = 0.5, \sqrt{s} = 13$ TeV) [31]; > 1530 GeV (second generation, CMS, $\beta = 1, \sqrt{s} = 13$ TeV) and > 1285 GeV (second generation, CMS, $\beta = 0.5, \sqrt{s} = 13$ TeV) [32]; and > 1560 GeV (second generation, ATLAS, $\beta = 1, \sqrt{s} = 13$ TeV) and > 1230 GeV (second generation, ATLAS, $\beta = 0.5, \sqrt{s} = 13$ TeV) [31]. All limits are presented at 95% C.L.

As for third generation leptoquarks, CMS results are the following: 1) assuming that all leptoquarks decay to a top quark and a τ lepton, the existence of pair produced, third-generation leptoquark up to a mass of 900 GeV ($\beta = 1, 13$ TeV) is excluded at 95% confidence level [33]; 2) assuming that all leptoquarks decay to a bottom quark and a τ lepton, the existence of pair produced, third-generation leptoquark up to a mass of 1020 GeV ($\beta = 1, 13$ TeV) is excluded at 95% confidence level [34]; 3) assuming that all leptoquarks decay to a bottom quark and a τ neutrino, the existence of pair produced, third-generation leptoquark up to a mass of 450 GeV ($\beta = 0, 7$ TeV) is excluded at 95% confidence level [35]. In a recent paper [36], the ATLAS collaboration has limits on pair production of third generation scalar leptoquarks where all possible decays of the leptoquark into a quark (t, b) and a lepton (τ, ν) of the third generation are considered. The limits are presented as a function of the leptoquark mass and the branching ratio into charged leptons for leptoquark of up-type ($LQ_3^{up} \rightarrow \tau\nu/b\tau$) and down-type ($LQ_3^d \rightarrow b\nu/t\tau$); many results are re-interpretation of previously published ATLAS searches. The collaboration finds that masses below 800 GeV are excluded for both LQ_3^u and LQ_3^d independently of the branching ratio, with masses below about 1 TeV being excluded for the limiting cases of branching ratios equal to zero or unity.

It is also possible to consider leptoquark states which couple only with the i -th generation quarks and the j -th generation leptons ($i \neq j$) without causing conflicts with severe indirect constraints. Such couplings have received renewed attention because they may provide an explanation to anomalies in rare $B - meson$ decays and the anomalous magnetic moment of the muon. See Ref. [37], [38] and [39] and references therein for collider search strategies and limits on the pair production cross sections of this class of leptoquark states. In this framework, a novel CMS result [40] presents a non-traditional search for pair production of LQs coupled to a top quark and a muon. As no deviation from the standard model prediction was observed, scalar LQs decaying exclusively into $top - \mu$ are excluded up to masses of 1420 GeV.

The magnetic-dipole-type and the electric-quadrupole-type interactions of a vector leptoquark are not determined even if we fix its gauge quantum numbers as listed in the Table 95.1 [41]. The production of vector leptoquarks depends in general on additional assumptions, where the leptoquark couplings and their pair production cross sections are enhanced relative to the scalar leptoquark contributions. The most stringent limits on vector LQ production are now from CMS [42] where previous searches for squarks and gluinos have been reinterpreted to constrain models of leptoquark production. LQ masses below 1530 GeV are excluded assuming the Yang-Mills case with coupling $\kappa = 1$, or 1115 GeV in the minimal coupling case

where $\kappa = 0$, placing the most stringent constraint to date from pair production of vector LQs.

The leptoquark pair-production cross sections in e^+e^- collisions depend on the leptoquark $SU(2) \times U(1)$ quantum numbers and Yukawa coupling with electron [43].

Searches for first generation leptoquark singly produced were performed by the HERA experiments. Since the leptoquark single-production cross section depends on its Yukawa coupling, the leptoquark mass limits from HERA are usually displayed in the mass-coupling plane. For leptoquark Yukawa coupling $\lambda = 0.1$, early ZEUS Collaboration bounds on the first-generation leptoquarks range from 248 to 290 GeV, depending on the leptoquark species [45]. The ZEUS Collaboration has recently released a new paper [46] where data corresponding to a luminosity of around 1 fb^{-1} have been used in the framework of $eeqq$ contact interactions (CI) to set limits on possible high-energy contributions beyond the Standard Model to electron-quark scattering. The analysis of the ep data has been based on simultaneous fits of parton distribution functions including contributions of Contact Interaction (CI) couplings to ep scattering. Several general CI models and scenarios with heavy leptoquarks were considered. As unambiguous deviations from the SM cannot be established, limits for CI compositeness scales and LQ mass scales were set that are in the TeV range. The H1 Collaboration has a comprehensive summary of searches for first generation leptoquarks using the full data sample collected in ep collisions at HERA (446 pb^{-1}). No evidence of production of leptoquarks was observed in final states with a large transverse momentum electron or large missing transverse momentum. For a coupling strength $\lambda = 0.3$, first generation leptoquarks with masses up to 800 GeV are excluded at 95% C.L. [48].

At the LHC, the CMS collaboration performed searches for single production of first and second generation leptoquarks [49], which is complementary to the HERA searches in the high λ region (for coupling strength $\lambda = 1.0$, first generation leptoquarks are excluded for masses up to 1.73 TeV and second generation leptoquark are excluded up to masses of 530 GeV). CMS also recently searched for third generation LQ decaying into τ and *bottom* in [50]. Assuming unit Yukawa coupling (λ), a third generation scalar leptoquark is excluded for masses below 740 GeV. Limits are also set on λ of the hypothesized leptoquark as a function of its mass. Above $\lambda = 1.4$, the results provide the best upper limit on the mass of a third-generation scalar leptoquark decaying to a τ lepton and a bottom quark.

Searches for LQ will continue with more LHC data, particularly in light of the renewed interest in this type of particle to explain violation of lepton flavor universality and other anomalies, which point to explanations laying outside the Standard Model.

96. Magnetic Monopoles

Revised August 2019 by D. Milstead (Stockholm U.) and E.J. Weinberg (Columbia U.).

96.1 Theory of magnetic monopoles

The symmetry between electric and magnetic fields in the source-free Maxwell's equations naturally suggests that electric charges might have magnetic counterparts, known as magnetic monopoles. Although the greatest interest has been in the super-massive monopoles that are a firm prediction of all grand unified theories, one cannot exclude the possibility of lighter monopoles.

In either case, the magnetic charge is constrained by a quantization condition first found by Dirac [1]. Consider a monopole with magnetic charge Q_M and a Coulomb magnetic field

$$\mathbf{B} = \frac{Q_M}{4\pi} \frac{\hat{\mathbf{r}}}{r^2}. \quad (96.1)$$

Any vector potential \mathbf{A} whose curl is equal to \mathbf{B} must be singular along some line running from the origin to spatial infinity. This Dirac string singularity could potentially be detected through the extra phase that the wavefunction of a particle with electric charge Q_E would acquire if it moved along a loop encircling the string. For the string to be unobservable, this phase must be a multiple of 2π . Requiring that this be the case for any pair of electric and magnetic charges gives the condition that all charges be integer multiples of minimum charges Q_E^{\min} and Q_M^{\min} obeying

$$Q_E^{\min} Q_M^{\min} = 2\pi. \quad (96.2)$$

(For monopoles which also carry an electric charge, called dyons [2], the quantization conditions on their electric charges can be modified. However, the constraints on magnetic charges, as well as those on all purely electric particles, will be unchanged.)

Another way to understand this result is to note that the conserved orbital angular momentum of a point electric charge moving in the field of a magnetic monopole has an additional component, with

$$\mathbf{L} = m\mathbf{r} \times \mathbf{v} - 4\pi Q_E Q_M \hat{\mathbf{r}} \quad (96.3)$$

Requiring the radial component of \mathbf{L} to be quantized in half-integer units yields Eq. 96.1.

If there are unbroken gauge symmetries in addition to the U(1) of electromagnetism, the above analysis must be modified [3] [4]. For example, a monopole could have both a U(1) magnetic charge and a color magnetic charge. The latter could combine with the color charge of a quark to give an additional contribution to the phase factor associated with a loop around the Dirac string, so that the U(1) charge could be the Dirac charge $Q_M^D \equiv 2\pi/e$, the result that would be obtained by substituting the electron charge into Eq. (96.1). On the other hand, for monopoles without color-magnetic charge, one would simply insert the quark electric charges into Eq. 96.1 and conclude that Q_M must be a multiple of $6\pi/e$.

The prediction of GUT monopoles arises from the work of 't Hooft [5] and Polyakov [6], who showed that certain spontaneously broken gauge theories have nonsingular classical solutions that lead to magnetic monopoles in the quantum theory. The simplest example occurs in a theory where the vacuum expectation value of a triplet Higgs field \mathbf{CE} breaks an SU(2) gauge symmetry down to the U(1) of electromagnetism and gives a mass M_V to two of the gauge bosons. In order to have finite energy, \mathbf{CE} must approach a vacuum value at infinity. However, there is a continuous family of possible vacua, since the scalar field potential determines only the magnitude v of $\langle \mathbf{CE} \rangle$, but not its orientation in the internal SU(2) space. In the monopole solution, the direction of \mathbf{CE} in internal space is correlated with the position in physical space; *i.e.*, $\phi^a \sim v\hat{r}^a$. The stability of the solution follows from the fact that this twisting Higgs field cannot be smoothly deformed to a spatially uniform vacuum configuration. Reducing the energetic cost of the spatial variation of \mathbf{CE} requires a nonzero gauge potential, which turns out to yield the magnetic field corresponding to a charge $Q_M = 4\pi/e$. Numerical solution of the classical field equations shows that the mass of this monopole is

$$M_{\text{mon}} \sim \frac{4\pi M_V}{e^2}. \quad (96.4)$$

The essential ingredient here was the fact that the Higgs fields at spatial infinity could be arranged in a topologically nontrivial configuration. A discussion of the general conditions under which this is possible is beyond the scope of this review, so we restrict ourselves to the two phenomenologically most important cases.

The first is the standard electroweak theory, with SU(2) \times U(1) broken to U(1). There are no topologically nontrivial configurations of the Higgs field, and hence no topologically stable monopole solutions.

The second is when any simple Lie group is broken to a subgroup with a U(1) factor, a case that includes all grand unified theories. The monopole mass is determined by the mass scale of the symmetry breaking that allows nontrivial topology. For example, an SU(5) model with

$$\text{SU}(5) \xrightarrow{M_X} \text{SU}(3) \times \text{SU}(2) \times \text{U}(1) \xrightarrow{M_W} \text{SU}(3) \times \text{U}(1) \quad (96.5)$$

has a monopole [7] with $Q_M = 2\pi/e$ and mass

$$M_{\text{mon}} \sim \frac{4\pi M_X}{g^2}, \quad (96.6)$$

where g is the SU(5) gauge coupling. For a unification scale of 10^{16} GeV, these monopoles would have a mass $M_{\text{mon}} \sim 10^{17} - 10^{18}$ GeV.

In theories with several stages of symmetry breaking, monopoles of different mass scales can arise. In an SO(10) theory with

$$\text{SO}(10) \xrightarrow{M_1} \text{SU}(4) \times \text{SU}(2) \times \text{SU}(2) \xrightarrow{M_2} \text{SU}(3) \times \text{SU}(2) \times \text{U}(1) \quad (96.7)$$

there is monopole with $Q_M = 2\pi/e$ and mass $\sim 4\pi M_1/g^2$ and a much lighter monopole with $Q_M = 4\pi/e$ and mass $\sim 4\pi M_2/g^2$ [8].

The central core of a GUT monopole contains the fields of the superheavy gauge bosons that mediate baryon number violation, so one might expect that baryon number conservation could be violated in baryon-monopole scattering. The surprising feature, pointed out by Callan [9] and Rubakov [10], is that these processes are not suppressed by powers of the gauge boson mass. Instead, the cross-sections for catalysis processes such as $p + \text{monopole} \rightarrow e^+ + \pi^0 + \text{monopole}$ are essentially geometric; *i.e.*, $\sigma_{\Delta B} \beta \sim 10^{-27} \text{ cm}^2$, where $\beta = v/c$. Note, however, that this catalysis is model-dependent and is not even a universal property of all GUT monopoles.

96.2 Production and Annihilation

GUT monopoles are far too massive to be produced in any foreseeable accelerator. However, they could have been produced in the early universe as topological defects arising via the Kibble mechanism [11] in a symmetry-breaking phase transition. Estimates of the initial monopole abundance, and of the degree to which it can be reduced by monopole-antimonopole annihilation, predict a present-day monopole abundance that exceeds by many orders of magnitude the astrophysical and experimental bounds described below [12]. Cosmological inflation and other proposed solutions to this primordial monopole problem generically lead to present-day abundances exponentially smaller than could be plausibly detected, although potentially observable abundances can be obtained in scenarios with carefully tuned parameters.

If monopoles light enough to be produced at colliders exist, one would expect that these could be produced by analogs of the electromagnetic processes that produce pairs of electrically charged particles. Because of the large size of the magnetic charge, this is a strong coupling problem for which perturbation theory cannot be trusted. Indeed, the problem of obtaining reliable quantitative estimates of the production cross-sections remains an open one, on which there is no clear consensus.

96.3 Astrophysical and Cosmological Bounds

If there were no galactic magnetic field, one would expect monopoles in the galaxy to have typical velocities of the order of $10^{-3}c$, comparable to the virial velocity in the galaxy (relevant if the monopoles cluster with the galaxy) and the peculiar velocity of the galaxy with respect to the CMB rest frame (relevant

if the monopoles are not bound to the galaxy). This situation is modified by the existence of a galactic magnetic field $B \sim 3\mu\text{G}$. A monopole with the Dirac charge and mass M would be accelerated by this field to a velocity

$$v_{\text{mag}} \sim \begin{cases} c, & M \lesssim 10^{11} \text{ GeV}, \\ 10^{-3}c \left(\frac{10^{17} \text{ GeV}}{M} \right)^{1/2}, & M \gtrsim 10^{11} \text{ GeV}. \end{cases} \quad (96.8)$$

Accelerating these monopoles drains energy from the magnetic field. Parker [13] obtained an upper bound on the flux of monopoles in the galaxy by requiring that the rate of this energy loss be small compared to the time scale on which the galactic field can be regenerated. With reasonable choices for the astrophysical parameters (see Ref. [14] for details), this Parker bound is

$$F < \begin{cases} 10^{-15} \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}, & M \lesssim 10^{17} \text{ GeV}, \\ 10^{-15} \left(\frac{M}{10^{17} \text{ GeV}} \right) \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}, & M \gtrsim 10^{17} \text{ GeV}. \end{cases} \quad (96.9)$$

Applying similar arguments to an earlier seed field that was the progenitor of the current galactic field leads to a tighter bound [15],

$$F < \left[\frac{M}{10^{17} \text{ GeV}} + (3 \times 10^{-6}) \right] 10^{-16} \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}. \quad (96.10)$$

Considering magnetic fields in galactic clusters gives a bound [16] which, although less secure, is about three orders of magnitude lower than the Parker bound.

A flux bound can also be inferred from the total mass of monopoles in the universe. If the monopole mass density is a fraction Ω_M of the critical density, and the monopoles were uniformly distributed throughout the universe, there would be a monopole flux

$$F_{\text{uniform}} = 1.3 \times 10^{-16} \Omega_M \left(\frac{10^{17} \text{ GeV}}{M} \right) \left(\frac{v}{10^{-3}c} \right) \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}. \quad (96.11)$$

If we assume that $\Omega_M \sim 0.1$, this gives a stronger constraint than the Parker bound for $M \sim 10^{15}$ GeV. However, monopoles with masses $\sim 10^{17}$ GeV are not ejected by the galactic field and can be gravitationally bound to the galaxy. In this case their flux within the galaxy is increased by about five orders of magnitude for a given value of Ω_M , and the mass density bound only becomes stronger than the Parker bound for $M \sim 10^{18}$ GeV.

A much more stringent flux bound applies to GUT monopoles that catalyze baryon number violation. The essential idea is that compact astrophysical objects would capture monopoles at a rate proportional to the galactic flux. These monopoles would then catalyze proton decay, with the energy released in the decay leading to an observable increase in the luminosity of the object. A variety of bounds, based on neutron stars [17–21], white dwarfs [22], and Jovian planets [23] have been obtained. These depend in the obvious manner on the catalysis cross section, but also on the details of the astrophysical scenarios; *e.g.*, on how much the accumulated density is reduced by monopole-antimonopole annihilation, and on whether monopoles accumulated in the progenitor star survive its collapse to a white dwarf or neutron star. The bounds obtained in this manner lie in the range

$$F \left(\frac{\sigma_{\Delta B} \beta}{10^{-27} \text{ cm}^2} \right) \sim (10^{-18} - 10^{-29}) \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}. \quad (96.12)$$

It is important to remember that not all GUT monopoles catalyze baryon number nonconservation. In particular, the intermediate mass monopoles that arise in some GUTs at later stages of symmetry-breaking are examples of theoretically motivated monopoles that are exempt from the bound of the above equation.

96.4 Searches for Magnetic Monopoles

To date there have been no confirmed observations of exotic particles possessing magnetic charge. Precision measurements of the properties of known particles have led to tight limits on the values of magnetic charge they may possess. Using the induction method (see below), the electron’s magnetic charge has been found to be $Q_e^m < 10^{-24} Q_M^D$ [24] (where Q_M^D is the Dirac charge). Furthermore, measurements of the anomalous magnetic moment of the muon have been used to place a model dependent lower limit of 120 GeV on the monopole mass¹ [25]. Nevertheless, guided mainly by Dirac’s argument and the predicted existence of monopoles from spontaneous symmetry breaking mechanisms, searches have been routinely made for monopoles produced at accelerators, in cosmic rays, and bound in matter [26]. Although the resultant limits from such searches are usually made under the assumption of a particle possessing only magnetic charge, most of the searches are also sensitive to dyons.

96.5 Search Techniques

Search strategies are determined by the expected interactions of monopoles as they pass through matter. These would give rise to a number of striking characteristic signatures. Since a complete description of monopole search techniques falls outside of the scope of this minireview, only the most common methods are described below. More comprehensive descriptions of search techniques can be found in Refs. [27] [28].

The induction method exploits the long-ranged electromagnetic interaction of the monopole with the quantum state of a superconducting ring which would lead to a monopole which passes through such a ring inducing a permanent current. The induction technique typically uses Superconducting Quantum Interference Devices (SQUID) technology for detection and is employed for searches for monopoles in cosmic rays and matter. Another approach is to exploit the electromagnetic energy loss of monopoles. Monopoles with Dirac charge would typically lose energy at a rate which is several thousand times larger than that expected from particles possessing the elementary electric charge. Consequently, scintillators, gas chambers and nuclear track detectors (NTDs) have been used in cosmic ray and collider experiments. A further approach, which has been used at colliders, is to search for particles describing a non-helical path in a uniform magnetic field.

96.5.1 Searches for Monopoles Bound in Matter

Monopoles have been sought in a range of bulk materials which it is assumed would have absorbed incident cosmic ray monopoles over a long exposure time of order million years. Materials which have been studied include moon rock, meteorites, manganese modules, and sea water [29, 30]. A stringent upper limit on the monopoles per nucleon ratio of $\sim 10^{-29}$ has been obtained [30].

96.5.2 Searches in Cosmic Rays

Direct searches for monopoles in cosmic rays refer to those experiments in which the passage of the monopole is measured by an active detector. Searches made assuming a catalysis processes in which GUT monopoles could induce nucleon decay are discussed in the next section. To interpret the results of the non-catalysis searches, the cross section for the catalysis process is typically either set to zero [31] or assigned a modest value (1mb) [32].

Although early cosmic ray searches using the induction technique [33] and NTDs [34] observed monopole candidates, none of these apparent observations have been confirmed. Recent experiments have typically employed large scale detectors. The MACRO experiment at the Gran Sasso underground laboratory comprised three different types of detector: liquid scintillator, limited stream tubes, and NTDs, which provided a total acceptance of $\sim 10000\text{m}^2$ for an isotropic flux. As shown in Fig. 96.1, this experiment has so far provided the most extensive β -dependent flux limits for GUT monopoles with Dirac charge [32]. Also shown are limits from an experiment at the OHYA mine in Japan [31], which used a 2000m^2 array of NTDs.

In Fig. 96.1, upper flux limits are also shown as a function of mass for monopole speed $\beta > 0.05$. In addition to MACRO

¹ Where no ambiguity is likely to arise, a reference to a monopole implies a particle possessing Dirac charge.

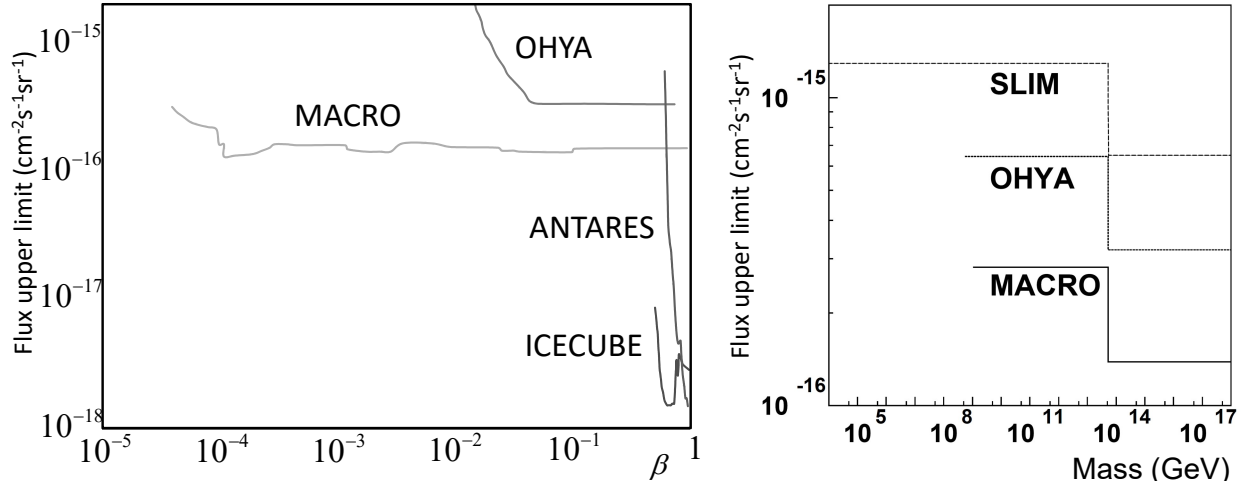

Figure 96.1: Upper flux limits for (left) GUT monopoles as a function of β (right) Monopoles as a function of mass for $\beta > 0.05$.

and OYHA flux limits, results from the SLIM [35] high-altitude experiment are shown. The SLIM experiment provided a good sensitivity to intermediate mass monopoles ($10^5 \lesssim M \lesssim 10^{12}$ GeV). In addition to the results shown in Fig. 96.1, limits as low as $\sim 1.5 \times 10^{-18} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ were obtained for monopoles with $\beta > 0.51$ and $\beta > 0.6$ by the IceCube [36] and Antares [37] experiments, respectively. Stringent constraints on the flux of ultra-relativistic monopoles have been obtained at the Pierre Auger Observatory [38] which was sensitive to monopoles with γ values ranging from 10^9 to 10^{12} , leading to flux limits in the range $10^{-15} - 2.5 \times 10^{-21} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$. The RICE [39] and ANITA-II experiments [40] at the South Pole have also sought ultra-relativistic monopoles with γ values of $10^7 \lesssim \gamma \lesssim 10^{12}$ and $10^9 \lesssim \gamma \lesssim 10^{13}$, respectively, and which produced flux limits as low as $2.5 \times 10^{-21} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$.

96.5.3 Searches via the Catalysis of Nucleon-Decay

Searches have been performed for evidence of the catalysed decay of a nucleon by a monopole, as predicted by the Callan-Rubakov mechanism. The searches are thus sensitive to the assumed value of the catalysis decay cross section. Searches have been made with the Soudan [41] and Macro [42] experiments, using tracking detectors. Searches at IMB [43], the underwater Lake Baikal experiment [44] and the The IceCube experiment [45] which exploit the Cerenkov effect have also been made. The resulting β -dependent flux limits from these experiments typically vary between $\sim 10^{-18}$ and $\sim 10^{-14} \text{ cm}^{-2} \text{ sr}^{-1} \text{ s}^{-1}$. A recent search for low energy neutrinos (assumed to be produced from induced proton decay in the sun) was made at Super-Kamiokande [46]. A model- and β -dependent of limit of $6.3 \times 10^{-24} (\frac{\beta}{10^{-3}})^2 \text{ cm}^{-2} \text{ sr}^{-1} \text{ s}^{-1}$ was obtained.

96.5.4 Searches at Colliders

Searches have been performed at hadron-hadron, electron-positron and lepton-hadron experiments. Collider searches can be broadly classed as being direct or indirect. In a direct search, evidence of the passage of a monopole through material, such as a charged particle track, is sought. In indirect searches, virtual monopole processes are assumed to influence the production rates of certain final states.

96.5.4.1 Direct Searches at Colliders

Collider experiments typically express their results in terms of upper limits on a production cross section and/or monopole mass. To calculate these limits, ansatzes are used to model the kinematics of monopole-antimonopole pair production processes since perturbative field theory cannot be used to calculate the rate and kinematic properties of produced monopoles. Limits therefore suffer from a degree of model-dependence, implying that a comparison between the results of different experiments can be problematic, in particular when this concerns excluded mass re-

gions. A conservative approach with as little model-dependence as possible is thus to present representative values of the upper cross-section limits as a function of one half the centre-of-mass energy of the collisions, as shown in Fig. 96.2 for recent results from high energy colliders.

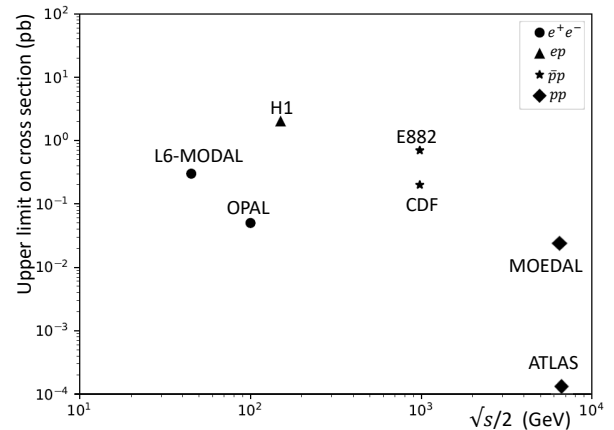

Figure 96.2: Upper limits on the production cross sections of monopoles from various collider-based experiments.

Searches for monopoles produced at the highest available energies in hadron-hadron collisions were made in pp collisions at the LHC by the ATLAS [47, 48] and MoEDAL [49, 50] experiments. The experiments looked for highly ionising particles leaving characteristic energy deposition profiles and stopped monopoles with the induction method, respectively. The charge-dependent mass limits extend up to around 4 TeV. The ATLAS work considers monopoles with $0.5Q_M^D$ and $2Q_M^D$ while MoEDAL quotes limits for monopoles with charges from Q_M^D to $5Q_M^D$. MoEDAL considered monopole-pair production via photon fusion along with, as is commonly used in hadron-hadron collisions, Drell-Yan processes [51]. Tevatron searches have also been carried out by the CDF [52] and E882 [53] experiments. The CDF experiment used a dedicated time-of-flight system whereas the E882 experiment employed the induction technique to search for stopped monopoles in discarded detector material which had been part of the CDF and D0 detectors using periods of luminosity. Earlier searches at the Tevatron, such as [54], used NTDs and were based on comparatively modest amounts of integrated luminosity. Lower energy hadron-hadron experiments have employed a variety of search techniques including plastic track detectors [55] and searches for trapped monopoles [56].

The only LEP-2 search was made by OPAL [57] which quoted

cross section limits for the production of monopoles possessing masses up to around 103 GeV. At LEP-1, searches were made with NTDs deployed around an interaction region. This allowed a range of charges to be sought for masses up to ~ 45 GeV. The L6-MODAL experiment [58] gave limits for monopoles with charges in the range $0.9Q_M^D$ and $3.6Q_M^D$, whilst an earlier search by the MODAL experiment was sensitive to monopoles with charges as low as $0.1Q_M^D$ [59]. The deployment of NTDs around the beam interaction point was also used at earlier e^+e^- colliders such as KEK [60] and PETRA [61]. Searches at e^+e^- facilities have also been made for particles following non-helical trajectories [62] [63].

There has so far been one search for monopole production in lepton-hadron scattering. Using the induction method, monopoles were sought which could have stopped in the aluminium beampipe which had been used by the H1 experiment at HERA [64]. Cross section limits were set for monopoles with charges in the range $Q_M^D - 6Q_M^D$ for masses up to around 140 GeV.

96.5.4.2 Indirect Searches at Colliders

It has been proposed that virtual monopoles can mediate processes which give rise to multi-photon final-states [65] [66]. Photon-based searches were made by the D0 [67] and L3 [68] experiments. The D0 work led to spin-dependent lower mass limits of between 610 and 1580 GeV, while L3 reported a lower mass limit of 510 GeV. However, it should be stressed that uncertainties on the theoretical calculations which were used to derive these limits are difficult to estimate.

INTRODUCTION TO THE PARTICLE LISTINGS

Illustrative key	999
Abbreviations	1000

Illustrative Key to the Particle Listings

Name of particle. "Old" name used before 1986 renaming scheme also given if different. See the section "Naming Scheme for Hadrons" for details.

$a_0(1200)$

$$I^G(J^{PC}) = 1^-(0^{++})$$

Particle quantum numbers (where known).

OMITTED FROM SUMMARY TABLE
Evidence not compelling, may be a kinematic effect.

Indicates particle omitted from Particle Physics Summary Table, implying particle's existence is not confirmed.

Quantity tabulated below.

$a_0(1200)$ MASS

Top line gives our best value (and error) of quantity tabulated here, based on weighted average of measurements used. Could also be from fit, best limit, estimate, or other evaluation. See next page for details.

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	CHG	COMMENT
1206 ± 7 OUR AVERAGE					
1210 ± 8 ± 9	3000	FENNER 87	MMS	-	3.5 $\pi^- p$
1198 ± 10		PIERCE 83	ASPK	+	2.1 $K^- p$
1216 ± 11 ± 9	1500	MERRILL 81	HBC	0	3.2 $K^- p$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
1192 ± 16		LYNCH 81	HBC	±	2.7 $\pi^- p$
1 Systematic error was added quadratically by us in our 1986 edition.					

General comments on particle.

"Document id" for this result; full reference given below.

Measurement technique. (See abbreviations on next page.)

Footnote number linking measurement to text of footnote.

$a_0(1200)$ WIDTH

Number of events above background.

Measured value used in averages, fits, limits, etc.

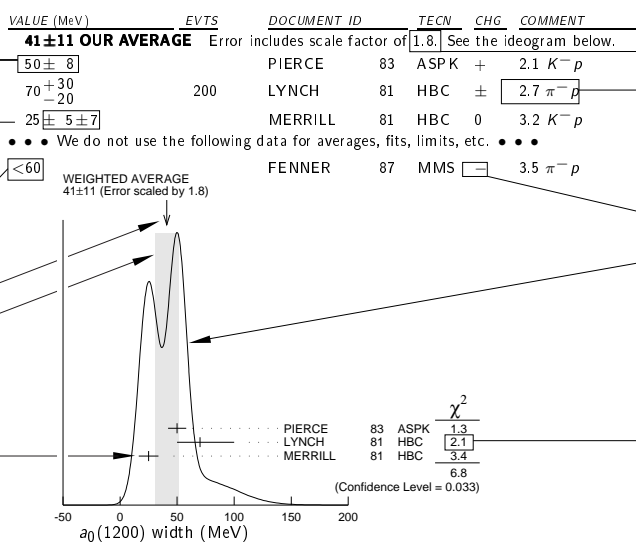

Error in measured value (often statistical only; followed by systematic if separately known; the two are combined in quadrature for averaging and fitting.)

Measured value *not used* in averages, fits, limits, etc. See the Introductory Text for explanations.

Arrow points to weighted average.

Shaded pattern extends $\pm 1\sigma$ (scaled by "scale factor" S) from weighted average.

Value and error for each experiment.

Scale factor > 1 indicates possibly inconsistent data.

Reaction producing particle, or general comments.

"Change bar" indicates result added or changed since previous edition.

Charge(s) of particle(s) detected.

Ideogram to display possibly inconsistent data. Curve is sum of Gaussians, one for each experiment (area of Gaussian = 1/error; width of Gaussian = \pm error). See Introductory Text for discussion.

Contribution of experiment to χ^2 (if no entry present, experiment not used in calculating χ^2 or scale factor because of very large error).

$a_0(1200)$ DECAY MODES

Partial decay mode (labeled by Γ_i).

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Γ_1 3π	(65.2 ± 1.3) %	S=1.7
Γ_2 $K\bar{K}$	(34.8 ± 1.3) %	S=1.7
Γ_3 $\eta\pi^\pm$	< 5 × 10 ⁻⁴	CL=95%

Our best value for branching fraction as determined from data averaging, fitting, evaluating, limit selection, etc. This list is basically a compact summary of results in the Branching Ratio section below.

$a_0(1200)$ BRANCHING RATIOS

Branching ratio.

Our best value (and error) of quantity tabulated, as determined from constrained fit (using *all significant* measured branching ratios for this particle).

Weighted average of measurements of this ratio only.

Footnote (referring to LYNCH 81).

VALUE	DOCUMENT ID	TECN	CHG	COMMENT	Γ_1/Γ	
0.652 ± 0.013 OUR FIT				Error includes scale factor of 1.7.		
0.643 ± 0.010 OUR AVERAGE						
0.64 ± 0.01	PIERCE 83	ASPK	+	2.1 $K^- p$		
0.74 ± 0.06	MERRILL 81	HBC	0	3.2 $K^- p$		
• • • We do not use the following data for averages, fits, limits, etc. • • •						
0.48 ± 0.15	² LYNCH 81	HBC	±	2.7 $\pi^- p$		
² Data has questionable background subtraction.						
$\Gamma(K\bar{K})/\Gamma_{total}$					Γ_2/Γ	
VALUE	DOCUMENT ID	TECN	CHG	COMMENT

Abbreviations Used in the Particle Listings

Indicator of Procedure Used to Obtain Our Result

OUR AVERAGE	From a weighted average of selected data.
OUR FIT	From a constrained or overdetermined multiparameter fit of selected data.
OUR EVALUATION	Not from a direct measurement, but evaluated from measurements of other quantities.
OUR ESTIMATE	Based on the observed range of the data. Not from a formal statistical procedure.
OUR LIMIT	For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

Measurement Techniques

(i.e., Detectors and Methods of Analysis)

A1	A1 Collaboration at MAMI
A2MM	A2 spectrometer at the Mainz Microtron, MAMI
ABRA	ABRACADABRA QCD axion dark matter search
ACCM	ACCMOR Collaboration
ADMX	Axion Dark Matter Experiment
AEMS	Argonne effective mass spectrometer
ALEP	ALEPH – CERN LEP detector
ALPS	Photon regeneration experiment
AMND	AMANDA South Pole neutrino detector
AMY	AMY detector at KEK-TRISTAN
ANAI	Direct DM detection exp. with NaI at Canfranc Underground Lab, Spain
ANIT	Antarctic Impulsive Transient Antenna balloon mission
ANTR	ANTARES underwater neutrino telescope in the Western Mediterranean Sea
APEX	FNAL APEX Collab.
ARG	ARGUS detector at DORIS
ARGD	Fit to semicircular amplitude path on Argand diagram
ASP	Anomalous single-photon detector
ASPK	Automatic spark chambers
ASTE	ASTERIX detector at LEAR
ASTR	Astronomy
ATLS	ATLAS detector at CERN LHC
AUGE	Pierre Auger Observatory
AURG	Resonant-mass gravitational wave AURIGA detector
B787	BNL experiment 787 detector
B791	BNL experiment 791 detector
B845	BNL experiment 845 detector
B852	BNL E-852
B865	BNL E865 detector
B871	BNL experiment 871 detector
B949	BNL E949 detector at AGS
BABR	BaBar Collab.
BAIK	Lake Baikal neutrino telescope
BAKS	Baksan underground scintillation telescope
BC	Bubble chamber
BDMP	Beam dump
BEAT	CERN BEATRICE Collab.
BEBC	Big European bubble chamber at CERN
BELL	Belle Collab.
BES	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BES2	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BES3	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BIS2	BIS-2 spectrometer at Serpukhov
BKEI	BENKEI spectrometer system at KEK Proton Synchrotron
BOLO	Bolometer, a cryogenic thermal detector
BONA	Bonanza nonmagnetic detector at DORIS
BORX	BOREXINO
BPWA	Barrelet-zero partial-wave analysis
C100	COSINE-100 experiment in South Korea
CALO	Calorimeter
CAST	CAST experiment at CERN
CBAL	Crystal Ball detector at SLAC-SPEAR or DORIS
CBAR	Crystal Barrel detector at CERN-LEAR
CBOX	Crystal Box at LAMPF
CBTP	CBELSA/TAPS Collaboration
CC	Cloud chamber
CCFR	Columbia-Chicago-Fermilab-Rochester detector
CDEX	China Dark Matter Experiment
CDF	Collider detector at Fermilab
CDF2	CDF-II Collab.
CDHS	CDHS neutrino detector at CERN
CDM2	CDMS II, Cryogenic Dark Matter Search at Soudan Underground Lab.

CDMS	CDMS Collaboration
CELL	CELLO detector at DESY
CGNT	CoGeNT dark matter search experiment
CHER	Cherenkov detector
CHM2	CHARM-II neutrino detector (glass) at CERN
CHOZ	Nuclear Power Station near Chooz, France
CHRM	CHARM neutrino detector (marble) at CERN
CHRS	CHORUS Collaboration – CERN SPS
CIB	Cosmic Infrared Background
CIBS	CERN-IHEP boson spectrometer
CLAS	Jefferson CLAS Collab.
CLE2	CLEO II detector at CESR
CLE3	CLEO III detector at CESR
CLEC	CLEO-c detector at CESR
CLEO	Cornell magnetic detector at CESR
CMB	Cosmic Microwave Background
CMD	Cryogenic magnetic detector at VEPP-2M, Novosibirsk
CMD2	Cryogenic magnetic detector 2 at VEPP-2M, Novosibirsk
CMD3	Cryogenic magnetic detector 3 at VEPP-2000, Novosibirsk
CMS	CMS detector at CERN LHC
CNTR	Counters
COMB	Combined analysis of data from independent experiments.
COMP	COMPASS experiment at the CERN SPS
COSM	Cosmology and astrophysics
COSY	COSY-TOF Collaboration
COUP	COUPP (the Chicagoland Observatory for Underground Particle Physics) Collab.
CPLR	CPLEAR Collaboration
CRBT	Crystal Ball and TAPS detector at MAMI
CRES	CRESST cryogenic detector
CRYB	Crystal Ball at BNL
CRYM	Crystal Ball detector at Mainz Microtron MAMI
CSB2	Columbia U. - Stony Brook BGO calorimeter inserted in NaI array
CSME	COSME Collaboration
CUOR	CUORICINO experiment at Gran Sasso Laboratory.
CUSB	Columbia U. - Stony Brook segmented NaI detector at CESR
D0	D0 detector at Fermilab Tevatron Collider
DAMA	DAMA, dark matter detector at Gran Sasso National Lab.
DASP	DESY double-arm spectrometer
DAYA	Daya Bay Collaboration
DBC	Deuterium bubble chamber
DCHZ	Double Chooz Collaboration
DEAP	DEAP-3600 DM search with argon at SNOLAB
DISP	Graviton mass measurement based on dispersion measure
DLCO	DELCO detector at SLAC-SPEAR or SLAC-PEP
DLPH	DELPHI detector at LEP
DM1	Magnetic detector no. 1 at Orsay DCI collider
DM2	Magnetic detector no. 2 at Orsay DCI collider
DMIC	DAMIC Dark Matter in CCD experiment at Fermilab
DMTP	Dark Matter Time Projection Chamber (DMTPC) directional detection experiment
DONU	DONUT Collab.
DPWA	Energy-dependent partial-wave analysis
DRFT	Directional dark matter detector at Boulby Underground Science Facility
DS50	DarkSide-50 Liquid Argon TPC at Gran Sasso National Laboratory
E137	SLAC E137 beam-dump experiment
E621	Fermilab E621 detector
E653	Fermilab E653 detector
E665	Fermilab E665 detector
E687	Fermilab E687 detector
E691	Fermilab E691 detector
E705	Fermilab E705 Spectrometer-Calorimeter
E731	Fermilab E731 Spectrometer-Calorimeter
E756	Fermilab E756 detector
E760	Fermilab E760 detector
E761	Fermilab E761 detector
E771	Fermilab E771 detector
E773	Fermilab E773 Spectrometer-Calorimeter
E789	Fermilab E789 detector
E791	Fermilab E791 detector
E799	Fermilab E799 Spectrometer-Calorimeter
E835	Fermilab E835 detector
EDE2	EDELWEISS II dark matter search Collaboration
EDE3	EDELWEISS III dark matter search Collaboration
EDEL	EDELWEISS dark matter search Collaboration
EHS	Four-pi detector at CERN

Abbreviations Used in the Particle Listings

ELEC	Electronic combination	KOLR	Kolar Gold Field underground detector
EMC	European muon collaboration detector at CERN	KOTO	KOTO experiment with K_L^0 beam at J-PARC
EMUL	Emulsions	KTEV	KTeV Collaboration
ESR	Electron spin resonance spectroscopy	L3	L3 detector at LEP
FAST	Fiber Active Scintillator Target detector at PSI	LASR	Laser
FBC	Freon bubble chamber	LASS	Large-angle superconducting solenoid spectrometer at SLAC
FENI	FENICE (at the ADONE collider of Frascati)	LATT	Lattice calculations
FIT	Fit to previously existing data	LEBC	Little European bubble chamber at CERN
FLAT	Large Area Telescope onboard the Fermi Gamma-Ray Space Telescope (Fermi-LAT)	LEGS	BNL LEGS Collab.
FMPS	Fermilab Multiparticle Spectrometer	LENA	Nonmagnetic lead-glass NaI detector at DORIS
FOCS	FNAL E831 FOCUS Collab.	LEP	From combination of all 4 LEP experiments: ALEPH, DELPHI, L3, OPAL
FRAB	ADONE $B\bar{B}$ group detector	LEPS	Low-Energy Pion Spectrometer at the Paul Scherrer Institute
FRAG	ADONE $\gamma\gamma$ group detector	LGW	Lead Glass Wall collaboration at SPEAR/SLAC
FRAM	ADONE MEA group detector	LHC	Combined analysis of LHC experiments
FREJ	FREJUS Collaboration – modular flash chamber detector (calorimeter)	LHCB	LHCb detector at CERN LHC
GA24	Hodoscope Cherenkov γ calorimeter (IHEP GAMS-2000) (CERN GAMS-4000)	L+P	Multichannel L + P model fit
GALX	GALLEX solar neutrino detector in the Gran Sasso Underground Lab.	LSD	Mont Blanc liquid scintillator detector
GAM2	IHEP hodoscope Cherenkov γ calorimeter GAMS-2000	LSND	Liquid Scintillator Neutrino Detector
GAM4	CERN hodoscope Cherenkov γ calorimeter GAMS-4000	LSW	Light Shining through a Wall
GAMS	IHEP hodoscope Cherenkov γ calorimeter GAMS-4 π	LUX	Large Underground Xenon experiment at SURF
GNO	Gallium Neutrino Observatory in the Gran Sasso Underground Lab.	MAC	MAC detector at PEP/SLAC
GOLI	CERN Goliath spectrometer	MAJD	Majorana Demonstrator experiment at SURF
GRAL	GRAAL Collaboration	MBNE	Fermilab MiniBooNE neutrino experiment
H1	H1 detector at DESY/HERA	MBR	Molecular beam resonance technique
HAWC	High Altitude Water Cherenkov Observatory experiment at Sierra Negra, Mexico	MCRO	MACRO detector in Gran Sasso
HBC	Hydrogen bubble chamber	MD1	Magnetic detector at VEPP-4, Novosibirsk
HDBC	Hydrogen and deuterium bubble chambers	MDRP	Millikan drop measurement
HDES	HADES Collaboration at GSI in Darmstadt	MEG	Muon to electron conversion detector at PSI
HDMO	Heidelberg-Moscow Experiment	MGFL	MAGIC and Fermi-LAT Collaborations
HDMS	Heidelberg Dark Matter Search Experiment	MGIC	MAGIC Telescopes gamma-ray observatory
HEBC	Helium bubble chamber	MICA	Underground mica deposits
HEPT	Helium proportional tubes	MICR	MICROSCOPE satellite test of weak equivalence principle
HERA	H1 and ZEUS Collaborations at DESY/HERA	MINS	Fermilab MINOS experiment
HERB	HERA-B detector at DESY/HERA	MIRA	MIRABELLE Liquid-hydrogen bubble chamber
HERM	HERMES detector at DESY/HERA	MLEV	Magnetic levitation
HESS	High Energy Stereoscopic System gamma-ray instrument	MLS	Modified Laurent Series
HFS	Hyperfine structure	MMS	Missing mass spectrometer
HLBC	Heavy-liquid bubble chamber	MOED	MoEDAL magnetic monopoles search experiment at LHC
HOME	Homestake underground scintillation detector	MPS	Multiparticle spectrometer at BNL
HPGE	High-purity Germanium detector	MPS2	Multiparticle spectrometer upgrade at BNL
HPS	Heavy Photon Search experiment at JLAB	MPSF	Multiparticle spectrometer at Fermilab
HPW	Harvard-Pennsylvania-Wisconsin detector	MPWA	Model-dependent partial-wave analysis
HRS	SLAC high-resolution spectrometer	MRK1	SLAC Mark-I detector
HYBR	Hybrid: bubble chamber + electronics	MRK2	SLAC Mark-II detector
HYCP	HyperCP Collab. (FNAL E-871)	MRK3	SLAC Mark-III detector
HYST	HAYSTAC axion search experiment	MRKJ	Mark-J detector at DESY
IACT	Imaging Air Cherenkov Telescope	MRS	Magnetic resonance spectrometer
ICAR	ICARUS experiment at Gran Sasso Laboratory.	MUG2	Muon ($g-2$)
ICCB	IceCube neutrino detector at South Pole	MWPC	Multi-Wire Proportional Chamber
IGEX	IGEX Collab.	NA14	CERN NA14
IMB	Irvine-Michigan-Brookhaven underground Cherenkov detector	NA31	CERN NA31 Spectrometer-Calorimeter
IMB3	Irvine-Michigan-Brookhaven underground Cherenkov detector	NA32	CERN NA32 Spectrometer
INDU	Magnetic induction	NA48	CERN NA48 Collaboration
IPWA	Energy-independent partial-wave analysis	NA49	CERN NA49 Collaboration
ISTR	IHEP ISTR+ spectrometer-calorimeter	NA60	CERN NA60 Collaboration
JADE	JADE detector at DESY	NA62	CERN NA62 Experiment
JPAC	Joint Physics Analysis Center (JPAC) Collaboration	NA64	CERN SPS NA64 Experiment
K246	KEK E246 detector with polarimeter	NAGE	NEWAGE, New generation WIMP-search experiment with advanced gaseous tracking
K2K	KEK to Super-Kamiokande	NAIA	NAIAD (NaI Advanced Detector) dark matter search experiment
K391	KEK E391a detector	ND	NaI detector at VEPP-2M, Novosibirsk
K470	KEK-E470 Stopping K detector	NEOS	NEOS Collaboration
KAM2	KAMIOKANDE-II underground Cherenkov detector	NEWS	NEWS-G direct dark matter search at LSM
KAMI	KAMIOKANDE underground Cherenkov detector	NICE	Serpukhov nonmagnetic precision spectrometer
KAR2	KARMEN2 calorimeter at the ISIS neutron spallation source at Rutherford	NMR	Nuclear magnetic resonance
KARM	KARMEN calorimeter at the ISIS neutron spallation source at Rutherford	NOMD	NOMAD Collaboration, CERN SPS
KEDR	detector operating at VEPP-4M collider (Novosibirsk)	NOVA	NOvA experiment with Fermilab's NuMI neutrino beam
KIMS	Korea Invisible Mass Search experiment at YangYang, Korea	NTEV	NuTeV Collab. at Fermilab
KLND	KamLand Collab. (Japan)	nTRV	neutron Time-Reversal Violation
KLOE	KLOE detector at DAFNE (the Frascati e+e- collider Italy)	NUSX	Mont Blanc NUSEX underground detector
		OBLX	OBELIX detector at LEAR
		OKA	OKA collaboration at U70 accelerator in Protvino, Russia
		OLYA	Detector at VEPP-2M and VEPP-4, Novosibirsk
		OMEG	CERN OMEGA spectrometer
		OPAL	OPAL detector at LEP
		OPER	OPERA experiment with emulsion tracking at Gran Sasso

Abbreviations Used in the Particle Listings

OSPK Optical spark chamber
 PIBE The PIBETA detector at the Paul Scherrer Institute (PSI), Switzerland.
 PICA PICASSO dark matter search experiment
 PICO PICO bubble chamber experiment in SNOLAB underground laboratory
 PIE3 π E3 beam-line of Paul Scherrer Institute
 PLAS Plastic detector
 PLUT DESY PLUTO detector
 PMLA PAMELA space spectrometer on Resurs-DK1 satellite
 PNDX PandaX dual-phase liquid xenon dark matter experiment at Jin-Ping
 PPTA Parkes Pulsar Timing Array
 PRMX The PRIMEX detector in Hall B at TJNAF
 PWA Partial-wave analysis
 QUAX QUAX axion search experiment
 RDK2 NIST rare radioactive decay experiment
 REDE Resonance depolarization
 RENO RENO Collaboration
 RICE Radio Ice Cherenkov Experiment
 RVUE Review of previous data
 SAGE US - Russian Gallium Experiment
 SCDM SuperCDMS experiment at Soudan Underground Lab.
 SELX FNAL SELEX Collab.
 SENS Sub-Electron-Noise Skipper CCD Experimental Instrument (SENSEI)
 SFM CERN split-field magnet
 SHF SLAC Hybrid Facility Photon Collaboration
 SHUK SHUKET: search for U(1) dark matter with an electromagnetic telescope
 SIGM Serpukhov CERN-IHEP magnetic spectrometer (SIGMA)
 SILI Silicon detector
 SIMP SIMPLE, dark matter detector at Laboratori Nazionali del Sud
 SKAM Super-Kamiokande Collab.
 SLAX Solar Axion Experiment in Canfranc Underground Laboratory
 SLD SLC Large Detector for e^+e^- colliding beams at SLAC
 SMPL SIMPLE, Superheated Instrument for Massive Particle Experiments
 SND Novosibirsk Spherical neutral detector at VEPP-2M
 SNDR SINDRUM spectrometer at PSI
 SNO SNO Collaboration (Sudbury Neutrino Observatory)
 SNO+ SNO+ Collaboration (Sudbury Neutrino Observatory)
 SOU2 Soudan 2 underground detector
 SOUD Soudan underground detector
 SPEC Spectrometer
 SPED From maximum of speed plot or resonant amplitude
 SPHR Bonn SAPHIR Collab.
 SPNX SPHINX spectrometer at IHEP accelerator
 SPRK Spark chamber
 SQID SQUID device
 STRC Streamer chamber
 SVD2 SVD-2 experiment at IHEP, Protvino
 T2K T2K Collaboration
 TASS DESY TASSO detector
 TEVA Combined analysis of CDF and $D\bar{0}$ experiments
 TEXO TEXONO Collab., ultra low energy Ge detector at Kuo-Sheng Laboratory
 THEO Theoretical or heavily model-dependent result
 TNF TNF-IHEP facility at 70 GeV IHEP accelerator
 TOF Time-of-flight
 TOPZ TOPAZ detector at KEK-TRISTAN
 TPC TPC detector at PEP/SLAC
 TPS Tagged photon spectrometer at Fermilab
 TRAP Penning trap
 TWST TWIST spectrometer at TRIUMF
 UA1 UA1 detector at CERN
 UA2 UA2 detector at CERN
 UA5 UA5 detector at CERN
 UCNA UCNA collaboration using polarized ultracold neutrons at LANSCE
 UKDM UK Dark Matter Collab.
 VES Vertex Spectrometer Facility at 70 GeV IHEP accelerator
 VLBI Very Long Baseline Interferometer
 VNS VENUS detector at KEK-TRISTAN
 VRTS Very Energetic Radiation Imaging Telescope Array System (VERITAS)
 WA75 CERN WA75 experiment
 WA82 CERN WA82 experiment

WA89 CERN WA89 experiment
 WARP Liquid argon detector for CDM searches at Gran Sasso
 WASA WASA detector at CELSIUS, Uppsala and at COSY, Juelich
 WDMX WISP Dark Matter eXperiment (WISPDIMX) for direct hidden photon search
 WIRE Wire chamber
 X100 XENON100 dark matter search experiment at Gran Sasso National Laboratory
 XE10 XENON10 experiment at Gran Sasso National Laboratory
 XE1T XENON1T dark matter search experiment at Gran Sasso National Laboratory
 XEBC Xenon bubble chamber
 XMAS XMASS, liquid xenon scintillation detector at Kamioka Observatory
 YUKA Graviton mass measurement based on Yukawa potential
 ZEP2 ZEPLIN-II dark matter detector
 ZEP3 ZEPLIN-III dark matter detector at Palmer Underground Lab.
 ZEPL ZEPLIN-I galactic dark matter detector
 ZEUS ZEUS detector at DESY/HERA

Conferences

Conferences are generally referred to by the location at which they were held (e.g., HAMBURG, TORONTO, CORNELL, BRIGHTON, etc.).

γ MASS

Results prior to 2008 are critiqued in GOLDHABER 10. All experimental results published prior to 2005 are summarized in detail by TU 05.

The following conversions are useful: $1 \text{ eV} = 1.783 \times 10^{-33} \text{ g} = 1.957 \times 10^{-6} m_e$; $\chi_C = (1.973 \times 10^{-7} \text{ m})(1 \text{ eV}/m_\gamma)$.

- RYUTOV 07 extends the method of RYUTOV 97 to the radius of Pluto's orbit.
- BONETTI 17 uses frequency-dependent time delays of repeating FRB with well-determined redshift, assuming the DM is caused by expected dispersion in IGM. There are several uncertainties, leading to mass limit $2.2 \times 10^{-14} \text{ eV}$.
- BONETTI 16 uses frequency-dependent time delays of FRB, assuming the DM is caused by expected dispersion in IGM. There are several uncertainties, leading to mass limit $1.8 \times 10^{-14} \text{ eV}$, if indeed the FRB is at the initially reported redshift.
- RETINO 16 looks for deviations from Ampere's law in the solar wind, using Cluster four spacecraft data. Authors quote a range of limits from $1.9 \times 10^{-15} \text{ eV}$ to $7.9 \times 10^{-14} \text{ eV}$ depending on the assumptions of the vector potential from the interplanetary magnetic field.
- EGOROV 14 studies chromatic dispersion of lensed quasar positions ("gravitational rainbows") that could be produced by any of several mechanisms, among them via photon mass. Limit not competitive but obtained on cosmological distance scales.
- ACCIOLY 10 limits come from possible alterations of anomalous magnetic moment of electron and gravitational deflection of electromagnetic radiation. Reported limits are not "claimed" by the authors and in any case are not competitive.
- When trying to measure m one must distinguish between measurements performed on large and small scales. If the photon acquires mass by the Higgs mechanism, the large-scale behavior of the photon might be effectively Maxwellian. If, on the other hand, one postulates the Proca regime for all scales, the very existence of the galactic field implies $m < 10^{-26} \text{ eV}$, as correctly calculated by YAMAGUCHI 59 and CHIBISOV 76.
- TU 06 continues the work of LUO 03, with extended LAKES 98 method, reporting the improved limit $\mu^2 A = (0.7 \pm 1.7) \times 10^{-13} \text{ T/m}$ if $A = 0.2 \mu\text{G}$ out to $4 \times 10^{22} \text{ m}$. Reported result $\mu = (0.9 \pm 1.5) \times 10^{-52} \text{ g}$ reduces to the frequentist mass limit $1.2 \times 10^{-19} \text{ eV}$ (FELDMAN 98).
- FULLEKRUG 04 adopted KROLL 71A method with newer and better Schumann resonance data. Result questionable because assumed frequency shift with photon mass is assumed to be linear. It is quadratic according to theorem by GOLDHABER 71B, KROLL 71, and PARK 71.
- LUO 03 extends LAKES 98 technique to set a limit on $\mu^2 A$, where μ^{-1} is the Compton wavelength χ_C of the massive photon and A is the ambient vector potential. The important departure is that the apparatus rotates, removing sensitivity to the direction of A . They take $A = 10^{12} \text{ Tm}$, due to "cluster level fields." But see comment of GOLDHABER 03 and reply by LUO 03B.
- LAKES 98 reports limits on torque on a toroid Cavendish balance, obtaining a limit on $\mu^2 A < 2 \times 10^{-9} \text{ Tm}^2/\text{m}^2$ via the Maxwell-Proca equations, where μ^{-1} is the characteristic length associated with the photon mass and A is the ambient vector potential in the Lorentz gauge. Assuming $A \approx 1 \times 10^{12} \text{ Tm}$ due to cluster fields he obtains $\mu^{-1} > 2 \times 10^{10} \text{ m}$, corresponding to $\mu < 1 \times 10^{-17} \text{ eV}$. A more conservative limit, using $A \approx (1 \mu\text{G})(600 \text{ pc})$ based on the galactic field, is $\mu^{-1} > 1 \times 10^9 \text{ m}$ or $\mu < 2 \times 10^{-16} \text{ eV}$.
- RYUTOV 97 uses a magnetohydrodynamics argument concerning survival of the Sun's field to the radius of the Earth's orbit. "To reconcile observations to theory, one has to

- reduce [the photon mass] by approximately an order of magnitude compared with" per DAVIS 75. "Secure limit, best by this method" (per GOLDHABER 10).
- FISCHBACH 94 analysis is based on terrestrial magnetic fields; approach analogous to DAVIS 75. Similar result based on a much smaller planet probably follows from more precise B field mapping. "Secure limit, best by this method" (per GOLDHABER 10).
 - CHERNIKOV 92, motivated by possibility that photon exhibits mass only below some unknown critical temperature, searches for departure from Ampere's Law at 1.24 K. See also RYAN 85.
 - RYAN 85, motivated by possibility that photon exhibits mass only below some unknown critical temperature, sets mass limit at $< (1.5 \pm 1.4) \times 10^{-42} \text{ g}$ based on Coulomb's Law departure limit at 1.36 K. We report the result as frequentist 90% CL (FELDMAN 98).
 - CHIBISOV 76 depends in critical way on assumptions such as applicability of virial theorem. Some of the arguments given only in unpublished references.
 - DAVIS 75 analysis of Pioneer-10 data on Jupiter's magnetic field. "Secure limit, best by this method" (per GOLDHABER 10).
 - FRANKEN 71 method is of dubious validity (KROLL 71A, JACKSON 99, GOLDHABER 10, and references therein).
 - KROLL 71A used low frequency Schumann resonances in cavity between the conducting earth and resistive ionosphere, overcoming objections to resonant-cavity methods (JACKSON 99, GOLDHABER 10, and references therein). "Secure limit, best by this method" (per GOLDHABER 10).
 - WILLIAMS 71 is landmark test of Coulomb's law. "Secure limit, best by this method" (per GOLDHABER 10).

γ CHARGE

OKUN 06 has argued that schemes in which all photons are charged are inconsistent. He says that if a neutral photon is also admitted to avoid this problem, then other problems emerge, such as those connected with the emission and absorption of charged photons by charged particles. He concludes that in the absence of a self-consistent phenomenological basis, interpretation of experimental data is at best difficult.

VALUE (e)	CHARGE	DOCUMENT ID	TECN	COMMENT
<1 × 10⁻⁴⁶	mixed	1 ALTSCHUL 07B	VLBI	Aharonov-Bohm effect
<1 × 10⁻³⁵	single	2 CAPRINI 05	CMB	Isotropy constraint
• • • We do not use the following data for averages, fits, limits, etc. • • •				
<1 × 10 ⁻³²	single	1 ALTSCHUL 07B	VLBI	Aharonov-Bohm effect
<3 × 10 ⁻³³	mixed	3 KOBYCHEV 05	VLBI	Smear as function of B-E _γ
<4 × 10 ⁻³¹	single	3 KOBYCHEV 05	VLBI	Deflection as function of B-E _γ
<8.5 × 10 ⁻¹⁷		4 SEMERTZIDIS 03		Laser light deflection in B-field
<3 × 10 ⁻²⁸	single	5 SIVARAM 95	CMB	For $\Omega_M = 0.3, h^2 = 0.5$
<5 × 10 ⁻³⁰		6 RAFFELT 94	TOF	Pulsar $t_1 - t_2$
<2 × 10 ⁻²⁸		7 COCCONI 92		VLBA radio telescope resolution
<2 × 10 ⁻³²		COCCONI 88	TOF	Pulsar $t_1 - t_2$ TOF

- ALTSCHUL 07B looks for Aharonov-Bohm phase shift in addition to geometric phase shift in radio interference fringes (VSOP mission).
- CAPRINI 05 uses isotropy of the cosmic microwave background to place stringent limits on possible charge asymmetry of the Universe. Charge limits are set on the photon, neutrino, and dark matter particles. Valid if charge asymmetries produced by different particles are not anticorrelated.
- KOBYCHEV 05 considers a variety of observable effects of photon charge for extragalactic compact radio sources. Best limits if source observed through a foreground cluster of galaxies.
- SEMERTZIDIS 03 reports the first laboratory limit on the photon charge in the last 30 years. Straightforward improvements in the apparatus could attain a sensitivity of 10^{-20} e .
- SIVARAM 95 requires that CMB photon charge density not overwhelm gravity. Result scales as $\Omega_M h^2$.
- RAFFELT 94 notes that COCCONI 88 neglects the fact that the time delay due to dispersion by free electrons in the interstellar medium has the same photon energy dependence as that due to bending of a charged photon in the magnetic field. His limit is based on the assumption that the entire observed dispersion is due to photon charge. It is a factor of 200 less stringent than the COCCONI 88 limit.
- See COCCONI 92 for less stringent limits in other frequency ranges. Also see RAFFELT 94 note.

graviton

$$J = 2$$

graviton MASS

Van Dam and Veltman (VANDAM 70), Iwasaki (IWASAKI 70), and Zakharov (ZAKHAROV 70) almost simultaneously showed that "... there is a discrete difference between the theory with zero-mass and a theory with finite mass, no matter how small as compared to all external momenta." The resolution of this "vDVZ discontinuity" has to do with whether the linear approximation is valid. De Rham *et al.* (DE-RHAM 11) have shown that nonlinear effects not captured in their linear treatment can give rise to a screening mechanism, allowing for massive gravity theories. See also GOLDHABER 10 and DE-RHAM 17 and references therein. Experimental limits have been set based on a Yukawa potential or signal dispersion. h_0 is the Hubble constant in units of $100 \text{ km s}^{-1} \text{ Mpc}^{-1}$.

The following conversions are useful: $1 \text{ eV} = 1.783 \times 10^{-33} g = 1.957 \times 10^{-6} m_e$; $\chi_C = (1.973 \times 10^{-7} \text{ m}) \times (1 \text{ eV}/m_e)$.

- CHOUDHURY 04 concludes from a study of weak-lensing data that masses heavier than about the inverse of 100 Mpc seem to be ruled out if the gravitation field has the Yukawa form.
- DESAI 18 limit based on dynamical mass models of galaxy cluster Abell 1689.
- GUPTA 18 obtains graviton mass limits using stacked clusters from 3 disparate surveys.
- RANA 18 limit, 68% CL, obtained using weak lensing mass profiles out to the radius at which the cluster density falls to 200 times the critical density of the Universe. Limit is based on the fractional change between Newtonian and Yukawa accelerations for the 50 most massive galaxy clusters in the Local Cluster Substructure Survey. Limits for other CL's and other density cuts are also given.
- RANA 18 limit, 68% CL, obtained using mass measurements via the SZ effect out to the radius at which the cluster density falls to 500 times the critical density of the Universe for 182 optically confirmed galaxy clusters in an Altacama Cosmology Telescope survey. Limits for other CL's and other density cuts are also given.
- ABBOTT 16 and ABBOTT 17 assumed a dispersion relation for gravitational waves modified relative to GR.
- ZAKHAROV 16 constrains range of Yukawa gravity interaction from S2 star orbit about black hole at Galactic center. The limit is $< 2.9 \times 10^{-21} \text{ eV}$ for $\delta = 100$.
- BRITO 13 explore massive graviton (spin-2) fluctuations around rotating black holes.
- BASKARAN 08 consider fluctuations in pulsar timing due to photon interactions ("surfing") with background gravitational waves.
- GRUZINOV 05 uses the DGP model (DVALI 00) showing that non-perturbative effects restore continuity with Einstein's equations as the graviton mass approaches 0, then bases his limit on Solar System observations.
- GERSHTEIN 04 use non-Einstein field relativistic theory of gravity (RTG), with a massive graviton, to obtain the 95% CL mass limit implied by the value of $\Omega_{tot} = 1.02 \pm 0.02$ current at the time of publication.
- DVALI 03 suggest scale of horizon distance via DGP model (DVALI 00). For a horizon distance of $3 \times 10^{26} \text{ m}$ (about age of Universe/ c ; GOLDHABER 10) this graviton mass limit is implied.
- FINN 02 analyze the orbital decay rates of PSR B1913+16 and PSR B1534+12 with a possible graviton mass as a parameter. The combined frequentist mass limit is at 90% CL.
- As of 2014, limits on dP/dt are now about 0.1% (see T. Damour, "Experimental tests of gravitational theory," in this Review).
- DAMOUR 91 is an analysis of the orbital period change in binary pulsar PSR 1913+16, and confirms the general relativity prediction to 0.8%. "The theoretical importance of the [rate of orbital period decay] measurement has long been recognized as a direct confirmation that the gravitational interaction propagates with velocity c (which is the immediate cause of the appearance of a damping force in the binary pulsar system) and thereby as a test of the existence of gravitational radiation and of its quadrupolar nature." TAYLOR 93 adds that orbital parameter studies now agree with general relativity to 0.5%, and set limits on the level of scalar contribution in the context of a family of tensor [spin 2]-biscalar theories.

Mass and Width of the W Boson

W MASS

The W-mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass-dependent width. To obtain the world average, common systematic uncertainties between experiments are properly taken into account. The LEP-2 average W mass based on published results is $80.376 \pm 0.033 \text{ GeV}$ [SCHAEL 13a]. The combined Tevatron data yields an average W mass of $80.387 \pm 0.016 \text{ GeV}$ [AALTONEN 13n]. A combination of the LEP average with this Tevatron average and the ATLAS value [AABOUD 18j], assuming a common systematic error of 7 MeV between the latter two [Jens Erler, 52nd Rencontres de Moriond

EW, March 2017], the world average W mass of 80.379 ± 0.012 GeV is obtained. OUR FIT quotes this value for the W mass.

- AABOUD 18J select $4.61M W^+ \rightarrow \mu^+ \nu_\mu$, $3.40M W^+ \rightarrow e^+ \nu_e$, $3.23M W^- \rightarrow \mu^- \bar{\nu}_\mu$ and $2.49M W^- \rightarrow e^- \bar{\nu}_e$ events in $4.6 \text{ fb}^{-1} pp$ data at 7 TeV. The W mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations. The systematic error includes 0.011 GeV experimental and 0.014 GeV modelling uncertainties.
- ABAZOV 14N is a combination of ABABOV 09AB and ABABOV 12F, also giving more details on the analysis.
- AALTONEN 12E select $470k W \rightarrow e \nu$ decays and $625k W \rightarrow \mu \nu$ decays in 2.2 fb^{-1} of Run-II data. The mass is determined using the transverse mass, transverse lepton momentum and transverse missing energy distributions, accounting for correlations. This result supersedes AALTONEN 07F. AALTONEN 14D gives more details on the procedures followed by the authors.
- ABDALLAH 08A use direct reconstruction of the kinematics of $W^+ W^- \rightarrow q \bar{q} \ell \nu$ and $W^+ W^- \rightarrow q \bar{q} q \bar{q}$ events for energies 172 GeV and above. The W mass was also extracted from the dependence of the WW cross section close to the production threshold and combined appropriately to obtain the final result. The systematic error includes ± 0.025 GeV due to final state interactions and ± 0.009 GeV due to LEP energy uncertainty.
- ABBIENDI 06 use direct reconstruction of the kinematics of $W^+ W^- \rightarrow q \bar{q} \ell \nu \ell$ and $W^+ W^- \rightarrow q \bar{q} q \bar{q}$ events. The result quoted here is obtained combining this mass value with the results using $W^+ W^- \rightarrow \ell \nu \ell \ell \nu \ell$ events in the energy range 183–207 GeV (ABBIENDI 03C) and the dependence of the WW production cross-section on m_{WW} at threshold. The systematic error includes ± 0.009 GeV due to the uncertainty on the LEP beam energy.
- ACHARD 06 use direct reconstruction of the kinematics of $W^+ W^- \rightarrow q \bar{q} \ell \nu \ell$ and $W^+ W^- \rightarrow q \bar{q} q \bar{q}$ events in the C.M. energy range 189–209 GeV. The result quoted here is obtained combining this mass value with those obtained from a direct W mass reconstruction at 172 and 183 GeV and with those from the dependence of the WW production cross-section on m_{WW} at 161 and 172 GeV (ACCIARRI 99).
- SCHAEEL 06 use direct reconstruction of the kinematics of $W^+ W^- \rightarrow q \bar{q} \ell \nu \ell$ and $W^+ W^- \rightarrow q \bar{q} q \bar{q}$ events in the C.M. energy range 183–209 GeV. The result quoted here is obtained combining this mass value with those obtained from the dependence of the W pair production cross-section on m_{WW} at 161 and 172 GeV (BARATE 97 and BARATE 97s respectively). The systematic error includes ± 0.009 GeV due to possible effects of final state interactions in the $q \bar{q} q \bar{q}$ channel and ± 0.009 GeV due to the uncertainty on the LEP beam energy.
- ABAZOV 02D improve the measurement of the W -boson mass including $W \rightarrow e \nu_e$ events in which the electron is close to a boundary of a central electromagnetic calorimeter module. Properly combining the results obtained by fitting $m_T(W)$, $p_T(e)$, and $p_T(\nu)$, this sample provides a mass value of 80.574 ± 0.045 GeV. The value reported here is a combination of this measurement with all previous DØ W -boson mass measurements.
- AFFOLDER 01E fit the transverse mass spectrum of 30115 $W \rightarrow e \nu_e$ events ($M_{WW} = 80.473 \pm 0.065 \pm 0.092$ GeV) and of 14740 $W \rightarrow \mu \nu_\mu$ events ($M_{WW} = 80.465 \pm 0.100 \pm 0.103$ GeV) obtained in the run IB (1994–95). Combining the electron and muon results, accounting for correlated uncertainties, yields $M_{WW} = 80.470 \pm 0.089$ GeV. They combine this value with their measurement of ABE 95P reported in run IA (1992–93) to obtain the quoted value.
- ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic $e^+ p$ and $e^- p$ neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.

- ABAZOV 12F select $1677k W \rightarrow e \nu$ decays in 4.3 fb^{-1} of Run-II data. The mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations.
- ABAZOV 09AB study the transverse mass, transverse electron momentum, and transverse missing energy in a sample of 0.5 million $W \rightarrow e \nu$ decays selected in Run-II data. The quoted result combines all three methods, accounting for correlations.
- AALTONEN 07F obtain high purity $W \rightarrow e \nu_e$ and $W \rightarrow \mu \nu_\mu$ candidate samples totaling 63,964 and 51,128 events respectively. The W mass value quoted above is derived by simultaneously fitting the transverse mass and the lepton, and neutrino p_T distributions.
- AKTAS 06 fit the Q^2 dependence ($300 < Q^2 < 30,000 \text{ GeV}^2$) of the charged-current differential cross section with a propagator mass. The first error is experimental and the second corresponds to uncertainties due to input parameters and model assumptions.
- CHEKANOV 02c fit the Q^2 dependence ($200 < Q^2 < 60000 \text{ GeV}^2$) of the charged-current differential cross sections with a propagator mass fit. The last error is due to the uncertainty on the probability density functions.
- BREITWEG 00D fit the Q^2 dependence ($200 < Q^2 < 22500 \text{ GeV}^2$) of the charged-current differential cross sections with a propagator mass fit. The last error is due to the uncertainty on the probability density functions.
- ALITTI 92B result has two contributions to the systematic error (± 0.83); one (± 0.81) cancels in m_{W/m_Z} and one (± 0.17) is noncancelling. These were added in quadrature. We choose the ALITTI 92B value without using the LEP m_Z value, because we perform our own combined fit.
- There are two contributions to the systematic error (± 0.84): one (± 0.81) which cancels in m_{W/m_Z} and one (± 0.21) which is non-cancelling. These were added in quadrature.
- ABE 89I systematic error dominated by the uncertainty in the absolute energy scale.
- ALBAJAR 89 result is from a total sample of 299 $W \rightarrow e \nu$ events.
- ALBAJAR 89 result is from a total sample of 67 $W \rightarrow \mu \nu$ events.
- ALBAJAR 89 result is from $W \rightarrow \tau \nu$ events.

The W mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations. The systematic error includes 0.007 GeV experimental and 0.024 GeV modelling uncertainties.

W WIDTH

The W width listed here corresponds to the width parameter in a Breit-Wigner distribution with mass-dependent width. To obtain the world average, common systematic uncertainties between experiments are properly taken into account. The LEP-2 average W width based on published results is 2.195 ± 0.083 GeV [SCHAEEL 13A]. The combined Tevatron data yields an average W width of 2.046 ± 0.049 GeV [FERMLAB-TM-2460-E].

OUR FIT uses these average LEP and Tevatron width values and combines them assuming no correlations.

- ABAZOV 09AK obtain this result fitting the high-end tail (100–200 GeV) of the transverse mass spectrum in $W \rightarrow e\nu$ decays.
- AALTONEN 08B obtain this result fitting the high-end tail (90–200 GeV) of the transverse mass spectrum in semileptonic $W \rightarrow e\nu_e$ and $W \rightarrow \mu\nu_\mu$ decays.
- ABDALLAH 08A use direct reconstruction of the kinematics of $W^+ W^- \rightarrow q\bar{q}\ell\nu$ and $W^+ W^- \rightarrow q\bar{q}q\bar{q}$ events. The systematic error includes ±0.065 GeV due to final state interactions.
- ABBIENDI 06 use direct reconstruction of the kinematics of $W^+ W^- \rightarrow q\bar{q}\ell\nu_\ell$ and $W^+ W^- \rightarrow q\bar{q}q\bar{q}$ events. The systematic error includes ±0.003 GeV due to the uncertainty on the LEP beam energy.
- ACHARD 06 use direct reconstruction of the kinematics of $W^+ W^- \rightarrow q\bar{q}\ell\nu_\ell$ and $W^+ W^- \rightarrow q\bar{q}q\bar{q}$ events in the C.M. energy range 189–209 GeV. The result quoted here is obtained combining this value of the width with the result obtained from a direct W mass reconstruction at 172 and 183 GeV (ACCIARRI 99).
- SCHAEEL 06 use direct reconstruction of the kinematics of $W^+ W^- \rightarrow q\bar{q}\ell\nu_\ell$ and $W^+ W^- \rightarrow q\bar{q}q\bar{q}$ events. The systematic error includes ±0.05 GeV due to possible effects of final state interactions in the $q\bar{q}q\bar{q}$ channel and ±0.01 GeV due to the uncertainty on the LEP beam energy.
- ABAZOV 02E obtain this result fitting the high-end tail (90–200 GeV) of the transverse-mass spectrum in semileptonic $W \rightarrow e\nu_e$ decays.
- AFFOLDER 00M fit the high transverse mass (100–200 GeV) $W \rightarrow e\nu_e$ and $W \rightarrow \mu\nu_\mu$ events to obtain $\Gamma(W) = 2.04 \pm 0.11$ (stat) ± 0.09 (syst) GeV. This is combined with the earlier CDF measurement (ABE 95C) to obtain the quoted result.
- ABBOTT 00B measure $R = 10.43 \pm 0.27$ for the $W \rightarrow e\nu_e$ decay channel. They use the SM theoretical predictions for $\sigma(W)/\sigma(Z)$ and $\Gamma(W \rightarrow e\nu_e)$ and the world average for $B(Z \rightarrow e e)$. The value quoted here is obtained combining this result (2.169 ± 0.070 GeV) with that of ABBOTT 99H.
- ABE 95W measured $R = 10.90 \pm 0.32 \pm 0.29$. They use $m_W = 80.23 \pm 0.18$ GeV, $\sigma(W)/\sigma(Z) = 3.35 \pm 0.03$, $\Gamma(W \rightarrow e\nu) = 225.9 \pm 0.9$ MeV, $\Gamma(Z \rightarrow e^+ e^-) = 83.98 \pm 0.18$ MeV, and $\Gamma(Z) = 2.4969 \pm 0.0038$ GeV.
- ALITTI 92 measured $R = 10.4^{+0.7}_{-0.6} \pm 0.3$. The values of $\sigma(Z)$ and $\sigma(W)$ come from $O(\alpha_s^2)$ calculations using $m_W = 80.14 \pm 0.27$ GeV, and $m_Z = 91.175 \pm 0.021$ GeV along with the corresponding value of $\sin^2\theta_W = 0.2274$. They use $\sigma(W)/\sigma(Z) = 3.26 \pm 0.07 \pm 0.05$ and $\Gamma(Z) = 2.487 \pm 0.010$ GeV.
- ALBAJAR 91 measured $R = 9.5^{+1.1}_{-1.0}$ (stat. + syst.). $\sigma(W)/\sigma(Z)$ is calculated in QCD at the parton level using $m_W = 80.18 \pm 0.28$ GeV and $m_Z = 91.172 \pm 0.031$ GeV along with $\sin^2\theta_W = 0.2322 \pm 0.0014$. They use $\sigma(W)/\sigma(Z) = 3.23 \pm 0.05$ and $\Gamma(Z) = 2.498 \pm 0.020$ GeV. This measurement is obtained combining both the electron and muon channels.

W+ DECAY MODES

W^- modes are charge conjugates of the modes below.

Mode	Fraction (Γ_i/Γ)	Confidence level
Γ_1 $\ell^+ \nu$	[a] (10.86 ± 0.09) %	
Γ_2 $e^+ \nu$	(10.71 ± 0.16) %

Γ (invisible)	Γ_{10}
This represents the width for the decay of the W boson into a charged particle with momentum below detectability, $p < 200$ MeV.	
VALUE (MeV)	DOCUMENT ID TECN COMMENT
30⁺⁵²₋₄₈ ± 33	¹ BARATE 99I ALEP $E_{cm}^{ee} = 161+172+183$ GeV
• • • We do not use the following data for averages, fits, limits, etc. • • •	
	² BARATE 99L ALEP $E_{cm}^{ee} = 161+172+183$ GeV

- BARATE 99I measure this quantity using the dependence of the total cross section $\sigma_W W$ upon a change in the total width. The fit is performed to the $W W$ measured cross sections at 161, 172, and 183 GeV. This partial width is < 139 MeV at 95%CL.
- BARATE 99L use W -pair production to search for effectively invisible W decays, tagging with the decay of the other W boson to Standard Model particles. The partial width for effectively invisible decay is < 27 MeV at 95%CL.

W BRANCHING RATIOS

Overall fits are performed to determine the branching ratios of the W boson. Averages on $W \rightarrow e\nu$, $W \rightarrow \mu\nu$, and $W \rightarrow \tau\nu$, and their correlations are obtained by combining results from the four LEP experiments properly taking into account the common systematic uncertainties and their correlations [SCHAEEL 13A]. A first fit determines the three individual leptonic branching ratios $B(W \rightarrow e\nu)$, $B(W \rightarrow \mu\nu)$, and $B(W \rightarrow \tau\nu)$. This fit has a $\chi^2 = 6.3$ for 9 degrees of freedom. The correlation coefficients between the branching fractions are 0.14 ($e-\mu$), -0.20 ($e-\tau$), -0.12 ($\mu-\tau$). A second fit assumes lepton universality and determines the leptonic branching ratio $B(W \rightarrow \ell\nu)$ and the hadronic branching ratio is derived as $B(W \rightarrow \text{hadrons}) = 1 - 3 B(W \rightarrow \ell\nu)$. This fit has a $\chi^2 = 15.4$ for 11 degrees of freedom.

⁴ ABREU 98C combine results from both the fully hadronic as well semileptonic WW final states after demonstrating that the W decay charged multiplicity is independent of the topology within errors.

TRIPLE GAUGE COUPLINGS (TGC'S)

Revised April 2017 by M.W. Grunewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Fourteen independent couplings, seven each for ZWW and γWW , completely describe the VWW vertices within the most general framework of the electroweak Standard Model (SM) consistent with Lorentz invariance and U(1) gauge invariance. Of each of the seven TGCs, three conserve C and P individually, three violate CP , and one violates C and P individually while conserving CP . Assumption of C and P conservation and electromagnetic gauge invariance reduces the number of independent VWW couplings to five: one common set [1,2]

Gauge & Higgs Boson Particle Listings

W

is $(\kappa_\gamma, \kappa_Z, \lambda_\gamma, \lambda_Z, g_1^Z)$, where $\kappa_\gamma = \kappa_Z = g_1^Z = 1$ and $\lambda_\gamma = \lambda_Z = 0$ in the Standard Model at tree level. The parameters κ_Z and λ_Z are related to the other three due to constraints of gauge invariance as follows: $\kappa_Z = g_1^Z - (\kappa_\gamma - 1) \tan^2 \theta_W$ and $\lambda_Z = \lambda_\gamma$, where θ_W is the weak mixing angle. The W magnetic dipole moment, μ_W , and the W electric quadrupole moment, q_W , are expressed as $\mu_W = e(1 + \kappa_\gamma + \lambda_\gamma)/2M_W$ and $q_W = -e(\kappa_\gamma - \lambda_\gamma)/M_W^2$.

Precision measurements of suitable observables at LEP1 has already led to an exploration of much of the TGC parameter space. At LEP2, the VWW coupling arises in W -pair production via s -channel exchange, or in single W production via the radiation of a virtual photon off the incident e^+ or e^- . At the Tevatron and the LHC, hard-photon bremsstrahlung off a produced W or Z signals the presence of a triple-gauge vertex. In order to extract the value of one TGC, the others are generally kept fixed to their SM values. While most analyses use the above gauge constraints in the extraction of TGCs, one analysis of W -pair events also determines the real and imaginary parts of all 14 couplings using unconstrained single-parameter fits [3]. The results are consistent. Some experiments have determined limits on the couplings under various non-LEP scenarios and assuming different values of the form factor Λ , where the coupling parameters are scaled by $1/(1 + s/\Lambda^2)^2$. For practical reasons it is not possible to quote all such determinations in the listings. For that the individual papers may be consulted. Recently, EFT-inspired sets of couplings [4,5], such as $c_{WWW}/\Lambda^2, c_W/\Lambda^2, c_B/\Lambda^2$ which are linearly related to the couplings discussed above, are also determined by the LHC experiments.

1 ABDALLAH 10 use data on the final states $e^+e^- \rightarrow jj\ell\nu, jjjj, jjX, \ell X$, at center-of-mass energies between 189-209 GeV at LEP2, where $j = \text{jet}$, $\ell = \text{lepton}$, and X represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

2 SCHAE1 05A study single-photon, single- W , and WW -pair production from 183 to 209 GeV. The result quoted here is derived from the WW -pair production sample. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

3 ABBIENDI 04D combine results from W^+W^- in all decay channels. Only CP -conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $0.923 < g_1^Z < 1.054$.

4 ACHARD 04b study WW -pair production, single- W production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained from the WW -pair production sample including data from 161 to 183 GeV, ACCIARRI 99q. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

5 SIRUNYAN 19CL study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3,572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $0.9939 < g_1^Z < 1.0074$.

6 SIRUNYAN 18BZ study $pp \rightarrow Z$ jet jet events at 13 TeV where $Z \rightarrow e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with p_T of the leading/sub-leading lepton $> 30/20$ GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the Z mass. The two highest p_T jets are selected with p_T of the leading/sub-leading jet $> 50/30$ GeV respectively and dijet invariant mass > 200 GeV. Templates in the transverse momentum of the Z are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limit is obtained: $0.965 < g_1^Z < 1.042$.

7 AABOUD 17s analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \rightarrow \infty$: $0.87 < g_1^Z < 1.12$.

8 AABOUD 17u analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \rightarrow \infty$: $0.979 < g_1^Z < 1.024$.

9 KHACHATRYAN 17o analyze WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $0.982 < g_1^Z < 1.035$.

10 SIRUNYAN 17x study $pp \rightarrow WW/WZ \rightarrow \ell\nu q\bar{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WW events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $0.9913 < g_1^Z < 1.024$.

11 AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming the LEP formulation and setting the form-factor Λ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.984 < g_1^Z < 1.027$.

12 AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analysing the WZ transverse momentum distribution, the resulting 95% C.L. limit is: $0.981 < g_1^Z < 1.029$.

13 AAD 14Y determine the electroweak Z -dijet cross section in 8 TeV pp collisions. $Z \rightarrow ee$ and $Z \rightarrow \mu\mu$ decays are selected with the di-lepton $p_T > 20$ GeV and mass in the 81-101 GeV range. Minimum two jets are required with $p_T > 55$ and 45 GeV and no additional jets with $p_T > 25$ GeV in the rapidity interval between them. The normalized p_T balance between the Z and the two jets is required to be < 0.15 . This leads to a selection of 900 events with dijet mass > 1 TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit $0.5 < g_1^Z < 1.26$ for a form factor value $\Lambda = \infty$.

14 AAD 13AL study WW production in pp collisions and select 1325 WW candidates in decay modes with electrons or muons with an expected background of 369 ± 61 events. Assuming the LEP formulation and setting the form-factor $\Lambda = \text{infinity}$, a fit to the

- transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.961 < g_1^Z < 1.052$. Supersedes AAD 12Ac.
- 15 CHATRCHYAN 13BF determine the $W^+ W^-$ production cross section using unlike sign di-lepton (e or μ) events with high p_T . The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of 247 ± 34 . The p_T distribution of the leading lepton is fitted to obtain 95% C.L. limits of $0.905 \leq g_1^Z \leq 1.095$.
- 16 AAD 12CD study WZ production in pp collisions and select 317 WZ candidates in three $\ell\nu$ decay modes with an expected background of 68.0 ± 10.0 events. The resulting 95% C.L. range is: $0.943 < g_1^Z < 1.093$. Supersedes AAD 12v.
- 17 AALTONEN 12AC study WZ production in $p\bar{p}$ collisions and select 63 WZ candidates in three $\ell\nu$ decay modes with an expected background of 7.9 ± 1.0 events. Based on the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported: $0.92 < g_1^Z < 1.20$ for a form factor of $\Lambda = 2$ TeV.
- 18 ABZOV 12AG combine new results with already published results on $W\gamma, WW$ and WZ production in order to determine the couplings with increased precision, superseding ABZOV 08R, ABZOV 11AC, ABZOV 09AJ, ABZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $g_1^Z = 1.022^{+0.032}_{-0.030}$.
- 19 ABZOV 11 study the $p\bar{p} \rightarrow 3\ell\nu$ process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the p_T spectrum of the Z boson leads to a 95% C.L. limit of $0.944 < g_1^Z < 1.154$, for a form factor $\Lambda = 2$ TeV.
- 20 AALTONEN 10K study $p\bar{p} \rightarrow W^+ W^-$ with $W \rightarrow e/\mu\nu$. The p_T of the leading (second) lepton is required to be > 20 (10) GeV. The final number of events selected is 654 of which 320 ± 47 are estimated to be background. The 95% C.L. interval is $0.76 < g_1^Z < 1.34$ for $\Lambda = 1.5$ TeV and $0.78 < g_1^Z < 1.30$ for $\Lambda = 2$ TeV.
- 21 ABZOV 09AD study the $p\bar{p} \rightarrow \ell\nu 2\text{jet}$ process arising in WW and WZ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the p_T spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $0.88 < g_1^Z < 1.20$.
- 22 ABZOV 09AJ study the $p\bar{p} \rightarrow 2\ell 2\nu$ process arising in WW production. They select 100 events with an expected WW signal of 65 events. An analysis of the p_T spectrum of the two charged leptons leads to 95% C.L. limits of $0.86 < g_1^Z < 1.3$, for a form factor $\Lambda = 2$ TeV.
- 23 ABDALLAH 08c determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+ e^- \rightarrow W^+ W^- \rightarrow (qq)(\ell\nu)$, where $\ell = e$ or μ . Values of all other couplings are fixed to their standard model values.
- 24 ABZOV 07z set limits on anomalous TGCs using the measured cross section and $p_T(Z)$ distribution in WZ production with both the W and the Z decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $0.86 < g_1^Z < 1.35$.
- 25 ABZOV 05s study $p\bar{p} \rightarrow WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\bar{\ell}'$ (ℓ and $\ell' = e$ or μ). Three events (estimated background 0.71 ± 0.08 events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale $\Lambda = 1.5$ TeV is $0.51 < g_1^Z < 1.66$, fixing λ_Z and κ_Z to their Standard Model values.
- 26 ABREU 01i combine results from $e^+ e^-$ interactions at 189 GeV leading to $W^+ W^-$ and $W\nu_e$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $0.84 < g_1^Z < 1.13$.
- 27 ABBOTT 99i perform a simultaneous fit to the $W\gamma, WW \rightarrow$ dilepton, $WW/WZ \rightarrow e\nu jj, WW/WZ \rightarrow \mu\nu jj$, and $WZ \rightarrow$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95%CL limits are $0.63 < g_1^Z < 1.57$, fixing λ_Z and κ_Z to their Standard Model values, and assuming Standard Model values for the $WW\gamma$ couplings.

- 1 ABDALLAH 10 use data on the final states $e^+ e^- \rightarrow jj\ell\nu, jjjj, jjX, \ell X$, at center-of-mass energies between 189–209 GeV at LEP2, where $j = \text{jet}$, $\ell = \text{lepton}$, and X represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.
- 2 SCHAE 05A study single-photon, single- W , and WW -pair production from 183 to 209 GeV. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- 3 ABBIENDI 04d combine results from $W^+ W^-$ in all decay channels. Only CP -conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $0.73 < \kappa_\gamma < 1.07$.
- 4 ACHARD 04d study WW -pair production, single- W production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99q. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- 5 AABOUD 17U analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \rightarrow \infty$: $0.939 < \kappa_\gamma < 1.064$.
- 6 SIRUNYAN 17x study $pp \rightarrow WW/WZ \rightarrow \ell\nu q\bar{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WV events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $0.956 < \kappa_\gamma < 1.063$.
- 7 CHATRCHYAN 14AB measure $W\gamma$ production cross section for $p_T^\gamma > 15$ GeV and $R(\ell,\gamma) > 0.7$, which is the separation between the γ and the final state charged lepton (e or μ) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. After background subtraction the number of $e\nu\gamma$ and $\mu\nu\gamma$ events is determined to be 3200 ± 325 and 4970 ± 543 respectively, compatible with expectations from the SM. This leads to a 95% CL limit of $0.62 < \kappa_\gamma < 1.29$, assuming other parameters have SM values.
- 8 AAD 13AN study $W\gamma$ production in pp collisions. In events with no additional jet, 4449 (6578) W decays to electron (muon) are selected, with an expected background of 1662 ± 262 (2538 ± 362) events. Analysing the photon p_T spectrum above 100 GeV yields a 95% C.L. limit of $0.59 < \kappa_\gamma < 1.46$. Supersedes AAD 12Bx.
- 9 CHATRCHYAN 13BF determine the $W^+ W^-$ production cross section using unlike sign di-lepton (e or μ) events with high p_T . The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of 247 ± 34 . The p_T distribution of the leading lepton is fitted to obtain 95% C.L. limits of $0.79 \leq \kappa_\gamma \leq 1.22$.
- 10 ABZOV 12AG combine new results with already published results on $W\gamma, WW$ and WZ production in order to determine the couplings with increased precision, superseding ABZOV 08R, ABZOV 11AC, ABZOV 09AJ, ABZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $\kappa_\gamma = 1.048^{+0.106}_{-0.105}$.
- 11 ABZOV 11AC study $W\gamma$ production in $p\bar{p}$ collisions at 1.96 TeV, with the W decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon E_T spectrum above 15 GeV yields at 95% C.L. the result: $0.6 < \kappa_\gamma < 1.4$ for a formfactor $\Lambda = 2$ TeV.
- 12 CHATRCHYAN 11M study $W\gamma$ production in pp collisions at $\sqrt{s} = 7$ TeV using 36 pb^{-1} pp data with the W decaying to electron and muon. The total cross section is measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$. The number of candidate (background) events is 452 (228 ± 21) for the electron channel and 520 (277 ± 25) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of $-0.11 < \kappa_\gamma < 2.04$.
- 13 AALTONEN 10K study $p\bar{p} \rightarrow W^+ W^-$ with $W \rightarrow e/\mu\nu$. The p_T of the leading (second) lepton is required to be > 20 (10) GeV. The final number of events selected is 654 of which 320 ± 47 are estimated to be background. The 95% C.L. interval is $0.37 < \kappa_\gamma < 1.72$ for $\Lambda = 1.5$ TeV and $0.43 < \kappa_\gamma < 1.65$ for $\Lambda = 2$ TeV.
- 14 AARON 09B study single- W production in $e p$ collisions at 0.3 TeV C.M. energy. They select 53 $W \rightarrow e/\mu$ events with a standard model expectation of 54.1 ± 7.4 events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of $-3.7 < \kappa_\gamma < -1.5$ or $0.3 < \kappa_\gamma < 1.5$, where the ambiguity is due to the quadratic dependence of the cross section to the coupling parameter.
- 15 ABZOV 09AD study the $p\bar{p} \rightarrow \ell\nu 2\text{jet}$ process arising in WW and WZ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the p_T spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $0.56 < \kappa_\gamma < 1.55$.
- 16 ABZOV 09AJ study the $p\bar{p} \rightarrow 2\ell 2\nu$ process arising in WW production. They select 100 events with an expected WW signal of 65 events. An analysis of the p_T spectrum of the two charged leptons leads to 95% C.L. limits of $0.46 < \kappa_\gamma < 1.83$, for a form factor $\Lambda = 2$ TeV.
- 17 ABZOV 08R use 0.7 fb^{-1} $p\bar{p}$ data at $\sqrt{s} = 1.96$ TeV to select 263 $W\gamma + X$ events, of which 187 constitute signal, with the W decaying into an electron or a muon, which is required to be well separated from a photon with $E_T > 9$ GeV. A likelihood fit to the photon E_T spectrum yields a 95% CL limit $0.49 < \kappa_\gamma < 1.51$ with other couplings fixed to their Standard Model values.

- ¹⁸ ABDALLAH 08c determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \rightarrow W^+W^- \rightarrow (qq)(\ell\nu)$, where $\ell = e$ or μ . Values of all other couplings are fixed to their standard model values.
- ¹⁹ AALTONEN 07L set limits on anomalous TGCs using the $p_T(W)$ distribution in WW and WZ production with the W decaying to an electron or muon and the Z to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are $0.54 < \kappa_\gamma < 1.39$ for a form factor scale $\Lambda = 1.5$ TeV.
- ²⁰ ABAZOV 06H study $\bar{p}p \rightarrow WW$ production with a subsequent decay $WW \rightarrow e^+\nu_e e^- \bar{\nu}_e$, $WW \rightarrow e^\pm \nu_e \mu^\mp \nu_\mu$ or $WW \rightarrow \mu^+ \nu_\mu \mu^- \bar{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 1$ TeV is $-0.05 < \kappa_\gamma < 2.29$, fixing $\lambda_\gamma = 0$. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $0.68 < \kappa < 1.45$.
- ²¹ ABAZOV 05J perform a likelihood fit to the photon E_T spectrum of $W\gamma + X$ events, where the W decays to an electron or muon which is required to be well separated from the photon. For $\Lambda = 2.0$ TeV the 95% CL limits are $0.12 < \kappa_\gamma < 1.96$. In the fit λ_γ is kept fixed to its Standard Model value.
- ²² ABREU 01i combine results from e^+e^- interactions at 189 GeV leading to W^+W^- , $W\nu_e$, and $\nu\bar{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $0.87 < \kappa_\gamma < 1.68$.
- ²³ BREITWEG 00 search for W production in events with large hadronic p_T . For $p_T > 20$ GeV, the upper limit on the cross section gives the 95% CL limit $-3.7 < \kappa_\gamma < 2.5$ (for $\lambda_\gamma = 0$).
- ²⁴ ABBOTT 99i perform a simultaneous fit to the $W\gamma$, $WW \rightarrow$ dilepton, $WW/WZ \rightarrow e\nu jj$, $WW/WZ \rightarrow \mu\nu jj$, and $WZ \rightarrow$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95% CL limits are $0.75 < \kappa_\gamma < 1.39$.

 λ_γ

- ¹ ABDALLAH 10 use data on the final states $e^+e^- \rightarrow jj\ell\nu$, $jjjj$, $jjjX$, ℓX , at center-of-mass energies between 189–209 GeV at LEP2, where $j =$ jet, $\ell =$ lepton, and X represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.
- ² SCHAEEL 05A study single-photon, single- W , and WW -pair production from 183 to 209 GeV. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- ³ ABBIENDI 04d combine results from W^+W^- in all decay channels. Only CP -conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $-0.13 < \lambda_\gamma < 0.01$.
- ⁴ ACHARD 04b study WW -pair production, single- W production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99q. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- ⁵ CHATRCHYAN 14AB measure $W\gamma$ production cross section for $p_T^\gamma > 15$ GeV and $R(\ell\gamma) > 0.7$, which is the separation between the γ and the final state charged lepton (e or μ) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. After background subtraction the number of $e\nu\gamma$ and $\mu\nu\gamma$ events is determined to be 3200 ± 325 and 4970 ± 543 respectively, compatible with expectations from the SM. This leads to a 95% CL limit of $-0.050 < \lambda_\gamma < 0.037$, assuming all other parameters have SM values.
- ⁶ AAD 13AN study $W\gamma$ production in pp collisions. In events with no additional jet, 4449 (6578) W decays to electron (muon) are selected, with an expected background of 1662 ± 262 (2538 \pm 362) events. Analysing the photon p_T spectrum above 100 GeV yields a 95% C.L. limit of $-0.065 < \lambda_\gamma < 0.061$. Supersedes AAD 12bx.
- ⁷ ABAZOV 12AG combine new results with already published results on $W\gamma$, WW and WZ production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $\lambda_\gamma = 0.007^{+0.021}_{-0.022}$.

- ⁸ ABAZOV 11AC study $W\gamma$ production in $p\bar{p}$ collisions at 1.96 TeV, with the W decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon E_T spectrum above 15 GeV yields at 95% C.L. the result: $-0.08 < \lambda_\gamma < 0.07$ for a formfactor $\Lambda = 2$ TeV.
- ⁹ CHATRCHYAN 11M study $W\gamma$ production in pp collisions at $\sqrt{s} = 7$ TeV using 36 pb⁻¹ pp data with the W decaying to electron and muon. The total cross section is measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell, \gamma) > 0.7$. The number of candidate (background) events is 452 (228 \pm 21) for the electron channel and 520 (277 \pm 25) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of $-0.18 < \lambda_\gamma < 0.17$.
- ¹⁰ AARON 09B study single- W production in ep collisions at 0.3 TeV C.M. energy. They select 53 $W \rightarrow e/\mu$ events with a standard model expectation of 54.1 ± 7.4 events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of $-2.5 < \lambda_\gamma < 2.5$.
- ¹¹ ABAZOV 09AD study the $p\bar{p} \rightarrow \ell\nu$ 2jet process arising in WW and WZ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the p_T spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $-0.10 < \lambda_\gamma < 0.11$.
- ¹² ABAZOV 09AJ study the $p\bar{p} \rightarrow 2\ell\nu$ process arising in WW production. They select 100 events with an expected $W\nu$ signal of 65 events. An analysis of the p_T spectrum of the two charged leptons leads to 95% C.L. limits of $-0.14 < \lambda_\gamma < 0.18$, for a form factor $\Lambda = 2$ TeV.
- ¹³ ABAZOV 08R use 0.7 fb⁻¹ $p\bar{p}$ data at $\sqrt{s} = 1.96$ TeV to select 263 $W\gamma + X$ events, of which 187 constitute signal, with the W decaying into an electron or a muon, which is required to be well separated from a photon with $E_T > 9$ GeV. A likelihood fit to the photon E_T spectrum yields a 95% CL limit $-0.12 < \lambda_\gamma < 0.13$ with other couplings fixed to their Standard Model values.
- ¹⁴ ABDALLAH 08c determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \rightarrow W^+W^- \rightarrow (qq)(\ell\nu)$, where $\ell = e$ or μ . Values of all other couplings are fixed to their standard model values.
- ¹⁵ AALTONEN 07L set limits on anomalous TGCs using the $p_T(W)$ distribution in WW and WZ production with the W decaying to an electron or muon and the Z to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are $-0.18 < \lambda_\gamma < 0.17$ for a form factor scale $\Lambda = 1.5$ TeV.
- ¹⁶ ABAZOV 06H study $\bar{p}p \rightarrow WW$ production with a subsequent decay $WW \rightarrow e^+\nu_e e^- \bar{\nu}_e$, $WW \rightarrow e^\pm \nu_e \mu^\mp \nu_\mu$ or $WW \rightarrow \mu^+ \nu_\mu \mu^- \bar{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 1$ TeV is $-0.97 < \lambda_\gamma < 1.04$, fixing $\kappa_\gamma = 1$. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $-0.29 < \lambda < 0.30$.
- ¹⁷ ABAZOV 05J perform a likelihood fit to the photon E_T spectrum of $W\gamma + X$ events, where the W decays to an electron or muon which is required to be well separated from the photon. For $\Lambda = 2.0$ TeV the 95% CL limits are $-0.20 < \lambda_\gamma < 0.20$. In the fit κ_γ is kept fixed to its Standard Model value.
- ¹⁸ ABREU 01i combine results from e^+e^- interactions at 189 GeV leading to W^+W^- , $W\nu_e$, and $\nu\bar{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $-0.11 < \lambda_\gamma < 0.23$.
- ¹⁹ BREITWEG 00 search for W production in events with large hadronic p_T . For $p_T > 20$ GeV, the upper limit on the cross section gives the 95% CL limit $-3.2 < \lambda_\gamma < 3.2$ for κ_γ fixed to its Standard Model value.
- ²⁰ ABBOTT 99i perform a simultaneous fit to the $W\gamma$, $WW \rightarrow$ dilepton, $WW/WZ \rightarrow e\nu jj$, $WW/WZ \rightarrow \mu\nu jj$, and $WZ \rightarrow$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95% CL limits are $-0.18 < \lambda_\gamma < 0.19$.

 κ_Z This coupling is CP -conserving (C and P -separately conserving).

- ¹ ACHARD 04b study WW -pair production, single- W production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the WW -pair production sample. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- ² SIRUNYAN 19CL study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $0.9921 < \kappa_Z < 1.0082$.
- ³ AABOUD 17s analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse

- momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \rightarrow \infty$: $0.85 < \kappa_Z < 1.16$.
- 4 KHACHATRYAN 17o analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $0.79 < \kappa_Z < 1.25$.
 - 5 AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming the LEP formulation and setting the form-factor Λ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.975 < \kappa_Z < 1.020$.
 - 6 AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analyzing the WZ transverse momentum distribution, the resulting 95% C.L. limit is: $0.81 < \kappa_Z < 1.30$.
 - 7 AAD 13AL study WW production in pp collisions and select 1325 WW candidates in decay modes with electrons or muons with an expected background of 369 ± 61 events. Assuming the LEP formulation and setting the form-factor $\Lambda = \infty$, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.957 < \kappa_Z < 1.043$. Supersedes AAD 12AC.
 - 8 AAD 12CD study WZ production in pp collisions and select 317 WZ candidates in three $\ell\nu$ decay modes with an expected background of 68.0 ± 10.0 events. The resulting 95% C.L. range is: $0.63 < \kappa_Z < 1.57$. Supersedes AAD 12V.
 - 9 AALTONEN 12AC study WZ production in $p\bar{p}$ collisions and select 63 WZ candidates in three $\ell\nu$ decay modes with an expected background of 7.9 ± 1.0 events. Based on the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported: $0.61 < \kappa_Z < 1.90$ for a form factor of $\Lambda = 2$ TeV.
 - 10 ABAZOV 11 study the $p\bar{p} \rightarrow 3\ell\nu$ process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the p_T spectrum of the Z boson leads to a 95% C.L. limit of $0.600 < \kappa_Z < 1.675$, for a form factor $\Lambda = 2$ TeV.
 - 11 ABAZOV 06H study $p\bar{p} \rightarrow WW$ production with a subsequent decay $WW \rightarrow e^+ \nu_e e^- \bar{\nu}_e$, $WW \rightarrow e^\pm \nu_e \mu^\mp \nu_\mu$ or $WW \rightarrow \mu^+ \nu_\mu \mu^- \bar{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $0.55 < \kappa_Z < 1.55$, fixing $\lambda_Z = 0$. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $0.68 < \kappa < 1.45$.
 - 12 ABAZOV 05s study $p\bar{p} \rightarrow WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\bar{\ell}'$ (ℓ and $\ell' = e$ or μ). Three events (estimated background 0.71 ± 0.08 events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale $\Lambda = 1$ TeV is $-1.0 < \kappa_Z < 3.4$, fixing λ_Z and g_Z^1 to their Standard Model values.

λ_Z This coupling is CP-conserving (C- and P- separately conserving).

- 1 ACHARD 04D study WW -pair production, single- W production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the WW -pair production sample. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- 2 SIRUNYAN 19CL study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $W(W)WZ$ category, while in the muon channel 3,996 (3,572) events are selected in the $W(W)WZ$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $-0.0065 < \lambda_Z < 0.0066$.
- 3 SIRUNYAN 18bz study $pp \rightarrow Z$ jet jet events at 13 TeV where $Z \rightarrow e^+ e^- / \mu^+ \mu^-$. Isolated electrons and muons are selected with p_T of the leading/sub-leading lepton $> 30/20$ GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the Z mass. The two highest p_T jets are selected with p_T of the leading/sub-leading jet $> 50/30$ GeV respectively and dijet invariant mass > 200 GeV. Templates in the transverse momentum of the Z are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limit is obtained $-0.010 < \lambda_Z < 0.010$.

- 4 ABOUD 17s analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \rightarrow \infty$: $-0.053 < \lambda_Z < 0.042$.
- 5 ABOUD 17u analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \rightarrow \infty$: $-0.013 < \lambda_Z < 0.013$.
- 6 KHACHATRYAN 17o analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $-0.018 < \lambda_Z < 0.016$.
- 7 SIRUNYAN 17X study $pp \rightarrow WW/WZ \rightarrow \ell\nu q\bar{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WW events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $-0.011 < \lambda_Z < 0.011$.
- 8 AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming the LEP formulation and setting the form-factor Λ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $-0.019 < \lambda_Z < 0.019$.
- 9 AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analyzing the WZ transverse momentum distribution, the resulting 95% C.L. limit is: $-0.016 < \lambda_Z < 0.016$.
- 10 AAD 14Y determine the electroweak Z -dijet cross section in 8 TeV pp collisions. $Z \rightarrow ee$ and $Z \rightarrow \mu\mu$ decays are selected with the di-lepton $p_T > 20$ GeV and mass in the 81-101 GeV range. Minimum two jets are required with $p_T > 55$ and 45 GeV and no additional jets with $p_T > 25$ GeV in the rapidity interval between them. The normalized p_T balance between the Z and the two jets is required to be < 0.15 . This leads to a selection of 900 events with dijet mass > 1 TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit $-0.15 < \lambda_Z < 0.13$ for a form factor value $\Lambda = \infty$.
- 11 AAD 13AL study WW production in pp collisions and select 1325 WW candidates in decay modes with electrons or muons with an expected background of 369 ± 61 events. Assuming the LEP formulation and setting the form-factor $\Lambda = \infty$, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $-0.062 < \lambda_Z < 0.059$. Supersedes AAD 12AC.
- 12 CHATRCHYAN 13BF determine the W^+W^- production cross section using unlike sign di-lepton (e or μ) events with high p_T . The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of 247 ± 34 . The p_T distribution of the leading lepton is fitted to obtain 95% C.L. limits of $-0.048 < \lambda_Z < 0.048$.
- 13 AAD 12CD study WZ production in pp collisions and select 317 WZ candidates in three $\ell\nu$ decay modes with an expected background of 68.0 ± 10.0 events. The resulting 95% C.L. range is: $-0.046 < \lambda_Z < 0.047$. Supersedes AAD 12V.
- 14 AALTONEN 12AC study WZ production in $p\bar{p}$ collisions and select 63 WZ candidates in three $\ell\nu$ decay modes with an expected background of 7.9 ± 1.0 events. Based on the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported: $-0.08 < \lambda_Z < 0.10$ for a form factor of $\Lambda = 2$ TeV.
- 15 ABAZOV 11 study the $p\bar{p} \rightarrow 3\ell\nu$ process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the p_T spectrum of the Z boson leads to a 95% C.L. limit of $-0.077 < \lambda_Z < 0.093$, for a form factor $\Lambda = 2$ TeV.
- 16 AALTONEN 10K study $p\bar{p} \rightarrow W^+W^-$ with $W \rightarrow e/\mu\nu$. The p_T of the leading (second) lepton is required to be > 20 (10) GeV. The final number of events selected is 654 of which 320 ± 47 are estimated to be background. The 95% C.L. interval is $-0.16 < \lambda_Z < 0.16$ for $\Lambda = 1.5$ TeV and $-0.14 < \lambda_Z < 0.15$ for $\Lambda = 2$ TeV.
- 17 ABAZOV 07Z set limits on anomalous TGCs using the measured cross section and $p_T(Z)$ distribution in WZ production with both the W and the Z decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $-0.17 < \lambda_Z < 0.21$.
- 18 ABAZOV 06H study $p\bar{p} \rightarrow WW$ production with a subsequent decay $WW \rightarrow e^+ \nu_e e^- \bar{\nu}_e$, $WW \rightarrow e^\pm \nu_e \mu^\mp \nu_\mu$ or $WW \rightarrow \mu^+ \nu_\mu \mu^- \bar{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $-0.39 < \lambda_Z < 0.39$, fixing $\kappa_Z = 1$. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $-0.29 < \lambda < 0.30$.
- 19 ABAZOV 05s study $p\bar{p} \rightarrow WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\bar{\ell}'$ (ℓ and $\ell' = e$ or μ). Three events (estimated background 0.71 ± 0.08 events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale $\Lambda = 1.5$ TeV is $-0.48 < \lambda_Z < 0.48$, fixing g_Z^1 and κ_Z to their Standard Model values.

κ_Z This coupling is CP-conserving but C- and P-violating.

¹ ABREU 01i combine results from e^+e^- interactions at 189 GeV leading to W^+W^- , $W e \nu_e$, and $\nu \bar{\nu} \gamma$ final states with results from ABREU 99L at 183 GeV to determine Δg_5^Z , $\Delta \kappa_\gamma$, and λ_γ . $\Delta \kappa_\gamma$ and λ_γ are simultaneously floated in the fit to determine μW .

² ABE 95G report $-1.3 < \kappa < 3.2$ for $\lambda=0$ and $-0.7 < \lambda < 0.7$ for $\kappa=1$ in $p\bar{p} \rightarrow e \nu_e \gamma X$ and $\mu \nu_\mu \gamma X$ at $\sqrt{s} = 1.8$ TeV.

³ ALITTI 92C measure $\kappa = 1^{+2.6}_{-2.9}$ and $\lambda = 0^{+1.7}_{-1.8}$ in $p\bar{p} \rightarrow e \nu_e \gamma X$ at $\sqrt{s} = 630$ GeV. At 95%CL they report $-3.5 < \kappa < 5.9$ and $-3.6 < \lambda < 3.5$.

⁴ SAMUEL 92 use preliminary CDF and UA2 data and find $-2.4 < \kappa < 3.7$ at 96%CL and $-3.1 < \kappa < 4.2$ at 95%CL respectively. They use data for $W\gamma$ production and radiative W decay.

⁵ SAMUEL 91 use preliminary CDF data for $p\bar{p} \rightarrow W\gamma X$ to obtain $-11.3 \leq \Delta \kappa \leq 10.9$. Note that their $\kappa = 1 - \Delta \kappa$.

⁶ GRIFOLS 88 uses deviation from ρ parameter to set limit $\Delta \kappa \lesssim 65 (M_W^2/\Lambda^2)$.

⁷ GROTC 87 finds the limit $-37 < \Delta \kappa < 73.5$ (90% CL) from the experimental limits on $e^+e^- \rightarrow \nu \bar{\nu} \gamma$ assuming three neutrino generations and $-19.5 < \Delta \kappa < 56$ for four generations. Note their $\Delta \kappa$ has the opposite sign as our definition.

⁸ VANDERBIJ 87 uses existing limits to the photon structure to obtain $|\Delta \kappa| < 33 (m_W/\Lambda)$. In addition VANDERBIJ 87 discusses problems with using the ρ parameter of the Standard Model to determine $\Delta \kappa$.

⁹ GRAU 85 uses the muon anomaly to derive a coupled limit on the anomalous magnetic dipole and electric quadrupole (λ) moments $1.05 > \Delta \kappa \ln(\Lambda/m_W) + \lambda/2 > -2.77$. In the Standard Model $\lambda = 0$.

¹⁰ SUZUKI 85 uses partial-wave unitarity at high energies to obtain $|\Delta \kappa| \lesssim 190 (m_W/\Lambda)^2$. From the anomalous magnetic moment of the muon, SUZUKI 85 obtains $|\Delta \kappa| \lesssim 2.2/\ln(\Lambda/m_W)$. Finally SUZUKI 85 uses deviations from the ρ parameter and obtains a very qualitative, order-of-magnitude limit $|\Delta \kappa| \lesssim 150 (m_W/\Lambda)^4$ if $|\Delta \kappa| \ll 1$.

¹¹ HERZOG 84 consider the contribution of W -boson to muon magnetic moment including anomalous coupling of $WW\gamma$. Obtain a limit $-1 < \Delta \kappa < 3$ for $\Lambda \gtrsim 1$ TeV.

 $c_{WW}/\Lambda^2, c_W/\Lambda^2, c_B/\Lambda^2$

These couplings are used in EFT-based approaches to anomalous couplings. They are linearly related to the couplings discussed above.

¹ AABOUD 19BA study WW production in decay modes with an electron and a muon. The charged leptons are each required to have a transverse momentum larger than 27 GeV and rapidity less than 2.5. The electron-muon system is required to have a mass larger than 55 GeV and a transverse momentum larger than 30 GeV. The missing transverse energy must be larger than 20 GeV. Events containing a jet with transverse momentum exceeding 35 GeV and rapidity smaller than 4.5 are rejected. A total of 12,659 events are selected in the data, with an expected background of 4240 ± 477 events. Analysing the transverse momentum spectrum of the leading charged lepton, the following 95% C.L. limits are derived in units of TeV^{-2} : $-3.4 < c_{WW}/\Lambda^2 < 3.3$, $-7.4 < c_W/\Lambda^2 < 4.1$, $-21 < c_B/\Lambda^2 < 18$, $-1.6 < c_{\overline{W}W}/\Lambda^2 < 1.6$, $-76 < c_{\overline{W}W}/\Lambda^2 < 76$.

W ANOMALOUS MAGNETIC MOMENT

The full magnetic moment is given by $\mu_W = e(1+\kappa+\lambda)/2m_W$. In the Standard Model, at tree level, $\kappa=1$ and $\lambda=0$. Some papers have defined $\Delta \kappa = 1-\kappa$ and assume that $\lambda=0$. Note that the electric quadrupole moment is given by $-e(\kappa-\lambda)/m_W^2$. A description of the parameterization

- ² SIRUNYAN 19AD study inclusive WZ production, with W and Z decaying to electrons or muons. The leading (subleading) charged lepton candidate from the Z boson decay is required to have a transverse momentum larger than 25 GeV (10 GeV). The charged lepton candidate from the W boson decay is required to have a transverse momentum larger than 25 GeV. The invariant mass of the two leptons from Z decay is required to be within 15 GeV of the Z mass, while the invariant mass of the tri-lepton system is required to exceed 100 GeV. A total of 3,831 tri-lepton events are observed, with a fitted SM WZ signal of 3166 ± 62 events and a fitted background of 666 ± 45 events. The approximated WZ invariant mass distribution is analyzed to set 95% C.L. limits as follows: $-4.1 < c_{WW}/\Lambda^2 < 1.1$, $-2.0 < c_{WWW}/\Lambda^2 < 2.1$, $-100 < c_B/\Lambda^2 < 160$, in units of TeV^{-2} .
- ³ SIRUNYAN 19cl study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $W(W/Z)$ category, while in the muon channel 3,996 (3,572) events are selected in the $W(W/Z)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limits are obtained in units of TeV^{-2} : $-1.58 < c_{WWW}/\Lambda^2 < 1.59$, $-2.00 < c_W/\Lambda^2 < 2.65$, $-8.78 < c_B/\Lambda^2 < 8.54$.
- ⁴ AABOUD 18q study $pp \rightarrow ZZ$ events at $\sqrt{s} = 13$ TeV with $Z \rightarrow e^+e^-$ or $Z \rightarrow \mu^+\mu^-$. The number of events observed in the $4e$, $2e2\mu$, and 4μ channels is 249, 465, and 303 respectively. Analysing the p_T spectrum of the leading Z boson, the following the following 95% C.L. limits are derived in units of TeV^{-4} : $-5.9 < c_{\tilde{B}W}/\Lambda^4 < 5.9$, $-3.0 < c_{WW}/\Lambda^4 < 3.0$, $-3.3 < c_{BW}/\Lambda^4 < 3.3$, $-2.7 < c_{BB}/\Lambda^4 < 2.8$.
- ⁵ SIRUNYAN 18bz study $pp \rightarrow Z$ jet events at 13 TeV where $Z \rightarrow e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with p_T of the leading/sub-leading lepton $> 30/20$ GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the Z mass. The two highest p_T jets are selected with p_T of the leading/sub-leading jet $> 50/30$ GeV respectively and dijet invariant mass > 200 GeV. Templates in the transverse momentum of the Z are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limits are obtained in units of TeV^{-2} : $-2.6 < c_{WWW}/\Lambda^2 < 2.6$ and $-8.4 < c_W/\Lambda^2 < 10.1$.
- ⁶ AABOUD 17s analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limits at 95% CL for the form factor cut-off scale $\Lambda_{FF} \rightarrow \infty$: $-33 < c_{WW}/\Lambda^2 < 30$, $-170 < c_B/\Lambda^2 < 160$, $-13 < c_{WWW}/\Lambda^2 < 9$, $-580 < c_{\tilde{W}W}/\Lambda^2 < 580$, $-11 < c_{\tilde{W}W}/\Lambda^2 < 11$, in units of TeV^{-2} .
- ⁷ AABOUD 17u analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limits at 95% CL for the form factor cut-off scale $\Lambda_{FF} \rightarrow \infty$: $-3.1 < c_{WWW}/\Lambda^2 < 3.1$, $-19 < c_B/\Lambda^2 < 20$, $-5.1 < c_W/\Lambda^2 < 5.8$, in units of TeV^{-2} .
- ⁸ KHACHATRYAN 17o analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set 95% C.L. limits of: $-260 < c_B/\Lambda^2 < 210$, $-4.2 < c_W/\Lambda^2 < 8.0$, $-4.6 < c_{WWW}/\Lambda^2 < 4.2$, in units of TeV^{-2} .
- ⁹ SIRUNYAN 17x study $pp \rightarrow WW/WZ \rightarrow \ell\nu q\bar{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WV events observed in the electron and muon channels. The following 95% C.L. limits in units of TeV^{-2} are obtained: $-2.7 < c_{WWW}/\Lambda^2 < 2.7$, $-14 < c_B/\Lambda^2 < 17$, $-2.0 < c_W/\Lambda^2 < 5.7$.
- ¹⁰ AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming an EFT formulation, a fit to the transverse momentum distribution of the leading charged lepton, leads to 95% C.L. ranges of: $-4.61 < c_{WWW}/\Lambda^2 < 4.60$, $-5.87 < c_W/\Lambda^2 < 10.54$ and $-20.9 < c_B/\Lambda^2 < 26.3$, in units of TeV^{-2} .
- ¹¹ AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analysing the WZ transverse momentum distribution, the resulting 95% C.L. limits are: $-3.9 < c_{WWW}/\Lambda^2 < 4.0$, $-4.3 < c_W/\Lambda^2 < 6.8$, and $-320 < c_B/\Lambda^2 < 210$, in units of TeV^{-2} .
- ¹² KHACHATRYAN 16Bi determine the W^+W^- production cross section using unlike sign di-lepton (e or μ) events with high p_T . The leptons have $p_T > 20$ GeV/ c and are isolated. Events are required to have no jets above p_T of 30 GeV/ c . 4847 (2233) events are selected with different (same) flavor leptons, with an expected total background of 1179 ± 123 (643 \pm 73) events. Analysing the di-lepton invariant mass spectrum, the following values are obtained: $c_{WWW}/\Lambda^2 = 0.1 \pm 3.2$, $c_W/\Lambda^2 = -3.6^{+5.0}_{-4.5}$ and $c_B/\Lambda^2 = -3.2^{+15.0}_{-14.5}$, in units of TeV^{-2} . The limits at 95% C.L. are: $-5.7 < c_{WWW}/\Lambda^2 < 5.9$, $-11.4 < c_W/\Lambda^2 < 5.4$ and $-29.2 < c_B/\Lambda^2 < 23.9$, in units of TeV^{-2} .

ANOMALOUS W/Z QUARTIC COUPLINGS

Revised November 2015 by M.W. Grunewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Quartic couplings, $WWZZ$, $WWZ\gamma$, $WW\gamma\gamma$, and $ZZ\gamma\gamma$, were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an

effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowers dimensional representation of operators (dimension 6) which presumes the $SU(2) \times U(1)$ gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings, a_0, a_c, a_n , are expressed in terms of the following dimension-6 operators [1,2];

$$\begin{aligned} L_6^0 &= -\frac{e^2}{16\Lambda^2} a_0 F^{\mu\nu} F_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ L_6^c &= -\frac{e^2}{16\Lambda^2} a_c F^{\mu\alpha} F_{\mu\beta} \vec{W}^\beta \cdot \vec{W}_\alpha \\ L_6^n &= -i\frac{e^2}{16\Lambda^2} a_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_\nu^{(j)} W^{(k)\alpha} F^{\mu\nu} \\ \tilde{L}_6^0 &= -\frac{e^2}{16\Lambda^2} \tilde{a}_0 F^{\mu\nu} \tilde{F}_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ \tilde{L}_6^n &= -i\frac{e^2}{16\Lambda^2} \tilde{a}_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_\nu^{(j)} W^{(k)\alpha} \tilde{F}^{\mu\nu} \end{aligned}$$

where F, W are photon and W fields, L_6^0 and L_6^c conserve C, P separately (\tilde{L}_6^0 conserves only C) and generate anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ couplings, L_6^n violates CP (\tilde{L}_6^n violates both C and P) and generates an anomalous $W^+W^-Z\gamma$ coupling, and Λ is an energy scale for new physics. For the $ZZ\gamma\gamma$ coupling the CP -violating term represented by L_6^n does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the $WW\gamma\gamma$ and $ZZ\gamma\gamma$ couplings separately, leading to two sets parametrized as a_0^V/Λ^2 and a_c^V/Λ^2 , where $V = W$ or Z .

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned} \mathcal{L}_{AQGC} &= -\frac{e^2}{8} \frac{a_0^W}{\Lambda^2} F_{\mu\nu} F^{\mu\nu} W^{+a} W_a^- \\ &\quad -\frac{e^2}{16} \frac{a_c^W}{\Lambda^2} F_{\mu\nu} F^{\mu\alpha} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ &\quad -e^2 g^2 \frac{\kappa_0^W}{\Lambda^2} F_{\mu\nu} Z^{\mu\nu} W^{+a} W_a^- \\ &\quad -\frac{e^2 g^2}{2} \frac{\kappa_c^W}{\Lambda^2} F_{\mu\nu} Z^{\mu\alpha} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ &\quad + \frac{f_{T,0}}{\Lambda^4} Tr[\widehat{W}_{\mu\nu} \widehat{W}^{\mu\nu}] \times Tr[\widehat{W}_{\alpha\beta} \widehat{W}^{\alpha\beta}] \end{aligned}$$

The energy scale of possible new physics is Λ , and $g = e/\sin(\theta_W)$, e being the unit electric charge and θ_W the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators a_0^W/Λ^2 and a_c^W/Λ^2 are associated with the $WW\gamma\gamma$ vertex. Among dimension 8 operators, κ_0^W/Λ^2 and κ_c^W/Λ^2 are associated with the $WWZ\gamma$ vertex, whereas the parameter $f_{T,0}/\Lambda^4$ contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters $f_{M,i}/\Lambda^4$ as follows [3]:

Gauge & Higgs Boson Particle Listings

W

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2 f_{M,0}}{g^2 \Lambda^4} - \frac{8M_W^2 f_{M,2}}{g'^2 \Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2 f_{M,1}}{g^2 \Lambda^4} - \frac{8M_W^2 f_{M,3}}{g'^2 \Lambda^4}$$

where $g' = e/\cos(\theta_W)$ and M_W is the invariant mass of the W boson. This relation provides a translation between limits on dimension 6 operators $a_{0,c}^W$ and $f_{M,j}/\Lambda^4$. It is further required [4] that $f_{M,0} = 2f_{M,2}$ and $f_{M,1} = 2f_{M,3}$ which suppresses contributions to the $WWZ\gamma$ vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total – $f_{S,i}$, $i = 1, 2$, $f_{M,i}$, $i = 0, \dots, 8$ and $f_{T,i}$, $i = 0, \dots, 9$ – each scaled by $1/\Lambda^4$.

The ATLAS collaboration [6], on the other hand, follows a K-matrix driven approach of Ref. 7 in which the anomalous couplings can be expressed in terms of two parameters α_4 and α_5 , which account for all BSM effects.

It is the early stages in the determination of quartic couplings by the LHC experiments. It is hoped that the two collaborations, ATLAS and CMS, will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison and allow for a possible LHC combination.

Anomalous W quartic couplings are measured by the experiments at LEP, the Tevatron, and the LHC. Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below). As discussed in the review on the “Anomalous W/Z quartic couplings (QGCS),” the measurements are typically done using different operator expansions which then do not allow the results to be compared and averaged. At least one common framework should be agreed upon for the use in the future publications by the experiments.

Some publications from LHC experiments derive limits for various assumed values of the form-factor cutoff Λ_{FF} . The values quoted below are for $\Lambda_{FF} \rightarrow \infty$.

¹ SIRUNYAN 19BM search for the final state $W^+W^-W^\pm$ using W decays to electrons or muons. Two event samples are considered, events with three leptons, or events with two oppositely charged leptons accompanied by two jets. In a kinematic region selected to enhance the effect of anomalous couplings, no events are selected in the data, and 95% C.L. upper limits are obtained as follows: $-1.2 < f_{T,0}/\Lambda^4 < 1.2$, $-3.3 < f_{T,1}/\Lambda^4 < 3.3$, $-2.7 < f_{T,2}/\Lambda^4 < 2.6$, in units of TeV^{-4} and without application of a form factor.

² SIRUNYAN 19BP study WZ plus 2 jets production, using W and Z decay channels with electrons or muons. In the data, 75 events are selected, with a fitted SM signal of 15.1 ± 1.6 events and a fitted background of 62.4 ± 2.8 events. The transverse mass distribution of the WZ system is analyzed to set the following limits at 95% C.L., in units of TeV^{-4} : $-9.15 < f_{M,0}/\Lambda^4 < 9.15$, $-9.15 < f_{M,1}/\Lambda^4 < 9.45$, $-26.5 < f_{S,0}/\Lambda^4 < 27.5$, $-41.2 < f_{S,1}/\Lambda^4 < 42.8$, $-0.75 < f_{T,0}/\Lambda^4 < 0.81$, $-0.49 < f_{T,1}/\Lambda^4 < 0.55$, $-1.49 < f_{T,2}/\Lambda^4 < 1.85$.

³ SIRUNYAN 19CQ search for anomalous electroweak production of vector boson pairs in association with two jets. Events are selected by requiring two jets with a large invariant mass and rapidity separation, one or two leptons (electrons or muons), and a W or Z boson decaying hadronically. In the $WV(ZV)$ channel, 347 (47) events are selected in the data, with a total expected background of 352 ± 19 (50.3 ± 5.8) events. Analysing the mass distribution of the WV or ZV system, the following 95% C.L. limits are obtained: $-2.7 < f_{S,0}/\Lambda^4 < 2.7$, $-3.4 < f_{S,1}/\Lambda^4 < 3.4$, $-0.69 < f_{M,0}/\Lambda^4 < 0.70$, $-2.0 < f_{M,1}/\Lambda^4 < 2.1$, $-1.3 < f_{M,6}/\Lambda^4 < 1.3$, $-3.4 < f_{M,7}/\Lambda^4 < 3.4$, $-0.12 < f_{T,0}/\Lambda^4 < 0.11$, $-0.12 < f_{T,1}/\Lambda^4 < 0.13$, $-0.28 < f_{T,2}/\Lambda^4 < 0.28$, in units of TeV^{-4} .

⁴ SIRUNYAN 18CC study pp collisions at $\sqrt{s} = 13$ TeV leading to a pair of same-sign W pairs decaying leptonically (e or μ) associated with a pair of jets. Isolated leptons with $p_T > 25$ (20) GeV for the leading (trailing) lepton, with $|\eta| < 2.5$ (2.4) for e (μ) and jets with $p_T > 30$ GeV, $|\eta| < 5.0$, $|\Delta\eta_{jj}| > 2.5$ and $m_{jj} > 500$ GeV is required. Further cuts are applied to minimize $Z \rightarrow ee$ events, non-prompt leptons and hadronically decaying taus. The number of selected events is 201, with an expected SM signal of 66.9 ± 2.4 and background of 138 ± 13 events. Analysing the dilepton invariant mass spectrum the following 95% C.L. limits are derived: $-7.7 < f_{S,0}/\Lambda^4 < 7.7$, $-21.6 < f_{S,1}/\Lambda^4 < 21.8$, $-6.0 < f_{M,0}/\Lambda^4 < 5.9$, $-8.7 < f_{M,1}/\Lambda^4 < 9.1$, $-11.9 < f_{M,6}/\Lambda^4 < 11.8$, $-13.3 < f_{M,7}/\Lambda^4 < 12.9$, $-0.62 < f_{T,0}/\Lambda^4 < 0.65$, $-0.28 < f_{T,1}/\Lambda^4 < 0.31$, $-0.89 < f_{T,2}/\Lambda^4 < 1.02$.

⁵ AABOUD 17AA analyze $W^\pm W^\pm$ production in association with two jets and W decay modes with electrons or muons. In the kinematic region of VBS the effect of anomalous QGCs is enhanced by requiring the transverse mass of the WW system to be larger than 400 GeV. In the data, 8 events are selected with a total background expected from SM processes of 3.8 ± 0.6 events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% CL limits on the QGCs: $-0.14 < \alpha_4 < 0.15$ and $-0.22 < \alpha_5 < 0.22$. Supersedes AAD 14AM.

⁶ AABOUD 17AG determine the $WW\gamma$ and $WZ\gamma$ cross sections in 8 TeV pp interactions by studying the final states $e\nu\mu\nu\gamma$ and $e\nu jj\gamma$ or $\mu\nu jj\gamma$. Upper limits on the production cross sections are derived in a fiducial region optimized for BSM physics. These are used to derive the following 95% C.L. upper limits for quartic couplings assuming the form scale factor, $\Lambda_{FF} = \infty$ (all in units of 10^3TeV^{-4}): $-0.3 < f_{M,0}/\Lambda^4 < 0.3$, $-0.5 < f_{M,1}/\Lambda^4 < 0.5$, $-1.8 < f_{M,2}/\Lambda^4 < 1.8$, $-1.1 < f_{M,4}/\Lambda^4 < 1.1$, $-1.7 < f_{M,5}/\Lambda^4 < 1.7$, $-0.6 < f_{M,6}/\Lambda^4 < 0.6$, $-1.1 < f_{M,7}/\Lambda^4 < 1.1$, $-0.1 < f_{T,0}/\Lambda^4 < 0.1$, $-0.2 < f_{T,1}/\Lambda^4 < 0.2$, $-0.4 < f_{T,4}/\Lambda^4 < 0.4$, $-1.5 < f_{T,5}/\Lambda^4 < 1.6$, $-1.9 < f_{T,6}/\Lambda^4 < 1.9$, $-4.3 < f_{T,7}/\Lambda^4 < 4.3$.

⁷ AABOUD 17D analyze electroweak diboson (WV , $V = W, Z$) production in association with a high-mass dijet system. In the data, 32 events are selected with an expected total background of 32 ± 12 events. Analysing the transverse mass distribution of the WV system, the following limits are set at 95% C.L.: $-0.024 < \alpha_4 < 0.030$ and $-0.028 < \alpha_5 < 0.033$.

- ⁸ AABOUD 17J analyze the $Z\gamma$ production in association with a high-mass dijet system, with the Z boson decaying into a pair of electrons, muons, or neutrinos. In the charged lepton (neutrino) channel, events are selected with a dijet mass larger than 500 (600) GeV and a transverse photon energy larger than 250 (150) GeV, with 2 (4) events selected in the data and 0.30 ± 0.08 (1.6 ± 0.5) expected background events. The observed event yield is used to determine 95% CL limits as follows: $-4.1 \times 10^3 < f_{T,9}/\Lambda^4 < 4.2 \times 10^3$, $-1.9 \times 10^3 < f_{T,8}/\Lambda^4 < 2.1 \times 10^3$, $-1.9 \times 10^1 < f_{T,0}/\Lambda^4 < 1.6 \times 10^1$, $-1.6 \times 10^2 < f_{M,0}/\Lambda^4 < 1.8 \times 10^2$, $-3.5 \times 10^2 < f_{M,1}/\Lambda^4 < 3.4 \times 10^2$, $-8.9 \times 10^2 < f_{M,2}/\Lambda^4 < 8.9 \times 10^2$, $-1.7 \times 10^3 < f_{M,3}/\Lambda^4 < 1.7 \times 10^3$, in units of TeV^{-4} and without application of a form factor.
- ⁹ AABOUD 17M analyze tri-boson $W^\pm W^\pm W^\mp$ production in decay channels with three charged leptons or two like-sign charged leptons with two jets, where the lepton can be an electron or muon. In the data, 24 tri-lepton events and 21 di-lepton plus jets events are selected, compared to a total event yield expected in the SM of 30.8 ± 3.0 and 21.9 ± 2.0 , respectively. Analysing the tri-lepton transverse mass or the transverse momentum sum of the two leptons, two jets and the missing transverse energy, the following limits at 95% CL are derived for the form factor cut-off scale $\Lambda_{FF} \rightarrow \infty$: $-0.13 < f_{S,0}/\Lambda^4 < 0.18$, $-0.21 < f_{S,1}/\Lambda^4 < 0.27$, in units of 10^4 TeV^{-4} , which are converted into the following limits: $-0.49 < \alpha_4 < 0.75$ and $-0.48 < \alpha_5 < 0.62$.
- ¹⁰ KHACHATRYAN 17AA analyse electroweak production of $Z\gamma$ in association with two hadronic jets, with the Z boson decaying to electron or muon pairs. Events with photon transverse momentum larger than 60 GeV and di-jet invariant mass larger than 400 GeV are selected. The $Z\gamma$ invariant mass spectrum is analysed to set 95% C.L. limits as follows: $-71 < f_{M,0}/\Lambda^4 < 75$, $-190 < f_{M,1}/\Lambda^4 < 182$, $-32 < f_{M,2}/\Lambda^4 < 31$, $-58 < f_{M,3}/\Lambda^4 < 59$, $-3.8 < f_{T,0}/\Lambda^4 < 3.4$, $-4.4 < f_{T,1}/\Lambda^4 < 4.4$, $-9.9 < f_{T,2}/\Lambda^4 < 9.0$, $-1.8 < f_{T,8}/\Lambda^4 < 1.8$, $-4.0 < f_{T,9}/\Lambda^4 < 4.0$, in units of TeV^{-4} and without application of a form factor.
- ¹¹ KHACHATRYAN 17M analyse electroweak production of $W\gamma$ in association with two hadronic jets, with the W boson decaying to electrons or muons. Events with photon transverse momentum larger than 200 GeV and di-jet invariant mass larger than 200 GeV are selected. The W transverse momentum spectrum is analysed to set 95% C.L. limits as follows: $-77 < f_{M,0}/\Lambda^4 < 74$, $-125 < f_{M,1}/\Lambda^4 < 129$, $-26 < f_{M,2}/\Lambda^4 < 26$, $-43 < f_{M,3}/\Lambda^4 < 44$, $-40 < f_{M,4}/\Lambda^4 < 40$, $-65 < f_{M,5}/\Lambda^4 < 65$, $-129 < f_{M,6}/\Lambda^4 < 129$, $-164 < f_{M,7}/\Lambda^4 < 162$, $-5.4 < f_{T,0}/\Lambda^4 < 5.6$, $-3.7 < f_{T,1}/\Lambda^4 < 4.0$, $-11 < f_{T,2}/\Lambda^4 < 12$, $-3.8 < f_{T,5}/\Lambda^4 < 3.8$, $-2.8 < f_{T,6}/\Lambda^4 < 3.0$, $-7.3 < f_{T,7}/\Lambda^4 < 7.7$, in units of TeV^{-4} and without application of a form factor.
- ¹² SIRUNYAN 17AD study pp collisions at $\sqrt{s} = 13 \text{ TeV}$ to determine the cross section of $ZZjj$ with the Z decaying to ee or $\mu\mu$. The ZZ mass distribution is used to set upper limits on the anomalous quartic couplings. The 95% upper limits for the relevant quartic couplings in units of TeV^{-4} are: $-0.46 < f_{T,0}/\Lambda^4 < 0.44$, $-0.61 < f_{T,1}/\Lambda^4 < 0.61$, $-1.2 < f_{T,2}/\Lambda^4 < 1.2$, $-0.84 < f_{T,8}/\Lambda^4 < 0.84$, $-1.8 < f_{T,9}/\Lambda^4 < 1.8$.
- ¹³ SIRUNYAN 17AR study pp collisions at $\sqrt{s} = 8 \text{ TeV}$ to determine the cross section of $pp \rightarrow W\gamma\gamma$ and $pp \rightarrow Z\gamma\gamma$ where $W \rightarrow \ell\nu$ and $Z \rightarrow \ell^+\ell^-$, ℓ being an electron or a muon. The number of W events in the e and μ channels is 63 and 108 respectively, and the number of Z events in the e and μ channels is 117 and 141. To increase sensitivity, the transverse momentum of the leading photon is required to be larger than 70 GeV. The 95% C.L. upper limits in units of TeV^{-4} are $-701 < f_{M,2}/\Lambda^4 < 683$, $-1170 < f_{M,3}/\Lambda^4 < 1220$, $-33.5 < f_{T,0}/\Lambda^4 < 34.0$, $-44.3 < f_{T,1}/\Lambda^4 < 44.8$, $-93.8 < f_{T,2}/\Lambda^4 < 93.2$.
- ¹⁴ AABOUD 16E study WW production in two-photon mediated pp collisions at 8 TeV where the W boson decays into an electron or muon, probing the $\gamma\gamma WW$ vertex for anomalous quartic gauge couplings. The lepton p_T is required to be larger than 30 GeV. Limits on anomalous couplings are determined from events with p_T larger than 120 GeV where the aQGC effect is enhanced and the SM background reduced; in the data corresponding to an integrated luminosity of 20.2fb^{-1} , 1 event is selected with an expected SM background of 0.37 ± 0.13 events. The 95% C.L. limits without a form-factor cutoff ($\Lambda_{\text{cutoff}} \rightarrow \infty$) are as follows: $-1.7 < a_0^W/\Lambda^2 < 1.7$ and $-6.4 < a_C^W/\Lambda^2 < 6.3$ in units of 10^{-6} GeV^{-2} . In terms of another set of variables: $-6.6 < f_{M,0}/\Lambda^4 < 6.6$ and $-24 < f_{M,1}/\Lambda^4 < 25$ in units of $10^{-11} \text{ GeV}^{-4}$.
- ¹⁵ AAD 16Q study $Z\gamma\gamma$ production in pp collisions. In events with no additional jets, 29 (22) Z decays to electron (muon) pairs are selected, with an expected background of 3.3 ± 1.1 (6.5 ± 2.0) events, as well as 19 Z decays to neutrino pairs with an expected background of 8.3 ± 4.4 events. Analysing the photon transverse momentum distribution for $m_{\gamma\gamma}$ above 200 GeV (300 GeV) for lepton (neutrino) events, yields the 95% C.L. limits: $-1.6 \times 10^4 < f_{M,2}/\Lambda^4 < 1.6 \times 10^4$, $-2.9 \times 10^4 < f_{M,3}/\Lambda^4 < 2.7 \times 10^4$, $-0.86 \times 10^2 < f_{T,0}/\Lambda^4 < 1.03 \times 10^2$, $-0.69 \times 10^3 < f_{T,5}/\Lambda^4 < 0.68 \times 10^3$, $-0.74 \times 10^4 < f_{T,9}/\Lambda^4 < 0.74 \times 10^4$ in units of TeV^{-4} and without application of a form factor Λ_{FF} .
- ¹⁶ KHACHATRYAN 16AX searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \rightarrow ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 13 events containing an $e^\pm\mu^\mp$ pair with $p_T(e, \mu) > 30 \text{ GeV}$ are selected in a total luminosity of 19.7 fb^{-1} , with an expected $\gamma\gamma \rightarrow WW$ signal of 5.3 ± 0.1 events and an expected background of 3.9 ± 0.5 events. When combining with the data collected at 7 TeV (KHACHATRYAN 13AA), and not assuming a form factor, the following 1-parameter limits at 95% C.L. are obtained from the $p_T(e, \mu)$ spectrum: $|a_0^W/\Lambda^2| < 1.1 \times 10^{-6} \text{ GeV}^{-2}$ ($a_C^W = 0$), and $|a_C^W/\Lambda^2| < 4.1 \times 10^{-6} \text{ GeV}^{-2}$ ($a_0^W = 0$). In terms of another set of variables: $|f_{M,0}/\Lambda^4| < 4.2 \times 10^{-12} \text{ GeV}^{-4}$, $|f_{M,1}/\Lambda^4| < 16 \times 10^{-12} \text{ GeV}^{-4}$, $|f_{M,2}/\Lambda^4| < 2.1 \times 10^{-12} \text{ GeV}^{-4}$, $|f_{M,3}/\Lambda^4| < 7.8 \times 10^{-12} \text{ GeV}^{-4}$.
- ¹⁷ AAD 15N study $W\gamma\gamma$ events in 8 TeV pp interactions, where the W decays into an electron or a muon. The events are characterized by an isolated lepton, a missing transverse energy due to the decay neutrino, and two isolated photons, with the p_T of the lepton and the photons being $> 20 \text{ GeV}$. The number of candidate events observed in the
- electron channel for $N(\text{jet}) \geq 0$ and $N(\text{jet}) = 0$ is 47 and 15, the corresponding numbers for the muon channel being 110 and 53. The backgrounds expected are 30.2 ± 7.4 , 8.7 ± 3.0 , 52.1 ± 12.2 , and 24.4 ± 8.3 respectively. The 95% C.L. limits on the values of the parameters $f_{T,0}/\Lambda^4$, $f_{M,2}/\Lambda^4$ and $f_{M,3}/\Lambda^4$ are $-0.9-0.9 \times 10^2$, $-0.8-0.8 \times 10^4$, and $-1.5-1.4 \times 10^4$ respectively, without application of a form factor Λ_{FF} .
- ¹⁸ KHACHATRYAN 15D study vector-boson-scattering tagged by two jets, requiring two same-sign charged leptons arising from $W^\pm W^\pm$ production and decay. The two jets must have a transverse momentum larger than 30 GeV, while the leptons, electrons or muons, must have a transverse momentum $> 20 \text{ GeV}$. The dijet mass is required to be $> 500 \text{ GeV}$, the dilepton mass $> 50 \text{ GeV}$, with additional requirement of differing from the Z mass by $> 15 \text{ GeV}$. In the two categories W^+W^+ and W^-W^- , 10 and 2 data events are observed in a data sample corresponding to an integrated luminosity of 19.4 fb^{-1} , with an expected background of 3.1 ± 0.6 and 2.6 ± 0.5 events. Analysing the distribution of the dilepton invariant mass, the following limits at 95% C.L. are obtained, in units of TeV^{-4} : $-38 < f_{S,0}/\Lambda^4 < 40$, $-118 < f_{S,1}/\Lambda^4 < 120$, $-33 < f_{M,0}/\Lambda^4 < 32$, $-44 < f_{M,1}/\Lambda^4 < 47$, $-65 < f_{M,6}/\Lambda^4 < 63$, $-70 < f_{M,7}/\Lambda^4 < 66$, $-4.2 < f_{T,0}/\Lambda^4 < 4.6$, $-1.9 < f_{T,1}/\Lambda^4 < 2.2$, $-5.2 < f_{T,2}/\Lambda^4 < 6.4$.
- ¹⁹ AAD 14AM analyze electroweak production of WW jet jet same-charge diboson plus two jets production, with the W bosons decaying to electron or muon, to study the quartic $WWWW$ coupling. In a kinematic region enhancing the electroweak production over the strong production, 34 events are observed in the data while 29.8 ± 2.4 events are expected with a background of 15.9 ± 1.9 events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% CL limits on the quartic gauge couplings: $-0.14 < \alpha_4 < 0.16$ and $-0.23 < \alpha_5 < 0.24$.
- ²⁰ CHATRCHYAN 14Q study $WV\gamma$ production in 8 TeV pp collisions, in the single lepton final state, with $W \rightarrow \ell\nu$, $Z \rightarrow \text{dijet}$ or $W \rightarrow \ell\nu$, $W \rightarrow \text{dijet}$, the dijet mass resolution precluding differentiation between the W and Z. p_T and pseudo-rapidity cuts are put on the lepton, the photon and the two jets to minimize backgrounds. The dijet mass is required to be between 70–100 GeV and $|\Delta\eta_{jj}| < 1.4$. The selected number of muon (electron) events are 183 (139), with SM expectation being 194.2 ± 11.5 (147.9 ± 10.7) including signal and background. The photon E_T distribution is used to set limits on the anomalous quartic couplings. The following 95% CL limits are deduced (all in units of TeV^{-2} or TeV^{-4}): $-21 < a_0^W/\Lambda^2 < 20$, $-34 < a_C^W/\Lambda^2 < 32$, $-12 < \kappa_0^W/\Lambda^2 < 10$ and $-18 < \kappa_C^W/\Lambda^2 < 17$; and $-25 < f_{T,0}/\Lambda^4 < 24 \text{ TeV}^{-4}$.
- ²¹ ABAZOV 13D searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \rightarrow ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 946 events containing an e^+e^- pair with missing energy are selected in a total luminosity of 9.7 fb^{-1} , with an expectation of 983 ± 108 events from Standard-Model processes. The following 1-parameter limits at 95% CL are obtained: $|a_0^W/\Lambda^2| < 4.3 \times 10^{-4} \text{ GeV}^{-2}$ ($a_C^W = 0$), $|a_C^W/\Lambda^2| < 1.5 \times 10^{-3} \text{ GeV}^{-2}$ ($a_0^W = 0$).
- ²² CHATRCHYAN 13AA searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \rightarrow ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 2 events containing an $e^\pm\mu^\mp$ pair with $p_T(e, \mu) > 30 \text{ GeV}$ are selected in a total luminosity of 5.05 fb^{-1} , with an expected $ppWW$ signal of 2.2 ± 0.4 events and an expected background of 0.84 ± 0.15 events. The following 1-parameter limits at 95% CL are obtained from the $p_T(e, \mu)$ spectrum: $|a_0^W/\Lambda^2| < 4.0 \times 10^{-6} \text{ GeV}^{-2}$ ($a_C^W = 0$), $|a_C^W/\Lambda^2| < 1.5 \times 10^{-5} \text{ GeV}^{-2}$ ($a_0^W = 0$).
- ²³ ABBIENDI 04B select $187 e^+e^- \rightarrow W^+W^-\gamma$ events in the C.M. energy range 180–209 GeV, where $E_\gamma > 2.5 \text{ GeV}$, the photon has a polar angle $|\cos\theta_\gamma| < 0.975$ and is well isolated from the nearest jet and charged lepton, and the effective masses of both fermion-antifermion systems agree with the W mass within $3\Gamma_W$. The measured differential cross section as a function of the photon energy and photon polar angle is used to extract the 95% CL limits: $-0.020 \text{ GeV}^{-2} < a_0/\Lambda^2 < 0.020 \text{ GeV}^{-2}$, $-0.053 \text{ GeV}^{-2} < a_C/\Lambda^2 < 0.037 \text{ GeV}^{-2}$ and $-0.16 \text{ GeV}^{-2} < a_n/\Lambda^2 < 0.15 \text{ GeV}^{-2}$.
- ²⁴ ABBIENDI 04L select $20 e^+e^- \rightarrow \nu\bar{\nu}\gamma$ acoplanar events in the energy range 180–209 GeV and $176 e^+e^- \rightarrow q\bar{q}\gamma\gamma$ events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ quartic couplings. Further combining with the $W^+W^-\gamma$ sample of ABBIENDI 04B the following one-parameter 95% CL limits are obtained: $-0.007 < a_0^Z/\Lambda^2 < 0.023 \text{ GeV}^{-2}$, $-0.029 < a_C^Z/\Lambda^2 < 0.029 \text{ GeV}^{-2}$, $-0.020 < a_0^W/\Lambda^2 < 0.020 \text{ GeV}^{-2}$, $-0.052 < a_C^W/\Lambda^2 < 0.037 \text{ GeV}^{-2}$.
- ²⁵ In the CM energy range 183 to 209 GeV HEISTER 04A select $30 e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$ events with two acoplanar, high energy and high transverse momentum photons. The photon-photon acoplanarity is required to be $> 5^\circ$, $E_\gamma/\sqrt{s} > 0.025$ (the more energetic photon having energy $> 0.2\sqrt{s}$), $p_{T,\gamma}/E_{\text{beam}} > 0.05$ and $|\cos\theta_\gamma| < 0.94$. A likelihood fit to the photon energy and recoil missing mass yields the following one-parameter 95% CL limits: $-0.012 < a_0^Z/\Lambda^2 < 0.019 \text{ GeV}^{-2}$, $-0.041 < a_C^Z/\Lambda^2 < 0.044 \text{ GeV}^{-2}$, $-0.060 < a_0^W/\Lambda^2 < 0.055 \text{ GeV}^{-2}$, $-0.099 < a_C^W/\Lambda^2 < 0.093 \text{ GeV}^{-2}$.
- ²⁶ ABDALLAH 03I select $122 e^+e^- \rightarrow W^+W^-\gamma$ events in the C.M. energy range 189–209 GeV, where $E_\gamma > 5 \text{ GeV}$, the photon has a polar angle $|\cos\theta_\gamma| < 0.95$ and is well isolated from the nearest charged fermion. A fit to the photon energy spectra yields $a_C/\Lambda^2 = 0.000 \pm 0.019 \text{ GeV}^{-2}$, $a_0/\Lambda^2 = -0.004 \pm 0.018 \text{ GeV}^{-2}$, $\bar{a}_0/\Lambda^2 = -0.007 \pm 0.019 \text{ GeV}^{-2}$, $\bar{a}_n/\Lambda^2 = -0.09 \pm 0.16 \text{ GeV}^{-2}$, and $\bar{a}_n/\Lambda^2 = +0.05 \pm 0.07 \text{ GeV}^{-2}$, keeping the other parameters fixed to their Standard Model values (0). The 95% CL limits are: $-0.063 \text{ GeV}^{-2} < a_C/\Lambda^2 < +0.032 \text{ GeV}^{-2}$, $-0.020 \text{ GeV}^{-2} < a_0/\Lambda^2 < +0.020 \text{ GeV}^{-2}$, $-0.020 \text{ GeV}^{-2} < \bar{a}_0/\Lambda^2 < +0.020 \text{ GeV}^{-2}$, $-0.18 \text{ GeV}^{-2} < \bar{a}_n/\Lambda^2 < +0.14 \text{ GeV}^{-2}$, $-0.16 \text{ GeV}^{-2} < \bar{a}_n/\Lambda^2 < +0.17 \text{ GeV}^{-2}$.
- ²⁷ ACHARD 02F select $86 e^+e^- \rightarrow W^+W^-\gamma$ events at 192–207 GeV, where $E_\gamma > 5 \text{ GeV}$ and the photon is well isolated. They also select 43 acoplanar $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$ events in this energy range, where the photon energies are $> 5 \text{ GeV}$ and $> 1 \text{ GeV}$ and the photon polar angles are between 14° and 166° . All these 43 events are in the recoil mass region corresponding to the Z ($75-110 \text{ GeV}$). Using the shape and normalization of the photon spectra in the $W^+W^-\gamma$ events, and combining with the 42 event sample from

Gauge & Higgs Boson Particle Listings

W, Z

189 GeV data (ACCIARRI 00T), they obtain: $a_0/\Lambda^2 = 0.000 \pm 0.010 \text{ GeV}^{-2}$, $a_c/\Lambda^2 = -0.013 \pm 0.023 \text{ GeV}^{-2}$, and $a_n/\Lambda^2 = -0.002 \pm 0.076 \text{ GeV}^{-2}$. Further combining the analyses of $W^+ W^- \gamma$ events with the low recoil mass region of $\nu\bar{\nu}\gamma\gamma$ events (including samples collected at 183 + 189 GeV), they obtain the following one-parameter 95% CL limits: $-0.015 \text{ GeV}^{-2} < a_0/\Lambda^2 < 0.015 \text{ GeV}^{-2}$, $-0.048 \text{ GeV}^{-2} < a_c/\Lambda^2 < 0.026 \text{ GeV}^{-2}$, and $-0.14 \text{ GeV}^{-2} < a_n/\Lambda^2 < 0.13 \text{ GeV}^{-2}$.

Z Boson

Z MASS

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). The fit is performed using the Z mass and width, the Z hadronic pole cross section, the ratios of hadronic to leptonic partial widths, and the Z pole forward-backward lepton asymmetries. This set is believed to be most free of correlations.

The Z-boson mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass dependent width. The value is 34 MeV greater than the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator. Also the LEP experiments term based on the standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted Z mass. See ACCIARRI 00q and ABBIENDI 04g for a detailed investigation of both these issues.

93.1 ± 1.0 ± 3.0	24	13	ALBAJAR	89	UA1	$E_{cm}^{pp} = 546,630 \text{ GeV}$

- ABBIENDI 01A error includes approximately 2.3 MeV due to statistics and 1.8 MeV due to LEP energy uncertainty.
- The error includes 1.6 MeV due to LEP energy uncertainty.
- The error includes 1.8 MeV due to LEP energy uncertainty.
- BARATE 00c error includes approximately 2.4 MeV due to statistics, 0.2 MeV due to experimental systematics, and 1.7 MeV due to LEP energy uncertainty.
- ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic e^+p and e^-p neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.
- ABBIENDI 04G obtain this result using the S-matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 34 MeV shift with respect to the Breit-Wigner fits.
- ACHARD 04c select $e^+e^- \rightarrow Z\gamma$ events with hard initial-state radiation. Z decays to $q\bar{q}$ and muon pairs are considered. The fit results obtained in the two samples are found consistent to each other and combined considering the uncertainty due to ISR modelling as fully correlated.
- ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the γ/Z interference term. The authors have corrected the measurement for the 34.1 MeV shift with respect to the Breit-Wigner fits. The error contains a contribution of $\pm 2.3 \text{ MeV}$ due to the uncertainty on the γZ interference.
- MIYABAYASHI 95 combine their low energy total hadronic cross-section measurement with the ACTON 93D data and perform a fit using an S-matrix formalism. As expected, this result is below the mass values obtained with the standard Breit-Wigner parametrization.
- Enters fit through W/Z mass ratio given in the W Particle Listings. The ALITTI 92B systematic error (± 0.93) has two contributions: one (± 0.92) cancels in m_W/m_Z and one (± 0.12) is noncancelling. These were added in quadrature.
- First error of ABE 89 is combination of statistical and systematic contributions; second is mass scale uncertainty.
- ABRAMS 89B uncertainty includes 35 MeV due to the absolute energy measurement.
- ALBAJAR 89 result is from a total sample of 33 $Z \rightarrow e^+e^-$ events.

Z WIDTH

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06).

2.42 $\begin{smallmatrix} +0.45 \\ -0.35 \end{smallmatrix}$ ± 1.0	480	9 ABRAMS	89B MRK2	$E_{cm}^{ee} = 89\text{--}93 \text{ GeV}$
2.7 $\begin{smallmatrix} +1.2 \\ -1.0 \end{smallmatrix}$ ± 1.3	24	10 ALBAJAR	89 UA1	$E_{cm}^{pp} = 546,630 \text{ GeV}$
2.7 ± 2.0 ± 1.0	25	11 ANSARI	87 UA2	$E_{cm}^{pp} = 546,630 \text{ GeV}$

- ABBIENDI 01A error includes approximately 3.6 MeV due to statistics, 1 MeV due to event selection systematics, and 1.3 MeV due to LEP energy uncertainty.
- The error includes 1.2 MeV due to LEP energy uncertainty.
- The error includes 1.3 MeV due to LEP energy uncertainty.
- BARATE 00c error includes approximately 3.8 MeV due to statistics, 0.9 MeV due to experimental systematics, and 1.3 MeV due to LEP energy uncertainty.
- ABBIENDI 04G obtain this result using the S-matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 1 MeV shift with respect to the Breit-Wigner fits.
- ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the γ/Z interference term. The authors have corrected the measurement for the 0.9 MeV shift with respect to the Breit-Wigner fits.

- ABREU 96R obtain this value from a study of the interference between initial and final state radiation in the process $e^+e^- \rightarrow Z \rightarrow \mu^+\mu^-$.
- ABRAMS 89B uncertainty includes 50 MeV due to the miniSAM background subtraction error.
- ALBAJAR 89 result is from a total sample of 33 $Z \rightarrow e^+e^-$ events.
- Quoted values of ANSARI 87 are from direct fit. Ratio of Z and W production gives either $\Gamma(Z) < (1.09 \pm 0.07) \times \Gamma(W)$, CL = 90% or $\Gamma(Z) = (0.82^{+0.19}_{-0.14} \pm 0.06) \times \Gamma(W)$. Assuming Standard-Model value $\Gamma(W) = 2.65 \text{ GeV}$ then gives $\Gamma(Z) < 2.89 \pm 0.19$ or $= 2.17^{+0.50}_{-0.37} \pm 0.16$.

[a] This parameter is not directly used in the overall fit but is derived using the fit results; see the note "The Z boson" and ref. LEP-SLC 06 (Physics Reports (Physics Letters C) **427** 257 (2006)).

[b] ℓ indicates each type of lepton (e , μ , and τ), not sum over them.

[c] Here ℓ indicates e or μ .

[d] The value is for the sum of the charge states or particle/antiparticle states indicated.

[e] This value is updated using the product of (i) the $Z \rightarrow b\bar{b}$ fraction from this listing and (ii) the b -hadron fraction in an unbiased sample of weakly decaying b -hadrons produced in Z-decays provided by the Heavy Flavor Averaging Group (HFLAV, http://www.slac.stanford.edu/xorg/hflav/osc/PDG_2009/#FRACZ).

[f] See the Particle Listings below for the γ energy range used in this measurement.

[g] For $m_{\gamma\gamma} = (60 \pm 5)$ GeV.

In our fit $\Gamma(\ell^+ \ell^-)$ is defined as the partial Z width for the decay into a pair of massless charged leptons. This parameter is not directly used in the 5-parameter fit assuming lepton universality but is derived using the fit results. See the note "The Z boson" and ref. LEP-SLC 06.

 $\Gamma((u\bar{u}+c\bar{c})/2)/\Gamma(\text{hadrons})$ Γ_9/Γ_8

This quantity is the branching ratio of $Z \rightarrow$ "up-type" quarks to $Z \rightarrow$ hadrons. Except ACKERSTAFF 97T the values of $Z \rightarrow$ "up-type" and $Z \rightarrow$ "down-type" branchings are extracted from measurements of $\Gamma(\text{hadrons})$, and $\Gamma(Z \rightarrow \gamma + \text{jets})$ where γ is a high-energy (>5 or 7 GeV) isolated photon. As the experiments use different procedures and slightly different values of M_Z , $\Gamma(\text{hadrons})$ and α_s in their extraction procedures, our average has to be taken with caution.

0.1623 ± 0.0085 ± 0.0209	⁶ ABREU	95D DLPH	$E_{\text{cm}}^{\text{ee}} = 88-94$ GeV

- ¹ ABE 05F use hadronic Z decays collected during 1996-98 to obtain an enriched sample of $c\bar{c}$ events using a double tag method. The single c -tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere). A multitag approach is used, defining 4 regions of the output value of the neural network and R_c is extracted from a simultaneous fit to the count rates of the 4 different tags. The quoted systematic error includes an uncertainty of ± 0.0006 due to the uncertainty on R_b .
- ² ABREU 00 obtain this result properly combining the measurement from the D^{*+} production rate ($R_c = 0.1610 \pm 0.0104 \pm 0.0077 \pm 0.0043$ (BR)) with that from the overall charm counting ($R_c = 0.1692 \pm 0.0047 \pm 0.0063 \pm 0.0074$ (BR)) in $c\bar{c}$ events. The systematic error includes an uncertainty of ± 0.0054 due to the uncertainty on the charmed hadron branching fractions.
- ³ BARATE 00B use exclusive decay modes to independently determine the quantities $R_c \times f(c \rightarrow X)$, $X = D^0, D^+, D_s^+, \text{ and } \Lambda_c$. Estimating $R_c \times f(c \rightarrow \Xi_c / \Omega_c) = 0.0034$, they simply sum over all the charm decays to obtain $R_c = 0.1738 \pm 0.0047 \pm 0.0088 \pm$

Gauge & Higgs Boson Particle Listings

Z

0.0075(BR). This is combined with all previous ALEPH measurements (BARATE 98T and BUSKULIC 94G, $R_C = 0.1681 \pm 0.0054 \pm 0.0062$) to obtain the quoted value.

⁴ACKERSTAFF 98E use an inclusive/exclusive double tag. In one jet $D^{*\pm}$ mesons are exclusively reconstructed in several decay channels and in the opposite jet a slow pion (opposite charge inclusive $D^{*\pm}$) tag is used. The b content of this sample is measured by the simultaneous detection of a lepton in one jet and an inclusively reconstructed $D^{*\pm}$ meson in the opposite jet. The systematic error includes an uncertainty of ± 0.006 due to the external branching ratios.

⁵ALEXANDER 96R obtain this value via direct charm counting, summing the partial contributions from D^0 , D^+ , D_S^+ , and Λ_c^+ , and assuming that strange-charmed baryons account for the 15% of the Λ_c^+ production. An uncertainty of ± 0.005 due to the uncertainties in the charm hadron branching ratios is included in the overall systematics.

⁶ABREU 95D perform a maximum likelihood fit to the combined p and p_T distributions of single and dilepton samples. The second error includes an uncertainty of ± 0.0124 due to models and branching ratios.

$R_b = \Gamma(b\bar{b})/\Gamma(\text{hadrons})$ Γ_{12}/Γ_8

OUR FIT is obtained by a simultaneous fit to several c - and b -quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06.

The Standard Model predicts $R_b = 0.21581$ for $m_t = 174.3$ GeV and $M_H = 150$ GeV.

¹ABE 05F use hadronic Z decays collected during 1996-98 to obtain an enriched sample of $b\bar{b}$ events using a double tag method. The single b-tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere; the key tag is obtained requiring the secondary vertex corrected mass to be above the D -meson mass). ABE 05F obtain $R_b = 0.21604 \pm 0.00098 \pm 0.00074$ where the systematic error includes an uncertainty of ± 0.00012 due to the uncertainty on R_C . The value reported here is obtained properly combining with ABE 98D. The quoted systematic error includes an uncertainty of ± 0.00012 due to the uncertainty on R_C .

²ACCIARRI 00 obtain this result using a double-tagging technique, with a high p_T lepton tag and an impact parameter tag in opposite hemispheres.

³ABBIENDI 99B tag $Z \rightarrow b\bar{b}$ decays using leptons and/or separated decay vertices. The b-tagging efficiency is measured directly from the data using a double-tagging technique.

⁴ABREU 99B obtain this result combining in a multivariate analysis several tagging methods (impact parameter and secondary vertex reconstruction, complemented by event shape variables). For R_C different from its Standard Model value of 0.172, R_b varies as $-0.024 \times (R_C - 0.172)$.

⁵BARATE 97F combine the lifetime-mass hemisphere tag (BARATE 97E) with event shape information and lepton tag to identify $Z \rightarrow b\bar{b}$ candidates. They further use c - and u d -selection tags to identify the background. For R_C different from its Standard Model value of 0.172, R_b varies as $-0.019 \times (R_C - 0.172)$.

⁶ABREU 95D perform a maximum likelihood fit to the combined p and p_T distributions of single and dilepton samples. The second error includes an uncertainty of ± 0.0023 due to models and branching ratios.

⁷BUSKULIC 94G perform a simultaneous fit to the p and p_T spectra of both single and dilepton events.

⁸JACOBSEN 91 tagged $b\bar{b}$ events by requiring coincidence of ≥ 3 tracks with significant impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties (± 0.014).

$<2.6 \times 10^{-6}$	95	³ AAD	15I ATLS	$E_{\text{cm}}^{pp} = 8$ TeV

¹ SIRUNYAN 19AJ study $Z \rightarrow J/\psi\gamma$ with $J/\psi \rightarrow \mu^+\mu^-$. Candidate events are selected by requiring a pair of oppositely charged muons and a well isolated photon. The leading (subleading) muon is required to have a transverse momentum larger than 20 GeV (4 GeV), while the photon must have a transverse energy larger than 33 GeV. Requiring the invariant mass of the $\mu\mu$ ($\mu\mu\gamma$) system in the range 3.0 to 3.2 (81 to 101) GeV, selects 183 data events which is consistent with the expected background. The 95% C.L. limit on the Z branching fraction is obtained assuming the J/ψ to be unpolarized.

² AABOUD 18BL study $Z \rightarrow J/\psi\gamma$ in 13 TeV pp interactions. Two triggers were used: isolated photon of $p_T > 35(25)$ GeV and a muon with $p_T > 18(24)$ GeV. The J/ψ is detected via its dimuon decay and it is required that the azimuthal angle between the photon and the J/ψ in the plane transverse to the beam direction is $> \pi/2$. The number of observed/expected background events is 92/89 ± 6 in the dimuon mass range 2.9–3.3 GeV leading to the quoted 95% C.L. limit.

³ AAD 15I use events with the highest p_T muon in the pair required to have $p_T > 20$ GeV, the dimuon mass required to be within 0.2 GeV of the $J/\psi(1S)$ mass and its transverse momentum required to be > 36 GeV. The photon is also required to have its $p_T > 36$ GeV.

VALUE	DOCUMENT ID	TECN	COMMENT
$0.67 \pm 0.18 \pm 0.05$	¹ SIRUNYAN	18DZ CMS	pp at 13 TeV

¹ SIRUNYAN 18DZ observe the decay $Z \rightarrow \Psi\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV, where Ψ includes J/ψ as well as $\psi(2S) \rightarrow J/\psi X$, and $\ell^+\ell^-$ represents an electron or muon pair while the J/ψ is detected via its $\mu^+\mu^-$ decay channel. To reduce systematic errors they determine the ratio of the branching fraction of this decay to that of $Z \rightarrow \mu^+\mu^- \mu^+\mu^-$ within phase-space cuts imposed on lepton transverse momentum and pseudo rapidity, dilepton invariant mass, and J/ψ transverse momentum. The number of selected $\Psi\mu^+\mu^-$ (Ψe^+e^-) candidate events is 29 (18). Analyzing the $\mu^+\mu^-$ and $\mu^+\mu^- \ell^+\ell^-$ invariant mass distributions, a yield of 13.0 ± 3.9 (11.2 ± 3.4) events for the $\Psi\mu^+\mu^-$ (Ψe^+e^-) mode is obtained. The ratio of the branching fractions is determined as $0.67 \pm 0.18 \pm 0.05$ within the selected phase-space cuts. Assuming extrapolation to full phase space cancels in the ratio, and using their measured value of $B(Z \rightarrow \mu^+\mu^- \mu^+\mu^-) = (1.20 \pm 0.08) \times 10^{-6}$, they estimate $B(Z \rightarrow J/\psi\ell^+\ell^-) = 8 \times 10^{-7}$.

$<1.5 \times 10^{-6}$	95	106	1 SIRUNYAN	19BR CMS	$E_{\text{cm}}^{pp} = 13 \text{ TeV}$

1 SIRUNYAN 19BR search for Z decays to a pair of Υ mesons in the channel $\Upsilon \rightarrow \mu^+\mu^-$. The invariant mass of the Υ candidates has to be in the range of 8.5 to 11 GeV. A total of 106 events are selected in the 20–140 GeV 4-muon invariant mass range. An un-binned extended maximum likelihood fit leads to the 95% C.L. upper limit, obtained assuming the Υ mesons to be unpolarised.

seen ¹ ABDALLAH 05c DLPH $E_{cm}^{ee} = 88-94$ GeV
seen ² BUSKULIC 96T ALEP $E_{cm}^{ee} = 88-94$ GeV
seen ³ ABREU 95v DLPH $E_{cm}^{ee} = 88-94$ GeV

¹ ABDALLAH 05c searched for the beauty strange baryon Ξ_b in the inclusive semileptonic decay channel $\Xi_b \rightarrow \Xi^- \ell^+ \nu_\ell X$. Evidence for the Ξ_b production is seen from the observation of Ξ^\mp production accompanied by a lepton of the same sign. From the excess of "right-sign" pairs $\Xi^\mp \ell^\mp$ compared to "wrong-sign" pairs $\Xi^\mp \ell^\pm$ the production rate is measured to be $B(b \rightarrow \Xi_b) \times B(\Xi_b \rightarrow \Xi^- \ell^+ X) = (3.0 \pm 1.0 \pm 0.3) \times 10^{-4}$ per lepton species, averaged over electrons and muons.

² BUSKULIC 96T investigate Ξ -lepton correlations and find a significant excess of "right-sign" pairs $\Xi^\mp \ell^\mp$ compared to "wrong-sign" pairs $\Xi^\mp \ell^\pm$. This excess is interpreted as evidence for Ξ_b semileptonic decay. The measured product branching ratio is $B(b \rightarrow \Xi_b) \times B(\Xi_b \rightarrow X_c X \ell^+ \nu_\ell) \times B(X_c \rightarrow \Xi^- X') = (5.4 \pm 1.1 \pm 0.8) \times 10^{-4}$ per lepton species, averaged over electrons and muons, with X_c a charmed baryon.

³ ABREU 95v observe an excess of "right-sign" pairs $\Xi^\mp \ell^\mp$ compared to "wrong-sign" pairs $\Xi^\mp \ell^\pm$ in jets: this excess is interpreted as evidence for the beauty strange baryon Ξ_b production, with $\Xi_b \rightarrow \Xi^- \ell^+ \nu_\ell X$. They find that the probability for this signal to come from non b-baryon decays is less than 5×10^{-4} and that Λ_b decays can account for less than 10% of these events. The Ξ_b production rate is then measured to be $B(b \rightarrow \Xi_b) \times B(\Xi_b \rightarrow \Xi^- \ell^+ X) = (5.9 \pm 2.1 \pm 1.0) \times 10^{-4}$ per lepton species, averaged over electrons and muons.

$\Gamma(b\text{-baryon } X)/\Gamma(\text{hadrons})$ Γ_{56}/Γ_8

"OUR EVALUATION" is obtained using our current values for $f(b \rightarrow b\text{-baryon})$ and $R_b = \Gamma(b\bar{b})/\Gamma(\text{hadrons})$. We calculate $\Gamma(b\text{-baryon } X)/\Gamma(\text{hadrons}) = R_b \times f(b \rightarrow b\text{-baryon})$. The decay fraction $f(b \rightarrow b\text{-baryon})$ was provided by the Heavy Flavor Averaging Group (<https://inflav.web.cern.ch/>).

Z HADRONIC POLE CROSS SECTION

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). This quantity is defined as

$$\sigma_h^0 = \frac{12\pi}{M_Z^2} \frac{\Gamma(e^+e^-)\Gamma(\text{hadrons})}{\Gamma_Z^2}$$

It is one of the parameters used in the Z lineshape fit.

² BARATE 00C error includes approximately 0.030 due to statistics, 0.026 due to experimental systematics, and 0.025 due to uncertainty in luminosity measurement.

Z VECTOR COUPLINGS

These quantities are the effective vector couplings of the Z to charged leptons and quarks. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e , A_μ , and A_τ . By convention the sign of g_A^e is fixed to be negative (and opposite to that of $g^{l'e}$ obtained using ν_e scattering measurements). For the light quarks, the sign of the couplings is assigned consistently with this assumption. The LEP/SLD-based fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e , A_μ , and A_τ measurements. See the note "The Z boson" and ref. LEP-SLC 06 for details. Where $p\bar{p}$ and $e\bar{p}$ data is quoted, OUR FIT value corresponds to a weighted average of this with the LEP/SLD fit result.

$g^{\nu\mu}$	VALUE	DOCUMENT ID	TECN	COMMENT
	0.502 ± 0.017	1 VILAIN	94 CHM2	From $\nu_\mu e$ scattering

¹VILAIN 94 derive this value from their measurement of the couplings $g_A^{\nu\mu} = -0.503 \pm 0.017$ and $g_V^{\nu\mu} = -0.035 \pm 0.017$ obtained from $\nu_\mu e$ scattering. We have re-evaluated this value using the current PDG values for g_A^e and g_V^e .

Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the Z these quantities are defined as

$$A_f = \frac{2g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$

where g_V^f and g_A^f are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the note "The Z boson" and ref. LEP-SLC 06.

A_e Using polarized beams, this quantity can also be measured as $(\sigma_L - \sigma_R) / (\sigma_L + \sigma_R)$, where σ_L and σ_R are the e^+e^- production cross sections for Z bosons produced with left-handed and right-handed electrons respectively.

- ¹ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $b\bar{b}$ events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying b-quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (25917 events) $A_b = 0.9173 \pm 0.0184 \pm 0.0173$. Taking into account all correlations with earlier results reported in ABE 03F, ABE 02G and ABE 99L, they obtain the quoted overall SLD result.
- ²ABE 03F obtain an enriched sample of $b\bar{b}$ events tagging on the invariant mass of a 3-dimensional topologically reconstructed secondary decay. The charge of the underlying b quark is obtained using a self-calibrating track-charge method. For the 1996–1998 data sample they measure $A_b = 0.906 \pm 0.022 \pm 0.023$. The value quoted here is obtained combining the above with the result of ABE 98L (1993–1995 data sample).
- ³ABE 02G tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously A_b and A_c .
- ⁴ABE 99L obtain an enriched sample of $b\bar{b}$ events tagging with an inclusive vertex mass cut. For distinguishing b and \bar{b} quarks they use the charge of identified K^\pm .

TRANSVERSE SPIN CORRELATIONS IN $Z \rightarrow \tau^+\tau^-$

The correlations between the transverse spin components of $\tau^+\tau^-$ produced in Z decays may be expressed in terms of the vector and axial-vector couplings:

$$C_{TT} = \frac{|g_A^\tau|^2 - |g_V^\tau|^2}{|g_A^\tau|^2 + |g_V^\tau|^2}$$

Gauge & Higgs Boson Particle Listings

Z

$$C_{TN} = -2 \frac{|g_A^\tau| |g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2} \sin(\Phi_{g_V^\tau} - \Phi_{g_A^\tau})$$

C_{TT} refers to the transverse-transverse (within the collision plane) spin correlation and C_{TN} refers to the transverse-normal (to the collision plane) spin correlation.

The longitudinal τ polarization P_τ ($= -A_\tau$) is given by:

$$P_\tau = -2 \frac{|g_A^\tau| |g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2} \cos(\Phi_{g_V^\tau} - \Phi_{g_A^\tau})$$

Here Φ is the phase and the phase difference $\Phi_{g_V^\tau} - \Phi_{g_A^\tau}$ can be obtained using both the measurements of C_{TN} and P_τ .

FORWARD-BACKWARD $e^+e^- \rightarrow f\bar{f}$ CHARGE ASYMMETRIES

These asymmetries are experimentally determined by tagging the respective lepton or quark flavor in e^+e^- interactions. Details of heavy flavor (c - or b -quark) tagging at LEP are described in the note on "The Z boson" and ref. LEP-SLC 06. The Standard Model predictions for LEP data have been (re)computed using the ZFITTER package (version 6.36) with input parameters $M_Z = 91.187$ GeV, $M_{top} = 174.3$ GeV, $M_{Higgs} = 150$ GeV, $\alpha_s = 0.119$, $\alpha^{(5)}(M_Z) = 1/128.877$ and the Fermi constant $G_F = 1.16637 \times 10^{-5}$ GeV⁻² (see the note on "The Z boson" for references). For non-LEP data the Standard Model predictions are as given by the authors of the respective publications.

 $A_{FB}^{(0,e)}$ CHARGE ASYMMETRY IN $e^+e^- \rightarrow e^+e^-$

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). For the Z peak, we report the pole asymmetry defined by $(3/4)A_e^2$ as determined by the nine-parameter fit to cross-section and lepton forward-backward asymmetry data.

¹ ABREU 00B tag the presence of an s quark requiring a high-momentum-identified charged kaon. The s-quark pole asymmetry is extracted from the charged-kaon asymmetry taking the expected d- and u-quark asymmetries from the Standard Model and using the measured values for the c- and b-quark asymmetries.
² ACKERSTAFF 97T measure the forward-backward asymmetry of various fast hadrons made of light quarks. Then using SU(2) isospin symmetry and flavor independence for down and strange quarks authors solve for the different quark types. The value reported here corresponds then to the forward-backward asymmetry for "down-type" quarks.

$A_{FB}^{(0,c)}$ CHARGE ASYMMETRY IN $e^+ e^- \rightarrow c\bar{c}$

OUR FIT, which is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06, refers to the Z pole asymmetry. The experimental values, on the other hand, correspond to the measurements carried out at the respective energies.

¹ ABDALLAH 05 obtain an enriched samples of b \bar{b} events using lifetime information. The quark (or antiquark) charge is determined with a neural network using the secondary vertex charge, the jet charge and particle identification.
² ABDALLAH 04F tag b- and c-quarks using semileptonic decays combined with charge flow information from the hemisphere opposite to the lepton. Enriched samples of c \bar{c} and b \bar{b} events are obtained using lifetime information.
³ ABBIENDI 03P tag heavy flavors using events with one or two identified leptons. This allows the simultaneous fitting of the b and c quark forward-backward asymmetries as well as the average B⁰-B⁰ mixing.
⁴ ABBIENDI 02I tag Z⁰ → b \bar{b} decays using a combination of secondary vertex and lepton tags. The sign of the b-quark charge is determined using an inclusive tag based on jet, vertex, and kaon charges.
⁵ HEISTER 02H measure simultaneously b and c quark forward-backward asymmetries using their semileptonic decays to tag the quark charge. The flavor separation is obtained with a discriminating multivariate analysis.
⁶ HEISTER 01D tag Z → b \bar{b} events using the impact parameters of charged tracks complemented with information from displaced vertices, event shape variables, and lepton identification. The b-quark direction and charge is determined using the hemisphere charge method along with information from fast kaon tagging and charge estimators of primary and secondary vertices. The change in the quoted value due to variation of A_{FB}^c and R_b is given as +0.103 (A_{FB}^c - 0.0651) - 0.440 (R_b - 0.21585).
⁷ ABREU 99Y tag Z → b \bar{b} and Z → c \bar{c} events by an exclusive reconstruction of several D meson decay modes (D^{*+}, D⁰, and D⁺ with their charge-conjugate states).
⁸ ACCIARRI 99D tag Z → b \bar{b} events using high p and p \bar{p} leptons. The analysis determines simultaneously a mixing parameter $\chi_b = 0.1192 \pm 0.0068 \pm 0.0051$ which is used to correct the observed asymmetry.
⁹ ACCIARRI 98U tag Z → b \bar{b} events using lifetime and measure the jet charge using the hemisphere charge.
¹⁰ ALEXANDER 97C identify the b and c events using a D/D* tag.

CHARGE ASYMMETRY IN $e^+ e^- \rightarrow q\bar{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on B⁰-B⁰ mixing and on other electroweak parameters.

$A_{FB}^{(0,b)}$ CHARGE ASYMMETRY IN $e^+ e^- \rightarrow b\bar{b}$

OUR FIT, which is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06, refers to the Z pole asymmetry. The experimental values,

ANOMALOUS $ZZ\gamma$, $Z\gamma\gamma$, AND ZZV COUPLINGS

Revised September 2013 by M.W. Grunewald (U. College Dublin and U. Ghent) and A. Gurtu (Formerly Tata Inst.).

In on-shell $Z\gamma$ production, deviations from the Standard Model for the $Z\gamma\gamma^*$ and $Z\gamma Z^*$ couplings may be described in terms of eight parameters, h_i^V ($i = 1, 4; V = \gamma, Z$) [1]. The parameters h_i^γ describe the $Z\gamma\gamma^*$ couplings and the parameters h_i^Z the $Z\gamma Z^*$ couplings. In this formalism h_1^V and h_2^V lead to CP -violating and h_3^V and h_4^V to CP -conserving effects. All these anomalous contributions to the cross section increase rapidly with center-of-mass energy. In order to ensure unitarity, these parameters are usually described by a form-factor representation, $h_i^V(s) = h_{i0}^V/(1 + s/\Lambda^2)^n$, where Λ is the energy scale for the manifestation of a new phenomenon and n is a sufficiently large power. By convention one uses $n = 3$ for $h_{1,3}^V$ and $n = 4$ for $h_{2,4}^V$. Usually limits on h_i^V 's are put assuming some value of Λ , sometimes ∞ .

In on-shell ZZ production, deviations from the Standard Model for the $ZZ\gamma^*$ and ZZZ^* couplings may be described by means of four anomalous couplings f_i^V ($i = 4, 5; V = \gamma, Z$) [2]. As above, the parameters f_i^γ describe the $ZZ\gamma^*$ couplings and the parameters f_i^Z the ZZZ^* couplings. The anomalous couplings f_5^V lead to violation of C and P symmetries while f_4^V introduces CP violation. Also here, formfactors depending on a scale Λ are used.

All these couplings h_i^V and f_i^V are zero at tree level in the Standard Model; they are measured in e^+e^- , $p\bar{p}$ and pp collisions at LEP, Tevatron and LHC.

h_i^V

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:

$$\begin{aligned} -0.12 < h_1^\gamma < +0.11, & \quad -0.07 < h_2^\gamma < +0.07, \\ -0.19 < h_3^\gamma < +0.06, & \quad -0.04 < h_4^\gamma < +0.13, \\ -0.05 < h_1^Z < +0.05, & \quad -0.04 < h_2^Z < +0.02, \\ -0.05 < h_3^Z < +0.00, & \quad +0.01 < h_4^Z < +0.05. \end{aligned}$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

¹ AAD 16Q study $Z\gamma$ production in pp collisions. In events with no additional jets, 10268 (12738) Z decays to electron (muon) pairs are selected, with an expected background of 1291 ± 340 (1537 ± 408) events, as well as 1039 Z decays to neutrino pairs with an expected background of 450 ± 96 events. Analyzing the photon transverse momentum distribution above 250 GeV (400 GeV) for lepton (neutrino) events, yields the 95% C.L. limits: $-7.8 \times 10^{-4} < h_3^Z < 8.6 \times 10^{-4}$, $-3.0 \times 10^{-6} < h_4^Z < 2.9 \times 10^{-6}$, $-9.5 \times 10^{-4} < h_3^\gamma < 9.9 \times 10^{-4}$, $-3.2 \times 10^{-6} < h_4^\gamma < 3.2 \times 10^{-6}$.

² KHACHATRYAN 16AE determine the $Z\gamma \rightarrow \nu\bar{\nu}\gamma$ cross section by selecting events with a photon of $E_T > 145$ GeV and $\cancel{E}_T > 140$ GeV. 630 candidate events are observed with an expected SM background of 269 ± 26 . The E_T spectrum of the photon is used to set 95% C.L. limits as follows: $-1.5 \times 10^{-3} < h_3^Z < 1.6 \times 10^{-3}$, $-3.9 \times 10^{-6} < h_4^Z < 4.5 \times 10^{-6}$, $-1.1 \times 10^{-3} < h_3^\gamma < 0.9 \times 10^{-3}$, $-3.8 \times 10^{-6} < h_4^\gamma < 4.3 \times 10^{-6}$.

³ KHACHATRYAN 15AC study $Z\gamma$ events in 8 TeV pp interactions, where the Z decays into 2 same-flavor, opposite sign leptons (e or μ) and a photon with $p_T > 15$ GeV. The p_T of a lepton is required to be > 20 GeV/ c , their effective mass > 50 GeV, and the photon should have a separation $\Delta R > 0.7$ with each lepton. The observed p_T distribution of the photons is used to extract the 95% C.L. limits: $-3.8 \times 10^{-3} < h_3^Z < 3.7 \times 10^{-3}$, $-3.1 \times 10^{-5} < h_4^Z < 3.0 \times 10^{-5}$, $-4.6 \times 10^{-3} < h_3^\gamma < 4.6 \times 10^{-3}$, $-3.6 \times 10^{-5} < h_4^\gamma < 3.5 \times 10^{-5}$.

⁴ CHATRCHYAN 14AB measure $Z\gamma$ production cross section for $p_T^\gamma > 15$ GeV and $R(\ell\gamma) > 0.7$, which is the separation between the $Z\gamma$ and the final state charged lepton (e or μ) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. The di-lepton mass is required to be > 50 GeV. After background subtraction the number of $e\gamma$ and $\mu\mu\gamma$ events is determined to be 3160 ± 120 and 5030 ± 233 respectively, compatible with expectations from the SM. This leads to a 95% CL limits of $-1 \times 10^{-2} < h_3^\gamma < 1 \times 10^{-2}$, $-9 \times 10^{-5} < h_4^\gamma < 9 \times 10^{-5}$, $-9 \times 10^{-3} < h_3^Z < 9 \times 10^{-3}$, $-8 \times 10^{-5} < h_4^Z < 8 \times 10^{-5}$, assuming h_1^V and h_2^V have SM values, $V = \gamma$ or Z .

⁵ AAD 13AN study $Z\gamma$ production in pp collisions. In events with no additional jet, 1417 (2031) Z decays to electron (muon) pairs are selected, with an expected background of 156 ± 54 (244 ± 64) events, as well as 662 Z decays to neutrino pairs with an expected background of 302 ± 42 events. Analyzing the photon p_T spectrum above 100 GeV yields the 95% C.L. limits: $-0.013 < h_3^Z < 0.014$, $-8.7 \times 10^{-5} < h_4^Z < 8.7 \times 10^{-5}$, $-0.015 < h_3^\gamma < 0.016$, $-9.4 \times 10^{-5} < h_4^\gamma < 9.2 \times 10^{-5}$. Supersedes AAD 12BX.

⁶ CHATRCHYAN 13Bi determine the $Z\gamma \rightarrow \nu\bar{\nu}\gamma$ cross section by selecting events with a photon of $E_T > 145$ GeV and a $\cancel{E}_T > 130$ GeV. 73 candidate events are observed with an expected SM background of 30.2 ± 6.5 . The E_T spectrum of the photon is used to set 95% C.L. limits as follows: $|h_3^Z| < 2.7 \times 10^{-3}$, $|h_4^Z| < 1.3 \times 10^{-5}$, $|h_3^\gamma| < 2.9 \times 10^{-3}$, $|h_4^\gamma| < 1.5 \times 10^{-5}$.

⁷ ABAZOV 12S study $Z\gamma$ production in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV using 6.2 fb^{-1} of data where the Z decays to electron (muon) pairs and the photon has at least 10 GeV of transverse momentum. In data, 304 (308) di-electron (di-muon) events are observed with an expected background of 255 ± 16 (285 ± 24) events. Based on the photon p_T spectrum, and including also earlier data and the $Z \rightarrow \nu\bar{\nu}$ decay mode (from ABAZOV 09L), the following 95% C.L. limits are reported: $|h_{03}^Z| < 0.026$, $|h_{04}^Z| < 0.0013$, $|h_{03}^\gamma| < 0.027$, $|h_{04}^\gamma| < 0.0014$ for a form factor scale of $\Lambda = 1.5$ TeV.

⁸ AALTONEN 11S study $Z\gamma$ events in $p\bar{p}$ interactions at $\sqrt{s} = 1.96$ TeV with integrated luminosity 5.1 fb^{-1} for $Z \rightarrow e^+e^-/\mu^+\mu^-$ and 4.9 fb^{-1} for $Z \rightarrow \nu\bar{\nu}$. For the charged lepton case, the two leptons must be of the same flavor with the transverse momentum/energy of one > 20 GeV and the other > 10 GeV. The isolated photon must have $E_T > 50$ GeV. They observe 91 events with 87.2 ± 7.8 events expected from standard model processes. For the $\nu\bar{\nu}$ case they require solitary photons with $E_T > 25$ GeV and missing $E_T > 25$ GeV and observe 85 events with standard model expectation of 85.9 ± 5.6 events. Taking the form factor $\Lambda = 1.5$ TeV they derive 95% C.L. limits as $|h_{3,4}^Z| < 0.022$ and $|h_{3,4}^\gamma| < 0.0009$.

⁹ CHATRCHYAN 11M study $Z\gamma$ production in pp collisions at $\sqrt{s} = 7$ TeV using 36 pb^{-1} pp data, where the Z decays to e^+e^- or $\mu^+\mu^-$. The total cross sections are measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$ with

- the dilepton invariant mass requirement of $M_{\ell\ell} > 50$ GeV. The number of $e^+e^- \gamma$ and $\mu^+\mu^- \gamma$ candidates is 81 and 90 with estimated backgrounds of 20.5 ± 2.5 and 27.3 ± 3.2 events respectively. The 95% CL limits for $ZZ\gamma$ couplings are $-0.05 < h_3^Z < 0.06$ and $-0.0005 < h_4^Z < 0.0005$, and for $Z\gamma\gamma$ couplings are $-0.07 < h_3^\gamma < 0.07$ and $-0.0005 < h_4^\gamma < 0.0006$.
- ¹⁰ ABAZOV 09L study $Z\gamma, Z \rightarrow \nu\bar{\nu}$ production in $p\bar{p}$ collisions at 1.96 TeV C.M. energy. They select 51 events with a photon of transverse energy E_T larger than 90 GeV, with an expected background of 17 events. Based on the photon E_T spectrum and including also Z decays to charged leptons (from ABAZOV 07M), the following 95% CL limits are reported: $|h_{30}^\gamma| < 0.033, |h_{40}^\gamma| < 0.0017, |h_{30}^Z| < 0.033, |h_{40}^Z| < 0.0017$.
- ¹¹ ABAZOV 07M use 968 $p\bar{p} \rightarrow e^+e^-/\mu^+\mu^- \gamma X$ candidates, at 1.96 TeV center of mass energy, to tag $p\bar{p} \rightarrow Z\gamma$ events by requiring $E_T(\gamma) > 7$ GeV, lepton-gamma separation $\Delta R_{\ell\gamma} > 0.7$, and di-lepton invariant mass > 30 GeV. The cross section is in agreement with the SM prediction. Using these $Z\gamma$ events they obtain 95% C.L. limits on each h_i^V , keeping all others fixed at their SM values. They report: $-0.083 < h_{30}^Z < 0.082, -0.0053 < h_{40}^Z < 0.0054, -0.085 < h_{30}^\gamma < 0.084, -0.0053 < h_{40}^\gamma < 0.0054$, for the form factor scale $\Lambda = 1.2$ TeV.
- ¹² Using data collected at $\sqrt{s} = 183\text{--}208$, ABDALLAH 07c select 1,877 $e^+e^- \rightarrow Z\gamma$ events with $Z \rightarrow q\bar{q}$ or $\nu\bar{\nu}$, 171 $e^+e^- \rightarrow ZZ$ events with $Z \rightarrow q\bar{q}$ or lepton pair (except an explicit τ pair), and 74 $e^+e^- \rightarrow Z\gamma^*$ events with a $q\bar{q}\mu^+\mu^-$ or $q\bar{q}e^+e^-$ signature, to derive 95% CL limits on h_i^V . Each limit is derived with other parameters set to zero. They report: $-0.23 < h_1^Z < 0.23, -0.30 < h_2^Z < 0.16, -0.14 < h_1^\gamma < 0.14, -0.049 < h_2^\gamma < 0.044$.
- ¹³ ACHARD 04H select 3515 $e^+e^- \rightarrow Z\gamma$ events with $Z \rightarrow q\bar{q}$ or $\nu\bar{\nu}$ at $\sqrt{s} = 189\text{--}209$ GeV to derive 95% CL limits on h_i^V . For deriving each limit the other parameters are fixed at zero. They report: $-0.153 < h_1^Z < 0.141, -0.087 < h_2^Z < 0.079, -0.220 < h_3^Z < 0.112, -0.068 < h_4^Z < 0.148, -0.057 < h_1^\gamma < 0.057, -0.050 < h_2^\gamma < 0.023, -0.059 < h_3^\gamma < 0.004, -0.004 < h_4^\gamma < 0.024$.
- ¹⁴ ABBIENDI, G 00c study $e^+e^- \rightarrow Z\gamma$ events (with $Z \rightarrow q\bar{q}$ and $Z \rightarrow \nu\bar{\nu}$) at 189 GeV to obtain the central values (and 95% CL limits) of these couplings: $h_1^Z = 0.000 \pm 0.100$ ($-0.190, 0.190$), $h_2^Z = 0.000 \pm 0.068$ ($-0.128, 0.128$), $h_3^Z = -0.074 \pm_{-0.103}^{+0.102}$ ($-0.269, 0.119$), $h_4^Z = 0.046 \pm 0.068$ ($-0.084, 0.175$), $h_1^\gamma = 0.000 \pm 0.061$ ($-0.115, 0.115$), $h_2^\gamma = 0.000 \pm 0.041$ ($-0.077, 0.077$), $h_3^\gamma = -0.080 \pm_{-0.041}^{+0.039}$ ($-0.164, -0.006$), $h_4^\gamma = 0.064 \pm_{-0.030}^{+0.033}$ ($+0.007, +0.134$). The results are derived assuming that only one coupling at a time is different from zero.
- ¹⁵ ABBOTT 98M study $p\bar{p} \rightarrow Z\gamma + X$, with $Z \rightarrow e^+e^-, \mu^+\mu^-, \nu\bar{\nu}$ at 1.8 TeV, to obtain 95% CL limits at $\Lambda = 750$ GeV: $|h_{30}^Z| < 0.36, |h_{40}^Z| < 0.05$ (keeping $h_2^Z = 0$), and $|h_{30}^\gamma| < 0.37, |h_{40}^\gamma| < 0.05$ (keeping $h_2^\gamma = 0$). Limits on the CP-violating couplings are $|h_{10}^Z| < 0.36, |h_{20}^Z| < 0.05$ (keeping $h_1^Z = 0$), and $|h_{10}^\gamma| < 0.37, |h_{20}^\gamma| < 0.05$ (keeping $h_1^\gamma = 0$).
- ¹⁶ ABREU 98k determine a 95% CL upper limit on $\sigma(e^+e^- \rightarrow \gamma + \text{invisible particles}) < 2.5$ pb using 161 and 172 GeV data. This is used to set 95% CL limits on $|h_{30}^\gamma| < 0.8$ and $|h_{50}^Z| < 1.3$, derived at a scale $\Lambda = 1$ TeV and with $n = 3$ in the form factor representation.
- f_i^V**
Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:
- $$-0.28 < f_4^Z < +0.32, \quad -0.34 < f_5^Z < +0.35,$$
- $$-0.17 < f_4^\gamma < +0.19, \quad -0.35 < f_5^\gamma < +0.32.$$
- Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

- ¹ AABOUD 19AY study ZZ production in the $\ell\ell\nu\nu$ decay channel. Events with a pair of isolated high-transverse momentum charged leptons (electron pairs or muon pairs), and with large missing energy, are selected. In the data, 371 (416) di-electron (di-muon) events are found, with a total expected background of 128 ± 8 (143 ± 8) events. Analysing the transverse momentum distribution of the charged dilepton system above 150 GeV, the following 95% C.L. limits are derived in units of 10^{-3} : $-1.2 < f_4^Z < 1.2, -1.0 < f_4^\gamma < 1.0, -1.2 < f_5^Z < 1.2, -1.0 < f_5^\gamma < 1.0$.
- ² AABOUD 18Q study $pp \rightarrow ZZ$ events at $\sqrt{s} = 13$ TeV with $Z \rightarrow e^+e^-$ or $Z \rightarrow \mu^+\mu^-$. The number of events observed in the $4e, 2e2\mu$, and 4μ channels is 249, 465, and 303 respectively. Analysing the p_T spectrum of the leading Z boson, the following the following 95% C.L. limits are derived in units of 10^{-4} : $-1.8 < f_4^\gamma < 1.8, -1.5 < f_4^Z < 1.5, -1.8 < f_5^\gamma < 1.8, -1.5 < f_5^Z < 1.5$.
- ³ SIRUNYAN 18BT study $ppZZ$ events at $\sqrt{s} = 13$ TeV with $Z \rightarrow e^+e^-$ or $Z \rightarrow \mu^+\mu^-$. The number of events observed in the $4e, 2e2\mu$, and 4μ channels is 220, 543 and 335 respectively. Analysing the 4-lepton invariant mass spectrum, the following 95% C.L. limits are derived in units of 10^{-3} : $-1.2 < f_4^\gamma < 1.3, -1.2 < f_4^Z < 1.0, -1.2 < f_5^\gamma < 1.3, -1.0 < f_5^Z < 1.3$.
- ⁴ KHACHATRYAN 15B study ZZ production in 8 TeV pp collisions. In the decay modes $ZZ \rightarrow 4e, 4\mu, 2e2\mu, 54, 75, 148$ events are observed, with an expected background of $2.2 \pm 0.9, 1.2 \pm 0.6, \text{ and } 2.4 \pm 1.0$ events, respectively. Analysing the 4-lepton invariant mass spectrum in the range from 110 GeV to 1200 GeV, the following 95% C.L. limits are obtained: $|f_4^Z| < 0.004, |f_5^Z| < 0.004, |f_4^\gamma| < 0.005, |f_5^\gamma| < 0.005$.
- ⁵ KHACHATRYAN 15Bc use the cross section measurement of the final state $pp \rightarrow ZZ \rightarrow 2\ell 2\nu$ (ℓ being an electron or a muon) at 7 and 8 TeV to put limits on these triple gauge couplings. Effective mass of the charged lepton pair is required to be in the range 83.5–98.5 GeV and the dilepton $p_T > 45$ GeV. The reduced missing E_T is required to be > 65 GeV, which takes into account the fake missing E_T due to detector effects. The numbers of e^+e^- and $\mu^+\mu^-$ events selected are 35 and 40 at 7 TeV and 176 and 271 at 8 TeV respectively. The production cross sections so obtained are in agreement with SM predictions. The following 95% C.L. limits are set: $-0.0028 < f_4^Z < 0.0032, -0.0037 < f_4^\gamma < 0.0033, -0.0029 < f_5^Z < 0.0031, -0.0033 < f_5^\gamma < 0.0037$. Combining with previous results (KHACHATRYAN 15B and CHATRCHYAN 13B) which include 7 TeV and 8 TeV data on the final states $pp \rightarrow ZZ \rightarrow 2\ell 2\ell'$ where ℓ and ℓ' are an electron or a muon, the best limits are $-0.0022 < f_4^Z < 0.0026, -0.0029 < f_4^\gamma < 0.0026, -0.0023 < f_5^Z < 0.0023, -0.0026 < f_5^\gamma < 0.0027$.
- ⁶ AAD 13z study ZZ production in pp collisions at $\sqrt{s} = 7$ TeV. In the $ZZ \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ final state they observe a total of 66 events with an expected background of 0.9 ± 1.3 . In the $ZZ \rightarrow \ell^+\ell^-\nu\nu$ final state they observe a total of 87 events with an expected background of 46.9 ± 5.2 . The limits on anomalous TGCs are determined using the observed and expected numbers of these ZZ events binned in p_T^Z . The 95% C.L. are as follows: for form factor scale $\Lambda = \infty, -0.015 < f_4^Z < 0.015, -0.013 < f_4^\gamma < 0.013, -0.016 < f_5^Z < 0.015, -0.013 < f_5^\gamma < 0.013$; for form factor scale $\Lambda = 3$ TeV, $-0.022 < f_4^Z < 0.023, -0.019 < f_4^\gamma < 0.019, -0.023 < f_5^Z < 0.023, -0.020 < f_5^\gamma < 0.019$.
- ⁷ CHATRCHYAN 13B study ZZ production in pp collisions and select 54 ZZ candidates in the Z decay channel with electrons or muons with an expected background of 1.4 ± 0.5 events. The resulting 95% C.L. ranges are: $-0.013 < f_4^Z < 0.015, -0.011 < f_4^\gamma < 0.012, -0.014 < f_5^Z < 0.014, -0.012 < f_5^\gamma < 0.012$.
- ⁸ Using data collected in the center of mass energy range 192–209 GeV, SCHAEL 09 select 318 $e^+e^- \rightarrow ZZ$ events with 319.4 expected from the standard model. Using this data they derive the following 95% CL limits: $-0.321 < f_4^Z < 0.318, -0.534 < f_4^\gamma < 0.534, -0.724 < f_5^Z < 0.733, -1.194 < f_5^\gamma < 1.190$.
- ⁹ ABAZOV 08k search for ZZ and $Z\gamma^*$ events with $1\text{fb}^{-1} p\bar{p}$ data at $\sqrt{s} = 1.96$ TeV in $(e\ell)(e\ell), (\mu\mu)(\mu\mu), (e\ell)(\mu\mu)$ final states requiring the lepton pair masses to be > 30 GeV. They observe 1 event, which is consistent with an expected signal of 1.71 ± 0.15 events and a background of 0.13 ± 0.03 events. From this they derive the following limits, for a form factor (Λ) value of 1.2 TeV: $-0.28 < f_{40}^Z < 0.28, -0.31 < f_{50}^Z < 0.29, -0.26 < f_{40}^\gamma < 0.26, -0.30 < f_{50}^\gamma < 0.28$.
- ¹⁰ Using data collected at $\sqrt{s} = 183\text{--}208$ GeV, ABDALLAH 07c select 171 $e^+e^- \rightarrow ZZ$ events with $Z \rightarrow q\bar{q}$ or lepton pair (except an explicit τ pair), and 74 $e^+e^- \rightarrow Z\gamma^*$ events with a $q\bar{q}\mu^+\mu^-$ or $q\bar{q}e^+e^-$ signature, to derive 95% CL limits on f_i^V . Each limit is derived with other parameters set to zero. They report: $-0.40 < f_4^Z < 0.42, -0.38 < f_5^Z < 0.62, -0.23 < f_4^\gamma < 0.25, -0.52 < f_5^\gamma < 0.48$.
- ¹¹ ABBIENDI 04c study ZZ production in e^+e^- collisions in the C.M. energy range 190–209 GeV. They select 340 events with an expected background of 432 events. Including the ABBIENDI 00N data at 183 and 189 GeV (118 events with an expected background of 65 events) they report the following 95% CL limits: $-0.45 < f_4^Z < 0.58, -0.94 < f_5^Z < 0.25, -0.32 < f_4^\gamma < 0.33, \text{ and } -0.71 < f_5^\gamma < 0.59$.
- ¹² ACHARD 03D study Z-boson pair production in e^+e^- collisions in the C.M. energy range 200–209 GeV. They select 549 events with an expected background of 432 events. Including the ACCIARRI 99G and ACCIARRI 99o data (183 and 189 GeV respectively, 286 events with an expected background of 241 events) and the 192–202 GeV ACCIARRI 01i results (656 events, expected background of 512 events), they report the following 95% CL limits: $-0.48 \leq f_4^Z \leq 0.46, -0.36 \leq f_5^Z \leq 1.03, -0.28 \leq f_4^\gamma \leq 0.28, \text{ and } -0.40 \leq f_5^\gamma \leq 0.47$.

ANOMALOUS W/Z QUARTIC COUPLINGS

Revised November 2015 by M.W. Grunewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Quartic couplings, $WWZZ, WWZ\gamma, WW\gamma\gamma$, and $ZZ\gamma\gamma$, were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an

effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lower dimensional representation of operators (dimension 6) which presumes the $SU(2) \times U(1)$ gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings, a_0, a_c, a_n , are expressed in terms of the following dimension-6 operators [1,2];

$$\begin{aligned} L_6^0 &= -\frac{e^2}{16\Lambda^2} a_0 F^{\mu\nu} F_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ L_6^c &= -\frac{e^2}{16\Lambda^2} a_c F^{\mu\alpha} F_{\mu\beta} \vec{W}^\beta \cdot \vec{W}_\alpha \\ L_6^n &= -i\frac{e^2}{16\Lambda^2} a_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_\nu^{(j)} W^{(k)\alpha} F^{\mu\nu} \\ \tilde{L}_6^0 &= -\frac{e^2}{16\Lambda^2} \tilde{a}_0 F^{\mu\nu} \tilde{F}_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ \tilde{L}_6^n &= -i\frac{e^2}{16\Lambda^2} \tilde{a}_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_\nu^{(j)} W^{(k)\alpha} \tilde{F}^{\mu\nu} \end{aligned}$$

where F, W are photon and W fields, L_6^0 and L_6^c conserve C, P separately (\tilde{L}_6^0 conserves only C) and generate anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ couplings, L_6^n violates CP (\tilde{L}_6^n violates both C and P) and generates an anomalous $W^+W^-Z\gamma$ coupling, and Λ is an energy scale for new physics. For the $ZZ\gamma\gamma$ coupling the CP -violating term represented by L_6^n does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the $WW\gamma\gamma$ and $ZZ\gamma\gamma$ couplings separately, leading to two sets parametrized as a_0^V/Λ^2 and a_c^V/Λ^2 , where $V = W$ or Z .

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned} \mathcal{L}_{AQGC} &= -\frac{e^2 a_0^W}{8 \Lambda^2} F_{\mu\nu} F^{\mu\nu} W^{+\alpha} W_a^- \\ &\quad -\frac{e^2 a_c^W}{16 \Lambda^2} F_{\mu\nu} F^{\mu\alpha} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ &\quad -e^2 g^2 \frac{\kappa_0^W}{\Lambda^2} F_{\mu\nu} Z^{\mu\nu} W^{+\alpha} W_a^- \\ &\quad -\frac{e^2 g^2 \kappa_c^W}{2 \Lambda^2} F_{\mu\nu} Z^{\mu\alpha} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ &\quad + \frac{f_{T,0}}{\Lambda^4} Tr[\widehat{W}_{\mu\nu} \widehat{W}^{\mu\nu}] \times Tr[\widehat{W}_{\alpha\beta} \widehat{W}^{\alpha\beta}] \end{aligned}$$

The energy scale of possible new physics is Λ , and $g = e/\sin(\theta_W)$, e being the unit electric charge and θ_W the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators a_0^W/Λ^2 and a_c^W/Λ^2 are associated with the $WW\gamma\gamma$ vertex. Among dimension 8 operators, κ_0^W/Λ^2 and κ_c^W/Λ^2 are associated with the $WWZ\gamma$ vertex, whereas the parameter $f_{T,0}/\Lambda^4$ contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters $f_{M,i}/\Lambda^4$ as follows [3]:

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2} \frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2} \frac{f_{M,2}}{\Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2} \frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2} \frac{f_{M,3}}{\Lambda^4}$$

where $g' = e/\cos(\theta_W)$ and M_W is the invariant mass of the W boson. This relation provides a translation between limits on dimension 6 operators $a_{0,c}^W$ and $f_{M,j}/\Lambda^4$. It is further required [4] that $f_{M,0} = 2f_{M,2}$ and $f_{M,1} = 2f_{M,3}$ which suppresses contributions to the $WWZ\gamma$ vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total – $f_{S,i}$, $i = 1, 2$, $f_{M,i}$, $i = 0, \dots, 8$ and $f_{T,i}$, $i = 0, \dots, 9$ – each scaled by $1/\Lambda^4$.

The ATLAS collaboration [6], on the other hand, follows a K-matrix driven approach of Ref. 7 in which the anomalous couplings can be expressed in terms of two parameters α_4 and α_5 , which account for all BSM effects.

It is the early stages in the determination of quartic couplings by the LHC experiments. It is hoped that the two collaborations, ATLAS and CMS, will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison and allow for a possible LHC combination.

$a_0/\Lambda^2, a_c/\Lambda^2$

Combining published and unpublished preliminary LEP results the following 95% CL intervals for the QGCs associated with the $ZZ\gamma\gamma$ vertex are derived (CERN-PH-EP/2005-051 or hep-ex/0511027):

$$\begin{aligned} -0.008 < a_0^Z/\Lambda^2 < +0.021 \\ -0.029 < a_c^Z/\Lambda^2 < +0.039 \end{aligned}$$

Anomalous Z quartic couplings have also been measured by the Tevatron and LHC experiments. As discussed in the review on "Anomalous W/Z quartic couplings," the coupling parameters in the Anomalous QGC Lagrangian may relate to processes involving only the W or only to the Z or to both. Thus, results on all other AQGCs are reported together in the W listings.

VALUE	DOCUMENT ID	TECN
•••	We do not use the following data for averages, fits, limits, etc. •••	
1	ABBIENDI	04L OPAL
2	HEISTER	04A ALEP
3	ACHARD	02G L3

- 1 **ABBIENDI 04L** select $20 e^+ e^- \rightarrow \nu \bar{\nu} \gamma \gamma$ acoplanar events in the energy range 180–209 GeV and $176 e^+ e^- \rightarrow q \bar{q} \gamma \gamma$ events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous $W^+ W^- \gamma \gamma$ and $Z Z \gamma \gamma$ quartic couplings. Further combining with the $W^+ W^- \gamma$ sample of **ABBIENDI 04B** the following one-parameter 95% CL limits are obtained: $-0.007 < a_0^Z/\Lambda^2 < 0.023 \text{ GeV}^{-2}$, $-0.029 < a_C^Z/\Lambda^2 < 0.029 \text{ GeV}^{-2}$, $-0.020 < a_0^W/\Lambda^2 < 0.020 \text{ GeV}^{-2}$, $-0.052 < a_C^W/\Lambda^2 < 0.037 \text{ GeV}^{-2}$.
- 2 In the CM energy range 183 to 209 GeV **HEISTER 04A** select $30 e^+ e^- \rightarrow \nu \bar{\nu} \gamma \gamma$ events with two acoplanar, high energy and high transverse momentum photons. The photon-photon acoplanarity is required to be $> 5^\circ$, $E_\gamma/\sqrt{s} > 0.025$ (the more energetic photon having energy $> 0.2 \sqrt{s}$), $p_{T\gamma}/E_{\text{beam}} > 0.05$ and $|\cos \theta_\gamma| < 0.94$. A likelihood fit to the photon energy and recoil missing mass yields the following one-parameter 95% CL limits: $-0.012 < a_0^Z/\Lambda^2 < 0.019 \text{ GeV}^{-2}$, $-0.041 < a_C^Z/\Lambda^2 < 0.044 \text{ GeV}^{-2}$, $-0.060 < a_0^W/\Lambda^2 < 0.055 \text{ GeV}^{-2}$, $-0.099 < a_C^W/\Lambda^2 < 0.093 \text{ GeV}^{-2}$.
- 3 **ACHARD 02c** study $e^+ e^- \rightarrow Z \gamma \gamma \rightarrow q \bar{q} \gamma \gamma$ events using data at center-of-mass energies from 200 to 209 GeV. The photons are required to be isolated, each with energy $> 5 \text{ GeV}$ and $|\cos \theta| < 0.97$, and the di-jet invariant mass to be compatible with that of the Z boson (74–111 GeV). Cuts on Z velocity ($\beta < 0.73$) and on the energy of the most energetic photon reduce the backgrounds due to non-resonant production of the $q \bar{q} \gamma \gamma$ state and due to ISR respectively, yielding a total of 40 candidate events of which 8.6 are expected to be due to background. The energy spectra of the least energetic photon are fitted for all ten center-of-mass energy values from 130 GeV to 209 GeV (as obtained adding to the present analysis 130–202 GeV data of **ACCIARRI 01E**, for a total of 137 events with an expected background of 34.1 events) to obtain the fitted values $a_0/\Lambda^2 = 0.00 \pm 0.02 \text{ GeV}^{-2}$ and $a_C/\Lambda^2 = 0.03 \pm 0.01 \text{ GeV}^{-2}$, where the other parameter is kept fixed to its Standard Model value (0). A simultaneous fit to both parameters yields the 95% CL limits $-0.02 \text{ GeV}^{-2} < a_0/\Lambda^2 < 0.03 \text{ GeV}^{-2}$ and $-0.07 \text{ GeV}^{-2} < a_C/\Lambda^2 < 0.05 \text{ GeV}^{-2}$.

 H^0 $J = 0$

In the following H^0 refers to the signal that has been discovered in the Higgs searches. Whereas the observed signal is labeled as a spin 0 particle and is called a Higgs Boson, the detailed properties of H^0 and its role in the context of electroweak symmetry breaking need to be further clarified. These issues are addressed by the measurements listed below.

Concerning mass limits and cross section limits that have been obtained in the searches for neutral and charged Higgs bosons, see the sections "Searches for Neutral Higgs Bosons" and "Searches for Charged Higgs Bosons (H^\pm and $H^{\pm\pm}$)", respectively.

1 Combined value from $\gamma\gamma$ and $ZZ^* \rightarrow 4\ell$ final states.

2 SIRUNYAN 17AV use 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$ with $H^0 \rightarrow ZZ^* \rightarrow 4\ell$ where $\ell = e, \mu$.

3 ATLAS and CMS data are fitted simultaneously.

4 AABOUD 18BM use 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$ with $H^0 \rightarrow ZZ^* \rightarrow 4\ell$ where $\ell = e, \mu$.

5 AABOUD 18BM use 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$ with $H^0 \rightarrow \gamma\gamma$.

6 AABOUD 18BM combine 13 TeV results with 7 and 8 TeV results. Other combined results are summarized in their Fig. 4.

7 KHACHATRYAN 15AM use up to 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$.

8 AAD 14W use 4.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 20.3 fb^{-1} at 8 TeV.

9 CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$.

10 CHATRCHYAN 14K use 4.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$.

11 KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$.

12 AAD 13AK use 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 20.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. Superseded by AAD 14W.

13 CHATRCHYAN 13J use 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 12.2 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$.

14 AAD 12AI obtain results based on 4.6–4.8 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 5.8–5.9 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. An excess of events over background with a local significance of 5.9 σ is observed at $m_{H^0} = 126 \text{ GeV}$. See also AAD 12DA.

15 CHATRCHYAN 12N obtain results based on 4.9–5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 5.1–5.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. An excess of events over background with a local significance of 5.0 σ is observed at about $m_{H^0} = 125 \text{ GeV}$. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

 H^0 SPIN AND CP PROPERTIES

The observation of the signal in the $\gamma\gamma$ final state rules out the possibility that the discovered particle has spin 1, as a consequence of the Landau-Yang theorem. This argument relies on the assumptions that the decaying particle is an on-shell resonance and that the decay products are indeed two photons rather than two pairs of boosted photons, which each could in principle be misidentified as a single photon.

Concerning distinguishing the spin 0 hypothesis from a spin 2 hypothesis, some care has to be taken in modelling the latter in order to ensure that the discriminating power is actually based on the spin properties rather than on unphysical behavior that may affect the model of the spin 2 state.

Under the assumption that the observed signal consists of a single state rather than an overlap of more than one resonance, it is sufficient to discriminate between distinct hypotheses in the spin analyses. On the other hand, the determination of the CP properties is in general much more difficult since in principle the observed state could consist of any admixture of CP-even and CP-odd components. As a first step, the compatibility of the data with distinct hypotheses of pure CP-even and pure CP-odd states with different spin assignments has been investigated. In order to treat the case of a possible mixing of different CP states, certain cross section ratios are considered. Those cross section ratios need to be distinguished from the amount of mixing between a CP-even and a CP-odd state, as the cross section ratios depend in addition also on the coupling strengths of the CP-even and CP-odd components to the involved particles. A small relative coupling implies a small sensitivity of the corresponding cross section ratio to effects of CP mixing.

- ¹ SIRUNYAN 19BL measure the anomalous HVV couplings from on-shell and off-shell production in the 4ℓ final state. Data of 80.2 fb^{-1} at 13 TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV are used. See their Tables VI and VII for anomalous HVV couplings of CP -violating and CP -conserving parameters with on- and off-shells.
- ² SIRUNYAN 19BZ constrain anomalous HVV couplings of the Higgs boson with data of 35.9 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$ using Higgs boson candidates with two jets produced in VBF, ggF, and VH that decay to $\tau\tau$. See their Table 2 and Fig. 10, which show 68% CL and 95% CL intervals. Combining those with the $H^0 \rightarrow 4\ell$ (SIRUNYAN 19BL, on-shell scenario), results shown in their Tables 3, 4, and Fig. 11 are obtained. A CP -violating parameter is set to be $f_{a3}\cos(\phi_{a3}) = (0.00 \pm 0.27) \times 10^{-3}$ and CP -conserving parameters are $f_{a2}\cos(\phi_{a2}) = (0.06 \pm 1.04) \times 10^{-3}$, $f_{\Lambda 1}\cos(\phi_{\Lambda 1}) = (0.00 \pm 0.53) \times 10^{-3}$, and $f_{\Lambda 1}^{\prime}\cos(\phi_{\Lambda 1}^{\prime}) = (0.0 \pm 1.1) \times 10^{-3}$.
- ³ AABOUD 18AJ study the tensor structure of the Higgs boson couplings using an effective Lagrangian using 36.1 fb^{-1} of pp collision data at $E_{\text{cm}} = 13 \text{ TeV}$. Constraints are set on the non-Standard-Model CP -even and CP -odd couplings to Z bosons and on the CP -odd coupling to gluons. See their Figs. 9 and 10, and Tables 10 and 11.
- ⁴ SIRUNYAN 17AM constrain anomalous couplings of the Higgs boson with 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$, 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$, and 38.6 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. See their Table 3 and Fig. 3, which show 68% CL and 95% CL intervals. A CP violation parameter f_{a3} is set to be $f_{a3}\cos(\phi_{a3}) = [-0.38, 0.46]$ at 95% CL ($\phi_{a3} = 0$ or π).
- ⁵ AAD 16 study $H^0 \rightarrow \gamma\gamma$ with an effective Lagrangian including CP even and odd terms in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. The data is consistent with the expectations for the Higgs boson of the Standard Model. Limits on anomalous couplings are also given.
- ⁶ AAD 16BL study VBF $H^0 \rightarrow \tau\tau$ with an effective Lagrangian including a CP odd term in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. The measurement is consistent with the expectation of the Standard Model. The CP -mixing parameter \bar{d} (a dimensionless coupling $\bar{d} = -(m_W^2/\Lambda^2)f_{\bar{d}}/W$) is constrained to the interval of $(-0.11, 0.05)$ at 68% CL under the assumption of $\bar{d} = \bar{d}_B$.
- ⁷ KHACHATRYAN 16AB search for anomalous pseudoscalar couplings of the Higgs boson to W and Z with 18.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Table 5 and Figs 5 and 6 for limits on possible anomalous pseudoscalar coupling parameters.
- ⁸ AAD 15AX compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$, using the process $H^0 \rightarrow WW^* \rightarrow e\nu\mu\nu$. 2^+ hypotheses are excluded at 84.5–99.4%CL, 0^- at 96.5%CL, 0^+ (field strength coupling) at 70.8%CL. See their Fig. 19 for limits on possible CP mixture parameters.
- ⁹ AAD 15CI compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 4.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$, using the processes $H^0 \rightarrow ZZ^* \rightarrow 4\ell$, $H^0 \rightarrow \gamma\gamma$ and combine with AAD 15AX data. 0^+ (field strength coupling), 0^- and several 2^+ hypotheses are excluded at more than 99.9% CL. See their Tables 7–9 for limits on possible CP mixture parameters.
- ¹⁰ AALTONEN 15 combine AALTONEN 15B and ABAZOV 14F data. An upper limit of 0.36 of the Standard Model production rate at 95% CL is obtained both for a 0^- and a 2^+ state. Assuming the SM event rate, the $J^{CP} = 0^-$ (2^+) hypothesis is excluded at the 5.0σ (4.9σ) level.
- ¹¹ AALTONEN 15B compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 9.45 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$, using the processes $ZH^0 \rightarrow \ell\ell b\bar{b}$, $WH^0 \rightarrow \ell\nu b\bar{b}$, and $ZH^0 \rightarrow \nu\nu b\bar{b}$. Bounds on the production rates of 0^- and 2^+ (graviton-like) states are set, see their tables II and III.
- ¹² KHACHATRYAN 15Y compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in up to 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$, using the processes $H^0 \rightarrow 4\ell$, $H^0 \rightarrow WW^*$, and $H^0 \rightarrow \gamma\gamma$. 0^- is excluded at 99.98% CL, and several 2^+ hypotheses are excluded at more than 99% CL. Spin 1 models are excluded at more than 99.999% CL in ZZ^* and WW^* modes. Limits on anomalous couplings and several cross section fractions, treating the case of CP -mixed states, are also given.
- ¹³ ABAZOV 14F compare the $J^{CP} = 0^+$ Standard Model assignment with $J^{CP} = 0^-$ and 2^+ (graviton-like coupling) hypotheses in up to 9.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. They use kinematic correlations between the decay products of the vector boson and the Higgs boson in the final states $ZH \rightarrow \ell\ell b\bar{b}$, $WH \rightarrow \ell\nu b\bar{b}$, and $ZH \rightarrow \nu\nu b\bar{b}$. The 0^- (2^+) hypothesis is excluded at 97.6% CL (99.0% CL). In order to treat the case of a possible mixture of a 0^+ state with another J^{CP} state, the cross section fractions $f_X = \sigma_X/(\sigma_{0^+} + \sigma_X)$ are considered, where $X = 0^-, 2^+$. Values for f_{0^-} (f_{2^+}) above 0.80 (0.67) are excluded at 95% CL under the assumption that the total cross section is that of the SM Higgs boson.
- ¹⁴ CHATRCHYAN 14AA compare the $J^{CP} = 0^+$ Standard Model assignment with various J^{CP} hypotheses in 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. $J^{CP} = 0^-$ and 1^{\pm} hypotheses are excluded at 99% CL, and several $J = 2$ hypotheses are excluded at 95% CL. In order to treat the case of a possible mixture of a 0^+ state with another J^{CP} state, the cross section fraction $f_{a3} = |a_3|^2 \sigma_3 / (|a_1|^2 \sigma_1 + |a_2|^2 \sigma_2 + |a_3|^2 \sigma_3)$ is considered, where the case $a_3 = 1$, $a_1 = a_2 = 0$ corresponds to a pure CP -odd state. Assuming $a_2 = 0$, a value for f_{a3} above 0.51 is excluded at 95% CL.
- ¹⁵ CHATRCHYAN 14G compare the $J^{CP} = 0^+$ Standard Model assignment with $J^{CP} = 0^-$ and 2^+ (graviton-like coupling) hypotheses in 4.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.4 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. Varying the fraction of the production of the 2^+ state via $g\bar{g}$ and $q\bar{q}$, 2^+ hypotheses are disfavored at CL between 83.7 and 99.8%. The 0^- hypothesis is disfavored against 0^+ at the 65.3% CL.
- ¹⁶ KHACHATRYAN 14P compare the $J^{CP} = 0^+$ Standard Model assignment with a 2^+ (graviton-like coupling) hypothesis in 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. Varying the fraction of the production of the 2^+ state via $g\bar{g}$ and $q\bar{q}$, 2^+ hypotheses are disfavored at CL between 71 and 94%.
- ¹⁷ AAD 13AJ compare the spin 0, CP -even hypothesis with specific alternative hypotheses of spin 0, CP -odd, spin 1, CP -even and CP -odd, and spin 2, CP -even models using the

Higgs boson decays $H \rightarrow \gamma\gamma$, $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ and combinations thereof. The data are compatible with the spin 0, CP -even hypothesis, while all other tested hypotheses are excluded at confidence levels above 97.8%.

- ¹⁸ CHATRCHYAN 13J study angular distributions of the lepton pairs in the ZZ^* channel where both Z bosons decay to e or μ pairs. Under the assumption that the observed particle has spin 0, the data are found to be consistent with the pure CP -even hypothesis, while the pure CP -odd hypothesis is disfavored.

H^0 DECAY WIDTH

The total decay width for a light Higgs boson with a mass in the observed range is not expected to be directly observable at the LHC. For the case of the Standard Model the prediction for the total width is about 4 MeV, which is three orders of magnitude smaller than the experimental mass resolution. There is no indication from the results observed so far that the natural width is broadened by new physics effects to such an extent that it could be directly observable. Furthermore, as all LHC Higgs channels rely on the identification of Higgs decay products, the total Higgs width cannot be measured indirectly without additional assumptions. The different dependence of on-peak and off-peak contributions on the total width in Higgs decays to ZZ^* and interference effects between signal and background in Higgs decays to $\gamma\gamma$ can provide additional information in this context. Constraints on the total width from the combination of on-peak and off-peak contributions in Higgs decays to ZZ^* rely on the assumption of equal on- and off-shell effective couplings. Without an experimental determination of the total width or further theoretical assumptions, only ratios of couplings can be determined at the LHC rather than absolute values of couplings.

- ¹ SIRUNYAN 19BL measure the width and anomalous HVV couplings from on-shell and off-shell production in the 4ℓ final state. Data of 80.2 fb^{-1} at 13 TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV are used. The total width for the SM-like couplings is measured to be also $[0.08, 9.16]$ MeV with 95% CL, assuming SM-like couplings for on- and off-shells (see their Table VIII). Constraints on the total width for anomalous HVV interaction cases are found in their Table IX. See their Table X for the Higgs boson signal strength in the off-shell region.
- ² AABOUD 18BP use 36.1 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. An observed upper limit on the off-shell Higgs signal strength of 3.8 is obtained at 95% CL using off-shell Higgs boson production in the $Z \rightarrow 4\ell$ and $Z \rightarrow 2\ell 2\nu$ decay channels ($\ell = e, \mu$). Combining with the on-shell signal strength measurements, the quoted upper limit on the Higgs boson total width is obtained, assuming the ratios of the relevant Higgs-boson couplings to the SM predictions are constant with energy from on-shell production to the high-mass range.
- ³ SIRUNYAN 17AV obtain an upper limit on the width from the $m_{4\ell}$ distribution in $ZZ^* \rightarrow 4\ell$ ($\ell = e, \mu$) decays. Data of 35.9 fb^{-1} pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$ is used. The expected limit is 1.60 GeV.
- ⁴ KHACHATRYAN 16BA combine the WW^* result with ZZ^* results of KHACHATRYAN 15BA and KHACHATRYAN 14D.
- ⁵ KHACHATRYAN 15AM combine $\gamma\gamma$ and $ZZ^* \rightarrow 4\ell$ results. The expected limit is 2.3 GeV.
- ⁶ KHACHATRYAN 15BA derive a lower limit on the total width from an upper limit on the decay flight distance $\tau < 1.9 \times 10^{-13} \text{ s}$. 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$ are used.
- ⁷ AAD 14W use 4.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 20.3 fb^{-1} at 8 TeV. The expected limit is 6.2 GeV.
- ⁸ KHACHATRYAN 16BA derive constraints on the total width from comparing WW^* production via on-shell and off-shell H^0 using 4.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.4 fb^{-1} at 8 TeV.
- ⁹ AAD 15BE derive constraints on the total width from comparing ZZ^* and WW^* production via on-shell and off-shell H^0 using 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. The K factor for the background processes is assumed to be equal to that for the signal.
- ¹⁰ KHACHATRYAN 15BA derive constraints on the total width from comparing ZZ^* production via on-shell and off-shell H^0 with an unconstrained anomalous coupling. 4ℓ final states in 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$ are used.
- ¹¹ CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The expected limit is 2.8 GeV.
- ¹² KHACHATRYAN 14D derive constraints on the total width from comparing ZZ^* production via on-shell and off-shell H^0 . 4ℓ and $\ell\nu\nu\ell$ final states in 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$ are used.
- ¹³ KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The expected limit is 3.1 GeV.

- 1 AABOUD 19AL combine results of 7, 8 (AAD 15CX), and 13 TeV for H^0 decaying to invisible final states.
- 2 SIRUNYAN 19Bo combine 13 TeV 35.9 fb⁻¹ results with 7, 8, 13 TeV (KHACHATRYAN 17F) for H^0 decaying to invisible final states. The quoted limit on the branching ratio is given for $m_{H^0} = 125.09$ GeV and assumes the Standard Model production rates. The branching ratio is obtained to be 0.05 ± 0.03 (stat) ± 0.07 (syst).
- 3 AABOUD 19AI search for $pp \rightarrow qqH^0X$ (VBF) with H^0 decaying to invisible final states using 36.1 fb⁻¹ of data. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.
- 4 AABOUD 19AL combine results of H^0 decaying to invisible final states with VBF(AABOUD 19AI), ZH , and WH productions (AABOUD 18, AABOUD 18CA), which use 36.1 fb⁻¹ of data at 13 TeV. The quoted limit is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH , and WH productions.
- 5 SIRUNYAN 19AT perform a combined fit with visible decay using 35.9 fb⁻¹ of data at 13 TeV.
- 6 SIRUNYAN 19Bo search for $pp \rightarrow qqH^0X$ (VBF) with H^0 decaying to invisible final states using 35.9 fb⁻¹ of data. The quoted limit on the branching ratio is given for $m_{H^0} = 125.09$ GeV and assumes the Standard Model production rates.
- 7 SIRUNYAN 19Bo combine the VBF channel with results of other 13 TeV analyses: SIRUNYAN 18BV and SIRUNYAN 18s. The quoted limit on the branching ratio is given for $m_{H^0} = 125.09$ GeV and assumes the Standard Model production rates.
- 8 AABOUD 18 search for $pp \rightarrow H^0ZX, Z \rightarrow ee, \mu\mu$ with H^0 decaying to invisible final states in 36.1 fb⁻¹ at $E_{cm} = 13$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rate for H^0Z production.
- 9 AABOUD 18CA search for H^0 decaying to invisible final states using WH, ZH and ZH productions, where W and Z hadronically decay. The data of 36.1 fb⁻¹ at $E_{cm} = 13$ TeV is used. The quoted limit assumes SM production cross sections with combining the contributions from WH, ZH, ggF and VBF production modes.
- 10 SIRUNYAN 18BV search for H^0 decaying to invisible final states associated with a $Z, Z \rightarrow \ell\ell$ using 35.9 fb⁻¹ at 13 TeV. The limit is obtained for $m_{H^0} = 125$ GeV and assuming the SM ZH^0 production cross section.
- 11 SIRUNYAN 18s search for H^0 decaying to invisible final states associated with an energetic jet or a $V, V \rightarrow q\bar{q}$ using 35.9 fb⁻¹ at 13 TeV.
- 12 AABOUD 17BD search for H^0 decaying to invisible final states with ≥ 1 jet and VBF events using 3.2 fb⁻¹ of pp collisions at $E_{cm} = 13$ TeV. A cross-section ratio R^{miss} is used in the measurement. The quoted limit is given for $m_{H^0} = 125$ GeV.
- 13 KHACHATRYAN 17F search for H^0 decaying to invisible final states with gluon fusion, VBF, ZH , and WH productions using 2.3 fb⁻¹ of pp collisions at $E_{cm} = 13$ TeV, 19.7 fb⁻¹ at 8 TeV, and 5.1 fb⁻¹ at 7 TeV. The quoted limit is given for $m_{H^0} =$

- 125 GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH , and WH productions.
- 14 AAD 16AF search for $pp \rightarrow qqH^0X$ (VBF) with H^0 decaying to invisible final states in 20.3 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.
- 15 AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The branching fraction of decays into BSM particles that are invisible or into undetected decay modes is measured for $m_{H^0} = 125.09$ GeV.
- 16 AAD 15BD search for $pp \rightarrow H^0WX$ and $pp \rightarrow H^0ZX$ with W or Z decaying hadronically and H^0 decaying to invisible final states using data at $E_{cm} = 8$ TeV. The quoted limit is given for $m_{H^0} = 125$ GeV, assumes the Standard Model rates for the production processes and is based on a combination of the contributions from H^0W, H^0Z and the gluon-fusion process.
- 17 AAD 15CX search for H^0 decaying to invisible final states with VBF, ZH , and WH productions using 20.3 fb⁻¹ at 8 TeV, and 4.7 fb⁻¹ at 7 TeV. The quoted limit is given for $m_{H^0} = 125.36$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH , and WH productions. The upper limit is improved to 0.23 by adding the measured visible decay rates.
- 18 AAD 14O search for $pp \rightarrow H^0ZX, Z \rightarrow \ell\ell$, with H^0 decaying to invisible final states in 4.5 fb⁻¹ at $E_{cm} = 7$ TeV and 20.3 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125.5$ GeV and assumes the Standard Model rate for H^0Z production.
- 19 CHATRCHYAN 14B search for $pp \rightarrow H^0ZX, Z \rightarrow \ell\ell$ and $Z \rightarrow b\bar{b}$, and also $pp \rightarrow qqH^0X$ with H^0 decaying to invisible final states using data at $E_{cm} = 7$ and 8 TeV. The quoted limit on the branching ratio is obtained from a combination of the limits from H^0Z and qqH^0X . It is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for the two production processes.
- 20 CHATRCHYAN 14B search for $pp \rightarrow H^0ZX$ with H^0 decaying to invisible final states and $Z \rightarrow \ell\ell$ in 4.9 fb⁻¹ at $E_{cm} = 7$ TeV and 19.7 fb⁻¹ at $E_{cm} = 8$ TeV, and also with $Z \rightarrow b\bar{b}$ in 18.9 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rate for H^0Z production.
- 21 CHATRCHYAN 14B search for $pp \rightarrow qqH^0X$ (vector boson fusion) with H^0 decaying to invisible final states in 19.5 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rate for qqH^0X production.

<0.046	95	1 SIRUNYAN	19CG CMS	$pp \rightarrow H^0Z, H^0 \rightarrow \gamma\text{invisible}, Z \rightarrow \ell\ell, 13$ TeV	

- 1 SIRUNYAN 19CG search for $pp \rightarrow H^0Z, Z \rightarrow ee, \mu\mu$ with H^0 decaying to invisible final states plus a γ in 137 fb⁻¹ at $E_{cm} = 13$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV assuming the Standard Model rate for H^0Z production and is obtained in the context of a theoretical model, where the undetected (invisible) is massless.

H^0 SIGNAL STRENGTHS IN DIFFERENT CHANNELS

The H^0 signal strength in a particular final state xx is given by the cross section times branching ratio in this channel normalized to the Standard Model (SM) value, $\sigma \cdot B(H^0 \rightarrow xx) / (\sigma \cdot B(H^0 \rightarrow xx))_{\text{SM}}$, for the specified mass value of H^0 . For the SM predictions, see DITTMAYER 11, DITTMAYER 12, and HEINEMEYER 13A. Results for fiducial and differential cross sections are also listed below.

Gauge & Higgs Boson Particle Listings

 H^0

- ¹ AAD 20 combine results of up to 79.8 fb^{-1} of data at $E_{\text{cm}} = 13 \text{ TeV}$, assuming $m_{H^0} = 125.09 \text{ GeV}$: $\gamma\gamma$, ZZ^* , WW^* , $\tau\tau$, $b\bar{b}$, $\mu\mu$, invisible, and off-shell analyses (see their Table I). The signal strengths for individual production processes are 1.04 ± 0.09 for gluon fusion, $1.21^{+0.24}_{-0.22}$ for vector boson fusion, $1.30^{+0.40}_{-0.38}$ for WH^0 production, $1.05^{+0.31}_{-0.29}$ for ZH^0 production, and $1.21^{+0.26}_{-0.24}$ for $t\bar{t}H^0 + tH^0$ production (see their Fig. 2 and Table IV). Several results with the simplified template cross section and κ -frameworks are presented: see their Figs. 9–11, Figs 20, 21 and Table VIII for stage-1 simplified template cross sections, their Figs. 12–17 and Tables X–XII for the κ -framework.
- ² SIRUNYAN 19AT combine results of 35.9 fb^{-1} of data at $E_{\text{cm}} = 13 \text{ TeV}$, assuming $m_{H^0} = 125.09 \text{ GeV}$. The signal strengths for individual production processes are $1.22^{+0.14}_{-0.12}$ for gluon fusion, $0.73^{+0.30}_{-0.27}$ for vector boson fusion, $2.18^{+0.58}_{-0.55}$ for WH^0 production, $0.87^{+0.44}_{-0.42}$ for ZH^0 production, and $1.18^{+0.30}_{-0.27}$ for $t\bar{t}H^0$ production. Several results with the simplified template cross section and κ -frameworks are presented: see their Fig. 8 and Table 5 for stage-0 simplified template cross sections, their Figs. 9–18 and Tables 7–11 for the κ -framework.
- ³ AAD 16AN perform fits to the ATLAS and CMS data at $E_{\text{cm}} = 7$ and 8 TeV . The signal strengths for individual production processes are $1.03^{+0.16}_{-0.14}$ for gluon fusion, $1.18^{+0.25}_{-0.23}$ for vector boson fusion, $0.89^{+0.40}_{-0.38}$ for WH^0 production, $0.79^{+0.38}_{-0.36}$ for ZH^0 production, and $2.3^{+0.7}_{-0.6}$ for $t\bar{t}H^0$ production.
- ⁴ AAD 16AN: The uncertainties represent statistics, experimental systematics, theory systematics on the background, and theory systematics on the signal. The quoted signal strengths are given for $m_{H^0} = 125.09 \text{ GeV}$. In the fit, relative branching ratios and relative production cross sections are fixed to those in the Standard Model.
- ⁵ AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1} , respectively, of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ⁶ SIRUNYAN 19BA measure differential cross sections for the Higgs boson transverse momentum, the number of jets, the rapidity of the Higgs boson and the transverse momentum of the leading jet using 35.9 fb^{-1} of data at $E_{\text{cm}} = 13 \text{ TeV}$ with $H^0 \rightarrow \gamma\gamma$, $H^0 \rightarrow ZZ^*$, and $H^0 \rightarrow b\bar{b}$. The total cross section for Higgs boson production is measured to be $61.1 \pm 6.0 \pm 3.7 \text{ pb}$ using $H^0 \rightarrow \gamma\gamma$ and $H^0 \rightarrow ZZ^*$ channels. Several coupling measurements in the κ -framework are performed.
- ⁷ AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The third uncertainty in the measurement is theory systematics. The signal strengths for individual production modes are $1.23 \pm 0.14^{+0.09}_{-0.08}$ for gluon fusion, $1.23^{+0.28}_{-0.27} + 0.13^{+0.11}_{-0.09}$ for vector boson fusion, $0.80^{+0.31}_{-0.30} \pm 0.17^{+0.10}_{-0.05}$ for W/ZH^0 production, and $1.81^{+0.52}_{-0.50} + 0.58^{+0.31}_{-0.55} - 0.12^{+0.16}_{-0.12}$ for $t\bar{t}H^0$ production. The quoted signal strengths are given for $m_{H^0} = 125.36 \text{ GeV}$.
- ⁸ AAD 15P measure total and differential cross sections of the process $pp \rightarrow H^0 X$ at $E_{\text{cm}} = 8 \text{ TeV}$ with 20.3 fb^{-1} . $\gamma\gamma$ and 4ℓ final states are used. $\sigma(pp \rightarrow H^0 X) = 33.0 \pm 5.3 \pm 1.6 \text{ pb}$ is given. See their Figs. 2 and 3 for data on differential cross sections.
- ⁹ KHACHATRYAN 15AM use up to 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The third uncertainty in the measurement is theory systematics. Fits to each production mode give the value of $0.85^{+0.19}_{-0.16}$ for gluon fusion, $1.16^{+0.37}_{-0.34}$ for vector boson fusion, $0.92^{+0.38}_{-0.36}$ for WH^0 , ZH^0 production, and $2.90^{+1.08}_{-0.94}$ for $t\bar{t}H^0$ production.
- ¹⁰ AAD 13AK use 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 20.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The combined signal strength is based on the $\gamma\gamma$, $ZZ^* \rightarrow 4\ell$, and $WW^* \rightarrow \ell\nu\ell\nu$ channels. The quoted signal strength is given for $m_{H^0} = 125.5 \text{ GeV}$. Reported statistical error value modified following private communication with the experiment.
- ¹¹ AALTONEN 13L combine all CDF results with $9.45\text{--}10.0 \text{ fb}^{-1}$ of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ¹² ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ¹³ AAD 12AI obtain results based on $4.6\text{--}4.8 \text{ fb}^{-1}$ of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and $5.8\text{--}5.9 \text{ fb}^{-1}$ at $E_{\text{cm}} = 8 \text{ TeV}$. An excess of events over background with a local significance of 5.9σ is observed at $m_{H^0} = 126 \text{ GeV}$. The quoted signal strengths are given for $m_{H^0} = 126 \text{ GeV}$. See also AAD 12DA.
- ¹⁴ CHATRCHYAN 12N obtain results based on $4.9\text{--}5.1 \text{ fb}^{-1}$ of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and $5.1\text{--}5.3 \text{ fb}^{-1}$ at $E_{\text{cm}} = 8 \text{ TeV}$. An excess of events over background with a local significance of 5.0σ is observed at about $m_{H^0} = 125 \text{ GeV}$. The combined signal strength is based on the $\gamma\gamma$, ZZ^* , WW^* , $\tau^+\tau^-$, and $b\bar{b}$ channels. The quoted signal strength is given for $m_{H^0} = 125.5 \text{ GeV}$. See also CHATRCHYAN 13Y.

- ¹ SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{\text{cm}} = 13 \text{ TeV}$.
- ² AAD 16AN perform fits to the ATLAS and CMS data at $E_{\text{cm}} = 7$ and 8 TeV . The signal strengths for individual production processes are 0.84 ± 0.17 for gluon fusion, 1.2 ± 0.4 for vector boson fusion, $1.6^{+1.2}_{-1.0}$ for WH^0 production, $5.9^{+2.8}_{-2.2}$ for ZH^0 production, and $5.0^{+1.8}_{-1.7}$ for $t\bar{t}H^0$ production.
- ³ AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09 \text{ GeV}$.
- ⁴ AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1} , respectively, of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ⁵ AABOUD 19F measure cross-sections times the $H^0 \rightarrow WW^*$ branching fraction in the $H^0 \rightarrow WW^* \rightarrow e\nu\mu\nu$ channel using 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$: $\sigma_{ggF} \times B(H^0 \rightarrow WW^*) = 11.4^{+1.2}_{-1.1} + 1.8^{+1.8}_{-1.7} \text{ pb}$ and $\sigma_{VBF} \times B(H^0 \rightarrow WW^*) = 0.50^{+0.24}_{-0.22} \pm 0.17 \text{ pb}$.
- ⁶ AAD 19A use 36.1 fb^{-1} data at 13 TeV . The cross section times branching fraction values are measured to be $0.67^{+0.31}_{-0.27} + 0.31^{+0.18}_{-0.14} \text{ pb}$ for WH^0 , $H^0 \rightarrow WW^*$ and $0.54^{+0.31}_{-0.24} + 0.15^{+0.15}_{-0.07} \text{ pb}$ for ZH^0 , $H^0 \rightarrow WW^*$.
- ⁷ SIRUNYAN 19AX measure the signal strengths, cross sections and so on using gluon fusion, VBF and VH^0 production processes with 35.9 fb^{-1} of data. The quoted signal strength is given for $m_{H^0} = 125.09 \text{ GeV}$. Signal strengths for each production process is found in their Fig. 9. Measured cross sections and ratios to the SM predictions in the stage-0 simplified template cross section framework are shown in their Fig. 10. $\kappa_F = 1.52^{+0.48}_{-0.41}$ and $\kappa_V = 1.10 \pm 0.08$ are obtained (see their Fig. 11 (right)).
- ⁸ AAD 16AO measure fiducial total and differential cross sections of gluon fusion process at $E_{\text{cm}} = 8 \text{ TeV}$ with 20.3 fb^{-1} using $H^0 \rightarrow WW^* \rightarrow e\nu\mu\nu$. The measured fiducial total cross section is $36.0 \pm 9.7 \text{ fb}$ in their fiducial region (Table 7). See their Fig. 6 for fiducial differential cross sections. The results are given for $m_{H^0} = 125 \text{ GeV}$.
- ⁹ AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125.36 \text{ GeV}$.
- ¹⁰ AAD 15AA use 4.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength for the gluon fusion and vector boson fusion mode is $1.02 \pm 0.19^{+0.22}_{-0.18}$ and $1.27^{+0.44}_{-0.40} + 0.30^{+0.30}_{-0.21}$, respectively. The quoted signal strengths are given for $m_{H^0} = 125.36 \text{ GeV}$.
- ¹¹ AAD 15AQ use 4.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125.36 \text{ GeV}$.
- ¹² AAD 15AQ combine their result on W/ZH^0 production with the results of AAD 15AA (gluon fusion and vector boson fusion, slightly updated). The quoted signal strength is given for $m_{H^0} = 125.36 \text{ GeV}$.
- ¹³ CHATRCHYAN 14G use 4.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.4 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_{H^0} = 125.6 \text{ GeV}$.
- ¹⁴ AAD 13AK use 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 20.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125.5 \text{ GeV}$. Superseded by AAD 15AA.
- ¹⁵ AALTONEN 13L combine all CDF results with $9.45\text{--}10.0 \text{ fb}^{-1}$ of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ¹⁶ ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ¹⁷ AAD 12AI obtain results based on 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 5.8 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strengths are given for $m_{H^0} = 126 \text{ GeV}$. See also AAD 12DA.
- ¹⁸ CHATRCHYAN 12N obtain results based on 4.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 5.1 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125.5 \text{ GeV}$. See also CHATRCHYAN 13Y.

- 1 SIRUNYAN 19AT perform a combine fit to 35.9 fb⁻¹ of data at $E_{cm} = 13$ TeV.
- 2 AABOUD 18AJ perform analyses using $H^0 \rightarrow ZZ^* \rightarrow 4\ell$ ($\ell = e, \mu$) with data of 36.1 fb⁻¹ at $E_{cm} = 13$ TeV. Results are given for $m_{H^0} = 125.09$ GeV. The inclusive cross section times branching ratio for $H^0 \rightarrow ZZ^*$ decay ($|\eta(H^0)| < 2.5$) is measured to be $1.73^{+0.26}_{-0.24}$ pb (with $1.34^{+0.09}_{-0.09}$ pb expected in the SM).
- 3 AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are $1.13^{+0.34}_{-0.31}$ for gluon fusion and $0.1^{+1.1}_{-0.6}$ for vector boson fusion.
- 4 AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09$ GeV.
- 5 AABOUD 19N measure the spectrum of the four-lepton invariant mass $m_{4\ell}$ ($\ell = e$ or μ) using 36.1 fb⁻¹ of data at $E_{cm} = 13$ TeV. The quoted signal strength upper limit is obtained from $180 \text{ GeV} < m_{4\ell} < 1200 \text{ GeV}$.
- 6 AABOUD 18BP measure an off-shell Higgs boson production using $ZZ \rightarrow 4\ell$ and $ZZ \rightarrow 2\ell 2\nu$ ($\ell = e, \mu$) decay channels with 36.1 fb⁻¹ of data at $E_{cm} = 13$ TeV. The quoted signal strength upper limit is obtained from a combination of these two channels, where $220 \text{ GeV} < m_{4\ell} < 2000 \text{ GeV}$ for $ZZ \rightarrow 4\ell$ and $250 \text{ GeV} < m_{\ell\ell}^{ZZ} < 2000 \text{ GeV}$ for $ZZ \rightarrow 2\ell 2\nu$ ($m_{\ell\ell}^{ZZ}$ is defined in their Section 5). See their Table 2 for each measurement.
- 7 SIRUNYAN 17AV use 35.9 fb⁻¹ of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength, obtained from the analysis of $H^0 \rightarrow ZZ^* \rightarrow 4\ell$ ($\ell = e, \mu$) decays, is given for $m_{H^0} = 125.09$ GeV. The signal strengths for different production modes are given in their Table 3. The fiducial and differential cross sections are shown in their Fig. 10.
- 8 AAD 16K use up to 4.7 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.36$ GeV.
- 9 KHACHATRYAN 16AR use data of 5.1 fb⁻¹ at $E_{cm} = 7$ TeV and 19.7 fb⁻¹ at 8 TeV. The fiducial cross sections for the production of 4 leptons via $H^0 \rightarrow 4\ell$ decays are measured to be $0.56^{+0.67+0.21}_{-0.44-0.06}$ fb at 7 TeV and $1.11^{+0.41+0.14}_{-0.35-0.10}$ fb at 8 TeV in their fiducial region (Table 2). The differential cross sections at $E_{cm} = 8$ TeV are also shown in Figs. 4 and 5. The results are given for $m_{H^0} = 125$ GeV.
- 10 AAD 15F use 4.5 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.36$ GeV. The signal strength for the gluon fusion production mode is $1.66^{+0.45+0.25}_{-0.41-0.15}$, while the signal strength for the vector boson fusion production mode is $0.26^{+1.60+0.36}_{-0.91-0.23}$.
- 11 AAD 14AR measure the cross section for $pp \rightarrow H^0 X$, $H^0 \rightarrow ZZ^*$ using 20.3 fb⁻¹ at $E_{cm} = 8$ TeV. They give $\sigma \cdot B = 2.11^{+0.53}_{-0.47} \pm 0.08$ fb in their fiducial region, where 1.30 ± 0.13 fb is expected in the Standard Model for $m_{H^0} = 125.4$ GeV. Various differential cross sections are also given, which are in agreement with the Standard Model expectations.
- 12 CHATRCHYAN 14AA use 5.1 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.6$ GeV. The signal strength for the gluon fusion and $t\bar{t}H$ production mode is $0.80^{+0.46}_{-0.36}$, while the signal strength for the vector boson fusion and WH^0 , ZH^0 production mode is $1.7^{+2.2}_{-2.1}$.
- 13 AAD 13AK use 4.7 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 20.7 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.5$ GeV.
- 14 CHATRCHYAN 13J obtain results based on $ZZ \rightarrow 4\ell$ final states in 5.1 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 12.2 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.8$ GeV. Superseded by CHATRCHYAN 14AA.

- 15 AAD 12AI obtain results based on 4.7–4.8 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 5.8 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strengths are given for $m_{H^0} = 126$ GeV. See also AAD 12DA.
- 16 CHATRCHYAN 12N obtain results based on 4.9–5.1 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 5.1–5.3 fb⁻¹ at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.0 σ is observed at about $m_{H^0} = 125$ GeV. The quoted signal strengths are given for $m_{H^0} = 125.5$ GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

- 1 SIRUNYAN 19AT perform a combine fit to 35.9 fb⁻¹ of data at $E_{cm} = 13$ TeV.
- 2 AABOUD 18BO use 36.1 fb⁻¹ of pp collisions at $E_{cm} = 13$ TeV. The signal strengths for the individual production modes are: $0.81^{+0.19}_{-0.18}$ for gluon fusion, $2.0^{+0.6}_{-0.5}$ for vector boson fusion, $0.7^{+0.9}_{-0.8}$ for VH^0 production ($V = W, Z$), and 0.5 ± 0.6 for $t\bar{t}H^0$ and tH^0 production. Other measurements of cross sections and couplings are summarized in their Section 10. The quoted values are given for $m_{H^0} = 125.09$ GeV.
- 3 AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are $1.10^{+0.23}_{-0.22}$ for gluon fusion, 1.3 ± 0.5 for vector boson fusion, $0.5^{+1.3}_{-1.2}$ for WH^0 production, $0.5^{+3.0}_{-2.5}$ for ZH^0 production, and $2.2^{+1.6}_{-1.3}$ for $t\bar{t}H^0$ production.
- 4 AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09$ GeV.
- 5 AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb⁻¹ and 9.7 fb⁻¹, respectively, of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.
- 6 SIRUNYAN 19L measure fiducial and differential cross sections of the process $pp \rightarrow H^0 \rightarrow \gamma\gamma$ at $E_{cm} = 13$ TeV with 35.9 fb⁻¹. See their Figs. 4–11.
- 7 SIRUNYAN 18DS use 35.9 fb⁻¹ of $pp \rightarrow H^0$ collisions with $H^0 \rightarrow \gamma\gamma$ at $E_{cm} = 13$ TeV. The Higgs mass is floated in the measurement of a signal strength. The result is $1.18^{+0.12}_{-0.11}$ (stat.) ± 0.09 (syst.) ± 0.07 (theory), which is largely insensitive to the Higgs mass around 125 GeV.
- 8 KHACHATRYAN 16G measure fiducial and differential cross sections of the process $pp \rightarrow H^0 X$, $H^0 \rightarrow \gamma\gamma$ at $E_{cm} = 8$ TeV with 19.7 fb⁻¹. See their Figs. 4–6 and Table 1 for data.
- 9 AAD 14BC use 4.5 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb⁻¹ at $E_{cm} = 8$ TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_{H^0} = 125.4$ GeV. The signal strengths for the individual production modes are: 1.32 ± 0.38 for gluon fusion, 0.8 ± 0.7 for vector boson fusion, 1.0 ± 1.6 for WH^0 production, $0.1^{+3.7}_{-0.1}$ for ZH^0 production, and $1.6^{+2.7}_{-1.8}$ for $t\bar{t}H^0$ production.
- 10 AAD 14BJ measure fiducial and differential cross sections of the process $pp \rightarrow H^0 X$, $H^0 \rightarrow \gamma\gamma$ at $E_{cm} = 8$ TeV with 20.3 fb⁻¹. See their Table 3 and Figs. 3–12 for data.
- 11 KHACHATRYAN 14P use 5.1 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb⁻¹ at $E_{cm} = 8$ TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_{H^0} = 124.7$ GeV. The signal strength for the gluon fusion and $t\bar{t}H$ production mode is $1.13^{+0.37}_{-0.31}$, while the signal strength for the vector boson fusion and WH^0 , ZH^0 production mode is $1.16^{+0.63}_{-0.58}$.
- 12 AAD 13AK use 4.7 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 20.7 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.5$ GeV.
- 13 AALTONEN 13L combine all CDF results with 9.45–10.0 fb⁻¹ of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

Gauge & Higgs Boson Particle Listings

 H^0

- ¹⁴ ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ¹⁵ AAD 12A1 obtain results based on 4.8 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 5.9 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strengths are given for $m_{H^0} = 126 \text{ GeV}$. See also AAD 12DA.
- ¹⁶ CHATRCHYAN 12N obtain results based on 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 5.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125.5 \text{ GeV}$. See also CHATRCHYAN 13Y.

 $c\bar{c}$ Final State

- ¹ SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{\text{cm}} = 13 \text{ TeV}$.
- ² AABOUD 18BN search for $V H^0, H^0 \rightarrow b\bar{b}$ ($V = W, Z$) using 79.8 fb^{-1} of pp collision data at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength corresponds to a significance of 4.9 standard deviations and is given for $m_{H^0} = 125 \text{ GeV}$.
- ³ SIRUNYAN 18DB search for $V H^0, H^0 \rightarrow b\bar{b}$ ($V = W, Z$) using 77.2 fb^{-1} of pp collision data at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength corresponds to a significance of 4.4 standard deviations and is given for $m_{H^0} = 125.09 \text{ GeV}$.
- ⁴ AAD 16AN perform fits to the ATLAS and CMS data at $E_{\text{cm}} = 7$ and 8 TeV . The signal strengths for individual production processes are 1.0 ± 0.5 for WH^0 production, 0.4 ± 0.4 for ZH^0 production, and 1.1 ± 1.0 for $t\bar{t}H^0$ production.
- ⁵ AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09 \text{ GeV}$.

- ⁶ AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1} , respectively, of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ⁷ AABOUD 19U measure cross sections of $pp \rightarrow V H^0, H^0 \rightarrow b\bar{b}$ production as a function of the gauge boson transverse momentum using data of 79.8 fb^{-1} . The kinematic fiducial volumes used is based on the simplified template cross section framework (reduced stage-1). See their Table 3 and Fig. 3.
- ⁸ AABOUD 18BN combine results of 79.8 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$ with results of $V H^0$ at $E_{\text{cm}} = 7$ and 8 TeV .
- ⁹ AABOUD 18BN combine results of $V H^0$ at $E_{\text{cm}} = 7, 8$ and 13 TeV with results of VBF (+gluon fusion) and $t\bar{t}H^0$ at $E_{\text{cm}} = 7, 8$, and 13 TeV to perform a search for the $H^0 \rightarrow b\bar{b}$ decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.4 standard deviations.
- ¹⁰ AABOUD 18BQ search for $H^0 \rightarrow b\bar{b}$ produced through vector-boson fusion (VBF) and VBF+ γ with 30.6 fb^{-1} pp collision data at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ¹¹ The signal strength is measured including all production modes (VBF, ggF, $V H^0, t\bar{t}H^0$).
- ¹² The signal strength is measured for VBF-only and others (ggF, $V H^0, t\bar{t}H^0$) are constrained to Standard Model expectations with uncertainties described in their Section VIII B.
- ¹³ AALTONEN 18C use 5.4 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The upper limit at 95% CL on $p\bar{p} \rightarrow H^0 \rightarrow b\bar{b}$ is 33 times the SM prediction, which corresponds to a cross section of 40.6 pb .
- ¹⁴ SIRUNYAN 18AE use 35.9 fb^{-1} of pp collision data at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength corresponds to 3.3 standard deviations and is given for $m_{H^0} = 125.09 \text{ GeV}$.
- ¹⁵ SIRUNYAN 18AE combine the result of 35.9 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$ with the results obtained from data of up to 5.1 fb^{-1} at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 18.9 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$ (CHATRCHYAN 14A1 and KHACHATRYAN 15Z). The quoted signal strength corresponds to 3.8 standard deviations and is given for $m_{H^0} = 125.09 \text{ GeV}$.
- ¹⁶ SIRUNYAN 18DB combine the result of 77.2 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$ with the results obtained from data of up to 5.1 fb^{-1} at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 18.9 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength corresponds to a significance of 4.8 standard deviations and is given for $m_{H^0} = 125.09 \text{ GeV}$.
- ¹⁷ SIRUNYAN 18DB combine results of 77.2 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$ with results of gluon fusion (ggF), VBF and $t\bar{t}H^0$ at $E_{\text{cm}} = 7 \text{ TeV}, 8 \text{ TeV}$ and 13 TeV to perform a search for the $H^0 \rightarrow b\bar{b}$ decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.6 standard deviations and is given for $m_{H^0} = 125.09 \text{ GeV}$.
- ¹⁸ SIRUNYAN 18E use 35.9 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$. They measure $\sigma \cdot B$ for gluon fusion production of $H^0 \rightarrow b\bar{b}$ with $p_T > 450 \text{ GeV}$, $|\eta| < 2.5$ to be $74 \pm 48^{+17}_{-10} \text{ fb}$.
- ¹⁹ AABOUD 17BA use 36.1 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$. They give $\sigma(W H) \cdot B(H^0 \rightarrow b\bar{b}) = 1.08^{+0.54}_{-0.47} \text{ pb}$ and $\sigma(Z H) \cdot B(H^0 \rightarrow b\bar{b}) = 0.57^{+0.26}_{-0.23} \text{ pb}$.
- ²⁰ AABOUD 17BA combine 7, 8 and 13 TeV analyses. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ²¹ AABOUD 16X search for vector-boson fusion production of H^0 decaying to $b\bar{b}$ in 20.2 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ²² AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125.36 \text{ GeV}$.
- ²³ AAD 15G use 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125.36 \text{ GeV}$.
- ²⁴ KHACHATRYAN 15Z search for vector-boson fusion production of H^0 decaying to $b\bar{b}$ in up to 19.8 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ²⁵ KHACHATRYAN 15Z combined vector boson fusion, WH^0, ZH^0 production, and $t\bar{t}H^0$ production results. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ²⁶ CHATRCHYAN 14A1 use up to 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 18.9 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$. See also CHATRCHYAN 14A1.
- ²⁷ AALTONEN 13L combine all CDF results with $9.45\text{--}10.0 \text{ fb}^{-1}$ of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ²⁸ ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- ²⁹ AAD 12A1 obtain results based on $4.6\text{--}4.8 \text{ fb}^{-1}$ of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. The quoted signal strengths are given in their Fig. 10 for $m_{H^0} = 126 \text{ GeV}$. See also Fig. 13 of AAD 12DA.
- ³⁰ AALTONEN 12T combine AALTONEN 12Q, AALTONEN 12R, AALTONEN 12S, ABAZOV 12P, ABAZOV 12P, and ABAZOV 12K. An excess of events over background is observed which is most significant in the region $m_{H^0} = 120\text{--}135 \text{ GeV}$, with a local significance of up to 3.3σ . The local significance at $m_{H^0} = 125 \text{ GeV}$ is 2.8σ , which corresponds to $(\sigma(H^0 W) + \sigma(H^0 Z)) \cdot B(H^0 \rightarrow b\bar{b}) = (0.23^{+0.09}_{-0.08}) \text{ pb}$, compared to the Standard Model expectation at $m_{H^0} = 125 \text{ GeV}$ of $0.12 \pm 0.01 \text{ pb}$. Superseded by AALTONEN 13M.
- ³¹ CHATRCHYAN 12N obtain results based on 5.0 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 5.1 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125.5 \text{ GeV}$. See also CHATRCHYAN 13Y.

< 7.4	95	5 KHACHATRYAN...15H	CMS	$pp \rightarrow H^0 X$, 7, 8 TeV
< 7.0	95	6 AAD	14AS ATLS	$pp \rightarrow H^0 X$, 7, 8 TeV
1 SIRUNYAN 19E search for $H^0 \rightarrow \mu^+ \mu^-$ using 35.9 fb ⁻¹ of pp collisions at $E_{cm} = 13$ TeV and combine with results of 7 TeV (5.0 fb ⁻¹) and 8 TeV (19.7 fb ⁻¹). The upper limit at 95% CL on the signal strength is 2.9, which corresponds to the SM Higgs boson branching fraction to a muon pair of 6.4×10^{-4} .				
2 AABOUD 17Y use 36.1 fb ⁻¹ of pp collisions at $E_{cm} = 13$ TeV, 20.3 fb ⁻¹ at 8 TeV and 4.5 fb ⁻¹ at 7 TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.				
3 SIRUNYAN 19AT perform a combine fit to 35.9 fb ⁻¹ of data at $E_{cm} = 13$ TeV.				
4 AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09$ GeV.				
5 KHACHATRYAN 15H use 5.0 fb ⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb ⁻¹ at 8 TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.				
6 AAD 14AS search for $H^0 \rightarrow \mu^+ \mu^-$ in 4.5 fb ⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb ⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.5$ GeV.

1 AABOUD 19AQ use 36.1 fb ⁻¹ of data. The first, second and third quoted errors are statistical, experimental systematic and theory systematic uncertainties, respectively. The quoted signal strength is given for $m_{H^0} = 125$ GeV and corresponds to 4.4 standard deviations. Combining with 7 TeV and 8 TeV results (AAD 15AH), the observed significance is 6.4 standard deviations. The cross sections in the $H^0 \rightarrow \tau\tau$ decay channel ($m_{H^0} = 125$ GeV) are measured to $3.77^{+0.60}_{-0.59}$ (stat) ± 0.87 (syst) pb for the inclusive, $0.28 \pm 0.09^{+0.11}_{-0.09}$ pb for VBF, and $3.1 \pm 1.0^{+1.6}_{-1.3}$ pb for gluon-fusion production. See their Table XI for the cross sections in the framework of simplified template cross sections.				
2 SIRUNYAN 19AF use 35.9 fb ⁻¹ of data. $H^0 W/Z$ channels are added with a few updates on gluon fusion and vector boson fusion with respect to SIRUNYAN 18Y. The quoted signal strength is given for $m_{H^0} = 125$ GeV and corresponds to 5.5 standard deviations. The signal strengths for the individual production modes are: $1.12^{+0.53}_{-0.50}$ for gluon fusion, $1.13^{+0.45}_{-0.42}$ for vector boson fusion, $3.39^{+1.68}_{-1.54}$ for WH^0 and $1.23^{+1.62}_{-1.35}$ for ZH^0 . See their Fig. 7 for other couplings (κ_V, κ_f).				
3 AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are 1.0 ± 0.6 for gluon fusion, 1.3 ± 0.4 for vector boson fusion, -1.4 ± 1.4 for WH^0 production, $2.2^{+2.2}_{-1.8}$ for ZH^0 production, and $-1.9^{+3.7}_{-3.3}$ for $t\bar{t}H^0$ production.				

- 4 AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09$ GeV.
- 5 AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb⁻¹ and 9.7 fb⁻¹, respectively, of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.
- 6 SIRUNYAN 19AF use 35.9 fb⁻¹ of data. The quoted signal strength is given for $m_{H^0} = 125$ GeV and corresponds to 2.3 standard deviations.
- 7 SIRUNYAN 19AT perform a combine fit to 35.9 fb⁻¹ of data at $E_{cm} = 13$ TeV. This combination is based on SIRUNYAN 18Y.
- 8 SIRUNYAN 18Y use 35.9 fb⁻¹ of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_{H^0} = 125.09$ GeV and corresponds to 4.9 standard deviations.
- 9 SIRUNYAN 18Y combine the result of 35.9 fb⁻¹ at $E_{cm} = 13$ TeV with the results obtained from data of 4.9 fb⁻¹ at $E_{cm} = 7$ TeV and 19.7 fb⁻¹ at $E_{cm} = 8$ TeV (KHACHATRYAN 15AM). The quoted signal strength is given for $m_{H^0} = 125.09$ GeV and corresponds to 5.9 standard deviations.
- 10 AAD 16AC measure the signal strength with $pp \rightarrow H^0 W/ZX$ processes using 20.3 fb⁻¹ of $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.
- 11 AAD 16K use up to 4.7 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.36$ GeV.
- 12 AAD 15AH use 4.5 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb⁻¹ at $E_{cm} = 8$ TeV. The third uncertainty in the measurement is theory systematics. The signal strength for the gluon fusion mode is $2.0 \pm 0.8^{+1.2}_{-0.8} \pm 0.3$ and that for vector boson fusion and W/ZH^0 production modes is $1.24^{+0.49+0.31}_{-0.45-0.29} \pm 0.08$. The quoted signal strength is given for $m_{H^0} = 125.36$ GeV.
- 13 CHATRCHYAN 14K use 4.9 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV. See also CHATRCHYAN 14AJ.
- 14 AALTONEN 13L combine all CDF results with 9.45–10.0 fb⁻¹ of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.
- 15 ABAZOV 13L combine all D0 results with up to 9.7 fb⁻¹ of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.
- 16 AAD 12AI obtain results based on 4.7 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV. The quoted signal strengths are given in their Fig. 10 for $m_{H^0} = 126$ GeV. See also Fig. 13 of AAD 12DA.
- 17 CHATRCHYAN 12N obtain results based on 4.9 fb⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 5.1 fb⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.5$ GeV. See also CHATRCHYAN 13Y.

$Z\gamma$ Final State

1 AABOUD 17AW search for $H^0 \rightarrow Z\gamma, Z \rightarrow ee, \mu\mu$ in 36.1 fb ⁻¹ of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_{H^0} = 125.09$ GeV. The upper limit on the branching ratio of $H^0 \rightarrow Z\gamma$ is 1.0% at 95% CL assuming the SM Higgs boson production.				
2 SIRUNYAN 18DQ search for $H^0 \rightarrow Z\gamma, Z \rightarrow ee, \mu\mu$ in 35.9 fb ⁻¹ of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength (see their Figs. 6 and 7) is given for $m_{H^0} = 125$ GeV.				
3 AAD 14I search for $H^0 \rightarrow Z\gamma \rightarrow \ell\ell\gamma$ in 4.5 fb ⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb ⁻¹ at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.5$ GeV.				
4 CHATRCHYAN 13BK search for $H^0 \rightarrow Z\gamma \rightarrow \ell\ell\gamma$ in 5.0 fb ⁻¹ of pp collisions at $E_{cm} = 7$ TeV and 19.6 fb ⁻¹ at $E_{cm} = 8$ TeV. A limit on cross section times branching ratio which corresponds to (4–25) times the expected Standard Model cross section is given in the range $m_{H^0} = 120$ –160 GeV at 95% CL. The quoted limit is given for $m_{H^0} = 125$ GeV, where 10 is expected for no signal.

- 1 SIRUNYAN 20c search for the production of four top quarks with same-sign and multilepton final states with 137 fb^{-1} pp collision data at $E_{\text{cm}} = 13 \text{ TeV}$. The results constrain the ratio of the top quark Yukawa coupling y_t to its Standard Model by comparing to the central value of a theoretical prediction (see their Refs. [1-2]), yielding $|y_t/y_t^{\text{SM}}| < 1.7$ at 95% CL. See their Fig. 5.
- 2 SIRUNYAN 19bY measure the top quark Yukawa coupling from $t\bar{t}$ kinematic distributions, the invariant mass of the top quark pair and the rapidity difference between t and \bar{t} , in the $\ell^+\ell^-$ final state with 35.8 fb^{-1} pp collision data at $E_{\text{cm}} = 13 \text{ TeV}$. The results constrain the ratio of the top quark Yukawa coupling to its Standard Model to be $1.07^{+0.34}_{-0.43}$ with an upper limit of 1.67 at 95% CL (see their Table III).
- 3 SIRUNYAN 18bU search for the production of four top quarks with same-sign and multilepton final states with 35.9 fb^{-1} pp collision data at $E_{\text{cm}} = 13 \text{ TeV}$. The results constrain the ratio of the top quark Yukawa coupling y_t to its Standard Model by comparing to the central value of a theoretical prediction (see their Ref. [16]), yielding $|y_t/y_t^{\text{SM}}| < 2.1$ at 95% CL.

- 1 AABOUD 18Ac combine results of $t\bar{t}H^0, H^0 \rightarrow \tau\tau, WW^*(\rightarrow \ell\nu\nu, \ell\nu q\bar{q}), ZZ^*(\rightarrow \ell\nu\nu, \ell\nu q\bar{q})$ with results of $t\bar{t}H^0, H^0 \rightarrow b\bar{b}$ (AABOUD 18T), $\gamma\gamma$ (AABOUD 18Bo), $ZZ^*(\rightarrow 4\ell)$ (AABOUD 18Aj) in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$. See their Table 14.
- 2 SIRUNYAN 18L use up to 5.1, 19.7 and 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 7, 8,$ and 13 TeV , respectively. The quoted signal strength corresponds to a significance of 5.2 standard deviations and is given for $m_{H^0} = 125.09 \text{ GeV}$. H^0 decay channels of $WW^*, ZZ^*, \gamma\gamma, \tau\tau,$ and $b\bar{b}$ are used. See their Table 1 and Fig. 2 for results on individual channels.
- 3 AAD 16AN: In the fit, relative branching ratios are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09 \text{ GeV}$.
- 4 SIRUNYAN 19R search for $t\bar{t}H^0$ production with H^0 decaying to $b\bar{b}$ in 35.9 fb^{-1} of data at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- 5 AABOUD 18Ac search for $t\bar{t}H^0$ production with H^0 decaying to $\tau\tau, WW^*(\rightarrow \ell\nu\nu, \ell\nu q\bar{q}), ZZ^*(\rightarrow \ell\nu\nu, \ell\nu q\bar{q})$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$. See their Table 13 and Fig. 13.
- 6 AABOUD 18Bk use 79.8 fb^{-1} data for $t\bar{t}H^0$ production with $H^0 \rightarrow \gamma\gamma$ and $ZZ^* \rightarrow 4\ell$ ($\ell = e, \mu$) and 36.1 fb^{-1} for other decay channels at $E_{\text{cm}} = 13 \text{ TeV}$. A significance of 5.8 standard deviations is observed for $m_{H^0} = 125.09 \text{ GeV}$ and its signal strength without the uncertainty of the $t\bar{t}H^0$ cross section is $1.32^{+0.28}_{-0.26}$. Combining with results of 7 and 8 TeV (AAD 16K), the significance is 6.3 standard deviations. Assuming Standard Model branching fractions, the total $t\bar{t}H^0$ production cross section at 13 TeV is measured to be $670 \pm 90^{+110}_{-100} \text{ fb}$.

- 7 AABOUD 18T search for $t\bar{t}H^0$ production with H^0 decaying to $b\bar{b}$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- 8 SIRUNYAN 18Bd search for $t\bar{t}H^0, H^0 \rightarrow b\bar{b}$ in the all-jet final state with 35.9 fb^{-1} pp collision data at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- 9 SIRUNYAN 18Bq search for $t\bar{t}H^0$ in final states with electrons, muons and hadronically decaying τ leptons ($H^0 \rightarrow WW^*, ZZ^*, \tau\tau$) with 35.9 fb^{-1} of pp collision data at $E_{\text{cm}} = 13 \text{ TeV}$. The quoted signal strength corresponds to a significance of 3.2 standard deviations and is given for $m_{H^0} = 125 \text{ GeV}$.
- 10 AAD 16AL search for $t\bar{t}H^0$ production with H^0 decaying to $\gamma\gamma$ in 4.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and $b\bar{b}, \tau\tau, \gamma\gamma, WW^*,$ and ZZ^* in 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$. This paper combines the results of previous papers, and the new result of this paper only is: $\mu = 1.6 \pm 2.6$.
- 11 AAD 16AN perform fits to the ATLAS and CMS data at $E_{\text{cm}} = 7$ and 8 TeV .
- 12 AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The third uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_{H^0} = 125.36 \text{ GeV}$.
- 13 AAD 15 search for $t\bar{t}H^0$ production with H^0 decaying to $\gamma\gamma$ in 4.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted result on the signal strength is equivalent to an upper limit of 6.7 at 95% CL and is given for $m_{H^0} = 125.4 \text{ GeV}$.
- 14 AAD 15Bc search for $t\bar{t}H^0$ production with H^0 decaying to $b\bar{b}$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. The corresponding upper limit is 3.4 at 95% CL. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- 15 AAD 15T search for $t\bar{t}H^0$ production with H^0 resulting in multilepton final states (mainly from $WW^*, \tau\tau, ZZ^*$) in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted result on the signal strength is given for $m_{H^0} = 125 \text{ GeV}$ and corresponds to an upper limit of 4.7 at 95% CL. The data sample is independent from AAD 15 and AAD 15Bc.
- 16 KHACHATRYAN 15AN search for $t\bar{t}H^0$ production with H^0 decaying to $b\bar{b}$ in 19.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted result on the signal strength is equivalent to an upper limit of 4.2 at 95% CL and is given for $m_{H^0} = 125 \text{ GeV}$.
- 17 KHACHATRYAN 14H search for $t\bar{t}H^0$ production with H^0 decaying to $b\bar{b}, \tau\tau, \gamma\gamma, WW^*,$ and ZZ^* , in 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125.6 \text{ GeV}$.
- 18 AALTONEN 13L combine all CDF results with $9.45\text{--}10.0 \text{ fb}^{-1}$ of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The quoted signal strength is given for $m_{H^0} = 125 \text{ GeV}$.
- 19 CHATRCHYAN 13x search for $t\bar{t}H^0$ production followed by $H^0 \rightarrow b\bar{b}$, one top decaying to $\ell\nu$ and the other to either $\ell\nu$ or $q\bar{q}$ in 5.0 fb^{-1} and 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7$ and 8 TeV . A limit on cross section times branching ratio which corresponds to $(4.0\text{--}8.6)$ times the expected Standard Model cross section is given for $m_{H^0} = 110\text{--}140 \text{ GeV}$ at 95% CL. The quoted limit is given for $m_{H^0} = 125 \text{ GeV}$, where 5.2 is expected for no signal.

 H^0H^0 ProductionThe 95% CL limits are for the cross section (CS) and Higgs self coupling (κ_λ) scaling factors both relative to the SM predictions.

- 1 AAD 20c combine results of up to 36.1 fb^{-1} data at $E_{\text{cm}} = 13 \text{ TeV}$ for $pp \rightarrow H^0H^0 \rightarrow b\bar{b}\gamma\gamma, b\bar{b}\tau\tau, b\bar{b}b\bar{b}, b\bar{b}WW^*, WW^*\gamma\gamma, WW^*WW^*$ (AABOUD 18Cw, AABOUD 18Cq, AABOUD 19A, AABOUD 19O, AABOUD 18Bu, and AABOUD 19T).
- 2 AAD 20e search non-resonant for H^0H^0 production using $H^0H^0 \rightarrow b\bar{b}\ell\nu\ell\nu$, where one of the Higgs bosons decays to $b\bar{b}$ and the other decays to either $WW^*, ZZ^*,$ or $\tau\tau$, with data of 139 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0H^0$ production cross section at 95% CL is measured to be 1.2 pb, which corresponds to about 40 times the SM prediction.
- 3 AABOUD 19A search for H^0H^0 production using $H^0H^0 \rightarrow b\bar{b}b\bar{b}$ with data of 36.1 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0H^0 \rightarrow b\bar{b}b\bar{b}$ production cross section at 95% is measured to be 147 fb, which corresponds to about 12.9 times the SM prediction.

- ⁴ AABOUD 19o search for $H^0 H^0$ production using $H^0 H^0 \rightarrow b\bar{b} WW^*$ with data of 36.1 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0$ production cross section at 95% CL is calculated to be 10 pb from the observed upper limit on the $pp \rightarrow H^0 H^0 \rightarrow b\bar{b} WW^*$ production cross section of 2.5 pb assuming the SM branching fractions. The former corresponds to about 300 times the SM prediction.
- ⁵ AABOUD 19T search for $H^0 H^0$ production using $H^0 H^0 \rightarrow WW^* WW^*$ with data of 36.1 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0$ production cross section at 95% is measured to be 5.3 pb, which corresponds to about 160 times the SM prediction.
- ⁶ SIRUNYAN 19 search for $H^0 H^0$ production using $H^0 H^0 \rightarrow \gamma\gamma b\bar{b}$ with data of 35.9 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0 \rightarrow \gamma\gamma b\bar{b}$ production cross section at 95% CL is measured to be 2.0 fb, which corresponds to about 24 times the SM prediction. The effective Higgs boson self-coupling $\kappa_\lambda (\lambda = \lambda_{HHH} / \lambda_{HHH}^{\text{SM}})$ is constrained to be $-11 < \kappa_\lambda < 17$ at 95% CL assuming all other Higgs boson couplings are at their SM value.
- ⁷ SIRUNYAN 19AB search for $H^0 H^0$ production using $H^0 H^0 \rightarrow b\bar{b} b\bar{b}$, where 4 heavy flavor jets from two Higgs bosons are resolved, with data of 35.9 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0 \rightarrow b\bar{b} b\bar{b}$ production cross section at 95% is measured to be 847 fb, which corresponds to about 75 times the SM prediction.
- ⁸ SIRUNYAN 19BE combine results of 13 TeV 35.9 fb^{-1} data: SIRUNYAN 19, SIRUNYAN 18A, SIRUNYAN 19AB, SIRUNYAN 19H, and SIRUNYAN 18F.
- ⁹ SIRUNYAN 19H search for $H^0 H^0$ production using $H^0 H^0 \rightarrow b\bar{b} b\bar{b}$, where one of $b\bar{b}$ pairs is highly boosted and the other one is resolved, with data of 35.9 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0 \rightarrow b\bar{b} b\bar{b}$ production cross section at 95% is measured to be 1980 fb, which corresponds to about 179 times the SM prediction.
- ¹⁰ AABOUD 18BU search for $H^0 H^0$ production using $\gamma\gamma WW^*$ with the final state of $\gamma\gamma \ell\nu\ell\nu$ using data of 36.1 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0 \rightarrow \gamma\gamma WW^*$ at 95% CL is measured to be 7.5 fb (see their Table 6).
- ¹¹ AABOUD 18CQ search for $H^0 H^0$ production using $H^0 H^0 \rightarrow b\bar{b} \tau\tau$ with data of 36.1 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0 \rightarrow b\bar{b} \tau\tau$ production cross section at 95% is measured to be 30.9 fb, which corresponds to about 12.7 times the SM prediction.
- ¹² AABOUD 18CW search for $H^0 H^0$ production using $H^0 H^0 \rightarrow \gamma\gamma b\bar{b}$ with data of 36.1 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0$ production cross section at 95% is measured to be 0.73 pb, which corresponds to about 22 times the SM prediction. The effective Higgs boson self-coupling κ_λ is constrained to be $-8.2 < \kappa_\lambda < 13.2$ at 95% CL assuming all other Higgs boson couplings are at their SM value.
- ¹³ SIRUNYAN 18A search for $H^0 H^0$ production using $H^0 H^0 \rightarrow b\bar{b} \tau\tau$ with data of 35.9 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0 \rightarrow b\bar{b} \tau\tau$ production cross section is measured to be 75.4 fb, which corresponds to about 30 times the SM prediction. Limits on Higgs-boson trilinear coupling λ_{HHH} and top Yukawa coupling y_t are also given (see their Fig. 6).
- ¹⁴ SIRUNYAN 18F search non-resonant for $H^0 H^0$ production using $H^0 H^0 \rightarrow b\bar{b} \ell\nu\ell\nu$, where $\ell\nu\ell\nu$ is either $WW \rightarrow \ell\nu\nu$ or $ZZ \rightarrow \ell\nu\nu$ (ℓ is e, μ or a leptonically decaying τ), with data of 35.9 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0 \rightarrow b\bar{b} \ell\nu\ell\nu$ production cross section at 95% CL is measured to be 72 fb, which corresponds to about 79 times the SM prediction.
- ¹⁵ SIRUNYAN 17CN search for $H^0 H^0$ production using $H^0 H^0 \rightarrow b\bar{b} \tau\tau$ with data of 18.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. Results are then combined with the published results of the $H^0 H^0 \rightarrow \gamma\gamma b\bar{b}$ and $H^0 H^0 \rightarrow b\bar{b} b\bar{b}$, which use data of up to 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0$ production cross section is measured to be 0.59 pb from $b\bar{b} \tau\tau$, which corresponds to about 59 times the SM prediction (gluon fusion). The combined upper limit is 0.43 pb, which is about 43 times the SM prediction. The quoted values are given for $m_{H^0} = 125 \text{ GeV}$.
- ¹⁶ AABOUD 16I search for $H^0 H^0$ production using $H^0 H^0 \rightarrow b\bar{b} b\bar{b}$ with data of 3.2 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0 \rightarrow b\bar{b} b\bar{b}$ production cross section is measured to be 1.22 pb. This result corresponds to about 108 times the SM prediction (gluon fusion), which is $11.3^{+0.9}_{-1.0} \text{ fb}$ (NNLO+NNLL) including top quark mass effects. The quoted values are given for $m_{H^0} = 125 \text{ GeV}$.
- ¹⁷ KHACHATRYAN 16BQ search for $H^0 H^0$ production using $H^0 H^0 \rightarrow \gamma\gamma b\bar{b}$ with data of 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The upper limit on the $pp \rightarrow H^0 H^0 \rightarrow \gamma\gamma b\bar{b}$ production is measured to be 1.85 fb, which corresponds to about 74 times the SM prediction and is translated into 0.71 pb for $gg \rightarrow H^0 H^0$ production cross section. Limits on Higgs-boson trilinear coupling λ are also given.
- ¹⁸ AAD 15CE search for $H^0 H^0$ production using $H^0 H^0 \rightarrow b\bar{b} \tau\tau$ and $H^0 H^0 \rightarrow \gamma\gamma WW$ with data of 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. These results are then combined with the published results of the $H^0 H^0 \rightarrow \gamma\gamma b\bar{b}$ and $H^0 H^0 \rightarrow b\bar{b} b\bar{b}$, which use data of up to 20.3 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The upper limits on the $pp \rightarrow H^0 H^0$ production cross section are measured to be 1.6 pb, 11.4 pb, 2.2 pb and 0.62 pb from $b\bar{b} \tau\tau, \gamma\gamma WW, \gamma\gamma b\bar{b}$ and $b\bar{b} b\bar{b}$, respectively. The combined upper limit is 0.69 pb, which corresponds to about 70 times the SM prediction. The quoted results are given for $m_{H^0} = 125.4 \text{ GeV}$. See their Table 4.

 tH^0 associated production cross section

VALUE	DOCUMENT ID	TECN	COMMENT
••• We do not use the following data for averages, fits, limits, etc. •••			
	1 SIRUNYAN 19BK CMS	pp, 13 TeV	
	2 KHACHATRYAN...16AU CMS	pp, 8 TeV	
¹ SIRUNYAN 19BK search for the tH^0 associated production using multipion signatures ($H^0 \rightarrow WW^*, H^0 \rightarrow \tau\tau, H^0 \rightarrow ZZ^*$) and signatures with a single lepton and a $b\bar{b}$ pair ($H^0 \rightarrow b\bar{b}$) using 35.9 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. Results are combined with $H^0 \rightarrow \gamma\gamma$ (SIRUNYAN 18DS). The observed 95% CL upper limit on the tH^0 production cross section times $H^0 \rightarrow WW^* + \tau\tau + ZZ^* + b\bar{b} + \gamma\gamma$ branching fraction is 1.94 pb (assuming SM $t\bar{t}H^0$ production cross section). See their Table X and Fig. 14. The values outside the ranges of $[-0.9, -0.5]$ and $[1.0, 2.1]$ times the standard model top quark Yukawa coupling are excluded at 95% CL.			

- ² KHACHATRYAN 16AU search for the tH^0 associated production in 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. The 95% CL upper limits on the tH^0 associated production cross section is measured to be 600–1000 fb depending on the assumed $\gamma\gamma$ branching ratios of the Higgs boson. The $\gamma\gamma$ branching ratio is varied to be by a factor of 0.5–3.0 of the Standard Model Higgs boson ($m_{H^0} = 125 \text{ GeV}$). The results of the signal strengths for a negative Higgs-boson trilinear coupling are given. The results are given for $m_{H^0} = 125 \text{ GeV}$.

 H^0 Production Cross Section in pp Collisions at $\sqrt{s} = 13 \text{ TeV}$ Assumes $m_{H^0} = 125 \text{ GeV}$

MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN SUPERSYMMETRIC MODELS

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars [H_1^0 and H_2^0], where we define $m_{H_1^0} < m_{H_2^0}$, a pseudoscalar (A^0), and a charged Higgs pair

(H^\pm). H_1^0 and H_2^0 are also called h and H in the literature. There are two free parameters in the Higgs sector which can be chosen to be m_{A^0} and $\tan\beta = v_2/v_1$, the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be $m_{H_1^0} \leq m_Z$, $m_{H_2^0} \geq m_Z$, $m_{A^0} \geq m_{H^0}$, and $m_{H^\pm} \geq m_W$.

However, as described in the review on "Status of Higgs Boson Physics" in this Volume these relations are violated by radiative corrections.

The observed signal at about 125 GeV, see section "H⁰", can be interpreted as one of the neutral Higgs bosons of supersymmetric models. Unless otherwise noted, we identify the lighter scalar H_1^0 with the Higgs discovered at 125 GeV at the LHC (AAD 12AI, CHATRCHYAN 12N).

Unless otherwise noted, the experiments in e^+e^- collisions search for the processes $e^+e^- \rightarrow H_1^0 Z^0$ in the channels used for the Standard Model Higgs searches and $e^+e^- \rightarrow H_2^0 A^0$ in the final states $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$. Unless otherwise stated, the following results assume no invisible H_1^0 or A^0 decays. Unless otherwise noted, the results are given in the m_h^{max} scenario, CARENA 13.

In $p\bar{p}$ and pp collisions the experiments search for a variety of processes, as explicitly specified for each entry. Limits on the A^0 mass arise from these direct searches, as well as from the relations valid in the minimal supersymmetric model between m_{A^0} and $m_{H_1^0}$. As discussed in the review on "Status of Higgs Boson Physics" in this Volume, these relations depend, via potentially large radiative corrections, on the mass of the t quark and on the supersymmetric parameters, in particular those of the stop sector. These indirect limits are weaker for larger t and \bar{t} masses. To include the radiative corrections to the Higgs masses, unless otherwise stated, the listed papers use theoretical predictions incorporating two-loop corrections, and the results are given for the m_h^{mod+} benchmark scenario, see CARENA 13.

Mass Limits for heavy neutral Higgs bosons (H_2^0, A^0) in the MSSM

The limits rely on $pp \rightarrow H_2^0/A^0 \rightarrow \tau^+\tau^-$ and assume that H_2^0 and A^0 are (sufficiently) mass degenerate. The limits depend on $\tan\beta$.

1	ABOUD 18G	search for production of $H_{2,3}^0/A^0 \rightarrow \tau^+\tau^-$ by gluon fusion and b -associated production in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 10 for excluded regions in the $m_{A^0} - \tan\beta$ plane in several MSSM scenarios.		
2	SIRUNYAN 18CX	search for production of $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ by gluon fusion and b -associated production in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in the $m_{A^0} - \tan\beta$ plane in several MSSM scenarios.		
3	AAD 20	combine measurements on H^0 production and decay using data taken in years 2015–2017 (up to 79.8 fb^{-1}) of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 19 for excluded region in the hMSSM parameter space.		
4	AAD 20C	combine searches for a scalar resonance decaying to $H^0 H^0$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV from ABOUD 19A, ABOUD 19O, ABOUD 18CQ, ABOUD 19T, ABOUD 18CW, and ABOUD 18BU. See their Fig. 7(b) for the excluded region in the hMSSM parameter space.		
5	SIRUNYAN 19CR	search for production of $H_{2,3}^0/A^0$ in gluon fusion and in association with a $b\bar{b}$ pair, decaying to $\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for the excluded region in the MSSM parameter space in the $m_h^{\text{mod}+}$ and hMSSM scenarios.		
6	SIRUNYAN 18A	search for production of a scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 (lower) for excluded regions in the $m_{A^0} - \tan\beta$ plane in the hMSSM scenario.		
7	SIRUNYAN 18BP	search for production of $H_{2,3}^0/A^0 \rightarrow b\bar{b}$ by b -associated production in 35.7 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H_{2,3}^0}, m_{A^0} = 0.3\text{--}1.3$ TeV, and Fig. 7 for excluded regions in the $m_{A^0} - \tan\beta$ plane in several MSSM scenarios.		
8	ABOUD 16AA	search for production of a Higgs boson in gluon fusion and in association with a $b\bar{b}$ pair followed by the decay $A^0 \rightarrow \tau^+\tau^-$ in 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5(a, b) for limits on cross section times branching ratio for $m_{A^0} = 200\text{--}1200$ GeV, and Fig. 5(c, d) for the excluded region in the MSSM parameter space in the $m_h^{\text{mod}+}$ and hMSSM scenarios.		
9	KHACHATRYAN 16A	search for production of a Higgs boson in gluon fusion and in association with a $b\bar{b}$ pair followed by the decay $H_{1,2}^0/A^0 \rightarrow \mu^+\mu^-$ in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.3 fb^{-1} at $E_{cm} = 8$ TeV. See their Fig. 7 for the excluded region in the MSSM parameter space in the $m_h^{\text{mod}+}$ benchmark scenario and Fig. 9 for limits on cross section times branching ratio.		
10	KHACHATRYAN 16P	search for gluon fusion production of an $H_{2,3}^0$ decaying to $H^0 H^0 \rightarrow b\bar{b}\tau^+\tau^-$ and an A^0 decaying to $ZH^0 \rightarrow \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 12 for excluded region in the $\tan\beta - \cos(\beta - \alpha)$ plane for $m_{H_{2,3}^0} = m_{A^0} = 300$ GeV.		
11	KHACHATRYAN 15AY	search for production of a Higgs boson in association with a b quark in the decay $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV and combine with CHATRCHYAN 13AG 7 TeV data. See their Fig. 6 for the limits on cross section times branching ratio for $m_{A^0} = 100\text{--}900$ GeV and Figs. 7–9 for the excluded region in the MSSM parameter space in various benchmark scenarios.		
12	AAD 14AW	search for production of a Higgs boson followed by the decay $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ in $19.5\text{--}20.3 \text{ fb}^{-1}$ of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 11 for the limits on cross section times branching ratio and their Figs. 9 and 10 for the excluded region in the MSSM parameter space. For $m_{A^0} = 140$ GeV, the region $\tan\beta > 5.4$ is excluded at 95% CL in the m_h^{max} scenario.		
13	KHACHATRYAN 14M	search for production of a Higgs boson in gluon fusion and in association with a b quark followed by the decay $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ in 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. See their Figs. 7 and 8 for one- and two-dimensional limits on cross section times branching ratio and their Figs. 5 and 6 for the excluded region in the MSSM parameter space. For $m_{A^0} = 140$ GeV, the region $\tan\beta > 3.8$ is excluded at 95% CL in the m_h^{max} scenario.		
14	AAD 13O	search for production of a Higgs boson in the decay $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ and $\mu^+\mu^-$ with $4.7\text{--}4.8 \text{ fb}^{-1}$ of pp collisions at $E_{cm} = 7$ TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and their Fig. 7 for the limits on cross		

section times branching ratio. For $m_{A^0} = 110\text{--}170$ GeV, $\tan\beta \gtrsim 10$ is excluded, and for $\tan\beta = 50$, m_{A^0} below 470 GeV is excluded at 95% CL in the m_h^{max} scenario.

- 15 AAIJ 13T search for production of a Higgs boson in the forward region in the decay $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ in 1.0 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. See their Fig. 2 for the limits on cross section times branching ratio and the excluded region in the MSSM parameter space.
- 16 CHATRCHYAN 13AG search for production of a Higgs boson in association with a b quark in the decay $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ in $2.7\text{--}4.8 \text{ fb}^{-1}$ of pp collisions at $E_{cm} = 7$ TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and Fig. 5 for the limits on cross section times branching ratio. For $m_{A^0} = 90\text{--}350$ GeV, upper bounds on $\tan\beta$ of 18–42 at 95% CL are obtained in the m_h^{max} scenario with $\mu = +200$ GeV.
- 17 AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.
- 18 AALTONEN 12X search for associated production of a Higgs boson and a b quark in the decay $H_{1,2}^0/A^0 \rightarrow b\bar{b}$, with 2.6 fb^{-1} of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Table III and Fig. 15 for the limit on cross section times branching ratio and Figs. 17, 18 for the excluded region in the MSSM parameter space.
- 19 ABAZOV 12G search for production of a Higgs boson in the decay $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ with 7.3 fb^{-1} of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV and combine with ABAZOV 11W and ABAZOV 11K. See their Figs. 4, 5, and 6 for the excluded region in the MSSM parameter space. For $m_{A^0} = 90\text{--}180$ GeV, $\tan\beta \gtrsim 30$ is excluded at 95% CL in the m_h^{max} scenario.
- 20 CHATRCHYAN 12K search for production of a Higgs boson in the decay $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ with 4.6 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. See their Fig. 3 and Table 4 for the excluded region in the MSSM parameter space. For $m_{A^0} = 160$ GeV, the region $\tan\beta > 7.1$ is excluded at 95% CL in the m_h^{max} scenario. Superseded by KHACHATRYAN 14M.
- 21 ABAZOV 11K search for associated production of a Higgs boson and a b quark, followed by the decay $H_{1,2}^0/A^0 \rightarrow b\bar{b}$, in 5.2 fb^{-1} of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 5/Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for $\mu = -200$ GeV.
- 22 ABAZOV 11W search for associated production of a Higgs boson and a b quark, followed by the decay $H_{1,2}^0/A^0 \rightarrow \tau\tau$, in 7.3 fb^{-1} of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.
- 23 AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb^{-1} of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 2 for the limit on $\sigma \cdot B(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.
- 24 ABDALLAH 08B give limits in eight CP -conserving benchmark scenarios and some CP -violating scenarios. See paper for excluded regions for each scenario. Supersedes ABDALLAH 04.
- 25 SCHAEEL 06B make a combined analysis of the LEP data. The quoted limit is for the m_h^{max} scenario with $m_t = 174.3$ GeV. In the CP -violating CPX scenario no lower bound on $m_{H_1^0}$ can be set at 95% CL. See paper for excluded regions in various scenarios. See Figs. 2–6 and Tabs. 14–21 for limits on $\sigma(ZH^0) \cdot B(H^0 \rightarrow b\bar{b}, \tau^+\tau^-)$ and $\sigma(H_1^0 H_2^0) \cdot B(H_1^0 H_2^0 \rightarrow b\bar{b}, \tau^+\tau^-)$.
- 26 ACOSTA 05Q search for $H_{1,2}^0/A^0$ production in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV with $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$. At $m_{A^0} = 100$ GeV, the obtained cross section upper limit is above theoretical expectation.
- 27 Search for $e^+e^- \rightarrow H_{1,2}^0/A^0$ in the final states $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$, and $e^+e^- \rightarrow H_{1,2}^0 Z$. Universal scalar mass of 1 TeV, $SU(2)$ gaugino mass of 200 GeV, and $\mu = -200$ GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for $m_t = 175$ GeV, and for the m_h^{max} scenario.
- 28 ABBIENDI 04M exclude $0.7 < \tan\beta < 1.9$, assuming $m_t = 174.3$ GeV. Limits for other MSSM benchmark scenarios, as well as for CP violating cases, are also given.
- 29 ABBIENDI 03G search for $e^+e^- \rightarrow H_1^0 Z$ followed by $H_1^0 \rightarrow A^0 A^0, A^0 \rightarrow c\bar{c}, gg$, or $\tau^+\tau^-$. In the no-mixing scenario, the region $m_{H_1^0} = 45\text{--}85$ GeV and $m_{A^0} = 2\text{--}9.5$ GeV is excluded at 95% CL.
- 30 ACHARD 02H also search for the final state $H_1^0 Z \rightarrow 2A^0 q\bar{q}, A^0 \rightarrow q\bar{q}$. In addition, the MSSM parameter set in the “large- μ ” and “no-mixing” scenarios are examined.
- 31 AKEROYD 02 examine the possibility of a light A^0 with $\tan\beta < 1$. Electroweak measurements are found to be inconsistent with such a scenario.
- 32 HEISTER 02 excludes the range $0.7 < \tan\beta < 2.3$. A wider range is excluded with different stop mixing assumptions. Updates BARATE 01C.

Neutral Higgs Bosons, Searches for

on $m_{H_1^0}$ can be set at 95% CL. See paper for excluded regions in various scenarios. See

Figs. 2–6 and Tabs. 14–21 for limits on $\sigma(ZH^0) \cdot \text{B}(H^0 \rightarrow b\bar{b}, \tau^+\tau^-)$ and $\sigma(H_1^0 H_2^0) \cdot \text{B}(H_1^0 H_2^0 \rightarrow b\bar{b}, \tau^+\tau^-)$.

³ Search for $e^+e^- \rightarrow H_1^0 A^0$ in the final states $b\bar{b}b\bar{b}$ and $b\bar{b}\tau^+\tau^-$, and $e^+e^- \rightarrow H_1^0 Z$. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 200 GeV, and $\mu = -200$ GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for $m_t = 175$ GeV, and for the m_h^{max} scenario.

⁴ ABBIENDI 04M exclude $0.7 < \tan\beta < 1.9$, assuming $m_t = 174.3$ GeV. Limits for other MSSM benchmark scenarios, as well as for CP violating cases, are also given.

⁵ ACHARD 02H also search for the final state $H_1^0 Z \rightarrow 2A^0 q\bar{q}$, $A^0 \rightarrow q\bar{q}$. In addition, the MSSM parameter set in the “large- μ ” and “no-mixing” scenarios are examined.

⁶ HEISTER 02 excludes the range $0.7 < \tan\beta < 2.3$. A wider range is excluded with different stop mixing assumptions. Updates BARATE 01c.

⁷ AALTONEN 12A0 combine AALTONEN 12x and ABAZOV 11k. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.

MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN EXTENDED HIGGS MODELS

This Section covers models which do not fit into either the Standard Model or its simplest minimal Supersymmetric extension (MSSM), leading to anomalous production rates, or nonstandard final states and branching ratios. In particular, this Section covers limits which may apply to generic two-Higgs-doublet models (2HDM), or to special regions of the MSSM parameter space where decays to invisible particles or to photon pairs are dominant (see the review on “Status of Higgs Boson Physics”). Concerning the mass limits for H^0 and A^0 listed below, see the footnotes or the comment lines for details on the nature of the models to which the limits apply.

The observed signal at about 125 GeV, see section “ H^0 ”, can be interpreted as one of the neutral Higgs bosons of an extended Higgs sector.

Mass Limits in General two-Higgs-doublet Models

¹ AAD 20 combine measurements on H^0 production and decay using data taken in years 2015–2017 (up to 79.8 fb^{-1}) of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 18 for excluded regions in various 2HDMs.

² SIRUNYAN 19AE search for a pseudoscalar resonance produced in association with a $b\bar{b}$ pair, decaying to $\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 4 for cross section limits for $m_{A^0} = 25\text{--}70$ GeV and comparison with some representative 2HDMs.

³ SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or b associated production, decaying to $ZH^0 \rightarrow \ell^+\ell^- b\bar{b}$ ($\ell = e, \mu$) or $\nu\bar{\nu}b\bar{b}$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Figs. 6 and 7 for excluded regions in the parameter space of various 2HDMs.

⁴ AABOUD 18AH search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to $ZH_2^0 \rightarrow \ell^+\ell^- b\bar{b}$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 6 for excluded regions in the parameter space of various 2HDMs.

⁵ AABOUD 18AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to ZH^0 in the final states $\nu\bar{\nu}b\bar{b}$ and $\ell^+\ell^- b\bar{b}$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Figs. 7 and 8 for excluded regions in the parameter space in various 2HDMs.

⁶ AABOUD 18BF search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^- \ell^+\ell^-$ and $\ell^+\ell^- \nu\bar{\nu}$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Figs. 8 and 9 for excluded parameter regions in 2HDM Type I and II.

⁷ AABOUD 18CE search for the process $pp \rightarrow H_2^0/A^0 t\bar{t}$ followed by the decay $H_2^0/A^0 \rightarrow t\bar{t}$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 12 for limits on cross section times branching ratio, and for lower limits on $\tan\beta$ for $m_{H_2^0}, m_{A^0} = 0.4\text{--}1.0$ TeV in the 2HDM type II.

⁸ HALLER 18 perform global fits in the framework of two-Higgs-doublet models (type I, II, lepton specific, flipped). See their Fig. 8 for extended parameter regions from fits to LHC H^0 measurements, Fig. 9 bottom and charm decays, Fig. 10 muon anomalous magnetic moment, Fig. 11 electroweak precision data, and Fig. 12 by combination of all data.

⁹ SIRUNYAN 18BP search for production of $H_2^0/A^0 \rightarrow b\bar{b}$ by b -associated production in 35.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H_2^0}, m_{A^0} = 0.3\text{--}1.3$ TeV, and Figs. 8 and 9 for excluded regions in the parameter space of type-II and flipped 2HDMs.

¹⁰ SIRUNYAN 18ED search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to ZH^0 in the final states $\nu\bar{\nu}b\bar{b}$ or $\ell^+\ell^- b\bar{b}$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 9 for excluded regions in the parameter space in Type I and II 2HDMs.

¹¹ AABOUD 17AN search for production of a heavy H_2^0 and/or A^0 decaying to $t\bar{t}$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 3 and Table III for excluded parameter regions in Type II Two-Higgs-Doublet-Models.

¹² SIRUNYAN 17AX search for $A^0 b\bar{b}$ production followed by the decay $A^0 \rightarrow \mu^+\mu^-$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. Limits are set in the range $m_{A^0} = 25\text{--}60$ GeV. See their Fig. 5 for upper limits on $\sigma(A^0 b\bar{b}) \cdot \text{B}(A^0 \rightarrow \mu^+\mu^-)$.

¹³ AAD 16AX search for production of a heavy H^0 state decaying to ZZ in the final states $\ell^+\ell^- \ell^+\ell^-$, $\ell^+\ell^- \nu\bar{\nu}$, $\ell^+\ell^- q\bar{q}$, and $\nu\bar{\nu}q\bar{q}$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Figs. 13 and 14 for excluded parameter regions in Type I and II models.

¹⁴ KHACHATRYAN 16P search for gluon fusion production of an H_2^0 decaying to $H^0 H^0 \rightarrow b\bar{b}\tau^+\tau^-$ and an A^0 decaying to $ZH^0 \rightarrow \ell^+\ell^- \tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 11 for limits on $\tan\beta$ for $m_{A^0} = 230\text{--}350$ GeV.

¹⁵ KHACHATRYAN 16W search for $A^0 b\bar{b}$ production followed by the decay $A^0 \rightarrow \tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 3 for upper limits on $\sigma(A^0 b\bar{b}) \cdot \text{B}(A^0 \rightarrow \tau^+\tau^-)$.

¹⁶ KHACHATRYAN 16Z search for $H_2^0 \rightarrow ZA^0$ followed by $A^0 \rightarrow b\bar{b}$ or $\tau^+\tau^-$, and $A^0 \rightarrow ZH_2^0$ followed by $H_2^0 \rightarrow b\bar{b}$ or $\tau^+\tau^-$, in 19.8 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 4 for cross section limits and Fig. 5 for excluded region in the parameter space.

¹⁷ AAD 15BK search for production of a heavy H_2^0 decaying to $H^0 H^0$ in the final state $b\bar{b}b\bar{b}$ in 19.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Figs. 15–18 for excluded regions in the parameter space.

¹⁸ AAD 15S search for production of A^0 decaying to $ZH^0 \rightarrow \ell^+\ell^- b\bar{b}$, $\nu\bar{\nu}b\bar{b}$ and $\ell^+\ell^- \tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Figs. 4 and 5 for excluded regions in the parameter space.

¹⁹ KHACHATRYAN 15BB search for $H_2^0, A^0 \rightarrow \gamma\gamma$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 10 for excluded regions in the two-Higgs-doublet model parameter space.

²⁰ KHACHATRYAN 15N search for production of A^0 decaying to $ZH^0 \rightarrow \ell^+\ell^- b\bar{b}$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 5 for excluded regions in the $\tan\beta - \cos(\beta - \alpha)$ plane for $m_{A^0} = 300$ GeV.

²¹ AAD 14M search for the decay cascade $H_2^0 \rightarrow H^\pm W^\mp \rightarrow H^0 W^\pm W^\mp, H^0$ decaying to $b\bar{b}$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Table IV for limits in a two-Higgs-doublet model for $m_{H_2^0} = 325\text{--}1025$ GeV and $m_{H^\pm} = 225\text{--}825$ GeV.

²² KHACHATRYAN 14Q search for $H_2^0 \rightarrow H^0 H^0$ and $A^0 \rightarrow ZH^0$ in 19.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Figs. 4 and 5 for limits on cross section times branching ratio for $m_{H_2^0, A^0} = 260\text{--}360$ GeV and their Figs. 7–9 for limits in two-Higgs-doublet models.

²³ AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV. See their Fig. 2 for the limit on $\sigma \cdot \text{B}(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.

²⁴ ABBIENDI 05A search for $e^+e^- \rightarrow H_1^0 A^0$ in general Type-II two-doublet models, with decays $H_1^0, A^0 \rightarrow q\bar{q}, gg, \tau^+\tau^-$, and $H_1^0 \rightarrow A^0 A^0$.

²⁵ ABDALLAH 05D search for $e^+e^- \rightarrow H^0 Z$ and $H^0 A^0$ with H^0, A^0 decaying to two jets of any flavor including gg . The limit is for SM $H^0 Z$ production cross section with $\text{B}(H^0 \rightarrow jj) = 1$.

²⁶ ABDALLAH 04O search for $Z \rightarrow b\bar{b}H^0, b\bar{b}A^0, \tau^+\tau^- H^0$ and $\tau^+\tau^- A^0$ in the final states $4b, b\bar{b}\tau^+\tau^-$, and 4τ . See paper for limits on Yukawa couplings.

²⁷ ABDALLAH 04O search for $e^+e^- \rightarrow H^0 Z$ and $H^0 A^0$, with H^0, A^0 decaying to $b\bar{b}, \tau^+\tau^-$, or $H^0 \rightarrow A^0 A^0$ at $E_{\text{cm}} = 189\text{--}208$ GeV. See paper for limits on couplings.

²⁸ ABBIENDI 02D search for $Z \rightarrow b\bar{b}H^0$ and $b\bar{b}A^0$ with $H_1^0/A^0 \rightarrow \tau^+\tau^-$, in the range $4 < m_H < 12$ GeV. See their Fig. 8 for limits on the Yukawa coupling.

See key on page 999

Gauge & Higgs Boson Particle Listings

Neutral Higgs Bosons, Searches for

- 29 ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{\text{cm}} \leq 189$ GeV. In addition to usual final states, the decays $H_1^0, A^0 \rightarrow q\bar{q}, gg$ are searched for. See their Figs. 15,16 for excluded regions.
- 30 ABBIENDI 99E search for $e^+e^- \rightarrow H^0 A^0$ and $H^0 Z$ at $E_{\text{cm}} = 183$ GeV. The limit is with $m_H = m_A$ in general two Higgs-doublet models. See their Fig. 18 for the exclusion limit in the $m_H - m_A$ plane. Updates the results of ACKERSTAFF 98s.
- 31 See Fig. 4 of ABREU 95H for the excluded region in the $m_{H^0} - m_{A^0}$ plane for general two-doublet models. For $\tan\beta > 1$, the region $m_{H^0} + m_{A^0} \lesssim 87$ GeV, $m_{H^0} < 47$ GeV is excluded at 95% CL.
- 32 PICH 92 analyse H^0 with $m_{H^0} < 2m_\mu$ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and π^\pm, η rare decays are shown in Figs. 3,4. The considered mass region is not totally excluded.

Mass Limits for H^0 with Vanishing Yukawa Couplings

These limits assume that H^0 couples to gauge bosons with the same strength as the Standard Model Higgs boson, but has no coupling to quarks and leptons (this is often referred to as "fermiophobic").

- 1 AALTONEN 13K search for $H^0 \rightarrow WW^*$ in 9.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV. A limit on cross section times branching ratio which corresponds to (1.3-6.6) times the expected cross section is given in the range $m_{H^0} = 110-200$ GeV at 95% CL.
- 2 AALTONEN 13L combine all CDF searches with $9.45-10.0 \text{ fb}^{-1}$ of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV.
- 3 AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV.
- 4 ABAZOV 13G search for $H^0 \rightarrow WW^*$ in 9.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV. A limit on cross section times branching ratio which corresponds to (2-9) times the expected cross section is given for $m_{H^0} = 100-200$ GeV at 95% CL.
- 5 ABAZOV 13H search for $H^0 \rightarrow \gamma\gamma$ in 9.6 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV.
- 6 ABAZOV 13I search for H^0 production in the final state with one lepton and two or more jets plus missing E_T in 9.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV. The search is sensitive to WH^0, ZH^0 and vector-boson fusion Higgs production with $H^0 \rightarrow WW^*$. A limit on cross section times branching ratio which corresponds to (8-30) times the expected cross section is given in the range $m_{H^0} = 100-200$ GeV at 95% CL.
- 7 ABAZOV 13J search for H^0 production in the final states $e e \mu, e \mu \mu, \mu \tau \tau$, and $e^\pm \mu^\pm$ in $8.6-9.7 \text{ fb}^{-1}$ of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV. The search is sensitive to WH^0, ZH^0 production with $H^0 \rightarrow WW^*, ZZ^*$, decaying to leptonic final states. A limit on cross section times branching ratio which corresponds to (2.4-13.0) times the expected cross section is given in the range $m_{H^0} = 100-200$ GeV at 95% CL.
- 8 ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV.
- 9 CHATRCHYAN 13AL search for $H^0 \rightarrow \gamma\gamma$ in 5.1 fb^{-1} and 5.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 7$ and 8 TeV.
- 10 AAD 12N search for $H^0 \rightarrow \gamma\gamma$ with 4.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 7$ TeV in the mass range $m_{H^0} = 110-150$ GeV.
- 11 AALTONEN 12AN search for $H^0 \rightarrow \gamma\gamma$ with 10 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV in the mass range $m_{H^0} = 100-150$ GeV.
- 12 CHATRCHYAN 12AO use data from CHATRCHYAN 12G, CHATRCHYAN 12E, CHATRCHYAN 12H, CHATRCHYAN 12I, CHATRCHYAN 12D, and CHATRCHYAN 12C.
- 13 AALTONEN 09AB search for $H^0 \rightarrow \gamma\gamma$ in 3.0 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV in the mass range $m_{H^0} = 70-150$ GeV. Associated $H^0 W, H^0 Z$ production and WW, ZZ fusion are considered.
- 14 ABAZOV 08U search for $H^0 \rightarrow \gamma\gamma$ in $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96$ TeV in the mass range $m_{H^0} = 70-150$ GeV. Associated $H^0 W, H^0 Z$ production and WW, ZZ fusion are considered. See their Tab. 1 for the limit on $\sigma \cdot B(H^0 \rightarrow \gamma\gamma)$, and see their Fig. 3 for the excluded region in the $m_{H^0} - B(H^0 \rightarrow \gamma\gamma)$ plane.

- 15 SCHAEEL 07 search for Higgs bosons in association with a fermion pair and decaying to WW^* . The limit is from this search and HEISTER 02L for a H^0 with SM production cross section.
- 16 Search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \rightarrow q\bar{q}, \ell^+ \ell^-$, or $\nu\bar{\nu}$, at $E_{\text{cm}} \leq 209$ GeV. The limit is for a H^0 with SM production cross section.
- 17 Updates ABREU 01F.
- 18 ACHARD 03C search for $e^+e^- \rightarrow ZH^0$ followed by $H^0 \rightarrow WW^*$ or ZZ^* at $E_{\text{cm}} = 200-209$ GeV and combine with the ACHARD 02c result. The limit is for a H^0 with SM production cross section. For $B(H^0 \rightarrow WW^*) + B(H^0 \rightarrow ZZ^*) = 1$, $m_{H^0} > 108.1$ GeV is obtained. See Fig. 6 for the limits under different BR assumptions.
- 19 For $B(H^0 \rightarrow \gamma\gamma) = 1$, $m_{H^0} > 117$ GeV is obtained.
- 20 ACHARD 02c search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \rightarrow q\bar{q}, \ell^+ \ell^-$, or $\nu\bar{\nu}$, at $E_{\text{cm}} \leq 209$ GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \rightarrow \gamma\gamma) = 1$, $m_{H^0} > 114$ GeV is obtained.
- 21 AFFOLDER 01H search for associated production of a $\gamma\gamma$ resonance and a W or Z (tagged by two jets, an isolated lepton, or missing E_T). The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. See their Fig. 11 for limits with $B(H^0 \rightarrow \gamma\gamma) < 1$.
- 22 ACCIARRI 00s search for associated production of a $\gamma\gamma$ resonance with a $q\bar{q}, \nu\bar{\nu}$, or $\ell^+ \ell^-$ pair in e^+e^- collisions at $E_{\text{cm}} = 189$ GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \rightarrow \gamma\gamma) = 1$, $m_{H^0} > 98$ GeV is obtained. See their Fig. 5 for limits on $B(H^0 \rightarrow \gamma\gamma) \cdot \sigma(e^+e^- \rightarrow H^0 \gamma) / \sigma(e^+e^- \rightarrow H^0 \gamma)$ (SM).
- 23 BARATE 00L search for associated production of a $\gamma\gamma$ resonance with a $q\bar{q}, \nu\bar{\nu}$, or $\ell^+ \ell^-$ pair in e^+e^- collisions at $E_{\text{cm}} = 88-202$ GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \rightarrow \gamma\gamma) = 1$, $m_{H^0} > 109$ GeV is obtained. See their Fig. 3 for limits on $B(H^0 \rightarrow \gamma\gamma) \cdot \sigma(e^+e^- \rightarrow H^0 \gamma) / \sigma(e^+e^- \rightarrow H^0 \gamma)$ (SM).
- 24 ABBIENDI 99O search for associated production of a $\gamma\gamma$ resonance with a $q\bar{q}, \nu\bar{\nu}$, or $\ell^+ \ell^-$ pair in e^+e^- collisions at 189 GeV. The limit is for a H^0 with SM production cross section. See their Fig. 4 for limits on $\sigma(e^+e^- \rightarrow H^0 Z^0) \times B(H^0 \rightarrow \gamma\gamma) \times B(X^0 \rightarrow \gamma\gamma)$ for various masses. Updates the results of ACKERSTAFF 98Y.
- 25 ABBOTT 99B search for associated production of a $\gamma\gamma$ resonance and a dijet pair. The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. Limits in the range of $\sigma(H^0 + Z/W) \cdot B(H^0 \rightarrow \gamma\gamma) = 0.80-0.34$ pb are obtained in the mass range $m_{H^0} = 65-150$ GeV.
- 26 ABREU 99P search for $e^+e^- \rightarrow H^0 \gamma$ with $H^0 \rightarrow b\bar{b}$ or $\gamma\gamma$, and $e^+e^- \rightarrow H^0 q\bar{q}$ with $H^0 \rightarrow \gamma\gamma$. See their Fig. 4 for limits on $\sigma \times B$. Explicit limits within an effective interaction framework are also given.

Mass Limits for H^0 Decaying to Invisible Final States

These limits are for a neutral scalar H^0 which predominantly decays to invisible final states. Standard Model values are assumed for the couplings of H^0 to ordinary particles unless otherwise stated.

- 1 AABOUD 19AI search for $H_{1,2}^0$ production by vector boson fusion and decay to invisible final states in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 6(b) for limits on cross section times branching ratios for $m_{H_{1,2}^0} = 0.1-3$ TeV.
- 2 AAD 15BD search for $p\bar{p} \rightarrow H^0 WX$ and $p\bar{p} \rightarrow H^0 ZX$ with W or Z decaying hadronically and H^0 decaying to invisible final states in 20.3 fb^{-1} at $E_{\text{cm}} = 8$ TeV. See their Fig. 6 for a limit on the cross section times branching ratio for $m_{H^0} = 115-300$ GeV.
- 3 AAD 15BH search for events with a jet and missing E_T in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. Limits on $\sigma(H^0) B(H^0 \rightarrow \text{invisible}) < (44-10)$ pb (95%CL) is given for $m_{H^0} = 115-300$ GeV.
- 4 AAD 14BA search for H^0 production in the decay mode $H^0 \rightarrow X^0 X^0$, where X^0 is a long-lived particle which decays to collimated pairs of $e^+e^-, \mu^+\mu^-,$ or $\pi^+\pi^-$ plus invisible particles, in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Figs. 15 and 16 for limits on cross section times branching ratio.
- 5 AAD 14O search for $p\bar{p} \rightarrow H^0 ZX, Z \rightarrow \ell\ell$, with H^0 decaying to invisible final states in 4.5 fb^{-1} at $E_{\text{cm}} = 7$ TeV and 20.3 fb^{-1} at $E_{\text{cm}} = 8$ TeV. See their Fig. 3 for a limit on the cross section times branching ratio for $m_{H^0} = 110-400$ GeV.
- 6 CHATRCHYAN 14B search for $p\bar{p} \rightarrow H^0 ZX, Z \rightarrow \ell\ell$ and $Z \rightarrow b\bar{b}$, and also $p\bar{p} \rightarrow qqH^0 X$ with H^0 decaying to invisible final states using data at $E_{\text{cm}} = 7$ and 8 TeV. See their Figs. 10, 11 for limits on the cross section times branching ratio for $m_{H^0} = 100-400$ GeV.

Gauge & Higgs Boson Particle Listings

Neutral Higgs Bosons, Searches for

- ⁷ AAD 13AG search for H^0 production in the decay mode $H^0 \rightarrow X^0 X^0$, where X^0 is a long-lived particle which decays to $\mu^+ \mu^- X^0$, in 1.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. See their Fig. 7 for limits on cross section times branching ratio.
- ⁸ AAD 13AT search for H^0 production in the decay $H^0 \rightarrow X^0 X^0$, where X^0 eventually decays to clusters of collimated $e^+ e^-$ pairs, in 2.04 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. See their Fig. 3 for limits on cross section times branching ratio.
- ⁹ CHATRCHYAN 13BJ search for H^0 production in the decay chain $H^0 \rightarrow X^0 X^0, X^0 \rightarrow \mu^+ \mu^- X^0$ in 5.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. See their Fig. 2 for limits on cross section times branching ratio.
- ¹⁰ AAD 12AQ search for H^0 production in the decay mode $H^0 \rightarrow X^0 X^0$, where X^0 is a long-lived particle which decays mainly to $b\bar{b}$ in the muon detector, in 1.94 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^0} = 120, 140 \text{ GeV}$, $m_{X^0} = 20, 40 \text{ GeV}$ in the $c\tau$ range of 0.5–35 m.
- ¹¹ AALTONEN 12AB search for H^0 production in the decay $H^0 \rightarrow X^0 X^0$, where X^0 eventually decays to clusters of collimated $\ell^+ \ell^-$ pairs, in 5.1 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. Cross section limits are provided for a benchmark MSSM model incorporating the parameters given in Table VI.
- ¹² AALTONEN 12U search for H^0 production in the decay mode $H^0 \rightarrow X^0 X^0$, where X^0 is a long-lived particle with $c\tau \approx 1 \text{ cm}$ which decays mainly to $b\bar{b}$, in 3.2 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. See their Figs. 9 and 10 for limits on cross section times branching ratio for $m_{H^0} = (130\text{--}170) \text{ GeV}$, $m_{X^0} = 20, 40 \text{ GeV}$.
- ¹³ ABBIENDI 10 search for $e^+ e^- \rightarrow H^0 Z$ with H^0 decaying invisibly. The limit assumes SM production cross section and $B(H^0 \rightarrow \text{invisible}) = 1$.
- ¹⁴ ABBIENDI 07 search for $e^+ e^- \rightarrow H^0 Z$ with $Z \rightarrow q\bar{q}$ and H^0 decaying to invisible final states. The H^0 width is varied between 1 GeV and 3 TeV. A limit $\sigma \cdot B(H^0 \rightarrow \text{invisible}) < (0.07\text{--}0.57) \text{ pb}$ (95%CL) is obtained at $E_{\text{cm}} = 206 \text{ GeV}$ for $m_{H^0} = 60\text{--}114 \text{ GeV}$.
- ¹⁵ Search for $e^+ e^- \rightarrow H^0 Z$ with H^0 decaying invisibly. The limit assumes SM production cross section and $B(H^0 \rightarrow \text{invisible}) = 1$.
- ¹⁶ ACCIARRI 00M search for $e^+ e^- \rightarrow ZH^0$ with H^0 decaying invisibly at $E_{\text{cm}} = 183\text{--}189 \text{ GeV}$. The limit assumes SM production cross section and $B(H^0 \rightarrow \text{invisible}) = 1$. See their Fig. 6 for limits for smaller branching ratios.

Mass Limits for Light A^0

These limits are for a pseudoscalar A^0 in the mass range below $\mathcal{O}(10) \text{ GeV}$.

- ¹ ABOUD 18AP search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- \mu^+ \mu^-$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 10(b) for limits on $B(H^0 \rightarrow A^0 A^0)$ in the range $m_{A^0} = 1\text{--}2.5, 4.5\text{--}8 \text{ GeV}$, assuming a type-II two-doublet plus singlet model with $\tan(\beta) = 5$.
- ² KHACHATRYAN 17AZ search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$, $\mu^+ \mu^- b\bar{b}$, and $\mu^+ \mu^- \tau^+ \tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Figs. 4, 5, and 6 for cross section limits in the range $m_{A^0} = 5\text{--}62.5 \text{ GeV}$. See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.
- ³ ABLIKIM 16E search for the process $J/\psi \rightarrow A^0 \gamma$ with A^0 decaying to $\mu^+ \mu^-$ and give limits on $B(J/\psi \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$ in the range $2.8 \times 10^{-8}\text{--}5.0 \times 10^{-6}$ (90% CL) for $0.212 \leq m_{A^0} \leq 3.0 \text{ GeV}$. See their Fig. 5.
- ⁴ KHACHATRYAN 16F search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 8 for cross section limits for $m_{A^0} = 4\text{--}8 \text{ GeV}$.
- ⁵ LEES 15H search for the process $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$ with A^0 decaying to $c\bar{c}$ and give limits on $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow c\bar{c})$ in the range $7.4 \times 10^{-5}\text{--}2.4 \times 10^{-3}$ (90% CL) for $4.00 \leq m_{A^0} \leq 8.95$ and $9.10 \leq m_{A^0} \leq 9.25 \text{ GeV}$. See their Fig. 6.
- ⁶ LEES 13C search for the process $\Upsilon(2S, 3S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$ with A^0 decaying to $\mu^+ \mu^-$ and give limits on $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$ in the range $(0.3\text{--}9.7) \times 10^{-6}$ (90% CL) for $0.212 \leq m_{A^0} \leq 9.20 \text{ GeV}$. See their Fig. 5(e) for limits on the $b\text{--}A^0$ Yukawa coupling derived by combining this result with AUBERT 09Z.

- ⁷ LEES 13L search for the process $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$ with A^0 decaying to $g\bar{g}$ or $s\bar{s}$ and give limits on $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow g\bar{g})$ between 1×10^{-6} and 2×10^{-2} (90% CL) for $0.5 \leq m_{A^0} \leq 9.0 \text{ GeV}$, and $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow s\bar{s})$ between 4×10^{-6} and 1×10^{-3} (90%CL) for $1.5 \leq m_{A^0} \leq 9.0 \text{ GeV}$. See their Fig. 4.
- ⁸ LEES 13R search for the process $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$ with A^0 decaying to $\tau^+ \tau^-$ and give limits on $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \tau^+ \tau^-)$ in the range $0.9\text{--}13 \times 10^{-5}$ (90% CL) for $3.6 \leq m_{A^0} \leq 9.2 \text{ GeV}$. See their Fig. 4 for limits on the $b\text{--}A^0$ Yukawa coupling derived by combining this result with AUBERT 09P.
- ⁹ ABLIKIM 12 searches for the process $\psi(3686) \rightarrow \pi \pi J/\psi, J/\psi \rightarrow A^0 \gamma$ with A^0 decaying to $\mu^+ \mu^-$. It gives mass dependent limits on $B(J/\psi \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$ in the range $4 \times 10^{-7}\text{--}2.1 \times 10^{-5}$ (90% C.L.) for $0.212 \leq m_{A^0} \leq 3.0 \text{ GeV}$. See their Fig. 2.
- ¹⁰ CHATRCHYAN 12V search for A^0 production in the decay $A^0 \rightarrow \mu^+ \mu^-$ with 1.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. A limit on $\sigma(A^0) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$ in the range $(1.5\text{--}7.5) \text{ pb}$ is given for $m_{A^0} = (5.5\text{--}8.7)$ and $(11.5\text{--}14) \text{ GeV}$ at 95% CL.
- ¹¹ AALTONEN 11P search in 2.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$ for the decay chain $t \rightarrow bH^+, H^+ \rightarrow W^+ A^0, A^0 \rightarrow \tau^+ \tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on $B(t \rightarrow bH^+)$ for $90 < m_{H^+} < 160 \text{ GeV}$.
- ¹² ABOUZAID 11A search for the decay chain $K_L \rightarrow \pi^0 \pi^0 A^0, A^0 \rightarrow \mu^+ \mu^-$ and give a limit $B(K_L \rightarrow \pi^0 \pi^0 A^0) \cdot B(A^0 \rightarrow \mu^+ \mu^-) < 1.0 \times 10^{-10}$ at 90% CL for $m_{A^0} = 214.3 \text{ MeV}$.
- ¹³ The search was motivated by PARK 05.
- ¹⁴ DEL-AMO-SANCHEZ 11J search for the process $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$ with A^0 decaying to invisible final states. They give limits on $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \text{invisible})$ in the range $(1.9\text{--}4.5) \times 10^{-6}$ (90% CL) for $0 \leq m_{A^0} \leq 8.0 \text{ GeV}$, and $(2.7\text{--}37) \times 10^{-6}$ for $8.0 \leq m_{A^0} \leq 9.2 \text{ GeV}$.
- ¹⁵ LEES 11H search for the process $\Upsilon(2S, 3S) \rightarrow A^0 \gamma$ with A^0 decaying hadronically and give limits on $B(\Upsilon(2S, 3S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \text{hadrons})$ in the range $1 \times 10^{-6}\text{--}8 \times 10^{-5}$ (90% CL) for $0.3 < m_{A^0} < 7 \text{ GeV}$. The decay rates for $\Upsilon(2S)$ and $\Upsilon(3S)$ are assumed to be equal up to the phase space factor. See their Fig. 5.
- ¹⁶ ANDREAS 10 analyze constraints from rare decays and other processes on a light A^0 with $m_{A^0} < 2m_\mu$ and give limits on its coupling to fermions at the level of 10^{-4} times the Standard Model value.
- ¹⁷ HYUN 10 search for the decay chain $B^0 \rightarrow K^{*0} A^0, A^0 \rightarrow \mu^+ \mu^-$ and give a limit on $B(B^0 \rightarrow K^{*0} A^0) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$ in the range $(2.26\text{--}5.53) \times 10^{-8}$ at 90%CL for $m_{A^0} = 212\text{--}300 \text{ MeV}$. The limit for $m_{A^0} = 214.3 \text{ MeV}$ is 2.26×10^{-8} .
- ¹⁸ HYUN 10 search for the decay chain $B^0 \rightarrow \rho^0 A^0, A^0 \rightarrow \mu^+ \mu^-$ and give a limit on $B(B^0 \rightarrow \rho^0 A^0) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$ in the range $(1.73\text{--}4.51) \times 10^{-8}$ at 90%CL for $m_{A^0} = 212\text{--}300 \text{ MeV}$. The limit for $m_{A^0} = 214.3 \text{ MeV}$ is 1.73×10^{-8} .
- ¹⁹ AUBERT 09P search for the process $\Upsilon(3S) \rightarrow A^0 \gamma$ with $A^0 \rightarrow \tau^+ \tau^-$ for $4.03 < m_{A^0} < 9.52$ and $9.61 < m_{A^0} < 10.10 \text{ GeV}$, and give limits on $B(\Upsilon(3S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \tau^+ \tau^-)$ in the range $(1.5\text{--}16) \times 10^{-5}$ (90% CL).
- ²⁰ AUBERT 09Z search for the process $\Upsilon(2S) \rightarrow A^0 \gamma$ with $A^0 \rightarrow \mu^+ \mu^-$ for $0.212 < m_{A^0} < 9.3 \text{ GeV}$ and give limits on $B(\Upsilon(2S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$ in the range $(0.3\text{--}8) \times 10^{-6}$ (90% CL).
- ²¹ AUBERT 09Z search for the process $\Upsilon(3S) \rightarrow A^0 \gamma$ with $A^0 \rightarrow \mu^+ \mu^-$ for $0.212 < m_{A^0} < 9.3 \text{ GeV}$ and give limits on $B(\Upsilon(3S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \mu^+ \mu^-)$ in the range $(0.3\text{--}5) \times 10^{-6}$ (90% CL).
- ²² TUNG 09 search for the decay chain $K_L \rightarrow \pi^0 \pi^0 A^0, A^0 \rightarrow \gamma \gamma$ and give a limit on $B(K_L \rightarrow \pi^0 \pi^0 A^0) \cdot B(A^0 \rightarrow \gamma \gamma)$ in the range $(2.4\text{--}10.7) \times 10^{-7}$ at 90%CL for $m_{A^0} = 194.3\text{--}219.3 \text{ MeV}$. The limit for $m_{A^0} = 214.3 \text{ MeV}$ is 2.4×10^{-7} .
- ²³ LOVE 08 search for the process $\Upsilon(1S) \rightarrow A^0 \gamma$ with $A^0 \rightarrow \mu^+ \mu^-$ (for $m_{A^0} < 2m_\tau$) and $A^0 \rightarrow \tau^+ \tau^-$. Limits on $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot B(A^0 \rightarrow \ell^+ \ell^-)$ in the range $10^{-6}\text{--}10^{-4}$ (90% CL) are given.
- ²⁴ BESSION 07 give a limit $B(\Upsilon(1S) \rightarrow \eta_b \gamma) \cdot B(\eta_b \rightarrow \tau^+ \tau^-) < 0.27\%$ (95% CL), which constrains a possible A^0 exchange contribution to the η_b decay.
- ²⁵ PARK 05 found three candidate events for $\Sigma^+ \rightarrow p \mu^+ \mu^-$ in the HyperCP experiment. Due to a narrow spread in dimuon mass, they hypothesize the events as a possible signal of a new boson. It can be interpreted as a neutral particle with $m_{A^0} = 214.3 \pm 0.5 \text{ MeV}$ and the branching fraction $B(\Sigma^+ \rightarrow p A^0) \cdot B(A^0 \rightarrow \mu^+ \mu^-) = (3.1^{+2.4}_{-1.9} \pm 1.5) \times 10^{-8}$.
- ²⁶ BALEST 95 give limits $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot 1.5 \times 10^{-5}$ at 90% CL for $m_{A^0} < 5 \text{ GeV}$. The limit becomes $< 10^{-4}$ for $m_{A^0} < 7.7 \text{ GeV}$.
- ²⁷ ANTREASIAN 90C give limits $B(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot 5.6 \times 10^{-5}$ at 90% CL for $m_{A^0} < 7.2 \text{ GeV}$. A^0 is assumed not to decay in the detector.

Other Mass Limits

We use a symbol H_1^0 if mass $< 125 \text{ GeV}$ or H_2^0 if mass $> 125 \text{ GeV}$. The notation H^0 is reserved for the 125 GeV particle.

- AAD 20c combine searches for a scalar resonance decaying to $H^0 H^0$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$ from AABOUD 19A, AABOUD 19O, AABOUD 18CQ, AABOUD 19T, AABOUD 18CW, and AABOUD 18BU. See their Fig. 5(a) for limits on cross section times branching ratio for $m_{H_2^0} = 0.26\text{--}3 \text{ TeV}$.
- SIRUNYAN 20 search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$ or $\tau^+ \tau^- \mu^+ \mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 10 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range $m_{A^0} = 4\text{--}15 \text{ GeV}$.
- AABOUD 19A search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}b\bar{b}$ in $27.5\text{--}36.1 \text{ fb}^{-1}$ of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 9(a) for limits on cross section times branching ratios for $m_{H_2^0} = 0.26\text{--}3 \text{ TeV}$.
- AABOUD 19AG search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- b\bar{b}$ in 36.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 6 (a) for limits on the product of production cross section (normalized to the SM) and branching ratios in the range $m_{A^0} = 20\text{--}60 \text{ GeV}$.
- AABOUD 19O search for a scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}WW^*$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 12 (left) for limits on cross section times branching ratio for $m_{H_2^0} = 0.5\text{--}3 \text{ TeV}$.
- AABOUD 19T search for a scalar resonance decaying to $H^0 H^0 \rightarrow WW^* WW^*$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 3 for limits on cross section times branching ratio for $m_{H_2^0} = 260\text{--}500 \text{ GeV}$, assuming SM decay rates for the H^0 .
- AABOUD 19V combine published ATLAS data to constrain two-Higgs-doublet plus singlet pseudoscalar model with A_1^0 decaying to invisible final states. See their Fig. 19 for excluded parameter regions.
- AABOUD 19Y search for a narrow scalar resonance produced by gluon fusion or b associated production, decaying to $\mu^+ \mu^-$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Figs. 4 and 5(a) for cross section limits for $m_{H_2^0} = 0.2\text{--}1.0 \text{ TeV}$.
- AALTONEN 19 search for b associated production of a scalar particle decaying to $b\bar{b}$ in 5.4 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. See their Fig. 3 for limits on cross section times branching ratio for $m_{H_{1,2}^0} = 100\text{--}300 \text{ GeV}$.
- SIRUNYAN 19 search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow \gamma\gamma b\bar{b}$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 9 (left) for limits on cross section times branching ratios for $m_{H_2^0} = 260\text{--}900 \text{ GeV}$.
- SIRUNYAN 19AE search for a scalar resonance produced in association with a $b\bar{b}$ pair, decaying to $\tau^+ \tau^-$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 4 for cross section limits for $m_{A^0} = 25\text{--}70 \text{ GeV}$.
- SIRUNYAN 19AN search for production of A_2^0 decaying to $H^0 A_1^0$ followed by $H^0 \rightarrow b\bar{b}, A_1^0 \rightarrow \text{invisible}$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$, in the mass range $m_{A_2^0} = 0.2\text{--}1.6 \text{ TeV}, m_{A_1^0} = 0.15\text{--}0.5 \text{ TeV}$. See their Fig. 6 for limits in terms of two-Higgs-doublet plus singlet pseudoscalar model.
- SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or b -associated production, decaying to $ZH^0 \rightarrow \ell^+ \ell^- b\bar{b}$ ($\ell = e, \mu$) or $\nu\bar{\nu}b\bar{b}$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 5 for cross section limits for $m_{A^0} = 0.22\text{--}1.0 \text{ TeV}$.
- SIRUNYAN 19B search for gluon fusion production of narrow scalar resonance with large transverse momentum, decaying to $b\bar{b}$, in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Figs. 7 and 8 for limits on cross section times branching ratio for the resonance mass of $50\text{--}350 \text{ GeV}$.
- SIRUNYAN 19BB search for the decay $H_1^0 \rightarrow \gamma\gamma$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$ and 35.9 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. See their Figs. 4–6 for limits on cross section times branching ratio for $m_{H_1^0} = 80\text{--}110 \text{ GeV}$ (some results in Fig. 5 for $m_{H_1^0} = 70\text{--}110 \text{ GeV}$).
- SIRUNYAN 19BD search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- b\bar{b}$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 5 for limits on the product of cross section times branching ratios in the range $m_{A^0} = 20\text{--}62.5 \text{ GeV}$. See also their Figs. 6 and 7 for interpretation of the data in terms of models with two Higgs doublets and a singlet.
- SIRUNYAN 19BE combine searches for $H_2^0 \rightarrow H^0 H^0$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$ in various H^0 decay modes, from SIRUNYAN 18A, SIRUNYAN 18AF, SIRUNYAN 18CW, SIRUNYAN 19, and SIRUNYAN 19H. See their Fig. 3 for limits on cross section times branching ratios for $m_{H_2^0} = 0.25\text{--}3 \text{ TeV}$.

Neutral Higgs Bosons, Searches for

- 18 SIRUNYAN 19BQ search for production of $H_{1,2}^0$ decaying to $A^0 A^0 \rightarrow \mu^+ \mu^- \mu^+ \mu^-$ in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_{1,2}^0} = 90\text{--}150$ GeV, $m_{A^0} = 0.25\text{--}3.55$ GeV.
- 19 SIRUNYAN 19CR search for production of $H_{2,3}^0/A^0$ in gluon fusion and in association with a $b\bar{b}$ pair, decaying to $\mu^+ \mu^-$ in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 6 for limits on cross section times branching ratio.
- 20 SIRUNYAN 19H search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}b\bar{b}$ in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV, where one $b\bar{b}$ pair is resolved and the other not. Limits on cross section times branching ratios for $m_{H_{2,3}^0} = 0.75\text{--}1.6$ TeV are obtained and combined with data from SIRUNYAN 18AF. See their Fig. 5 (right).
- 21 AABOUD 18AA search for production of a scalar resonance decaying to $Z\gamma$, with Z decaying hadronically, in 36.1 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 8(a) for limits on cross section times branching ratio for $m_{H_{2,3}^0} = 1.0\text{--}6.8$ TeV.
- 22 AABOUD 18AG search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \gamma\gamma gg$ in 36.7 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 2 and Table 6 for cross section limits in the range $m_{A^0} = 20\text{--}60$ GeV.
- 23 AABOUD 18AH search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to $ZH_{2,3}^0 \rightarrow \ell^+ \ell^- b\bar{b}$ in 36.1 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 5 for cross section limits for $m_{A^0} = 230\text{--}800$ GeV and $m_{H_{2,3}^0} = 130\text{--}700$ GeV.
- 24 AABOUD 18AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to ZH^0 in the final states $\nu\bar{\nu}b\bar{b}$ and $\ell^+ \ell^- b\bar{b}$ in 36.1 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 6 for cross section limits for $m_{A^0} = 0.2\text{--}2$ TeV. See also AABOUD 18CC.
- 25 AABOUD 18BF search for production of a heavy $H_{2,3}^0$ state decaying to ZZ in the final states $\ell^+ \ell^- \ell^+ \ell^-$ and $\ell^+ \ell^- \nu\bar{\nu}$ in 36.1 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 6 for upper limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.2\text{--}1.2$ TeV assuming ggF or VBF with the NWA. See their Fig. 7 for upper limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.4\text{--}1.0$ TeV assuming ggF, and with several assumptions on its width.
- 26 AABOUD 18BU search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow \gamma\gamma WW^*$ in 36.1 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 4 for limits on cross section times branching ratios for $m_{H_{2,3}^0} = 260\text{--}500$ GeV.
- 27 AABOUD 18BX search for associated production of WH^0 or ZH^0 followed by the decay $H^0 \rightarrow A^0 A^0 \rightarrow b\bar{b}b\bar{b}$ in 36.1 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 9 for limits on cross section times branching ratios for $m_{A^0} = 20\text{--}60$ GeV. See also their Fig. 10 for the dependence of the limit on A^0 lifetime.
- 28 AABOUD 18CQ search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}\tau^+ \tau^-$ in 36.1 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 2 (above) for limits on cross section times branching ratios for $m_{H_{2,3}^0} = 260\text{--}1000$ GeV.
- 29 AABOUD 18F search for production of a narrow scalar resonance decaying to $W^+ W^-$ and ZZ , followed by hadronic decays of W and Z , in 36.7 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 5(c) for limits on cross section times branching ratio for $m_{H_{2,3}^0} = 1.2\text{--}3.0$ TeV.
- 30 AAIJ 18AM search for gluon-fusion production of $H_{1,2}^0$ decaying to $\mu\tau$ in 2 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_{1,2}^0} = 45\text{--}195$ GeV.
- 31 AAIJ 18AQ search for gluon-fusion production of a scalar particle A^0 decaying to $\mu^+ \mu^-$ in 1.99 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV and 0.98 fb⁻¹ at $E_{\text{cm}} = 7$ TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{A^0} = 5.5\text{--}15$ GeV (using the $E_{\text{cm}} = 8$ TeV data set).
- 32 AAIJ 18AQ search for the decay $H^0 \rightarrow A^0 A^0$, with one of the A^0 decaying to $\mu^+ \mu^-$, in 1.99 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV and 0.98 fb⁻¹ at $E_{\text{cm}} = 7$ TeV. See their Fig. 5 (right) for limits on the product of branching ratios for $m_{A^0} = 5.5\text{--}15$ GeV (using the $E_{\text{cm}} = 8$ TeV data set).
- 33 SIRUNYAN 18AF search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}b\bar{b}$ in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV, where both $b\bar{b}$ pairs are not resolved. See their Fig. 9 for limits on cross section times branching ratios for $m_{H_{2,3}^0} = 0.75\text{--}3$ TeV.
- 34 SIRUNYAN 18BA search for production of a heavy $H_{2,3}^0$ state decaying to ZZ in the final states $\ell^+ \ell^- \ell^+ \ell^-$, $\ell^+ \ell^- q\bar{q}$, and $\ell^+ \ell^- \nu\bar{\nu}$ in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Figs. 10 and 11 for upper limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.13\text{--}3$ TeV with several assumptions on its width and on the fraction of Vector-Boson-Fusion of the total production cross section.
- 35 SIRUNYAN 18CW search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}b\bar{b}$ in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV, where both $b\bar{b}$ pairs are resolved. See their Fig. 9 for limits on cross section times branching ratios for $m_{H_{2,3}^0} = 260\text{--}1200$ GeV.
- 36 SIRUNYAN 18DK search for production of a scalar resonance decaying to $Z\gamma$, with Z decaying to $\ell^+ \ell^-$ or hadronically, in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.35\text{--}4$ TeV for different assumptions on the width of the resonance.
- 37 SIRUNYAN 18DT search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+ \tau^- b\bar{b}$ in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 7 for limits on the product of branching ratios in the range $m_{A^0} = 15\text{--}60$ GeV. See also their Fig. 8 for interpretation of the data in terms of models with two Higgs doublets and a singlet.
- 38 SIRUNYAN 18DU search for production of a narrow scalar resonance decaying to $\gamma\gamma$ in 35.9 fb⁻¹ (taken in 2016) of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 3 (right) for limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.5\text{--}5$ TeV for several values of its width-to-mass ratio.
- 39 SIRUNYAN 18ED search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to ZH^0 in the final states $\nu\bar{\nu}b\bar{b}$ or $\ell^+ \ell^- b\bar{b}$ in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 8 for cross section limits for $m_{A^0} = 0.8\text{--}2$ TeV.
- 40 SIRUNYAN 18EE search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- \tau^+ \tau^-$ in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 4 for limits on the product of branching ratios in the range $m_{A^0} = 15\text{--}62.5$ GeV, normalized to the SM production cross section. See also their Fig. 5 for interpretation of the data in terms of models with two Higgs doublets and a singlet.
- 41 SIRUNYAN 18F search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow WWb\bar{b}$ or $ZZb\bar{b}$ in the final state $\ell\ell\nu\nu b\bar{b}$ in 35.9 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratios for $m_{H_{2,3}^0} = 250\text{--}900$ GeV.
- 42 AABOUD 17 search for production of a scalar resonance decaying to $Z\gamma$ in 3.2 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 4 for the limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.25\text{--}3.0$ TeV.
- 43 AABOUD 17AW search for production of a scalar resonance decaying to $Z\gamma$ in 36.1 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.25\text{--}2.4$ TeV.
- 44 KHACHATRYAN 17AZ search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$, $\mu^+ \mu^- b\bar{b}$, and $\mu^+ \mu^- \tau^+ \tau^-$ in 19.7 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Figs. 4, 5, and 6 for cross section limits in the range $m_{A^0} = 5\text{--}62.5$ GeV. See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.
- 45 KHACHATRYAN 17D search for production of a scalar resonance decaying to $Z\gamma$ in 19.7 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV and 2.7 fb⁻¹ at $E_{\text{cm}} = 13$ TeV. See their Figs. 3 and 4 for the limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.2\text{--}2.0$ TeV.
- 46 KHACHATRYAN 17R search for production of a narrow scalar resonance decaying to $\gamma\gamma$ in 12.9 fb⁻¹ (taken in 2016) of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.5\text{--}4.5$ TeV for several values of its width-to-mass ratio. Limits from combination with KHACHATRYAN 16M are shown in their Figs. 4 and 6.
- 47 SIRUNYAN 17CN search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}\tau^+ \tau^-$ in 18.3 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 5 (above) and Table II for limits on the cross section times branching ratios for $m_{H_{2,3}^0} = 0.3\text{--}1$ TeV, and Fig. 6 (above) and Table III for the corresponding limits by combining with data from KHACHATRYAN 16BQ and KHACHATRYAN 15R.
- 48 SIRUNYAN 17Y search for production of a scalar resonance decaying to $Z\gamma$ in 19.7 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV and 2.7 fb⁻¹ at $E_{\text{cm}} = 13$ TeV. See their Figs. 3, 4 and Table 3 for limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.7\text{--}3.0$ TeV, and Fig. 5 for the corresponding limits for $m_{H_{2,3}^0} = 0.2\text{--}3.0$ TeV from combination with KHACHATRYAN 17D data.
- 49 AABOUD 16AB search for associated production of WH^0 with the decay $H^0 \rightarrow A^0 A^0 \rightarrow b\bar{b}b\bar{b}$ in 3.2 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 8 for limits on cross section times branching ratios for $m_{A^0} = 20\text{--}60$ GeV.
- 50 AABOUD 16AE search for production of a narrow scalar resonance decaying to $W^+ W^-$ and ZZ in 3.2 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.5\text{--}3$ TeV.
- 51 AABOUD 16H search for production of a scalar resonance decaying to $\gamma\gamma$ in 3.2 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 12 for limits on cross section times branching ratio for $m_{H_{2,3}^0} = 0.2\text{--}2$ TeV with different assumptions on the width.
- 52 AABOUD 16I search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}b\bar{b}$ in 3.2 fb⁻¹ of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 10(c) for limits on cross section times branching ratios for $m_{H_{2,3}^0} = 0.5\text{--}3$ TeV.
- 53 AAD 16AX search for production of a heavy H^0 state decaying to ZZ in the final states $\ell^+ \ell^- \ell^+ \ell^-$, $\ell^+ \ell^- \nu\bar{\nu}$, $\ell^+ \ell^- q\bar{q}$, and $\nu\bar{\nu}q\bar{q}$ in 20.3 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 12 for upper limits on $\sigma(H^0) B(H^0 \rightarrow ZZ)$ for m_{H^0} ranging from 140 GeV to 1000 GeV.
- 54 AAD 16C search for production of a heavy H^0 state decaying to $W^+ W^-$ in the final states $\ell\nu\ell\nu$ and $\ell\nu q\bar{q}$ in 20.3 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Figs. 12, 13, and 16 for upper limits on $\sigma(H^0) B(H^0 \rightarrow W^+ W^-)$ for m_{H^0} ranging from 300 GeV to 1000 or 1500 GeV with various assumptions on the total width of H^0 .
- 55 AAD 16L search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \gamma\gamma\gamma\gamma$ in 20.3 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 4 (upper right) for limits on cross section times branching ratios (normalized to the SM H^0 cross section) for $m_{A^0} = 10\text{--}60$ GeV.
- 56 AAD 16L search for the decay $H_{2,3}^0 \rightarrow A^0 A^0 \rightarrow \gamma\gamma\gamma\gamma$ in 20.3 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 4 (lower right) for limits on cross section times branching ratios for $m_{H_{2,3}^0} = 600$ GeV and $m_{A^0} = 10\text{--}245$ GeV, and Table 5 for limits for $m_{H_{2,3}^0} = 300$ and 900 GeV.
- 57 AALTONEN 16C search for electroweak associated production of $H_{1,2}^0 H^\pm$ followed by the decays $H^\pm \rightarrow H_{1,2}^0 W^*$, $H_{1,2}^0 \rightarrow \gamma\gamma$ for $m_{H_{1,2}^0} = 10\text{--}105$ GeV and $m_{H^\pm} = 30\text{--}300$ GeV. See their Fig. 3 for excluded parameter region in a two-doublet model in which $H_{1,2}^0$ has no direct decay to fermions.
- 58 KHACHATRYAN 16BG search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}b\bar{b}$ in 19.7 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 6 for limits on the cross section times branching ratios for $m_{H_{2,3}^0} = 1.15\text{--}3$ TeV.
- 59 KHACHATRYAN 16BQ search for a resonance decaying to $H^0 H^0 \rightarrow \gamma\gamma b\bar{b}$ in 19.7 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 9 for limits on the cross section times branching ratios for $m_{H_{2,3}^0} = 0.26\text{--}1.1$ TeV.
- 60 KHACHATRYAN 16F search for the decay $H^0 \rightarrow H_{1,2}^0 H_{1,2}^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$ in 19.7 fb⁻¹ of pp collisions at $E_{\text{cm}} = 8$ TeV. See their Fig. 8 for cross section limits for $m_{H_{1,2}^0} = 4\text{--}8$ GeV.

See key on page 999

Gauge & Higgs Boson Particle Listings
Neutral Higgs Bosons, Searches for

- 61 KHACHATRYAN 16M search for production of a narrow resonance decaying to $\gamma\gamma$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$ and 3.3 fb^{-1} at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 3 (top) for limits on cross section times branching ratio for $m_{H^0} = 0.5\text{--}4 \text{ TeV}$.
- 62 KHACHATRYAN 16P search for gluon fusion production of an H^0_2 decaying to $H^0 H^0 \rightarrow b\bar{b}\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 8 (lower right) for cross section limits for $m_{H^0_2} = 260\text{--}350 \text{ GeV}$.
- 63 KHACHATRYAN 16P search for gluon fusion production of an A^0 decaying to $ZH^0 \rightarrow \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 10 for cross section limits for $m_{H^0_2} = 220\text{--}350 \text{ GeV}$.
- 64 AAD 15BK search for production of a heavy H^0_2 decaying to $H^0 H^0$ in the final state $b\bar{b}\tau^+\tau^-$ in 19.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 14(c) for $\sigma(H^0_2) \text{B}(H^0_2 \rightarrow H^0 H^0)$ for $m_{H^0_2} = 500\text{--}1500 \text{ GeV}$ with $\Gamma_{H^0_2} = 1 \text{ GeV}$.
- 65 AAD 15BZ search for the decay $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+\mu^-\tau^+\tau^-$ ($m_{H^0} = 125 \text{ GeV}$) in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 6 for limits on cross section times branching ratio for $m_{A^0} = 3.7\text{--}50 \text{ GeV}$.
- 66 AAD 15BZ search for a state H^0_2 via the decay $H^0_2 \rightarrow A^0 A^0 \rightarrow \mu^+\mu^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 6 for limits on cross section times branching ratio for $m_{H^0_2} = 100\text{--}500 \text{ GeV}$ and $m_{A^0} = 5 \text{ GeV}$.
- 67 AAD 15CE search for production of a heavy H^0_2 decaying to $H^0 H^0$ in the final states $b\bar{b}\tau^+\tau^-$ and $\gamma\gamma WW^*$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$ and combine with data from AAD 15H and AAD 15BK. A limit $\sigma(H^0_2) \text{B}(H^0_2 \rightarrow H^0 H^0) < 2.1\text{--}0.011 \text{ pb}$ (95% CL) is given for $m_{H^0_2} = 260\text{--}1000 \text{ GeV}$. See their Fig. 6.
- 68 AAD 15H search for production of a heavy H^0_2 decaying to $H^0 H^0$ in the final state $\gamma\gamma b\bar{b}$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. A limit of $\sigma(H^0_2) \text{B}(H^0_2 \rightarrow H^0 H^0) < 3.5\text{--}0.7 \text{ pb}$ is given for $m_{H^0_2} = 260\text{--}500 \text{ GeV}$ at 95% CL. See their Fig. 3.
- 69 AAD 15S search for production of A^0 decaying to $ZH^0 \rightarrow \ell^+\ell^-b\bar{b}, \nu\bar{\nu}b\bar{b}$ and $\ell^+\ell^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 3 for cross section limits for $m_{A^0} = 200\text{--}1000 \text{ GeV}$.
- 70 KHACHATRYAN 15AW search for production of a heavy state H^0_2 of an electroweak singlet extension of the Standard Model via the decays of H^0_2 to W^+W^- and ZZ in up to 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and up to 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$ in the range $m_{H^0_2} = 145\text{--}1000 \text{ GeV}$. See their Figs. 8 and 9 for limits in the parameter space of the model.
- 71 KHACHATRYAN 15BB search for production of a resonance H^0 decaying to $\gamma\gamma$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^0} = 150\text{--}850 \text{ GeV}$.
- 72 KHACHATRYAN 15N search for production of A^0 decaying to $ZH^0 \rightarrow \ell^+\ell^-b\bar{b}$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 3 for limits on cross section times branching ratios for $m_{A^0} = 225\text{--}600 \text{ GeV}$.
- 73 KHACHATRYAN 15O search for production of a high-mass narrow resonance A^0 decaying to $ZH^0 \rightarrow q\bar{q}\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 6 for limits on cross section times branching ratios for $m_{A^0} = 800\text{--}2500 \text{ GeV}$.
- 74 KHACHATRYAN 15R search for a narrow scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}b\bar{b}$ in 17.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 5 (top) for limits on cross section times branching ratios for $m_{H^0} = 0.27\text{--}1.1 \text{ TeV}$.
- 75 AAD 14AP search for a second H^0 state decaying to $\gamma\gamma$ in addition to the state at about 125 GeV in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 4 for limits on cross section times branching ratio for $m_{H^0} = 65\text{--}600 \text{ GeV}$.
- 76 AAD 14M search for the decay cascade $H^0_2 \rightarrow H^\pm W^\mp \rightarrow H^0 W^\pm W^\mp, H^0$ decaying to $b\bar{b}$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Table III for limits on cross section times branching ratio for $m_{H^0_2} = 325\text{--}1025 \text{ GeV}$ and $m_{H^\pm} = 225\text{--}925 \text{ GeV}$.
- 77 CHATRYAN 14G search for a second H^0 state decaying to $WW^{(*)}$ in addition to the observed signal at about 125 GeV using 4.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.4 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 21 (right) for cross section limits in the mass range $110\text{--}600 \text{ GeV}$.
- 78 KHACHATRYAN 14P search for a second H^0 state decaying to $\gamma\gamma$ in addition to the observed signal at about 125 GeV using 5.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$ and 19.7 fb^{-1} at $E_{\text{cm}} = 8 \text{ TeV}$. See their Figs. 27 and 28 for cross section limits in the mass range $110\text{--}150 \text{ GeV}$.
- 79 AALTONEN 13P search for production of a heavy Higgs boson H^0 that decays into a charged Higgs boson H^\pm and a lighter Higgs boson H^0 via the decay chain $H^0 \rightarrow H^\pm W^\mp, H^\pm \rightarrow W^\pm H^0, H^0 \rightarrow b\bar{b}$ in the final state $\ell\nu$ plus 4 jets in 8.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. See their Fig. 4 for limits on cross section times branching ratio in the $m_{H^\pm}\text{--}m_{H^0}$ plane for $m_{H^0} = 126 \text{ GeV}$.
- 80 CHATRYAN 13BJ search for H^0 production in the decay chain $H^0 \rightarrow A^0 A^0, A^0 \rightarrow \mu^+\mu^-$ in 5.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. See their Fig. 2 for limits on cross section times branching ratio.
- 81 AALTONEN 11P search in 2.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$ for the decay chain $t \rightarrow bH^+, H^+ \rightarrow W^+ A^0, A^0 \rightarrow \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on $\text{B}(t \rightarrow bH^+)$ for $90 < m_{H^+} < 160 \text{ GeV}$.
- 82 ABBIENDI 10 search for $e^+e^- \rightarrow ZH^0$ with the decay chain $H^0 \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_2^0, \tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + (\gamma \text{ or } Z^*)$, when $\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0$ are nearly degenerate. For a mass difference of 2 (4) GeV, a lower limit on m_{H^0} of 108.4 (107.0) GeV (95% CL) is obtained for SM ZH^0 cross section and $\text{B}(H^0 \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_2^0) = 1$.
- 83 SCHAE 10 search for the process $e^+e^- \rightarrow H^0 Z$ followed by the decay chain $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+\tau^-\tau^+\tau^-$ with $Z \rightarrow \ell^+\ell^-, \nu\bar{\nu}$ at $E_{\text{cm}} = 183\text{--}209 \text{ GeV}$. For a $H^0 Z Z$ coupling equal to the SM value, $\text{B}(H^0 \rightarrow A^0 A^0) = \text{B}(A^0 \rightarrow \tau^+\tau^-) = 1$, and $m_{A^0} = 4\text{--}10 \text{ GeV}$, m_{H^0} up to 107 GeV is excluded at 95% CL.
- 84 ABAZOV 09v search for H^0 production followed by the decay chain $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+\mu^-\mu^+\mu^-$ or $\mu^+\mu^-\tau^+\tau^-$ in 4.2 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. See their Fig. 3 for limits on $\sigma(H^0)\text{B}(H^0 \rightarrow A^0 A^0)$ for $m_{A^0} = 3.6\text{--}19 \text{ GeV}$.
- 85 ABBIENDI 05A search for $e^+e^- \rightarrow H^0_1 A^0$ in general Type-II two-doublet models, with decays $H^0_1, A^0 \rightarrow q\bar{q}, gg, \tau^+\tau^-$, and $H^0_1 \rightarrow A^0 A^0$.
- 86 ABBIENDI 04k search for $e^+e^- \rightarrow H^0 Z$ with H^0 decaying to two jets of any flavor including gg . The limit is for SM production cross section with $\text{B}(H^0 \rightarrow jj) = 1$.
- 87 ABDALLAH 04 consider the full combined LEP and LEP2 datasets to set limits on the Higgs coupling to W or Z bosons, assuming SM decays of the Higgs. Results in Fig. 26.
- 88 ACHARD 04B search for $e^+e^- \rightarrow H^0 Z$ with H^0 decaying to $b\bar{b}, c\bar{c}$, or gg . The limit is for SM production cross section with $\text{B}(H^0 \rightarrow jj) = 1$.
- 89 ACHARD 04F search for H^0 with anomalous coupling to gauge boson pairs in the processes $e^+e^- \rightarrow H^0 \gamma, e^+e^- H^0, H^0 Z$ with decays $H^0 \rightarrow f\bar{f}, \gamma\gamma, Z\gamma$, and $W^* W^*$ at $E_{\text{cm}} = 189\text{--}209 \text{ GeV}$. See paper for limits.
- 90 ABBIENDI 03f search for $H^0 \rightarrow$ anything in $e^+e^- \rightarrow H^0 Z$, using the recoil mass spectrum of $Z \rightarrow e^+e^-$ or $\mu^+\mu^-$. In addition, it searched for $Z \rightarrow \nu\bar{\nu}$ and $H^0 \rightarrow e^+e^-$ or photons. Scenarios with large width or continuum H^0 mass distribution are considered. See their Figs. 11–14 for the results.
- 91 ABBIENDI 03G search for $e^+e^- \rightarrow H^0_1 Z$ followed by $H^0_1 \rightarrow A^0 A^0, A^0 \rightarrow c\bar{c}, gg$, or $\tau^+\tau^-$ in the region $m_{H^0_1} = 45\text{--}86 \text{ GeV}$ and $m_{A^0} = 2\text{--}11 \text{ GeV}$. See their Fig. 7 for the limits.
- 92 Search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \rightarrow q\bar{q}, \ell^+\ell^-, \nu\bar{\nu}$, at $E_{\text{cm}} \leq 209 \text{ GeV}$. The limit is for a H^0 with SM production cross section and $\text{B}(H^0 \rightarrow f\bar{f})=0$ for all fermions f .
- 93 For $\text{B}(H^0 \rightarrow \gamma\gamma)=1, m_{H^0} > 113.1 \text{ GeV}$ is obtained.
- 94 HEISTER 02M search for $e^+e^- \rightarrow H^0 Z$, assuming that H^0 decays to $q\bar{q}, gg$, or $\tau^+\tau^-$ only. The limit assumes SM production cross section.
- 95 ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{\text{cm}} \leq 189 \text{ GeV}$. In addition to usual final states, the decays $H^0_1, A^0 \rightarrow q\bar{q}, gg$ are searched for. See their Figs. 15,16 for excluded regions.
- 96 ACCIARRI 00R search for $e^+e^- \rightarrow H^0 \gamma$ with $H^0 \rightarrow b\bar{b}, Z\gamma$, or $\gamma\gamma$. See their Fig. 3 for limits on $\sigma\text{--B}$. Explicit limits within an effective interaction framework are also given, for which the Standard Model Higgs search results are used in addition.
- 97 ACCIARRI 00R search for the two-photon type processes $e^+e^- \rightarrow e^+e^- H^0$ with $H^0 \rightarrow b\bar{b}$ or $\gamma\gamma$. See their Fig. 4 for limits on $\Gamma(H^0 \rightarrow \gamma\gamma)\text{B}(H^0 \rightarrow \gamma\gamma \text{ or } b\bar{b})$ for $m_{H^0}=70\text{--}170 \text{ GeV}$.
- 98 GONZALEZ-GARCIA 98B use $D\bar{0}$ limit for $\gamma\gamma$ events with missing E_T in $p\bar{p}$ collisions (ABBOTT 98) to constrain possible ZH or WH production followed by unconventional $H \rightarrow \gamma\gamma$ decay which is induced by higher-dimensional operators. See their Figs. 1 and 2 for limits on the anomalous couplings.
- 99 KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no $H^0_1 Z Z$ coupling and obtain $m_{H^0_1} \gtrsim 5 \text{ GeV}$ or $m_{A^0} \gtrsim 5 \text{ GeV}$ for $\tan\beta > 50$. Other Higgs bosons are assumed to be much heavier.
- 100 ALEXANDER 96H give $\text{B}(Z \rightarrow H^0 \gamma)\text{B}(H^0 \rightarrow q\bar{q}) < 1\text{--}4 \times 10^{-5}$ (95%CL) and $\text{B}(Z \rightarrow H^0 \gamma)\text{B}(H^0 \rightarrow b\bar{b}) < 0.7\text{--}2 \times 10^{-5}$ (95%CL) in the range $20 < m_{H^0} < 80 \text{ GeV}$.

SEARCHES FOR A HIGGS BOSON
WITH STANDARD MODEL COUPLINGS

These listings are based on experimental searches for a scalar boson whose couplings to W, Z and fermions are precisely those of the Higgs boson predicted by the three-generation Standard Model with the minimal Higgs sector.

For a review and a bibliography, see the review on "Status of Higgs Boson Physics."

Indirect Mass Limits for H^0 from Electroweak Analysis

The mass limits shown below apply to a Higgs boson H^0 with Standard Model couplings whose mass is a priori unknown.

For limits obtained before the direct measurement of the top quark mass, see the 1996 (Physical Review D54 1 (1996)) Edition of this Review. Other studies based on data available prior to 1996 can be found in the 1998 Edition (The European Physical Journal C 3 1 (1998)) of this Review.

Charged Higgs Bosons (H^\pm and $H^{\pm\pm}$), Searches for

CONTENTS:

- H^\pm (charged Higgs) mass limits for $m_{H^\pm} < m(\text{top})$
- H^\pm (charged Higgs) mass limits for $m_{H^\pm} > m(\text{top})$
- $H^{\pm\pm}$ (doubly-charged Higgs boson) mass limits
 - Limits for $H^{\pm\pm}$ with $T_3 = \pm 1$
 - Limits for $H^{\pm\pm}$ with $T_3 = 0$

H^\pm (charged Higgs) mass limits for $m_{H^\pm} < m(\text{top})$

Unless otherwise stated, LEP limits assume $B(H^+ \rightarrow \tau^+ \nu) + B(H^+ \rightarrow c\bar{s}) = 1$, and hold for all values of $B(H^+ \rightarrow \tau^+ \nu_\tau)$, and assume H^+ weak isospin of $T_3 = +1/2$. In the following, $\tan\beta$ is the ratio of the two vacuum expectation values in two-doublet models (2HDM).

The limits are also applicable to point-like technipions. For a discussion of techniparticles, see the Review of Dynamical Electroweak Symmetry Breaking in this Review.

Limits obtained at the LHC are given in the $m_h^{\text{mod-}}$ benchmark scenario, see CARENA 13, and hold for all $\tan\beta$ values.

For limits obtained in hadronic collisions before the observation of the top quark, and based on the top mass values inconsistent with the current measurements, see the 1996 (Physical Review D54 1 (1996)) Edition of this Review.

Searches in e^+e^- collisions at and above the Z pole have conclusively ruled out the existence of a charged Higgs in the region $m_{H^\pm} \lesssim 45$ GeV, and are meanwhile superseded by the searches in higher energy e^+e^- collisions at LEP. Results that are by now obsolete are therefore not included in this compilation, and can be found in a previous Edition (The European Physical Journal C15 1 (2000)) of this Review.

In the following, and unless otherwise stated, results from the LEP experiments (ALEPH, DELPHI, L3, and OPAL) are assumed to derive from the study of the $e^+e^- \rightarrow H^+H^-$ process. Limits from $b \rightarrow s\gamma$ decays are usually stronger in generic 2HDM models than in Supersymmetric models.

- 1 AAD 15AF search for $t\bar{t}$ production followed by $t \rightarrow bH^+, H^+ \rightarrow \tau^+ \nu$ in 19.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. Upper limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau\nu)$ between 2.3×10^{-3} and 1.3×10^{-2} (95% CL) are given for $m_{H^\pm} = 80\text{--}160$ GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM. The region $m_{H^\pm} < 140$ GeV is excluded for $\tan\beta > 1$ in the considered scenarios.
- 2 KHACHATRYAN 15AX search for $t\bar{t}$ production followed by $t \rightarrow bH^+, H^+ \rightarrow \tau^+ \nu$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8$ TeV. Upper limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau\nu)$ between 1.2×10^{-2} and 1.5×10^{-3} (95% CL) are given for $m_{H^\pm} = 80\text{--}160$ GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM. The region $m_{H^\pm} < 155$ GeV is excluded for $\tan\beta > 1$ in the considered scenarios.
- 3 LEP 13 give a limit that refers to the Type II scenario. The limit for $B(H^+ \rightarrow \tau\nu) = 1$ is 94 GeV (95% CL), and for $B(H^+ \rightarrow c\bar{s}) = 1$ the region below 80.5 as well as the region 83-88 GeV is excluded (95% CL). LEP 13 also search for the decay mode $H^+ \rightarrow A^0 W^+$ with $A^0 \rightarrow b\bar{b}$, which is not negligible in Type I models. The limit in Type I models is 72.5 GeV (95% CL) if $m_{A^0} > 12$ GeV.
- 4 ABBIENDI 12 also search for the decay mode $H^+ \rightarrow A^0 W^+$ with $A^0 \rightarrow b\bar{b}$.
- 5 SIRUNYAN 19AH search for H^+ in the decay of a pair-produced t quark, or in associated $t bH^+$ or nonresonant $b\bar{b}H^+ W^-$ production, followed by $H^+ \rightarrow \tau^+ \nu$, in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. Upper limits on cross section times branching ratio between 6 pb and 5 fb (95% CL) are given for $m_{H^\pm} = 80\text{--}3000$ GeV (including the non-resonant production near the top quark mass), see their Fig. 6 (left). See their Fig. 6 (right) for the excluded regions in the $m_h^{\text{mod-}}$ scenario of the MSSM.
- 6 SIRUNYAN 19BP search for vector boson fusion production of H^+ decaying to $H^+ \rightarrow W^+ Z \rightarrow \ell^+ \nu \ell^+ \ell^-$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^\pm} = 0.3\text{--}2.0$ TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.
- 7 SIRUNYAN 19CC search for $t \rightarrow bH^+$ from pair produced top quarks, with the decay chain $H^+ \rightarrow W^+ A^0, A^0 \rightarrow \mu^+ \mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 2 for limits on the product of branching ratios for $m_{A^0} = 15\text{--}75$ GeV.
- 8 SIRUNYAN 19CQ search for vector boson fusion production of H^+ decaying to $H^+ \rightarrow W^+ Z \rightarrow \ell^+ \nu q\bar{q}$ or $q\bar{q}\ell^+ \ell^-$ in 35.9 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H^\pm} = 0.6\text{--}2.0$ TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.
- 9 AABOUD 18BW search for $\bar{t}bH^+$ associated production or the decay $t \rightarrow bH^+$, followed by $H^+ \rightarrow \tau^+ \nu$, in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 8(a) for upper limits on cross section times branching ratio for $m_{H^\pm} = 90\text{--}2000$ GeV, and Fig. 8(b) for limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau^+ \nu)$ for $m_{H^\pm} = 90\text{--}160$ GeV. See also their Fig. 9 for the excluded region in the hMSSM parameter space.
- 10 AABOUD 18CD search for $\bar{t}bH^+$ associated production followed by $H^+ \rightarrow t\bar{b}$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 8 for upper limits on cross section times branching ratio for $m_{H^\pm} = 0.2\text{--}2$ TeV. See also their Fig. 9 for the excluded region in the parameter space of the $m_h^{\text{mod-}}$ and hMSSM scenarios of the MSSM. The theory predictions overlaid to the experimental limits to determine the excluded m_{H^\pm} range are shown without their respective uncertainty band.
- 11 AABOUD 18CH search for vector boson fusion production of H^\pm decaying to $H^\pm \rightarrow W^\pm Z \rightarrow \ell^\pm \nu \ell^\pm \ell^-$ in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^\pm} = 0.2\text{--}0.9$ TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.
- 12 HALLER 18 give 95% CL lower limits on m_{H^\pm} of 590 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for $(b \rightarrow s\gamma)$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Universite user on 06 January 2021

- 13 SIRUNYAN 18D search for $t\bar{t}$ production followed by $t \rightarrow bH^+$, $H^+ \rightarrow c\bar{b}$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 3 for upper limits on $B(t \rightarrow bH^+)$ for $m_{H^+} = 90\text{--}150 \text{ GeV}$ assuming that $B(H^+ \rightarrow c\bar{b}) = 1$ and $B(t \rightarrow bH^+) + B(t \rightarrow bW^+) = 1$.
- 14 MISIAK 17 give 95% CL lower limits on m_{H^+} between 570 and 800 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for $B(b \rightarrow s(d)\gamma)$.
- 15 SIRUNYAN 17AE search for vector boson fusion production of H^\pm decaying to $H^\pm \rightarrow W^\pm Z \rightarrow \ell^\pm \nu \ell^+ \ell^-$ in 15.2 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^\pm} = 0.2\text{--}2.0 \text{ TeV}$, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.
- 16 AABOUD 16A search for $t(b) H^\pm$ associated production followed by $H^\pm \rightarrow \tau^\pm \nu$ in 3.2 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. Upper limits on $\sigma(t(b) H^\pm) B(H^\pm \rightarrow \tau \nu)$ between 1.9 pb and 15 fb (95% CL) are given for $m_{H^\pm} = 200\text{--}2000 \text{ GeV}$, see their Fig. 6. See their Fig. 7 for the excluded regions in the hMSSM scenario.
- 17 AAD 16AJ search for $t(b) H^\pm$ associated production followed by $H^\pm \rightarrow tb$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 6 for upper limits on $\sigma(t(b) H^\pm) B(H^\pm \rightarrow tb)$ for $m_{H^\pm} = 200\text{--}600 \text{ GeV}$.
- 18 AAD 16AJ search for H^\pm production from quark-antiquark annihilation, followed by $H^\pm \rightarrow tb$, in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 10 for upper limits on $\sigma(H^\pm) B(H^\pm \rightarrow tb)$ for $m_{H^\pm} = 400\text{--}3000 \text{ GeV}$.
- 19 AAD 15AF search for tH^\pm associated production followed by $H^\pm \rightarrow \tau^\pm \nu$ in 19.5 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. Upper limits on $\sigma(tH^\pm) B(H^\pm \rightarrow \tau \nu)$ between 760 and 4.5 fb (95% CL) are given for $m_{H^\pm} = 180\text{--}1000 \text{ GeV}$. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM.
- 20 AAD 15M search for vector boson fusion production of H^\pm decaying to $H^\pm \rightarrow W^\pm Z \rightarrow q\bar{q}\ell^+\ell^-$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Fig. 2 for limits on cross section times branching ratio for $m_{H^\pm} = 200\text{--}1000 \text{ GeV}$, and Fig. 3 for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.
- 21 KHACHATRYAN 15AX search for tH^\pm associated production followed by $H^\pm \rightarrow tb$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. Upper limits on $\sigma(tH^\pm) B(H^\pm \rightarrow t\bar{b})$ between 2.0 and 0.13 pb (95% CL) are given for $m_{H^\pm} = 180\text{--}600 \text{ GeV}$. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.
- 22 KHACHATRYAN 15AX search for tH^\pm associated production followed by $H^\pm \rightarrow \tau^\pm \nu$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. Upper limits on $\sigma(tH^\pm) B(H^\pm \rightarrow \tau \nu)$ between 380 and 25 fb (95% CL) are given for $m_{H^\pm} = 180\text{--}600 \text{ GeV}$. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.
- 23 KHACHATRYAN 15BF search for $t\bar{t}$ production followed by $t \rightarrow bH^+$, $H^+ \rightarrow c\bar{s}$ in 19.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. Upper limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow c\bar{s})$ between 1.2×10^{-2} and 6.5×10^{-2} (95% CL) are given for $m_{H^+} = 90\text{--}160 \text{ GeV}$.
- 24 AAD 14M search for the decay cascade $H_2^0 \rightarrow H^\pm W^\mp \rightarrow H^0 W^\pm W^\mp$, H^0 decaying to $b\bar{b}$ in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. See their Table III for limits on cross section times branching ratio for $m_{H_2^0} = 325\text{--}1025 \text{ GeV}$ and $m_{H^\pm} = 225\text{--}925 \text{ GeV}$.
- 25 AALTONEN 14A measure $B(t \rightarrow b\tau\nu) = 0.096 \pm 0.028$ using 9 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. For $m_{H^\pm} = 80\text{--}140 \text{ GeV}$, this measured value is translated to a limit $B(t \rightarrow bH^+) < 0.059$ at 95% CL assuming $B(H^+ \rightarrow \tau^+\nu) = 1$.
- 26 AAD 13AC search for $t\bar{t}$ production followed by $t \rightarrow bH^+$, $H^+ \rightarrow c\bar{s}$ (flavor unidentified) in 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. Upper limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow c\bar{s})$ between 0.05 and 0.01 (95% CL) are given for $m_{H^\pm} = 90\text{--}150 \text{ GeV}$ and $B(H^+ \rightarrow c\bar{s}) = 1$.
- 27 AAD 13V search for $t\bar{t}$ production followed by $t \rightarrow bH^+$, $H^+ \rightarrow \tau^+\nu$ through violation of lepton universality with 4.6 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. Upper limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau^+\nu) = 1$. By combining with AAD 12BH, the limits improve to 0.008 to 0.034 for $m_{H^\pm} = 90\text{--}160 \text{ GeV}$. See their Fig. 7 for the excluded region in the m_h^{max} scenario of the MSSM.
- 28 AAD 12BH search for $t\bar{t}$ production followed by $t \rightarrow bH^+$, $H^+ \rightarrow \tau^+\nu$ with 4.6 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. Upper limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau^+\nu) = 1$ (95% CL) are given for $m_{H^\pm} = 90\text{--}160 \text{ GeV}$ and $B(H^+ \rightarrow \tau^+\nu) = 1$. See their Fig. 8 for the excluded region in the m_h^{max} scenario of the MSSM.
- 29 CHATRCHYAN 12AA search for $t\bar{t}$ production followed by $t \rightarrow bH^+$, $H^+ \rightarrow \tau^+\nu$ with 2 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. Upper limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau^+\nu) = 1$ (95% CL) are given for $m_{H^\pm} = 80\text{--}160 \text{ GeV}$ and $B(H^+ \rightarrow \tau^+\nu) = 1$.
- 30 AALTONEN 11P search in 2.7 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$ for the decay chain $t \rightarrow bH^+$, $H^+ \rightarrow W^+ A^0$, $A^0 \rightarrow \tau^+ \tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau^+ \tau^-)$ for $90 < m_{H^\pm} < 160 \text{ GeV}$.
- 31 DESCHAMPS 10 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays, $b \rightarrow s\gamma$, B_s mixings, and $Z \rightarrow b\bar{b}$. The limit holds irrespective of $\tan\beta$.
- 32 AALTONEN 09AJ search for $t \rightarrow bH^+$, $H^+ \rightarrow c\bar{s}$ in $t\bar{t}$ events in 2.2 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. Upper limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow c\bar{s})$ between 0.08 and 0.32 (95% CL) are given for $m_{H^\pm} = 60\text{--}150 \text{ GeV}$ and $B(H^+ \rightarrow c\bar{s}) = 1$.
- 33 ABZOV 09AC search for $t \rightarrow bH^+$, $H^+ \rightarrow \tau^+\nu$ in $t\bar{t}$ events in 0.9 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. Upper limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau^+\nu) = 1$ (95% CL) are given for $m_{H^\pm} = 80\text{--}155 \text{ GeV}$ and $B(H^+ \rightarrow \tau^+\nu) = 1$. See their Fig. 4 for an excluded region in a MSSM scenario.
- 34 ABZOV 09AG measure $t\bar{t}$ cross sections in final states with ℓ + jets ($\ell = e, \mu$), $\ell\ell$, and $\tau\ell$ in 1 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$, which constrains possible $t \rightarrow bH^+$ branching fractions. Upper limits (95% CL) on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau^+\nu) = 1$ ($B(H^+ \rightarrow c\bar{s}) = 1$) for $m_{H^\pm} = 80\text{--}155 \text{ GeV}$.
- 35 ABZOV 09AI search for $t \rightarrow bH^+$ in $t\bar{t}$ events in 1 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. Final states with ℓ + jets ($\ell = e, \mu$), $\ell\ell$, and $\tau\ell$ are examined. Upper limits on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau^+\nu) = 1$ ($B(H^+ \rightarrow c\bar{s}) = 1$) for $m_{H^\pm} = 80\text{--}155 \text{ GeV}$. A simultaneous extraction of $B(t \rightarrow bH^+)$ and the $t\bar{t}$ cross section is performed, yielding a limit on $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau^+\nu) = 1$ ($B(H^+ \rightarrow c\bar{s}) = 1$) for $m_{H^\pm} = 80\text{--}155 \text{ GeV}$. See their Figs. 5–8 for excluded regions in several MSSM scenarios.
- 36 ABZOV 09P search for H^\pm production by $q\bar{q}'$ annihilation followed by $H^\pm \rightarrow t\bar{b}$ decay in 0.9 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. Cross section limits in several two-doublet models are given for $m_{H^\pm} = 180\text{--}300 \text{ GeV}$. A region with $20 \lesssim \tan\beta \lesssim 70$ is excluded (95% CL) for $180 \text{ GeV} \lesssim m_{H^\pm} \lesssim 184 \text{ GeV}$ in type-I models.
- 37 ABULENCIA 06E search for associated $H^0 W$ production in $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. A fit is made for $t\bar{t}$ production processes in dilepton, lepton + jets, and lepton + τ final states, with the decays $t \rightarrow W^+ b$ and $t \rightarrow H^+ b$ followed by $H^+ \rightarrow \tau^+ \nu$, $c\bar{s}$, $t^* \bar{b}$, or $W^+ H^0$. Within the MSSM the search is sensitive to the region $\tan\beta < 1$ or > 30 in the mass range $m_{H^\pm} = 80\text{--}160 \text{ GeV}$. See Fig. 2 for the excluded region in a certain MSSM scenario.
- 38 ABDALLAH 04I search for $e^+ e^- \rightarrow H^+ H^-$ with H^\pm decaying to $\tau\nu$, $c\bar{s}$, or $W^* A^0$ in Type-I two-Higgs-doublet models.
- 39 ABBIENDI 03 give a limit $m_{H^\pm} > 1.28 \tan\beta \text{ GeV}$ (95% CL) in Type II two-doublet models.
- 40 ABZOV 02B search for a charged Higgs boson in top decays with $H^+ \rightarrow \tau^+ \nu$ at $E_{\text{cm}} = 1.8 \text{ TeV}$. For $m_{H^\pm} = 75 \text{ GeV}$, the region $\tan\beta > 32.0$ is excluded at 95% CL. The excluded mass region extends to over 140 GeV for $\tan\beta$ values above 100.
- 41 BORZUMATI 02 point out that the decay modes such as $b\bar{b} W$, $A^0 W$, and supersymmetric ones can have substantial branching fractions in the mass range explored at LEP II and Tevatron.
- 42 ABBIENDI 01Q give a limit $\tan\beta/m_{H^\pm} < 0.53 \text{ GeV}^{-1}$ (95% CL) in Type II two-doublet models.
- 43 BARATE 01E give a limit $\tan\beta/m_{H^\pm} < 0.40 \text{ GeV}^{-1}$ (90% CL) in Type II two-doublet models. An independent measurement of $B \rightarrow \tau\nu X$ gives $\tan\beta/m_{H^\pm} < 0.49 \text{ GeV}^{-1}$ (90% CL).
- 44 GAMBINO 01 use the world average data in the summer of 2001 $B(b \rightarrow s\gamma) = (3.23 \pm 0.42) \times 10^{-4}$. The limit applies for Type-II two-doublet models.
- 45 AFFOLDER 00I search for a charged Higgs boson in top decays with $H^+ \rightarrow \tau^+ \nu$ in $p\bar{p}$ collisions at $E_{\text{cm}} = 1.8 \text{ TeV}$. The excluded mass region extends to over 120 GeV for $\tan\beta$ values above 100 and $B(\tau\nu) = 1$. If $B(t \rightarrow bH^+) \gtrsim 0.6$, m_{H^\pm} up to 160 GeV is excluded. Updates ABE 97L.
- 46 ABBOTT 99E search for a charged Higgs boson in top decays in $p\bar{p}$ collisions at $E_{\text{cm}} = 1.8 \text{ TeV}$, by comparing the observed $t\bar{t}$ cross section (extracted from the data assuming the dominant decay $t \rightarrow bW^+$) with theoretical expectation. The search is sensitive to regions of the domains $\tan\beta \lesssim 1$, $50 < m_{H^\pm} (\text{GeV}) \lesssim 120$ and $\tan\beta \gtrsim 40$, $50 < m_{H^\pm} (\text{GeV}) \lesssim 160$. See Fig. 3 for the details of the excluded region.
- 47 ACKERSTAFF 99D measure the Michel parameters ρ , ξ , η , and $\xi\delta$ in leptonic τ decays from $Z \rightarrow \tau\tau$. Assuming $e\text{--}\mu$ universality, the limit $m_{H^\pm} > 0.97 \tan\beta \text{ GeV}$ (95% CL) is obtained for two-doublet models in which only one doublet couples to leptons.
- 48 ACCIARRI 97F give a limit $m_{H^\pm} > 2.6 \tan\beta \text{ GeV}$ (90% CL) from their limit on the exclusive $B \rightarrow \tau\nu X$ branching ratio.
- 49 AMMAR 97B measure the Michel parameter ρ from $\tau \rightarrow e\nu\nu$ decays and assumes e/μ universality to extract the Michel η parameter from $\tau \rightarrow \mu\nu\nu$ decays. The measurement is translated to a lower limit on m_{H^\pm} in a two-doublet model $m_{H^\pm} > 0.97 \tan\beta \text{ GeV}$ (90% CL).
- 50 COARASA 97 reanalyzed the constraint on the $(m_{H^\pm}, \tan\beta)$ plane derived from the inclusive $B \rightarrow \tau\nu X$ branching ratio in GROSSMAN 95B and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.
- 51 GUCHAIT 97 studies the constraints on m_{H^\pm} set by Tevatron data on $\ell\tau$ final states in $t\bar{t} \rightarrow (Wb)(Hb)$, $W \rightarrow \ell\nu$, $H \rightarrow \tau\nu$. See Fig. 2 for the excluded region.
- 52 MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large $B_c \rightarrow \tau\nu$ background to $B_u \rightarrow \tau\nu$ decays. Stronger limits are obtained.
- 53 STAHL 97 fit τ lifetime, leptonic branching ratios, and the Michel parameters and derive limit $m_{H^\pm} > 1.5 \tan\beta \text{ GeV}$ (90% CL) for a two-doublet model. See also STAHL 94.
- 54 ALAM 95 measure the inclusive $b \rightarrow s\gamma$ branching ratio at $\mathcal{T}(4S)$ and give $B(b \rightarrow s\gamma) < 4.2 \times 10^{-4}$ (95% CL), which translates to the limit $m_{H^\pm} > [244 + 63/(\tan\beta)^{1.3}] \text{ GeV}$ in the Type II two-doublet model. Light supersymmetric particles can invalidate this bound.
- 55 BUSKULIC 95 give a limit $m_{H^\pm} > 1.9 \tan\beta \text{ GeV}$ (90% CL) for Type-II models from $b \rightarrow \tau\nu X$ branching ratio, as proposed in GROSSMAN 94.

H^\pm (charged Higgs) mass limits for $m_{H^\pm} > m(\text{top})$

Limits obtained at the LHC are given in the $m_h^{\text{mod-}}$ benchmark scenario, see CARENA 13, and depend on the $\tan\beta$ values.

1 AABOUD 18Bw search for $\bar{t}bH^+$ associated production in 36.1 fb^{-1} of pp collisions at $E_{\text{cm}} = 13 \text{ TeV}$. See also their Fig. 9 for the excluded region in the hMSSM parameter space.

Gauge & Higgs Boson Particle Listings

Charged Higgs Bosons (H^\pm and $H^{\pm\pm}$), Searches for

$H^{\pm\pm}$ (doubly-charged Higgs boson) mass limits

This section covers searches for a doubly-charged Higgs boson with couplings to lepton pairs. Its weak isospin T_3 is thus restricted to two possibilities depending on lepton chiralities: $T_3(H^{\pm\pm}) = \pm 1$, with the coupling $g_{\ell\ell}$ to $\ell_L^- \ell_L^-$ and $\ell_R^+ \ell_R^+$ ("left-handed") and $T_3(H^{\pm\pm}) = 0$, with the coupling to $\ell_R^- \ell_R^-$ and $\ell_L^+ \ell_L^+$ ("right-handed"). These Higgs bosons appear in some left-right symmetric models based on the gauge group $SU(2)_L \times SU(2)_R \times U(1)$, the type-II seesaw model, and the Zee-Babu model. The two cases are listed separately in the following. Unless noted, one of the lepton flavor combinations is assumed to be dominant in the decay.

Limits for $H^{\pm\pm}$ with $T_3 = \pm 1$

- AABOUD 19K search for pair production of $H^{++}H^{--}$ followed by the decay $H^{\pm\pm} \rightarrow W^\pm W^\pm$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The search is interpreted in a doublet-triplet extension of the scalar sector with a vev of 0.1 GeV, leading to $B(H^{\pm\pm} \rightarrow W^\pm W^\pm) = 1$. See their Fig. 5 for limits on the cross section for $m_{H^{++}}$ between 200 and 700 GeV.
- See their Figs. 11(b) and 13 for limits with smaller branching ratios.
- AAD 15AG search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.
- AAD 15AP search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The limit assumes 100% branching ratio to the specified final state.
- CHATRCHYAN 12AU search for $H^{++}H^{--}$ production with 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 6 for limits including associated $H^{++}H^-$ production or assuming different scenarios.
- ABDALLAH 03 search for $H^{++}H^{--}$ pair production either followed by $H^{++} \rightarrow \tau^+\tau^+$, or decaying outside the detector.
- ABBIENDI 02c searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$ ($\ell, \ell' = e, \mu, \tau$). The limit holds for $\ell = \ell' = \tau$, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$.
- SIRUNYAN 19CQ search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \rightarrow W^\pm W^\pm \rightarrow qq\ell\nu$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 0.6 and 2 TeV.

- SIRUNYAN 18CC search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \rightarrow W^\pm W^\pm$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 200 and 1000 GeV.
- KANEMURA 15 examine the case where H^{++} decays preferentially to $W^{(*)}W^{(*)}$ and estimate that a lower mass limit of ~ 84 GeV can be derived from the same-sign dilepton data of AAD 15AG if H^{++} decays with 100% branching ratio to $W^{(*)}W^{(*)}$.
- KHACHATRYAN 15D search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \rightarrow W^\pm W^\pm$ in 19.4 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H^{++}}$ between 160 and 800 GeV.
- KANEMURA 14 examine the case where H^{++} decays preferentially to $W^{(*)}W^{(*)}$ and estimate that a lower mass limit of ~ 60 GeV can be derived from the same-sign dilepton data of AAD 12CQ.
- AAD 13Y search for $H^{++}H^{--}$ production in a generic search of events with three charged leptons in 4.6 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state.
- AAD 12AY search for $H^{++}H^{--}$ production with 1.6 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state.
- AAD 12CQ search for $H^{++}H^{--}$ production with 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.
- ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb^{-1} of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV.
- AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb^{-1} of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV.
- AALTONEN 08AA search for $H^{++}H^{--}$ production in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit assumes 100% branching ratio to the specified final state.
- ABAZOV 08V search for $H^{++}H^{--}$ production in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit is for $B(H \rightarrow \mu\mu) = 1$. The limit is updated in ABAZOV 12A.
- AKTAS 06A search for single $H^{\pm\pm}$ production in ep collisions at HERA. Assuming that H^{++} only couples to $e^+ \mu^+$ with $g_{e\mu} = 0.3$ (electromagnetic strength), a limit $m_{H^{++}} > 141$ GeV (95% CL) is derived. For the case where H^{++} couples to $e\tau$ only the limit is 112 GeV.
- ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\bar{p}$ collisions. The limit is valid for $g_{\ell\ell} < 10^{-8}$ so that the Higgs decays outside the detector.
- ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm} \rightarrow \mu^\pm \mu^\pm$. The limit is valid for $g_{\mu\mu} \gtrsim 10^{-7}$.
- ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \rightarrow e^\mp e^\mp H^{\pm\pm}$, and via t -channel exchange in $e^+e^- \rightarrow e^+e^-$. In the direct case, and assuming $B(H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm) = 1$, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} \leq 160$ GeV (see Fig. 6). In the second case, indirect limits on h_{ee} are set for $m_{H^{\pm\pm}} < 2$ TeV (see Fig. 8).
- GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\bar{M}}/G_F < 0.14$ (90% CL), where $G_{M\bar{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210$ GeV if the Yukawa couplings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.
- ASAKA 95 point out that H^{++} decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does not apply.
- ACTON 92M limit assumes $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.
- ACTON 92M from $\Delta\Gamma_Z < 40$ MeV.
- SWARTZ 90 assume $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$ (any flavor). The limits are valid for the Higgs-lepton coupling $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7} [m_{H^{\pm\pm}}/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

Gauge & Higgs Boson Particle Listings

Charged Higgs Bosons (H^\pm and $H^{\pm\pm}$), Searches for, New Heavy Bosons

- See their Figs. 12(b) and 14 for limits with smaller branching ratios.
- AAD 15AG search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.
- AAD 15AP search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at $E_{\text{cm}} = 8 \text{ TeV}$. The limit assumes 100% branching ratio to the specified final state.
- ABDALLAH 03 search for $H^{++}H^{--}$ pair production either followed by $H^{++} \rightarrow \tau^+ \tau^+$, or decaying outside the detector.
- ACHARD 03F search for $e^+e^- \rightarrow H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$. The limit holds for $\ell = \ell' = \tau$, and slightly different limits apply for other flavor combinations. The limit is valid for $g_{\ell\ell} \gtrsim 10^{-7}$.
- ABBIENDI 02c searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm (\ell, \ell' = e, \mu, \tau)$, the limit holds for $\ell = \ell' = \tau$, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$.
- AAD 12AY search for $H^{++}H^{--}$ production with 1.6 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. The limit assumes 100% branching ratio to the specified final state.
- AAD 12CQ search for $H^{++}H^{--}$ production with 4.7 fb^{-1} of pp collisions at $E_{\text{cm}} = 7 \text{ TeV}$. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.
- ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$.
- AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb^{-1} of $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$.
- ABAZOV 08v search for $H^{++}H^{--}$ production in $p\bar{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$. The limit is for $B(H \rightarrow \mu\mu) = 1$. The limit is updated in ABAZOV 12A.
- AKTAS 06A search for single $H^{\pm\pm}$ production in ep collisions at HERA. Assuming that H^{++} only couples to $e^+ \mu^+$ with $g_{e\mu} = 0.3$ (electromagnetic strength), a limit $m_{H^{++}} > 141 \text{ GeV}$ (95% CL) is derived. For the case where H^{++} couples to $e\tau$ only the limit is 112 GeV .
- ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\bar{p}$ collisions. The limit is valid for $g_{\ell\ell} < 10^{-8}$ so that the Higgs decays outside the detector.
- ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm} \rightarrow \mu^\pm \mu^\pm$. The limit is valid for $g_{\mu\mu} \gtrsim 10^{-7}$.
- ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \rightarrow e^\mp e^\mp H^{\pm\pm}$, and via t -channel exchange in $e^+e^- \rightarrow e^+e^-$. In the direct case, and assuming $B(H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm) = 1$, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} < 160 \text{ GeV}$ (see Fig. 6). In the second case, indirect limits on h_{ee} are set for $m_{H^{\pm\pm}} < 2 \text{ TeV}$ (see Fig. 8).
- GORDEEV 97 search for muonium-antimuonium conversion and find $G_{MM}/G_F < 0.14$ (90% CL), where G_{MM} is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210 \text{ GeV}$ if the Yukawa couplings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.
- ACTON 92M limit assumes $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.
- ACTON 92M from $\Delta\Gamma_Z < 40 \text{ MeV}$.
- SWARTZ 90 assume $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$ (any flavor). The limits are valid for the Higgs-lepton coupling $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7} [m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

New Heavy Bosons (W' , Z' , leptoquarks, etc.), Searches for

We list here various limits on charged and neutral heavy vector bosons (other than W 's and Z 's), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axiglons. The latest unpublished results are described in "W' Searches" and "Z' Searches" reviews. For recent searches on scalar bosons which could be identified as Higgs bosons, see the listings in the Higgs boson section.

[W'-Boson Searches](#)

MASS LIMITS FOR W' (HEAVY CHARGED VECTOR BOSON OTHER THAN W) IN HADRON COLLIDER EXPERIMENTS

Couplings of W' to quarks and leptons are taken to be identical with those of W . The following limits are obtained from $p\bar{p}$ or $pp \rightarrow W'X$ with W' decaying to the mode indicated in the comments. New decay channels (e.g., $W' \rightarrow WZ$) are assumed to

See key on page 999

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

be suppressed. The most recent preliminary results can be found in the “ W' -boson searches” review above.

- AABOUD 19B search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N , with N decaying to ℓj . See their Figs. 7 and 8 for excluded regions in $M_{W_R} - M_N$ plane.
- AABOUD 19E search for right-handed W' in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limit on $\sigma \cdot B$.
- AAD 19c search for W' with SM-like couplings in pp collisions at $\sqrt{s} = 13$ TeV. Bosonic decays and $W - W'$ interference are neglected. The limits on e and μ separately are 6.0 and 5.1 TeV respectively. See their Fig. 2 for limits on $\sigma \cdot B$.
- AAD 19d search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3400$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 3800$ GeV and $M_{W'} > 3500$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 9 for limits on $\sigma \cdot B$.
- SIRUNYAN 19AY limits shown for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. $W - W'$ interference and bosonic decays of W' are not included. See their Fig. 5 for limits on $\sigma \cdot B$. Limits in the context of a nonuniversal gauge interaction are shown in Fig. 7. Model independent limits on $\sigma B A \epsilon$ can be seen in Fig. 8.
- SIRUNYAN 19CP present a statistical combinations of searches for W' decaying to pairs of bosons or leptons in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. If we assume $M_{W'} = M_{Z'}$, the limit becomes $M_{W'} > 4500$ GeV for $g_V = 3$ and $M_{W'} > 5000$ GeV for $g_V = 1$. See their Figs. 2 and 3 for limits on $\sigma \cdot B$.
- SIRUNYAN 19I search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2800$ GeV if we assume $M_{W'} = M_{Z'}$.
- AABOUD 18AF give the limit above for right-handed W' using pp collisions at $\sqrt{s} = 13$ TeV. These limits also exclude W bosons with left-handed couplings with masses below 2.9 TeV, at the 95% confidence level. $W' \rightarrow \ell\nu_R$ is assumed to be forbidden. See their Fig.5 for limits on $\sigma \cdot B$ for both cases of left- and right-handed W' .
- AABOUD 18AI search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2670$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2930$ GeV and $M_{W'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 5 for limits on $\sigma \cdot B$.
- AABOUD 18AK search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2800$ GeV for $g_V = 1$.
- AABOUD 18AL search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2900$ GeV for $g_V = 1$.
- AABOUD 18BG limit is for W' with SM-like couplings using pp collisions at $\sqrt{s} = 13$ TeV. Bosonic decays of W' and $W - W'$ interference are neglected. See Fig. 2 for limits on $\sigma \cdot B$.
- AABOUD 18CH search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2260$ GeV for $g_V = 1$.
- AABOUD 18F search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3000$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{W'} > 3500$ GeV and $M_{W'} > 3100$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.5 for limits on $\sigma \cdot B$.
- AABOUD 18K limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. $W - W'$ interference and bosonic decays of W' are not included. See their Fig. 4 for limit on $\sigma \cdot B$.
- SIRUNYAN 18 limit is for right-handed W' using pp collisions at $\sqrt{s} = 13$ TeV. $W' \rightarrow \ell\nu_R$ decay is assumed to be forbidden. The limit becomes $M_{W'} > 3.4$ TeV if $M_{\nu_R} \ll M_{W'}$. See their Fig. 5 for exclusion limits on W' models having both left- and right-handed couplings.
- SIRUNYAN 18AX search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. See their Fig.6 for limits on $\sigma \cdot B$.
- SIRUNYAN 18AZ limit is derived for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. No interference with SM W process is considered. The bosonic decays are assumed to be negligible. See their Fig.6 for limits on $\sigma \cdot B$.

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Université user on 06 January 2021

- 19 SIRUNYAN 18BK search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3100$ GeV for $g_V = 1$.
- 20 SIRUNYAN 18Bo limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV.
- 21 SIRUNYAN 18CV search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N , with N decaying to ℓj . The quoted limit is for $M_N = M_{W_R}/2$. See their Fig. 6 for excluded regions in the $M_{W_R} - M_N$ plane.
- 22 SIRUNYAN 18DJ search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2270$ GeV for $g_V = 1$.
- 23 SIRUNYAN 18ED search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The limit above is for heavy-vector-triplet W' with $g_V = 3$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2900$ GeV and $M_{W'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively.
- 24 SIRUNYAN 18P give this limit for a heavy-vector-triplet W' with $g_V = 3$. If they assume $M_{Z'} = M_{W'}$, the limit increases to $M_{W'} > 3800$ GeV.
- 25 AABOUD 17AK search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit above is for a W' boson having axial-vector SM couplings and decaying to quarks with 75% branching fraction.
- 26 AABOUD 17AO search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a W' in the heavy-vector-triplet model with $g_V = 3$. See their Fig.4 for limits on $\sigma \cdot B$.
- 27 AABOUD 17B search for resonances decaying to HW ($H \rightarrow b\bar{b}, c\bar{c}; W \rightarrow \ell\nu$) in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 1750$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2310$ GeV and $M_{W'} > 1730$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.3 for limits on $\sigma \cdot B$.
- 28 KHACHATRYAN 17J search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into τ and hypothetical heavy neutrino N_τ , with N_τ decaying into τj . The quoted limit is for $M_{N_\tau} = M_{W_R}/2$. The limit becomes $M_{W_R} > 2350$ GeV (1630 GeV) for $M_{W_R}/M_{N_\tau} = 0.8$ (0.2). See their Fig. 4 for excluded regions in the $M_{W_R} - M_{N_\tau}$ plane.
- 29 KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
- 30 KHACHATRYAN 17Z limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. The bosonic decays of W' and the interference with SM W process are neglected.
- 31 SIRUNYAN 17A search for resonances decaying to WZ with $WZ \rightarrow \ell\nu q\bar{q}, q\bar{q}q\bar{q}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2000$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{W'} > 2400$ GeV and $M_{W'} > 2300$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.6 for limits on $\sigma \cdot B$.
- 32 SIRUNYAN 17AK search for resonances decaying to WZ or HW in pp collisions at $\sqrt{s} = 8$ and 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2300$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2400$ GeV for both $g_V = 3$ and $g_V = 1$. See their Fig.1 and 2 for limits on $\sigma \cdot B$.
- 33 SIRUNYAN 17H search for right-handed W' in pp collisions at $\sqrt{s} = 13$ TeV. W' is assumed to decay into τ and a heavy neutrino N , with N decaying to $\tau q\bar{q}$. The limit above assumes $M_N = M_{W'}/2$.
- 34 SIRUNYAN 17I limit is for a right-handed W' using pp collisions at $\sqrt{s} = 13$ TeV. The limit becomes $M_{W'} > 2400$ GeV for $M_{\nu R} \ll M_{W'}$.
- 35 SIRUNYAN 17R search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. Mass regions $M_{W'} < 2370$ GeV and $2870 < M_{W'} < 2970$ GeV are excluded for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the excluded mass regions are $1000 < M_{W'} < 2500$ GeV and $2760 < M_{W'} < 3300$ GeV for $g_V = 3$; $1000 < M_{W'} < 2430$ GeV and $2810 < M_{W'} < 3130$ GeV for $g_V = 1$. See their Fig.5 for limits on $\sigma \cdot B$.
- 36 AABOUD 16AE search for resonances decaying to VV ($V = W$ or Z) in pp collisions at $\sqrt{s} = 13$ TeV. Results from $\nu\nu q\bar{q}, \nu\ell q\bar{q}, \ell\ell q\bar{q}$ and qqq final states are combined. The quoted limit is for a heavy-vector-triplet W' with $g_V = 3$ and $M_{W'} = M_{Z'}$.
- 37 AABOUD 16V limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. The bosonic decays of W' and the interference with SM W process are neglected.
- 38 AAD 16R search for $W' \rightarrow WZ$ in pp collisions at $\sqrt{s} = 8$ TeV. $\ell\nu\ell'\ell', \ell\ell q\bar{q}, \ell\nu q\bar{q}$, and all hadronic channels are combined. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_{W'}/M_{W'})^2$.
- 39 AAD 16S search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a W' having SM-like couplings to quarks.
- 40 KHACHATRYAN 16AO limit is for a SM-like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit combines $t \rightarrow qq\bar{b}$ and $t \rightarrow \ell\nu b$ events.
- 41 KHACHATRYAN 16AP search for a resonance decaying to HW in pp collisions at $\sqrt{s} = 8$ TeV. Both H and W are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$.
- 42 KHACHATRYAN 16BD search for resonance decaying to HW in pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit is for heavy-vector-triplet (HVT) W' with $g_V = 3$. The HVT model $m_{W'} = m_{Z'} > 1.8$ TeV is also obtained by combining $W'/Z' \rightarrow WH/ZH \rightarrow \ell\nu b\bar{b}, qq\tau\tau, qq\bar{b}b$, and $qqqqqq$ channels.
- 43 KHACHATRYAN 16K search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
- 44 KHACHATRYAN 16L search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.
- 45 KHACHATRYAN 16O limit is for W' having universal couplings. Interferences with the SM amplitudes are assumed to be absent.
- 46 AAD 15AU search for W' decaying into the WZ final state with $W \rightarrow q\bar{q}'$, $Z \rightarrow \ell^+\ell^-$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_{W'}/M_{W'})^2$.
- 47 AAD 15AV limit is for a SM like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. $W' \rightarrow \ell\nu$ decay is assumed to be forbidden.
- 48 AAD 15AZ search for W' decaying into the WZ final state with $W \rightarrow \ell\nu$, $Z \rightarrow q\bar{q}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_{W'}/M_{W'})^2$.
- 49 AAD 15CP search for W' decaying into the WZ final state with $W \rightarrow q\bar{q}$, $Z \rightarrow q\bar{q}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_{W'}/M_{W'})^2$.
- 50 AAD 15R limit is for a SM like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. $W' \rightarrow \ell\nu$ decay is assumed to be forbidden.
- 51 AAD 15V search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.
- 52 KHACHATRYAN 15C search for W' decaying via WZ to fully leptonic final states using pp collisions at $\sqrt{s}=8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = M_{W'}/M_{Z'}$.
- 53 KHACHATRYAN 15T limit is for W' with SM-like coupling which interferes the SM W boson constructively using pp collisions at $\sqrt{s} = 8$ TeV. For W' without interference, the limit becomes > 3280 GeV.
- 54 KHACHATRYAN 14O search for right-handed W_R in pp collisions at $\sqrt{s} = 8$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N , with N decaying into ℓj . The quoted limit is for $M_{\nu eR} = M_{\nu \mu R} = M_{W_R}/2$. See their Fig. 3 and Fig. 5 for excluded regions in the $M_{W_R} - M_\nu$ plane.
- 55 AABOUD 19BB search for right handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and a boosted hypothetical heavy neutrino N , with N decaying to ℓ and a large radius jet $j = q\bar{q}$. See their Fig. 7 for excluded regions in $M_{W_R} - M_N$ plane.
- 56 SIRUNYAN 19V search for a new resonance decaying to a top quark and a heavy vector-like bottom partner B decaying to Hb (or a bottom quark and a heavy vector-like top partner T decaying to Ht) in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on $\sigma \cdot B$.
- 57 AABOUD 18AA search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 9 for the exclusion limit in $M_{W'} - \sigma B$ plane.
- 58 AABOUD 18AD search for resonances decaying to HX ($H \rightarrow b\bar{b}$, $X \rightarrow q\bar{q}'$) in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs. 3-5 for limits on $\sigma \cdot B$.
- 59 AABOUD 18CJ search for heavy-vector-triplet W' in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for model with $g_V = 3$ assuming $M_{W'} = M_{Z'}$. The limit becomes $M_{W'} > 5500$ GeV for model with $g_V = 1$.
- 60 KHACHATRYAN 17U search for resonances decaying to HW ($H \rightarrow b\bar{b}$; $W \rightarrow \ell\nu$) in pp collisions at $\sqrt{s} = 13$ TeV. The limit on the heavy-vector-triplet model is $M_{Z'} = M_{W'} > 2$ TeV for $g_V = 3$, in which constraints from the $Z' \rightarrow HZ$ ($H \rightarrow b\bar{b}$; $Z \rightarrow \ell^+\ell^-, \nu\bar{\nu}$) are combined. See their Fig.3 and Fig.4 for limits on $\sigma \cdot B$.
- 61 AAD 15BB search for W' decaying into WH with $W \rightarrow \ell\nu$, $H \rightarrow b\bar{b}$. See their Fig. 4 for the exclusion limits in the heavy vector triplet benchmark model parameter space.
- 62 AALTONEN 15C limit is for a SM-like right-handed W' assuming $W' \rightarrow \ell\nu$ decays are forbidden, using $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV. See their Fig. 3 for limit on $g_{W'}/g_W$.
- 63 KHACHATRYAN 15V search new resonance decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.
- 64 AAD 14AT search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 3a for the exclusion limit in $m_{W'} - \sigma B$ plane.
- 65 AAD 14S search for W' decaying into the WZ final state with $W \rightarrow \ell\nu$, $Z \rightarrow \ell\ell$ using pp collisions at $\sqrt{s}=8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_{W'}/M_{W'})^2$.
- 66 KHACHATRYAN 14 search for W' decaying into WZ final state with $W \rightarrow q\bar{q}$, $Z \rightarrow q\bar{q}$ using pp collisions at $\sqrt{s}=8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_{W'}/M_{W'})^2$.
- 67 KHACHATRYAN 14A search for W' decaying into the WZ final state with $W \rightarrow \ell\nu$, $Z \rightarrow q\bar{q}$, or $W \rightarrow q\bar{q}$, $Z \rightarrow \ell\ell$. pp collisions data at $\sqrt{s}=8$ TeV are used for the search. See their Fig. 13 for the exclusion limit on the number of events in the mass-width plane.
- 68 AAD 13AO search for W' decaying into the WZ final state with $W \rightarrow \ell\nu$, $Z \rightarrow 2j$ using pp collisions at $\sqrt{s}=7$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_{W'}/M_{W'})^2$.
- 69 CHATRYAN 13AJ search for resonances decaying to WZ pair, using the hadronic decay modes of W and Z , in pp collisions at $\sqrt{s}=7$ TeV. See their Fig. 7 for the limit on the cross section.
- 70 CHATRYAN 13AQ limit is for W' with SM-like coupling which interferes with the SM W boson using pp collisions at $\sqrt{s}=7$ TeV.
- 71 CHATRYAN 13E limit is for W' with SM-like coupling which interferes with the SM W boson using pp collisions at $\sqrt{s}=7$ TeV. For W' with right-handed coupling, the bound becomes >1850 GeV (>1910 GeV) if W' decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings are present, the limit becomes >1640 GeV.
- 72 CHATRYAN 13U search for W' decaying to the WZ final state, with W decaying into jets, in pp collisions at $\sqrt{s}=7$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_{W'}/M_{W'})^2$.
- 73 The AAD 12AV quoted limit is for a SM-like right-handed W' using pp collisions at $\sqrt{s}=7$ TeV. $W' \rightarrow \ell\nu$ decay is assumed to be forbidden.
- 74 AAD 12BB use pp collisions data at $\sqrt{s}=7$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_{W'}/M_{W'})^2$.
- 75 AAD 12CK search for $pp \rightarrow tW'$, $W' \rightarrow \bar{t}q$ events in pp collisions. See their Fig. 5 for the limit on $\sigma \cdot B$.
- 76 AAD 12CR use pp collisions at $\sqrt{s}=7$ TeV.

See key on page 999

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

- 77 AAD 12M search for right-handed W_R in pp collisions at $\sqrt{s} = 7$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N , with N decaying into ℓjj . See their Fig. 4 for the limit in the $m_N - m_{W_R}$ plane.
- 78 AALTONEN 12N search for $p\bar{p} \rightarrow t W', W' \rightarrow \bar{t} d$ events in $p\bar{p}$ collisions. See their Fig. 3 for the limit on $\sigma \cdot B$.
- 79 CHATRCHYAN 12AR search for $pp \rightarrow t W', W' \rightarrow \bar{t} d$ events in pp collisions. See their Fig. 2 for the limit on $\sigma \cdot B$.
- 80 CHATRCHYAN 12BG search for right-handed W_R in pp collisions $\sqrt{s} = 7$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N , with N decaying into ℓjj . See their Fig. 3 for the limit in the $m_N - m_{W_R}$ plane.
- 81 ABAZOV 11H use data from $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV. The quoted limit is obtained assuming $W' W Z$ coupling strength is the same as the ordinary $W W Z$ coupling strength in the Standard Model.
- 82 ABAZOV 11L limit is for W' with SM-like coupling which interferes with the SM W boson, using $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV. For W' with right-handed coupling, the bound becomes >885 GeV (>890 GeV) if W' decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings present, the limit becomes >916 GeV.
- 83 AALTONEN 10N use $p\bar{p}$ collision data at $\sqrt{s}=1.96$ TeV. The quoted limit assumes $g_{W' W Z} / g_{W W Z} = (M_{W'} / M_W)^2$. See their Fig. 4 for limits in mass-coupling plane.
- 84 AALTONEN 09AC search for new particle decaying to dijets using $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV.
- 85 The ACOSTA 03B quoted limit is for $M_{W'} \gg M_{\nu_R}$, using $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV. For $M_{W'} < M_{\nu_R}$, $M_{W'}$ between 225 and 566 GeV is excluded.
- 86 The quoted limit is obtained assuming $W' W Z$ coupling strength is the same as the ordinary $W W Z$ coupling strength in the Standard Model, using $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV. See their Fig. 2 for the limits on the production cross sections as a function of the W' width.
- 87 AFFOLDER 01i combine a new bound on $W' \rightarrow e \nu$ of 754 GeV, using $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV, with the bound of ABE 00 on $W' \rightarrow \mu \nu$ to obtain quoted bound.
- 88 ABE 97G search for new particle decaying to dijets using $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV.
- 89 For bounds on W_R with nonzero right-handed mass, see Fig. 5 from ABACHI 96c.
- 90 ABACHI 95E assume that the decay $W' \rightarrow W Z$ is suppressed and that the neutrino from W' decay is stable and has a mass significantly less $m_{W'}$.
- 91 RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.

W_R (Right-Handed W Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89b, and COLANGELO 91. $g_R = g_L$ assumed. [Limits in the section MASS LIMITS for W' below are also valid for W_R if $m_{\nu_R} \ll m_{W_R}$.] Some limits assume manifest left-right symmetry, i.e., the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 89b. Limits on the $W_L - W_R$ mixing angle ζ are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

1 The quoted limit is for manifest left-right symmetric model.

2 CZAKON 99 perform a simultaneous fit to charged and neutral sectors.

- 3 PRIEELS 14 limit is from $\mu^+ \rightarrow e^+ \nu \bar{\nu}$ decay parameter ξ'' , which is determined by the positron polarization measurement.
- 4 WAUTERS 10 limit is from a measurement of the asymmetry parameter of polarized ^{60}Co β decays. The listed limit assumes no mixing.
- 5 ZHANG 08 limit uses a lattice QCD calculation of the relevant hadronic matrix elements, while BEALL 82 limit used the vacuum saturation approximation.
- 6 MELCONIAN 07 measure the neutrino angular asymmetry in β^+ -decays of polarized ^{37}K , stored in a magneto-optical trap. Result is consistent with SM prediction and does not constrain the $W_L - W_R$ mixing angle appreciably.
- 7 SCHUMANN 07 limit is from measurements of the asymmetry $\langle \bar{\nu}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing is assumed.
- 8 CYBURT 05 limit follows by requiring that three light ν_R 's decouple when $T_{dec} > 140$ MeV. For different T_{dec} , the bound becomes $M_{W_R} > 3.3 \text{ TeV} (T_{dec} / 140 \text{ MeV})^{3/4}$.
- 9 THOMAS 01 limit is from measurement of β^+ polarization in decay of polarized ^{12}N . The listed limit assumes no mixing.
- 10 ACKERSTAFF 99D limit is from τ decay parameters. Limit increase to 145 GeV for zero mixing.
- 11 BARENBOIM 98 assumes minimal left-right model with Higgs of $\text{SU}(2)_R$ in $\text{SU}(2)_L$ doublet. For Higgs in $\text{SU}(2)_L$ triplet, $m_{W_R} > 1100$ GeV. Bound calculated from effect of corresponding Z_{LR} on electroweak data through $Z-Z_{LR}$ mixing.
- 12 The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from $K_L - K_S$ mass difference.
- 13 STAHL 97 limit is from fit to τ -decay parameters.
- 14 ALLET 96 measured polarization-asymmetry correlation in ^{12}N β^+ decay. The listed limit assumes zero $L-R$ mixing.
- 15 KUZNETSOV 95 limit is from measurements of the asymmetry $\langle \bar{\nu}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94b.
- 16 KUZNETSOV 94b limit is from measurements of the asymmetry $\langle \bar{\nu}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed.
- 17 BHATTACHARYYA 93 uses $Z-Z'$ mixing limit from LEP '90 data, assuming a specific Higgs sector of $\text{SU}(2)_L \times \text{SU}(2)_R \times \text{U}(1)$ gauge model. The limit is for $m_t = 200$ GeV and slightly improves for smaller m_t .
- 18 SEVERIJNS 93 measured polarization-asymmetry correlation in ^{107}In β^+ decay. The listed limit assumes zero $L-R$ mixing. Value quoted here is from SEVERIJNS 94 erratum.
- 19 IMAZATO 92 measure positron asymmetry in $K^+ \rightarrow \mu^+ \nu_\mu$ decay and obtain $\xi_{\mu^+} > 0.990$ (90% CL). If W_R couples to $u\bar{u}$ with full weak strength ($V_{us}^R = 1$), the result corresponds to $m_{W_R} > 653$ GeV. See their Fig. 4 for m_{W_R} limits for general $|V_{us}^R|^2 = 1 - |V_{ud}^R|^2$.
- 20 POLAK 92b limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming $\zeta=0$. Supersedes POLAK 91.
- 21 AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.
- 22 COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.
- 23 POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming $\zeta=0$. Superseded by POLAK 92b.
- 24 BARBIERI 89b limit holds for $m_{\nu_R} \leq 10$ MeV.
- 25 LANGACKER 89b limit is for any ν_R mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.
- 26 BALKE 88 limit is for $m_{\nu_{eR}} = 0$ and $m_{\nu_{\mu R}} \leq 50$ MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.
- 27 JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point e^+ spectrum in the decay of the highly polarized μ^+ .
- 28 STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay e^+ spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.
- 29 BERGSMA 83 set limit $m_{W_2} / m_{W_1} > 1.9$ at CL = 90%.
- 30 CARR 83 is TRIUMF experiment with a highly polarized μ^+ beam. Looked for deviation from $V-A$ at the high momentum end of the decay e^+ energy spectrum. Limit from previous world-average muon polarization parameter is $m_{W_R} > 240$ GeV. Assumes a light right-handed neutrino.
- 31 BEALL 82 limit is obtained assuming that W_R contribution to $K_L^0 - K_S^0$ mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

Limit on $W_L - W_R$ Mixing Angle ζ

Lighter mass eigenstate $W_1 = W_L \cos \zeta - W_R \sin \zeta$. Light ν_R assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

- ¹ ACKERSTAFF 99D limit is from τ decay parameters.
² CZAKON 99 perform a simultaneous fit to charged and neutral sectors.
³ The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from $K_L - K_S$ mass difference.
⁴ MISHRA 92 limit is from the absence of extra large- x , large- y $\bar{\nu}_\mu N \rightarrow \bar{\nu}_\mu X$ events at Tevatron, assuming left-handed ν and right-handed $\bar{\nu}$ in the neutrino beam. The result gives $\zeta^2(1-2m_{W_1}^2/m_{W_2}^2) < 0.0015$. The limit is independent of ν_{R^1} mass.
⁵ AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed.
⁶ BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.
⁷ First JODIDIO 86 result assumes $m_{W_R} = \infty$, second is for unconstrained m_{W_R} .

See the related review(s):

Z'-Boson Searches

MASS LIMITS for Z' (Heavy Neutral Vector Boson Other Than Z)

Limits for Z'_{SM}

Z'_{SM} is assumed to have couplings with quarks and leptons which are identical to those of Z, and decays only to known fermions. The most recent preliminary results can be found in the "Z'-boson searches" review above.

- ¹ AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
² AABOUD 18AB search for resonances decaying to $b\bar{b}$ in pp collisions at $\sqrt{s} = 13$ TeV.
³ AABOUD 18G search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
⁴ SIRUNYAN 18BB search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig.5 for limits on the Z' coupling strengths with light quarks.
⁵ SIRUNYAN 18B0 search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
⁶ AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
⁷ KHACHATRYAN 17H search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
⁸ KHACHATRYAN 17T search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 8, 13$ TeV.

- ⁹ KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
¹⁰ AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
¹¹ KHACHATRYAN 15AE search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 8$ TeV.
¹² KHACHATRYAN 15V search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.
¹³ AAD 14V search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 8$ TeV.
¹⁴ BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \rightarrow Z')B(Z' \rightarrow W^+W^-)$ to constrain the Z - Z' mixing parameter ξ . See their Fig. 11 for limits in $M_{Z'} - \xi$ plane.
¹⁵ AABOUD 16AA search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
¹⁶ AAD 15AM search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 8$ TeV.
¹⁷ AAD 13S search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 7$ TeV.
¹⁸ CHATRCHYAN 13A use pp collisions at $\sqrt{s}=7$ TeV.
¹⁹ CHATRCHYAN 13AF search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV and 8 TeV.
²⁰ AAD 12CC search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV.
²¹ CHATRCHYAN 120 search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 7$ TeV.
²² AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
²³ ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
²⁴ The quoted limit assumes $g_{WWZ'}/g_{WWZ} = (M_W/M_{Z'})^2$. See their Fig. 4 for limits in mass-coupling plane.
²⁵ AALTONEN 09AC search for new particle decaying to dijets.
²⁶ ERLER 09 give 95% CL limit on the Z - Z' mixing $-0.0026 < \theta < 0.0006$.
²⁷ ABDALLAH 06c use data $\sqrt{s} = 130-207$ GeV.
²⁸ ACOSTA 05R search for resonances decaying to tau lepton pairs in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
²⁹ ABBIENDI 04c give 95% CL limit on Z - Z' mixing $-0.00422 < \theta < 0.00091$. $\sqrt{s} = 91$ to 207 GeV.
³⁰ ABAZOV 01B search for resonances in $p\bar{p} \rightarrow e^+e^-$ at $\sqrt{s}=1.8$ TeV. They find $\sigma \cdot B(Z' \rightarrow ee) < 0.06$ pb for $M_{Z'} > 500$ GeV.
³¹ CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.
³² ABREU 00s uses LEP data at $\sqrt{s}=90$ to 189 GeV.
³³ BARATE 00i search for deviations in cross section and asymmetries in $e^+e^- \rightarrow$ fermions at $\sqrt{s}=90$ to 183 GeV. Assume $\theta=0$. Bounds in the mass-mixing plane are shown in their Figure 18.
³⁴ ERLER 99 give 90%CL limit on the Z - Z' mixing $-0.0041 < \theta < 0.0003$. $\rho_0=1$ is assumed.
³⁵ ABE 97s find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $M_{Z'} > 600$ GeV at $\sqrt{s}=1.8$ TeV.
³⁶ VILAIN 94B assume $m_t = 150$ GeV.
³⁷ ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes $B(Z' \rightarrow q\bar{q})=0.7$. See their Fig.5 for limits in the $m_{Z'} - B(q\bar{q})$ plane.
³⁸ RIZZO 93 analyses CDF limit on possible two-jet resonances.
³⁹ ABE 90f use data for $R, R_{\ell\ell}$, and $A_{\ell\ell}$. They fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

Limits for Z'_{LR}

Z'_{LR} is the extra neutral boson in left-right symmetric models. $g_L = g_R$ is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by specific left-right symmetric models (see the Note on the W'). Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. Direct search bounds assume decays to Standard Model fermions only, unless noted.

- 1 DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0012 < \theta < 0.0004$.
- 2 ABE 97s find $\sigma(Z') \times B(e^+ e^-, \mu^+ \mu^-) < 40 \text{ fb}$ for $m_{Z'} > 600 \text{ GeV}$ at $\sqrt{s} = 1.8 \text{ TeV}$.
- 3 BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \rightarrow Z') \cdot B(Z' \rightarrow W^+ W^-)$ to constrain the Z-Z' mixing parameter ξ . See their Fig. 10 for limits in $M_{Z'} - \xi$ plane.
- 4 ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0013 < \theta < 0.0006$.
- 5 ABDALLAH 06c give 95% CL limit $|\theta| < 0.0028$. See their Fig. 14 for limit contours in the mass-mixing plane.
- 6 ABBIENDI 04g give 95% CL limit on Z-Z' mixing $-0.00098 < \theta < 0.00190$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.
- 7 CHEUNG 01b limit is derived from bounds on contact interactions in a global electroweak analysis.
- 8 ABREU 00s give 95% CL limit on Z-Z' mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s} = 90$ to 189 GeV.
- 9 BARATE 00i search for deviations in cross section and asymmetries in $e^+ e^- \rightarrow$ fermions at $\sqrt{s} = 90$ to 183 GeV. Assume $\theta = 0$. Bounds in the mass-mixing plane are shown in their Figure 18.
- 10 CHAY 00 also find $-0.0003 < \theta < 0.0019$. For g_R free, $m_{Z'} > 430 \text{ GeV}$.
- 11 ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of $Q_{W'}(Cs)$ is due to the exchange of Z' . The data are better described in a certain class of the Z' models including Z'_{LR} and Z'_χ .
- 12 CASALBUONI 99 discuss the discrepancy between the observed and predicted values of $Q_{W'}(Cs)$. It is shown that the data are better described in a class of models including the Z'_{LR} model.
- 13 CZAKON 99 perform a simultaneous fit to charged and neutral sectors. Assumes manifest left-right symmetric model. Finds $|\theta| < 0.0042$.
- 14 ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0009 < \theta < 0.0017$.
- 15 ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in E_6 .
- 16 BARENBOIM 98 also gives 68% CL limits on the Z-Z' mixing $-0.0005 < \theta < 0.0033$. Assumes Higgs sector of minimal left-right model.
- 17 CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.
- 18 VILAIN 94b assume $m_t = 150 \text{ GeV}$ and $\theta = 0$. See Fig. 2 for limit contours in the mass-mixing plane.
- 19 RIZZO 93 analyses CDF limit on possible two-jet resonances.
- 20 GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1 \text{ MeV}$. A specific Higgs sector is assumed. See also GRIFOLS 90d, RIZZO 91.
- 21 BARBIERI 89b limit holds for $m_{\nu_R} \lesssim 10 \text{ MeV}$. Bounds depend on assumed supernova core temperature.

Limits for Z'_χ

Z'_χ is the extra neutral boson in $\text{SO}(10) \rightarrow \text{SU}(5) \times \text{U}(1)_\chi$. $g_\chi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 6 AAD 12cc search for resonances decaying to $e^+ e^-, \mu^+ \mu^-$ in pp collisions at $\sqrt{s} = 7 \text{ TeV}$.
- 7 AALTONEN 11i search for resonances decaying to $\mu^+ \mu^-$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$.
- 8 ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to $e^+ e^-$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$.
- 9 DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0011 < \theta < 0.0007$.
- 10 AALTONEN 09v search for resonances decaying to $\mu^+ \mu^-$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$.
- 11 ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0016 < \theta < 0.0006$.
- 12 ABDALLAH 06c give 95% CL limit $|\theta| < 0.0031$. See their Fig. 14 for limit contours in the mass-mixing plane.
- 13 ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$.
- 14 ABBIENDI 04g give 95% CL limit on Z-Z' mixing $-0.00099 < \theta < 0.00194$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.
- 15 BARGER 03b limit is from the nucleosynthesis bound on the effective number of light neutrino $\delta N_\nu < 1$. The quark-hadron transition temperature $T_C = 150 \text{ MeV}$ is assumed. The limit with $T_C = 400 \text{ MeV}$ is $>4300 \text{ GeV}$.
- 16 CHEUNG 01b limit is derived from bounds on contact interactions in a global electroweak analysis.
- 17 ABREU 00s give 95% CL limit on Z-Z' mixing $|\theta| < 0.0017$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s} = 90$ to 189 GeV.
- 18 BARATE 00i search for deviations in cross section and asymmetries in $e^+ e^- \rightarrow$ fermions at $\sqrt{s} = 90$ to 183 GeV. Assume $\theta = 0$. Bounds in the mass-mixing plane are shown in their Figure 18.
- 19 CHO 00 use various electroweak data to constrain Z' models assuming $m_H = 100 \text{ GeV}$. See Fig. 3 for limits in the mass-mixing plane.
- 20 ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of $Q_{W'}(Cs)$ is due to the exchange of Z' . The data are better described in a certain class of the Z' models including Z'_{LR} and Z'_χ .
- 21 ROSNER 00 discusses the possibility that a discrepancy between the observed and predicted values of $Q_{W'}(Cs)$ is due to the exchange of Z' . The data are better described in a certain class of the Z' models including Z'_χ .
- 22 ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0020 < \theta < 0.0015$.
- 23 ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in E_6 .
- 24 CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.
- 25 ABE 97s find $\sigma(Z') \times B(e^+ e^-, \mu^+ \mu^-) < 40 \text{ fb}$ for $m_{Z'} > 600 \text{ GeV}$ at $\sqrt{s} = 1.8 \text{ TeV}$.
- 26 Z-Z' mixing is assumed to be zero. $\sqrt{s} = 57.77 \text{ GeV}$.
- 27 VILAIN 94b assume $m_t = 150 \text{ GeV}$ and $\theta = 0$. See Fig. 2 for limit contours in the mass-mixing plane.
- 28 FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos $\Delta N_\nu < 0.5$ and is valid for $m_{\nu_R} < 1 \text{ MeV}$.
- 29 ABE 90F use data for $R, R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24 \text{ GeV}$ and $m_Z = 91.13 \pm 0.03 \text{ GeV}$.
- 30 Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that ν_R is light ($\lesssim 1 \text{ MeV}$).
- 31 GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1 \text{ MeV}$. See also GRIFOLS 90d, RIZZO 91.

Limits for Z'_ψ

Z'_ψ is the extra neutral boson in $E_6 \rightarrow \text{SO}(10) \times \text{U}(1)_\psi$. $g_\psi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
- SIRUNYAN 18BB search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
- AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
- KHACHATRYAN 17T search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 8, 13$ TeV.
- CHATRCHYAN 12c search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 7$ TeV.
- BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \rightarrow Z')B(Z' \rightarrow W^+W^-)$ to constrain the Z - Z' mixing parameter ξ . See their Fig. 10 for limits in $M_{Z'}-\xi$ plane.
- AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
- KHACHATRYAN 15AE search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 8$ TeV.
- AAD 14V search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 8$ TeV.
- CHATRCHYAN 13AF search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV and 8 TeV.
- AAD 12cc search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV.
- CHATRCHYAN 12M search for resonances decaying to e^+e^- or $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV.
- AALTONEN 11i search for resonances decaying to $\mu^+\mu^-$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
- ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
- DEL-AGUILA 10 give 95% CL limit on the Z - Z' mixing $-0.0019 < \theta < 0.0007$.
- AALTONEN 09v search for resonances decaying to $\mu^+\mu^-$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
- ERLER 09 give 95% CL limit on the Z - Z' mixing $-0.0018 < \theta < 0.0009$.
- ABDALLAH 06c give 95% CL limit $|\theta| < 0.0027$. See their Fig. 14 for limit contours in the mass-mixing plane.
- ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
- ABBIENDI 04G give 95% CL limit on Z - Z' mixing $-0.00129 < \theta < 0.00258$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.
- BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino $\delta N_\nu < 1$. The quark-hadron transition temperature $T_C = 150$ MeV is assumed. The limit with $T_C = 400$ MeV is > 1100 GeV.
- ABREU 00s give 95% CL limit on Z - Z' mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s} = 90$ to 189 GeV.
- BARATE 00i search for deviations in cross section and asymmetries in $e^+e^- \rightarrow$ fermions at $\sqrt{s} = 90$ to 183 GeV. Assume $\theta = 0$. Bounds in the mass-mixing plane are shown in their Figure 18.
- CHO 00 use various electroweak data to constrain Z' models assuming $m_H = 100$ GeV. See Fig. 3 for limits in the mass-mixing plane.
- ERLER 99 give 90% CL limit on the Z - Z' mixing $-0.0013 < \theta < 0.0024$.
- CONRAD 98 limit is from measurements at CCFR, assuming no Z - Z' mixing.
- ABE 97s find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s} = 1.8$ TeV.
- VILAIN 94B assume $m_t = 150$ GeV and $\theta = 0$. See Fig. 2 for limit contours in the mass-mixing plane.
- ABE 90f use data for $R, R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90f fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.
- Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that ν_R is light ($\lesssim 1$ MeV).
- GRIFOLS 90D limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also RIZZO 91.

Limits for Z_η

Z_η is the extra neutral boson in E_6 models, corresponding to $Q_\eta = \sqrt{3/8} Q_X - \sqrt{5/8} Q_\psi$. $g_\eta = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
- BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \rightarrow Z')B(Z' \rightarrow W^+W^-)$ to constrain the Z - Z' mixing parameter ξ . See their Fig. 9 for limits in $M_{Z'}-\xi$ plane.
- AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
- AAD 12cc search for resonances decaying to $e^+e^-, \mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV.
- AALTONEN 11i search for resonances decaying to $\mu^+\mu^-$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
- ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
- DEL-AGUILA 10 give 95% CL limit on the Z - Z' mixing $-0.0023 < \theta < 0.0027$.
- AALTONEN 09v search for resonances decaying to $\mu^+\mu^-$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
- ERLER 09 give 95% CL limit on the Z - Z' mixing $-0.0047 < \theta < 0.0021$.
- ABDALLAH 06c give 95% CL limit $|\theta| < 0.0092$. See their Fig. 14 for limit contours in the mass-mixing plane.
- ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
- ABBIENDI 04G give 95% CL limit on Z - Z' mixing $-0.00447 < \theta < 0.00331$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.
- BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino $\delta N_\nu < 1$. The quark-hadron transition temperature $T_C = 150$ MeV is assumed. The limit with $T_C = 400$ MeV is > 3300 GeV.
- ABREU 00s give 95% CL limit on Z - Z' mixing $|\theta| < 0.0024$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s} = 90$ to 189 GeV.
- BARATE 00i search for deviations in cross section and asymmetries in $e^+e^- \rightarrow$ fermions at $\sqrt{s} = 90$ to 183 GeV. Assume $\theta = 0$. Bounds in the mass-mixing plane are shown in their Figure 18.
- CHO 00 use various electroweak data to constrain Z' models assuming $m_H = 100$ GeV. See Fig. 3 for limits in the mass-mixing plane.
- ERLER 99 give 90% CL limit on the Z - Z' mixing $-0.0062 < \theta < 0.0011$.
- CONRAD 98 limit is from measurements at CCFR, assuming no Z - Z' mixing.
- ABE 97s find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s} = 1.8$ TeV.
- VILAIN 94B assume $m_t = 150$ GeV and $\theta = 0$. See Fig. 2 for limit contours in the mass-mixing plane.
- ABE 90f use data for $R, R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90f fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.
- These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) constrains Z' masses if ν_R is light ($\lesssim 1$ MeV).
- GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.

¹ AABOUD 19As search for a resonance decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. Limits are also set on Z' masses in simplified Dark Matter models.

² AAD 19D search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2900$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 3800$ GeV and $M_{Z'} > 3500$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 9 for limits on $\sigma \cdot B$.

³ SIRUNYAN 19AA search for a resonance decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a leptophobic top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$.

⁴ SIRUNYAN 19CP present a statistical combinations of searches for Z' decaying to pairs of bosons or leptons in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. If we assume $M_{Z'} = M_{W'}$, the limit becomes $M_{Z'} > 4500$ GeV for $g_V = 3$ and $M_{Z'} > 5000$ GeV for $g_V = 1$. See their Figs. 2 and 3 for limits on $\sigma \cdot B$.

⁵ SIRUNYAN 19I search for resonances decaying to ZW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2800$ GeV if we assume $M_{Z'} = M_{W'}$.

⁶ AABOUD 18AB search for resonances decaying to $b\bar{b}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' with SM-like couplings to quarks. See their Fig. 6 for limits on $\sigma \cdot B$.

⁷ AABOUD 18AI search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2650$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{Z'} > 2930$ GeV and $M_{Z'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 5 for limits on $\sigma \cdot B$.

⁸ AABOUD 18AK search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2750$ GeV for $g_V = 1$.

⁹ AABOUD 18B search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 1$. See their Fig.11 for limits on $\sigma \cdot B$.

¹⁰ AABOUD 18BI search for a resonance decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a top-color assisted TC Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. The limits for wider resonances are available. See their Fig. 14 for limits on $\sigma \cdot B$.

¹¹ AABOUD 18F search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 3500$ GeV and $M_{Z'} > 3100$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.5 for limits on $\sigma \cdot B$.

¹² SIRUNYAN 18ED search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit above is for heavy-vector-triplet Z' with $g_V = 3$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2900$ GeV and $M_{Z'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively.

¹³ SIRUNYAN 18P give this limit for a heavy-vector-triplet Z' with $g_V = 3$. If they assume $M_{Z'} = M_{W'}$, the limit increases to $M_{Z'} > 3800$ GeV.

¹⁴ AABOUD 17AK search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' boson having axial-vector coupling strength with quarks $g_q = 0.2$. The limit is 2100 GeV if $g_q = 0.1$.

¹⁵ AABOUD 17AO search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a Z' in the heavy-vector-triplet model with $g_V = 3$. See their Fig.4 for limits on $\sigma \cdot B$.

¹⁶ SIRUNYAN 17AK search for resonances decaying to WW or HZ in pp collisions at $\sqrt{s} = 8$ and 13 TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2400$ GeV for both $g_V = 3$ and $g_V = 1$. See their Fig.1 and 2 for limits on $\sigma \cdot B$.

¹⁷ SIRUNYAN 17Q search for a resonance decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a resonance with relative width $\Gamma_{Z'}/M_{Z'} = 0.01$. Limits for wider resonances are available. See their Fig.6 for limits on $\sigma \cdot B$.

¹⁸ SIRUNYAN 17R search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. Mass regions $M_{Z'} < 1150$ GeV and 1250 GeV $< M_{Z'} < 1670$ GeV are excluded for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the excluded mass regions are $1000 < M_{Z'} < 2500$ GeV and $2760 < M_{Z'} < 3300$ GeV for $g_V = 3$; $1000 < M_{Z'} < 2430$ GeV and $2810 < M_{Z'} < 3130$ GeV for $g_V = 1$. See their Fig.5 for limits on $\sigma \cdot B$.

¹⁹ AABOUD 19AJ search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\bar{q}$ and produced in association with a high p_T photon. For a leptophobic axial-vector Z' in the mass region 250 GeV $< M_{Z'} < 950$ GeV, the Z' coupling with quarks g_q is constrained below 0.18. See their Fig.2 for limits in $M_{Z'} - g_q$ plane.

²⁰ AABOUD 19D search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\bar{q}$ and produced in association with a high- p_T photon or jet. For a leptophobic axial-vector Z' in the mass region 100 GeV $< M_{Z'} < 220$ GeV, the Z' coupling with quarks g_q is constrained below 0.23. See their Fig. 6 for limits in $M_{Z'} - g_q$ plane.

²¹ AABOUD 19V search for Dark Matter simplified Z' decaying invisibly or decaying to fermion pair in pp collisions at $\sqrt{s} = 13$ TeV.

²² AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 4 for limits in the heavy vector triplet model couplings.

²³ LONG 19 uses the weak charge data of Cesium and proton to constrain mass of Z' in the 3–3.1 models.

²⁴ PANDEY 19 obtain limits on Z' induced neutrino non-standard interaction (NSI) parameter ϵ from LHC and IceCube data. See their Fig.2 for limits in $M_{Z'} - \epsilon$ plane, where $\epsilon = g_q g_V v^2 / (2 M_{Z'}^2)$.

²⁵ SIRUNYAN 19AL search for a new resonance decaying to a top quark and a heavy vector-like top partner in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on Z' production cross section.

²⁶ SIRUNYAN 19AN search for a Dark Matter (DM) simplified model Z' decaying to H DM in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 7 for limits on the signal strength modifiers.

²⁷ SIRUNYAN 19CB search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\bar{q}$. For a leptophobic Z' in the mass region 50–300 GeV, the Z' coupling with quarks g'_q is constrained below 0.2. See their Figs. 4 and 5 for limits on g'_q in the mass range $50 < M_{Z'} < 450$ GeV.

²⁸ SIRUNYAN 19CD search in pp collisions at $\sqrt{s} = 13$ TeV for a leptophobic Z' produced in association of high p_T ISR photon and decaying to $q\bar{q}$. See their Fig. 2 for limits on the Z' coupling strength g'_q to $q\bar{q}$ in the mass range between 10 and 125 GeV.

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

- 29 SIRUNYAN 19D search for a narrow neutral vector resonance decaying to $H\gamma$. See their Fig. 3 for exclusion limit in $M_{Z'}$ - $\sigma \cdot B$ plane. Upper limits on the production of $H\gamma$ resonances are set as a function of the resonance mass in the range of 720–3250 GeV.
- 30 AABOUD 18AA search for a narrow neutral vector boson decaying to $H\gamma$. See their Fig. 10 for the exclusion limit in $M_{Z'}$ - $\sigma \cdot B$ plane.
- 31 AABOUD 18CJ search for heavy-vector-triplet Z' in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for model with $g_V = 3$ assuming $M_{Z'} = M_{W'}$. The limit becomes $M_{Z'} > 5500$ GeV for model with $g_V = 1$.
- 32 AABOUD 18N search for a narrow resonance decaying to $q\bar{q}$ in pp collisions at $\sqrt{s} = 13$ TeV using trigger level analysis to improve the low mass region sensitivity. See their Fig. 5 for limits in the mass-coupling plane in the Z' mass range 450–1800 GeV.
- 33 AALIJ 18AQ search for spin-0 and spin-1 resonances decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ and 8 TeV in the mass region near 10 GeV. See their Figs. 4 and 5 for limits on $\sigma \cdot B$.
- 34 SIRUNYAN 18DR searches for $\mu^+\mu^-$ resonances produced in association with b -jets in the pp collision data with $\sqrt{s} = 8$ TeV and 13 TeV. An excess of events near $m_{\mu\mu} = 28$ GeV is observed in the 8 TeV data. See their Fig. 3 for the measured fiducial signal cross sections at $\sqrt{s} = 8$ TeV and the 95% CL upper limits at $\sqrt{s} = 13$ TeV.
- 35 SIRUNYAN 18E search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV in the mass range 50–300 GeV. See their Fig.7 for limits in the mass-coupling plane.
- 36 SIRUNYAN 18I search for a narrow resonance decaying to $b\bar{b}$ in pp collisions at $\sqrt{s} = 8$ TeV using dedicated b -tagged dijet triggers to improve the sensitivity in the low mass region. See their Fig. 3 for limits on $\sigma \cdot B$ in the Z' mass range 325–1200 GeV.
- 37 AABOUD 17B search for resonances decaying to HZ ($H \rightarrow b\bar{b}, c\bar{c}, Z \rightarrow \ell^+\ell^-, \nu\bar{\nu}$) in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 1490$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2310$ GeV and $M_{Z'} > 1730$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.3 for limits on $\sigma \cdot B$.
- 38 KHACHATRYAN 17AX search for lepto-phobic resonances decaying to four leptons in pp collisions at $\sqrt{s} = 8$ TeV.
- 39 KHACHATRYAN 17U search for resonances decaying to HZ ($H \rightarrow b\bar{b}, c\bar{c}, Z \rightarrow \ell^+\ell^-, \nu\bar{\nu}$) in pp collisions at $\sqrt{s} = 13$ TeV. The limit on the heavy-vector-triplet model is $M_{Z'} = M_{W'} > 2$ TeV for $g_V = 3$, in which constraints from the $W' \rightarrow HW$ ($H \rightarrow b\bar{b}, W \rightarrow \ell\nu$) are combined. See their Fig.3 and Fig.4 for limits on $\sigma \cdot B$.
- 40 SIRUNYAN 17A search for resonances decaying to WW with $WW \rightarrow \ell\nu q\bar{q}, q\bar{q}q\bar{q}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 1600$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2400$ GeV and $M_{Z'} > 2300$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.6 for limits on $\sigma \cdot B$.
- 41 SIRUNYAN 17AP search for resonances decaying into a SM-like Higgs scalar H and a light pseudo scalar A . A is assumed to decay invisibly. See their Fig.9 for limits on $\sigma \cdot B$.
- 42 SIRUNYAN 17T search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV in the mass range 100–300 GeV. See their Fig.3 for limits in the mass-coupling plane.
- 43 SIRUNYAN 17V search for a new resonance decaying to a top quark and a heavy vector-like top partner T in pp collisions at $\sqrt{s} = 13$ TeV. See their table 5 for limits on the Z' production cross section for various values of $M_{Z'}$ and M_T in the range of $M_{Z'} = 1500$ –2500 GeV and $M_T = 700$ –1500 GeV.
- 44 AABOUD 16 search for a narrow resonance decaying into $b\bar{b}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' with SM-like couplings to quarks. See their Fig.6 for limits on $\sigma \cdot B$.
- 45 AAD 16L search for $Z' \rightarrow a\gamma, a \rightarrow \gamma\gamma$ in pp collisions at $\sqrt{s} = 8$ TeV. See their Table 6 for limits on $\sigma \cdot B$.
- 46 AAD 16S search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' having coupling strength with quark $g_q = 0.3$ and is taken from their Figure 3.
- 47 KHACHATRYAN 16AP search for a resonance decaying to HZ in pp collisions at $\sqrt{s} = 8$ TeV. Both H and Z' are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$.
- 48 KHACHATRYAN 16E search for a leptophobic top-color Z' decaying to $t\bar{t}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes that $\Gamma_{Z'}/M_{Z'} = 0.012$. Also $m_{Z'} < 2.9$ TeV is excluded for wider topcolor Z' with $\Gamma_{Z'}/M_{Z'} = 0.1$.
- 49 AAD 15A search for narrow resonance decaying to $t\bar{t}$ using pp collisions at $\sqrt{s} = 8$ TeV. See Fig. 11 for limit on $\sigma \cdot B$.
- 50 AAD 15AT search for monoton production plus large missing E_T events in pp collisions at $\sqrt{s} = 8$ TeV and give constraints on a Z' model having $Z'u\bar{t}$ coupling. Z' is assumed to decay invisibly. See their Fig. 6 for limits on $\sigma \cdot B$.
- 51 AAD 15CD search for decays of Higgs bosons to 4ℓ states via Z' bosons, $H \rightarrow Z'Z' \rightarrow 4\ell$ or $H \rightarrow Z'Z' \rightarrow 4\ell$. See Fig. 5 for the limit on the signal strength of the $H \rightarrow Z'Z' \rightarrow 4\ell$ process and Fig. 16 for the limit on $H \rightarrow Z'Z' \rightarrow 4\ell$.
- 52 KHACHATRYAN 15F search for monoton production plus large missing E_T events in pp collisions at $\sqrt{s} = 8$ TeV and give constraints on a Z' model having $Z'u\bar{t}$ coupling. Z' is assumed to decay invisibly. See Fig. 3 for limits on $\sigma \cdot B$.
- 53 KHACHATRYAN 15O search for narrow Z' resonance decaying to ZH in pp collisions at $\sqrt{s} = 8$ TeV. See their Fig. 6 for limit on $\sigma \cdot B$.
- 54 AAD 14AT search for a narrow neutral vector boson decaying to $Z\gamma$. See their Fig. 3b for the exclusion limit in $M_{Z'} - \sigma \cdot B$ plane.
- 55 KHACHATRYAN 14A search for new resonance in the WW ($\ell\nu q\bar{q}$) and the ZZ ($\ell\ell q\bar{q}$) channels using pp collisions at $\sqrt{s}=8$ TeV. See their Fig.13 for the exclusion limit on the number of events in the mass-width plane.
- 56 MARTINEZ 14 use various electroweak data to constrain the Z' boson in the 3-3-1 models.
- 57 AAD 13AQ search for a leptophobic top-color Z' decaying to $t\bar{t}$. The quoted limit assumes that $\Gamma_{Z'}/M_{Z'} = 0.012$.
- 58 CHATRCHYAN 13BM search for top-color Z' decaying to $t\bar{t}$ using pp collisions at $\sqrt{s}=8$ TeV. The quoted limit is for $\Gamma_{Z'}/M_{Z'} = 0.012$.
- 59 CHATRCHYAN 13AP search for top-color leptophobic Z' decaying to $t\bar{t}$ using pp collisions at $\sqrt{s}=7$ TeV. The quoted limit is for $\Gamma_{Z'}/M_{Z'} = 0.012$.

- 60 AAD 12BV search for narrow resonance decaying to $t\bar{t}$ using pp collisions at $\sqrt{s}=7$ TeV. See their Fig. 7 for limit on $\sigma \cdot B$.
- 61 AAD 12K search for narrow resonance decaying to $t\bar{t}$ using pp collisions at $\sqrt{s}=7$ TeV. See their Fig. 5 for limit on $\sigma \cdot B$.
- 62 AALTONEN 12AR search for chromophilic Z' in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. See their Fig. 5 for limit on $\sigma \cdot B$.
- 63 AALTONEN 12N search for $p\bar{p} \rightarrow tZ', Z' \rightarrow T\bar{u}$ events in $p\bar{p}$ collisions. See their Fig. 3 for the limit on $\sigma \cdot B$.
- 64 ABASOV 12R search for top-color Z' boson decaying exclusively to $t\bar{t}$. The quoted limit is for $\Gamma_{Z'}/M_{Z'} = 0.012$.
- 65 CHATRCHYAN 12AI search for $pp \rightarrow tt$ events and give constraints on a Z' model having $Z'\bar{t}t$ coupling. See their Fig. 4 for the limit in mass-coupling plane.
- 66 Search for resonance decaying to $t\bar{t}$. See their Fig. 6 for limit on $\sigma \cdot B$.
- 67 Search for narrow resonance decaying to $t\bar{t}$. See their Fig. 4 for limit on $\sigma \cdot B$.
- 68 Search for narrow resonance decaying to $t\bar{t}$. See their Fig. 3 for limit on $\sigma \cdot B$.
- 69 CHATRCHYAN 11O search for same-sign top production in pp collisions induced by a hypothetical FCNC Z' at $\sqrt{s} = 7$ TeV. See their Fig. 3 for limit in mass-coupling plane.
- 70 Search for narrow resonance decaying to $t\bar{t}$. See their Fig. 3 for limit on $\sigma \cdot B$.
- 71 Search for narrow resonance decaying to $t\bar{t}$. See their Fig. 2 for limit on $\sigma \cdot B$.
- 72 BARGER 03b use the nucleosynthesis bound on the effective number of light neutrino δN_{ν} . See their Figs.4–5 for limits in general E_6 motivated models.
- 73 CHO 00 use various electroweak data to constrain Z' models assuming $m_H=100$ GeV. See Fig. 2 for limits in general E_6 -motivated models.
- 74 CHO 98 study constraints on four-Fermi contact interactions obtained from low-energy electroweak experiments, assuming no Z - Z' mixing.
- 75 Search for Z' decaying to dijets at $\sqrt{s}=1.8$ TeV. For Z' with electromagnetic strength coupling, no bound is obtained.

Searches for Z' with Lepton-Flavor-Violating decays

The following limits are obtained from $p\bar{p}$ or $pp \rightarrow Z'X$ with Z' decaying to the mode indicated in the comments.

- 1 AABOUD 18CM search for a new particle with lepton-flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs. 4, 5, and 6 for limits on $\sigma \cdot B$.
- 2 SIRUNYAN 18AT search for a narrow resonance Z' decaying into $e\mu$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig.5 for limit on $\sigma \cdot B$ in the range of $600 \text{ GeV} < M_{Z'} < 5000$ GeV.
- 3 AABOUD 16P search for new particle with lepton flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs.2, 3, and 4 for limits on $\sigma \cdot B$.
- 4 KHACHATRYAN 16BE search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s} = 8$ TeV in the range of $200 \text{ GeV} < M_{Z'} < 2000$ GeV. See their Fig.4 for limits on $\sigma \cdot B$ and their Table 5 for bounds on various masses.
- 5 AAD 15O search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s} = 8$ TeV in the range of $500 \text{ GeV} < M_{Z'} < 3000$ GeV. See their Fig. 2 for limits on $\sigma \cdot B$.
- 6 AAD 11H search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s} = 7$ TeV in the range of $700 \text{ GeV} < M_{Z'} < 1000$ GeV. See their Fig. 3 for limits on $\sigma \cdot B$.
- 7 AAD 11Z search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s} = 7$ TeV in the range $700 \text{ GeV} < M_{Z'} < 2000$ GeV. See their Fig. 3 for limits on $\sigma \cdot B$.
- 8 ABULENCIA 06M search for new particle Z' with lepton flavor violating decay in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV in the range of $100 \text{ GeV} < M_{Z'} < 800$ GeV. See their Fig. 4 for limits in the mass-coupling plane.

Indirect Constraints on Kaluza-Klein Gauge Bosons

Bounds on a Kaluza-Klein excitation of the Z boson or photon in $d=1$ extra dimension. These bounds can also be interpreted as a lower bound on $1/R$, the size of the extra dimension. Unless otherwise stated, bounds assume all fermions live on a single brane and all gauge fields occupy the $4+d$ -dimensional bulk. See also the section on "Extra Dimensions" in the "Searches" Listings in this Review.

VALUE (TeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • •	We do not use the following data for averages, fits, limits, etc. • • •			
> 4.7		1 MUECK 02	RVUE	Electroweak
> 3.3	95	2 CORNET 00	RVUE	$e\nu qq'$
>5000		3 DELGADO 00	RVUE	e_K

> 1.6	90	8 NATH 99	RVUE	Electroweak
> 3.4	95	9 STRUMIA 99	RVUE	Electroweak

- 1 MUECK 02 limit is 2σ and is from global electroweak fit ignoring correlations among observables. Higgs is assumed to be confined on the brane and its mass is fixed. For scenarios of bulk Higgs, of brane-SU(2)_L, bulk-U(1)_Y, and of bulk-SU(2)_L, brane-U(1)_Y, the corresponding limits are > 4.6 TeV, > 4.3 TeV and > 3.0 TeV, respectively.
- 2 Bound is derived from limits on $e\nu qq'$ contact interaction, using data from HERA and the Tevatron.

See key on page 999

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

- ³ Bound holds only if first two generations of quarks lives on separate branes. If quark mixing is not complex, then bound lowers to 400 TeV from Δm_K .
- ⁴ See Figs. 1 and 2 of DELGADO 00 for several model variations. Special boundary conditions can be found which permit KK states down to 950 GeV and that agree with the measurement of $Q_{WW}(Cs)$. Quoted bound assumes all Higgs bosons confined to brane; placing one Higgs doublet in the bulk lowers bound to 2.3 TeV.
- ⁵ Bound is derived from global electroweak analysis assuming the Higgs field is trapped on the matter brane. If the Higgs propagates in the bulk, the bound increases to 3.8 TeV.
- ⁶ Bound is derived from global electroweak analysis but considering only presence of the KK W bosons.
- ⁷ Global electroweak analysis used to obtain bound independent of position of Higgs on brane or in bulk.
- ⁸ Bounds from effect of KK states on G_F , α , M_{WW} , and M_Z . Hard cutoff at string scale determined using gauge coupling unification. Limits for $d=2,3,4$ rise to 3.5, 5.7, and 7.8 TeV.
- ⁹ Bound obtained for Higgs confined to the matter brane with $m_H=500$ GeV. For Higgs in the bulk, the bound increases to 3.5 TeV.

See the related review(s): Leptoquarks

MASS LIMITS for Leptoquarks from Pair Production

These limits rely only on the color or electroweak charge of the leptoquark.

- 1 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$ ($q = u, d, s, c$). The limit quoted above assumes scalar leptoquark with $B(\nu b) = 1$.
- 2 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$ ($q = u, d, s, c$). The limit quoted above assumes scalar leptoquark with $B(\nu t) = 1$.
- 3 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$ ($q = u, d, s, c$). The limit quoted above assumes scalar leptoquark with $B(\nu q) = 1$.
- 4 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$ ($q = u, d, s, c$). The limit quoted above assumes vector leptoquark with $B(\nu b) = 1$ and $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1560$ GeV.
- 5 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$ ($q = u, d, s, c$). The limit quoted above assumes vector leptoquark with $B(\nu t) = 1$ and $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1475$ GeV.
- 6 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$ ($q = u, d, s, c$). The limit quoted above assumes vector leptoquark with $B(\nu q) = 1$ and $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1560$ GeV.
- 7 AABOUD 19AX search for leptoquarks using $e\bar{e}jj$ events in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes $B(eq) = 1$.
- 8 AABOUD 19AX search for leptoquarks using $\mu\mu jj$ events in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes $B(\mu q) = 1$.
- 9 AABOUD 19X search for scalar leptoquarks decaying to $t\nu$ in pp collisions at $\sqrt{s} = 13$ TeV.
- 10 AABOUD 19X search for scalar leptoquarks decaying to $b\tau$ in pp collisions at $\sqrt{s} = 13$ TeV.
- 11 AABOUD 19X search for scalar leptoquarks decaying to $b\nu$ in pp collisions at $\sqrt{s} = 13$ TeV.
- 12 AABOUD 19X search for scalar leptoquarks decaying to $\tau\tau$ in pp collisions at $\sqrt{s} = 13$ TeV.
- 13 SIRUNYAN 19BI search for a pair of scalar leptoquarks decaying to $\mu\mu jj$ and $\mu\nu jj$ final states in pp collisions at $\sqrt{s} = 13$ TeV. Limits are shown as a function of β where β is the branching fraction to a muon and a quark. For $\beta = 1.0$ (0.5) LQ masses up to 1530 (1285) GeV are excluded. See Fig. 9 for exclusion limits in the plane of β and LQ mass.
- 14 SIRUNYAN 19BJ search for a pair of scalar leptoquarks decaying to $e\bar{e}jj$ and $e\nu jj$ final states in pp collisions at $\sqrt{s} = 13$ TeV. Limits are shown as a function of the branching fraction β to an electron and a quark. For $\beta = 1.0$ (0.5) LQ masses up to 1435 (1270) GeV are excluded. See Fig. 9 for exclusion limits in the plane of β and LQ mass.
- 15 SIRUNYAN 19Y search for a pair of third generation scalar leptoquarks, each decaying to τ and a jet. Assuming $B(\tau b) = 1$, leptoquark masses below 1.02 TeV are excluded.
- 16 SIRUNYAN 18CZ search for scalar leptoquarks decaying to τt in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes $B(\tau t) = 1$.
- 17 SIRUNYAN 18EC set limits for scalar and vector leptoquarks decaying to $\mu t, \tau t$, and νb . The limit quoted above assumes scalar leptoquark with $B(\mu t) = 1$.
- 18 SIRUNYAN 18EC set limits for scalar and vector leptoquarks decaying to $\mu t, \tau t$, and νb . The limit quoted above assumes vector leptoquark with all possible combinations of branching fractions to $\mu t, \tau t$, and νb .
- 19 SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with $B(b\nu) = 1$. Vector leptoquarks with $\kappa = 1$ are excluded below masses of 1810 GeV.
- 20 SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with $B(q\nu) = 1$. Vector leptoquarks with $\kappa = 1$ are excluded below masses of 1790 GeV.
- 21 SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with $B(\nu t) = 1$. Vector leptoquarks with $\kappa = 1$ are excluded below masses of 1780 GeV.
- 22 SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$. $\kappa = 1$ and $LQ \rightarrow b\nu$ are assumed.
- 23 SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$. $\kappa = 1$ and $LQ \rightarrow q\nu$ with $q = u, d, s, c$ are assumed.
- 24 SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu, b\nu$, and $q\nu$. $\kappa = 1$ and $LQ \rightarrow t\nu$ are assumed.
- 25 KHACHATRYAN 17J search for scalar leptoquarks decaying to τb using pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes $B(\tau b) = 1$.
- 26 SIRUNYAN 17H search for scalar leptoquarks using $\tau\tau bb$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(\tau b) = 1$.

New Heavy Bosons

- 27 AAD 16G search for scalar leptoquarks using $eejj$ events in collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(eq) = 1$.
- 28 AAD 16G search for scalar leptoquarks using $\mu\mu jj$ events in collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(\mu q) = 1$.
- 29 AAD 16G search for scalar leptoquarks decaying to $b\nu$. The limit above assumes $B(b\nu) = 1$.
- 30 AAD 16G search for scalar leptoquarks decaying to $t\nu$. The limit above assumes $B(t\nu) = 1$.
- 31 KHACHATRYAN 16AF search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(eq) = 1$. For $B(eq) = 0.5$, the limit becomes 850 GeV.
- 32 KHACHATRYAN 16AF search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(\mu q) = 1$. For $B(\mu q) = 0.5$, the limit becomes 760 GeV.
- 33 KHACHATRYAN 15AJ search for scalar leptoquarks using $\tau\tau tt$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(\tau t) = 1$.
- 34 KHACHATRYAN 14T search for scalar leptoquarks decaying to τb using pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(\tau b) = 1$. See their Fig. 5 for the exclusion limit as function of $B(\tau b)$.
- 35 SIRUNYAN 19BC search for scalar leptoquark (LQ) pair production in pp collisions at $\sqrt{s} = 13$ TeV. One LQ is assumed to decay to μq , while the other decays to dark matter pair and SM particles. See their Fig. 4 for limits in $M_{LQ} - M_{DM}$ plane.
- 36 AAD 13AE search for scalar leptoquarks using $\tau\tau bb$ events in pp collisions at $E_{cm} = 7$ TeV. The limit above assumes $B(\tau b) = 1$.
- 37 CHATRCHYAN 13M search for scalar and vector leptoquarks decaying to τb in pp collisions at $E_{cm} = 7$ TeV. The limit above is for scalar leptoquarks with $B(\tau b) = 1$.
- 38 AAD 12H search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $E_{cm} = 7$ TeV. The limit above assumes $B(eq) = 1$. For $B(eq) = 0.5$, the limit becomes 607 GeV.
- 39 AAD 12O search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $E_{cm} = 7$ TeV. The limit above assumes $B(\mu q) = 1$. For $B(\mu q) = 0.5$, the limit becomes 594 GeV.
- 40 CHATRCHYAN 12AG search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $E_{cm} = 7$ TeV. The limit above assumes $B(eq) = 1$. For $B(eq) = 0.5$, the limit becomes 640 GeV.
- 41 CHATRCHYAN 12AG search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $E_{cm} = 7$ TeV. The limit above assumes $B(\mu q) = 1$. For $B(\mu q) = 0.5$, the limit becomes 650 GeV.
- 42 CHATRCHYAN 12BO search for scalar leptoquarks decaying to νb in pp collisions at $\sqrt{s} = 7$ TeV. The limit above assumes $B(\nu b) = 1$.
- 43 AAD 11D search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $E_{cm} = 7$ TeV. The limit above assumes $B(eq) = 1$. For $B(eq) = 0.5$, the limit becomes 319 GeV.
- 44 AAD 11D search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $E_{cm} = 7$ TeV. The limit above assumes $B(\mu q) = 1$. For $B(\mu q) = 0.5$, the limit becomes 362 GeV.
- 45 ABZOV 11V search for scalar leptoquarks using $e\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit above assumes $B(eq) = 0.5$.
- 46 CHATRCHYAN 11N search for scalar leptoquarks using $e\nu jj$ events in pp collisions at $E_{cm} = 7$ TeV. The limit above assumes $B(eq) = 0.5$.
- 47 KHACHATRYAN 11D search for scalar leptoquarks using $eejj$ events in pp collisions at $E_{cm} = 7$ TeV. The limit above assumes $B(eq) = 1$.
- 48 KHACHATRYAN 11E search for scalar leptoquarks using $\mu\mu jj$ events in pp collisions at $E_{cm} = 7$ TeV. The limit above assumes $B(\mu q) = 1$.
- 49 ABZOV 10L search for pair productions of scalar leptoquark state decaying to νb in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit above assumes $B(\nu b) = 1$.
- 50 ABZOV 09 search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit above assumes $B(\mu q) = 1$. For $B(\mu q) = 0.5$, the limit becomes 270 GeV.
- 51 ABZOV 09AF search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit above assumes $B(eq) = 1$. For $B(eq) = 0.5$ the bound becomes 284 GeV.
- 52 AALTONEN 08P search for vector leptoquarks using $\tau^+ \tau^- b\bar{b}$ events in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. Assuming Yang-Mills (minimal) couplings, the mass limit is >317 GeV (251 GeV) at 95% CL for $B(\tau b) = 1$.
- 53 Search for pair production of scalar leptoquark state decaying to τb in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit above assumes $B(\tau b) = 1$.
- 54 Search for scalar leptoquarks using $\nu\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit above assumes $B(\nu q) = 1$.
- 55 ABZOV 07J search for pair productions of scalar leptoquark state decaying to νb in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit above assumes $B(\nu b) = 1$.
- 56 ABZOV 06A search for scalar leptoquarks using $\mu\mu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV and 1.96 TeV. The limit above assumes $B(\mu q) = 1$. For $B(\mu q) = 0.5$, the limit becomes 204 GeV.
- 57 ABZOV 06L search for scalar leptoquarks using $\nu\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV and at 1.96 TeV. The limit above assumes $B(\nu q) = 1$.
- 58 ABULENCA 06T search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted limit assumes $B(\mu q) = 1$. For $B(\mu q) = 0.5$ or 0.1, the bound becomes 208 GeV or 143 GeV, respectively. See their Fig. 4 for the exclusion limit as a function of $B(\mu q)$.
- 59 ABZOV 05H search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV and 1.96 TeV. The limit above assumes $B(eq) = 1$. For $B(eq) = 0.5$ the bound becomes 234 GeV.
- 60 ACOSTA 05P search for scalar leptoquarks using $eejj$, $e\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit above assumes $B(eq) = 1$. For $B(eq) = 0.5$ and 0.1, the bound becomes 205 GeV and 145 GeV, respectively.
- 61 ABBIENDI 03R search for scalar/vector leptoquarks in $e^+ e^-$ collisions at $\sqrt{s} = 189-209$ GeV. The quoted limits are for charge $-4/3$ isospin 0 scalar-leptoquark with $B(\ell q) = 1$. See their table 12 for other cases.
- 62 ABZOV 02 search for scalar leptoquarks using $\nu\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The bound holds for all leptoquark generations. Vector leptoquarks are likewise constrained to lie above 200 GeV.
- 63 ABZOV 01D search for scalar leptoquarks using $e\nu jj$, $eejj$, and $\nu\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The limit above assumes $B(eq) = 1$. For $B(eq) = 0.5$ and 0, the bound becomes 204 and 79 GeV, respectively. Bounds for vector leptoquarks are also given. Supersedes ABBOTT 98E.
- 64 ABBIENDI 00M search for scalar/vector leptoquarks in $e^+ e^-$ collisions at $\sqrt{s} = 183$ GeV. The quoted limits are for charge $-4/3$ isospin 0 scalar-leptoquarks with $B(\ell q) = 1$. See their Table 8 and Figs. 6-9 for other cases.
- 65 ABBOTT 00c search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The limit above assumes $B(\mu q) = 1$. For $B(\mu q) = 0.5$ and 0, the bound becomes 180 and 79 GeV respectively. Bounds for vector leptoquarks are also given.
- 66 AFFOLDER 00k search for scalar leptoquark using $\nu\nu cc$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The quoted limit assumes $B(\nu c) = 1$. Bounds for vector leptoquarks are also given.
- 67 AFFOLDER 00k search for scalar leptoquark using $\nu\nu bb$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The quoted limit assumes $B(\nu b) = 1$. Bounds for vector leptoquarks are also given.
- 68 ABBOTT 99j search for leptoquarks using $\mu\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The quoted limit is for a scalar leptoquark with $B(\mu q) = B(\nu q) = 0.5$. Limits on vector leptoquarks range from 240 to 290 GeV.
- 69 ABBOTT 98E search for scalar leptoquarks using $e\nu jj$, $eejj$, and $\nu\nu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The limit above assumes $B(eq) = 1$. For $B(eq) = 0.5$ and 0, the bound becomes 204 and 79 GeV, respectively.
- 70 ABBOTT 98j search for charge $-1/3$ third generation scalar and vector leptoquarks in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The quoted limit is for scalar leptoquark with $B(\nu b) = 1$.
- 71 ABE 98s search for scalar leptoquarks using $\mu\mu jj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The limit is for $B(\mu q) = 1$. For $B(\mu q) = B(\nu q) = 0.5$, the limit is > 160 GeV.
- 72 GROSS-PILCHER 98 is the combined limit of the CDF and DØ Collaborations as determined by a joint CDF/DØ working group and reported in this FINAL Technical Memo. Original data published in ABE 97x and ABBOTT 98E.
- 73 ABE 97f search for third generation scalar and vector leptoquarks in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The quoted limit is for scalar leptoquark with $B(\tau b) = 1$.
- 74 ABE 97x search for scalar leptoquarks using $eejj$ events in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. The limit is for $B(eq) = 1$.
- 75 Limit is for charge $-1/3$ isospin-0 leptoquark with $B(\ell q) = 2/3$.
- 76 First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.
- 77 Limits are for charge $-1/3$, isospin-0 scalar leptoquarks decaying to $\ell^- q$ or νq with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks.
- 78 KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of $d e^+$ and $u \bar{\nu}$ ($s \mu^+$ and $c \bar{\nu}$). See paper for limits for specific branching ratios.
- 79 BARTEL 87B limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint $B(X \rightarrow c \bar{\nu}_\mu) + B(X \rightarrow s \mu^+) = 1$.
- 80 BEHREND 86B assumed that a charge 2/3 spinless leptoquark, χ , decays either into $s \mu^+$ or $c \bar{\nu}$: $B(\chi \rightarrow s \mu^+) + B(\chi \rightarrow c \bar{\nu}) = 1$.

MASS LIMITS for Leptoquarks from Single Production

These limits depend on the q - ℓ -leptoquark coupling g_{LQ} . It is often assumed that $g_{LQ}^2/4\pi = 1/137$. Limits shown are for a scalar, weak isoscalar, charge $-1/3$ leptoquark.

- 1 SIRUNYAN 18BJ search for single production of charge 2/3 scalar leptoquarks decaying to τb in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes $B(\tau b) = 1$ and the leptoquark coupling strength $\lambda = 1$.
- 2 KHACHATRYAN 16AG search for single production of charge $\pm 1/3$ scalar leptoquarks using $eejj$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(eq) = 1$ and the leptoquark coupling strength $\lambda = 1$.
- 3 KHACHATRYAN 16AG search for single production of charge $\pm 1/3$ scalar leptoquarks using $\mu\mu jj$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(\mu q) = 1$ and the leptoquark coupling strength $\lambda = 1$.
- 4 ABRAMOWICZ 12A limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R . See their Figs. 12-17 and Table 4 for states with different quantum numbers.
- 5 Limit from single production in Z decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes $B(\ell q) = 2/3$. The limit is 77 GeV if first and second leptoquarks are degenerate.
- 6 DEY 16 use the 2010-2012 IceCube PeV energy data set to constrain the leptoquark production cross section through the $\nu q \rightarrow LQ \rightarrow \nu q$ process. See their Figure 4 for the exclusion limit in the mass-coupling plane.
- 7 AARON 11A search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 2-3 and Tables 1-4 for detailed limits.

See key on page 999

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

⁸ The quoted limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R . See their Figs. 3–5 for limits on states with different quantum numbers.

⁹ ABAZOV 07E search for leptoquark single production through qg fusion process in $p\bar{p}$ collisions. See their Fig. 4 for exclusion plot in mass-coupling plane.

¹⁰ AKTAS 05B limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R . See their Fig. 3 for limits on states with different quantum numbers.

¹¹ CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs.6–10 and Tables 1–8 for detailed limits.

¹² CHEKANOV 03B limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R . See their Figs. 11–12 and Table 5 for limits on states with different quantum numbers.

¹³ For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 4 and Fig. 5.

¹⁴ CHEKANOV 02 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–7 and Tables 5–6 for detailed limits.

¹⁵ For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 3.

¹⁶ See their Fig. 14 for limits in the mass-coupling plane.

¹⁷ BREITWEG 00E search for $F=0$ leptoquarks in e^+p collisions. For limits in mass-coupling plane, see their Fig. 11.

¹⁸ ABREU 99G limit obtained from process $e\gamma \rightarrow LQ+q$. For limits on vector and scalar states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 4 and Table 2.

¹⁹ For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 13 and Fig. 14. ADLOFF 99 also search for leptoquarks with lepton-flavor violating couplings. ADLOFF 99 supersedes AID 96B.

²⁰ DERRICK 97 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 5–8 and Table 1 for detailed limits.

²¹ DERRICK 93 search for single leptoquark production in ep collisions with the decay $e q$ and νq . The limit is for leptoquark coupling of electromagnetic strength and assumes $B(eq) = B(\nu q) = 1/2$. The limit for $B(eq) = 1$ is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

³ ZHANG 18A give bounds on leptoquark induced four-fermion interactions from $D \rightarrow K\ell\nu$. The authors inform us that the shape parameter of the vector form factor in both the abstract and the conclusions of ZHANG 18A should be $r_{+1} = 2.16 \pm 0.07$ rather than ± 0.007 . The numbers listed in their Table 7 are correct.

⁴ BARRANCO 16 give bounds on leptoquark induced four-fermion interactions from $D \rightarrow K\ell\nu$ and $D_S \rightarrow \ell\nu$.

⁵ KUMAR 16 gives bound on SU(2) singlet scalar leptoquark with charge $-1/3$ from $K^0 - \bar{K}^0$ mixing, $K \rightarrow \pi\nu\bar{\nu}$, $K_L^0 \rightarrow \mu^+\mu^-$, and $K_L^0 \rightarrow \mu^\pm e^\mp$ decays.

⁶ BESSAA 15 obtain limit on leptoquark induced four-fermion interactions from the ATLAS and CMS limit on the $\bar{q}q\bar{e}e$ contact interactions.

⁷ SAHO 15A obtain limit on leptoquark induced four-fermion interactions from $B_{s,d} \rightarrow \mu^+\mu^-$ for $\lambda \simeq O(1)$.

⁸ SAKAKI 13 explain the $B \rightarrow D^{(*)}\tau\bar{\nu}$ anomaly using Wilson coefficients of leptoquark-induced four-fermion operators.

⁹ KOSNIK 12 obtains limits on leptoquark induced four-fermion interactions from $b \rightarrow s\ell^+\ell^-$ decays.

¹⁰ AARON 11c limit is for weak isotriplet spin-0 leptoquark at strong coupling $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds of eq contact interactions.

¹¹ DORSNER 11 give bounds on scalar, weak singlet, charge $4/3$ leptoquark from K, B, τ decays, meson mixings, $LFV, g-2$ and $Z \rightarrow b\bar{b}$.

¹² AKTAS 07A search for lepton-flavor violation in ep collision. See their Tables 4–7 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

¹³ SCHAE 07A limit is for the weak-isoscalar spin-0 left-handed leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 35.

¹⁴ SMIRNOV 07 obtains mass limits for the vector and scalar chiral leptoquark states from $K \rightarrow e\mu, B \rightarrow e\tau$ decays.

¹⁵ CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs.6–10 and Tables 1–8 for detailed limits.

¹⁶ ADLOFF 03 limit is for the weak isotriplet spin-0 leptoquark at strong coupling $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds on $e^\pm q$ contact interactions.

¹⁷ The bound is derived from $B(B^0 \rightarrow e^\pm\mu^\mp) < 1.7 \times 10^{-7}$.

¹⁸ CHEKANOV 02 search for lepton-flavor violation in ep collisions. See their Tables 1–4 for limits on lepton-flavor violating and four-fermion interactions induced by various leptoquarks.

¹⁹ CHEUNG 01B quoted limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark with a coupling of electromagnetic strength. The limit is derived from bounds on contact interactions in a global electroweak analysis. For the limits of leptoquarks with different quantum numbers, see Table 5.

²⁰ ACCIARRI 00P limit is for the weak isoscalar spin-0 leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 4.

²¹ ADLOFF 00 limit is for the weak isotriplet spin-0 leptoquark at strong coupling, $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 2. ADLOFF 00 limits are from the Q^2 spectrum measurement of $e^+p \rightarrow e^+X$.

²² BARATE 00i search for deviations in cross section and jet-charge asymmetry in $e^+e^- \rightarrow q\bar{q}$ due to t -channel exchange of a leptoquark at $\sqrt{s}=130$ to 183 GeV. Limits for other scalar and vector leptoquarks are also given in their Table 22.

²³ BARGER 00 explain the deviation of atomic parity violation in cesium atoms from prediction is explained by scalar leptoquark exchange.

²⁴ GABRIELLI 00 calculate various process with lepton flavor violation in leptoquark models.

²⁵ ZARNECKI 00 limit is derived from data of HERA, LEP, and Tevatron and from various low-energy data including atomic parity violation. Leptoquark coupling with electromagnetic strength is assumed.

²⁶ ABBIENDI 99 limits are from $e^+e^- \rightarrow q\bar{q}$ cross section at 130–136, 161–172, 183 GeV. See their Fig. 8 and Fig. 9 for limits in mass-coupling plane.

²⁷ ABE 98v quoted limit is from $B(B_S \rightarrow e^\pm\mu^\mp) < 8.2 \times 10^{-6}$. ABE 98v also obtain a similar limit on $M_{LQ} > 20.4$ TeV from $B(B_d \rightarrow e^\pm\mu^\mp) < 4.5 \times 10^{-6}$. Both bounds assume the non-canonical association of the b quark with electrons or muons under SU(4).

²⁸ ACCIARRI 98j limit is from $e^+e^- \rightarrow q\bar{q}$ cross section at $\sqrt{s}=130$ –172 GeV which can be affected by the t - and u -channel exchanges of leptoquarks. See their Fig. 4 and Fig. 5 for limits in the mass-coupling plane.

²⁹ ACKERSTAFF 98v limits are from $e^+e^- \rightarrow q\bar{q}$ and $e^+e^- \rightarrow b\bar{b}$ cross sections at $\sqrt{s} = 130$ –172 GeV, which can be affected by the t - and u -channel exchanges of leptoquarks. See their Fig. 21 and Fig. 22 for limits of leptoquarks in mass-coupling plane.

³⁰ DEANDREA 97 limit is for \bar{R}_2 leptoquark obtained from atomic parity violation (APV). The coupling of leptoquark is assumed to be electromagnetic strength. See Table 2 for limits of the four-fermion interactions induced by various scalar leptoquark exchange. DEANDREA 97 combines APV limit and limits from Tevatron and HERA. See Fig. 1–4 for combined limits of leptoquark in mass-coupling plane.

³¹ DERRICK 97 search for lepton-flavor violation in ep collision. See their Tables 2–5 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

³² GROSSMAN 97 estimate the upper bounds on the branching fraction $B \rightarrow \tau^+\tau^- (X)$ from the absence of the B decay with large missing energy. These bounds can be used to constrain leptoquark induced four-fermion interactions.

³³ JADACH 97 limit is from $e^+e^- \rightarrow q\bar{q}$ cross section at $\sqrt{s}=172.3$ GeV which can be affected by the t - and u -channel exchanges of leptoquarks. See their Fig. 1 for limits on vector leptoquarks in mass-coupling plane.

³⁴ KUZNETSOV 95b use π, K, B, τ decays and μe conversion and give a list of bounds on the leptoquark mass and the fermion mixing matrix in the Pati-Salam model. The quoted limit is from $K_L \rightarrow \mu e$ decay assuming zero mixing.

³⁵ MIZUKOSHI 95 calculate the one-loop radiative correction to the Z-physics parameters in various scalar leptoquark models. See their Fig. 4 for the exclusion plot of third generation leptoquark models in mass-coupling plane.

³⁶ BHATTACHARYYA 94 limit is from one-loop radiative correction to the leptonic decay width of the Z. $m_H=250$ GeV, $\alpha_S(m_Z)=0.12$, $m_t=180$ GeV, and the electroweak strength of leptoquark coupling are assumed. For leptoquark coupled to $\bar{t}_L t_R, \bar{\tau}_L \tau_R$, and $\bar{\nu}_\tau$, see Fig. 2 in BHATTACHARYYA 94b erratum and Fig. 3.

³⁷ DAVIDSON 94 gives an extensive list of the bounds on leptoquark-induced four-fermion interactions from π, K, D, B, μ, τ decays and meson mixings, etc. See Table 15 of DAVIDSON 94 for detail.

¹ ABRAMOWICZ 19 obtain a limit on $\lambda/M_{LQ} > 1.16$ TeV $^{-1}$ for weak isotriplet spin-0 leptoquark S_1^+ . We obtain the limit quoted above by converting the limit on λ/M_{LQ} for S_1^+ assuming $\lambda = \sqrt{4\pi}$. See their Table 5 for the limits of leptoquarks with different quantum numbers. These limits are derived from bounds of eq contact interactions.

² MANDAL 19 give bounds on leptoquarks from τ -decays, leptonic dipole moments, lepton-flavor-violating processes, and K decays.

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

- ³⁸ KUZNETSOV 94 gives mixing independent bound of the Pati-Salam leptoquark from the cosmological limit on $\pi^0 \rightarrow \nu\bar{\nu}$.
- ³⁹ LEURER 94, LEURER 94B limits are obtained from atomic parity violation and apply to any chiral leptoquark which couples to the first generation with electromagnetic strength. For a nonchiral leptoquark, universality in $\pi_{\ell 2}$ decay provides a much more stringent bound.
- ⁴⁰ MAHANTA 94 gives bounds of P - and T -violating scalar-leptoquark couplings from atomic and molecular experiments.
- ⁴¹ From $(\pi \rightarrow e\nu)/(\pi \rightarrow \mu\nu)$ ratio. SHANKER 82 assumes the leptoquark induced four-fermion coupling $4g^2/M^2 (\bar{\nu}_e \ell u_R) (\bar{\ell} \ell e_R)$ with $g=0.004$ for spin-0 leptoquark and $g^2/M^2 (\bar{\nu}_e \ell \mu_L) (\bar{\ell} \ell e_R)$ with $g \approx 0.6$ for spin-1 leptoquark.

- ¹ SIRUNYAN 18B0 search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
- ² KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
- ³ KHACHATRYAN 16K search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
- ⁴ KHACHATRYAN 16L search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.
- ⁵ KHACHATRYAN 15V search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.
- ⁶ KHACHATRYAN 17Y search for pair production of color-octet gauge boson g_A each decaying to $4j$ in pp collisions at $\sqrt{s} = 8$ TeV.
- ⁷ AAD 16W search for a new resonance decaying to a pair of b and B_H in pp collisions at $\sqrt{s} = 8$ TeV. The vector-like quark B_H is assumed to decay to bH . See their Fig. 3 and Fig. 4 for limits on $\sigma \cdot B$.
- ⁸ KHACHATRYAN 16E search for KK gluon decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 8$ TeV.
- ⁹ KHACHATRYAN 15AV search for pair productions of neutral color-octet weak-triplet scalar particles (θ^0), decaying to $b\bar{b}$, Zg or γg , in pp collisions at $\sqrt{s} = 8$ TeV. The θ^0 particle is often predicted in coloron (G' , color-octet gauge boson) models and appear in the pp collisions through $G' \rightarrow \theta^0 \theta^0$ decays. Assuming $B(\theta^0 \rightarrow b\bar{b}) = 0.5$, they give limits $m_{\theta^0} > 623$ GeV (426 GeV) for $m_{G'} = 2.3 m_{\theta^0}$ ($m_{G'} = 5 m_{\theta^0}$).
- ¹⁰ AALTONEN 13R search for new resonance decaying to $\sigma\sigma$, with hypothetical strongly interacting σ particle subsequently decaying to 2 jets, in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV, using data corresponding to an integrated luminosity of 6.6 fb⁻¹. For 50 GeV $< m_\sigma < m_{g_A}/2$, axigluons in mass range 150–400 GeV are excluded.
- ¹¹ CHATRCHYAN 13A search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 7$ TeV.
- ¹² CHATRCHYAN 13AS search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.
- ¹³ CHATRCHYAN 13AU search for the pair produced color-octet vector bosons decaying to $q\bar{q}$ pairs in pp collisions. The quoted limit is for $B(g_A \rightarrow q\bar{q}) = 1$.
- ¹⁴ ABAZOV 12R search for massive color octet vector particle decaying to $t\bar{t}$. The quoted limit assumes g_A couplings with light quarks are suppressed by 0.2.
- ¹⁵ CHATRCHYAN 11Y search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 7$ TeV.
- ¹⁶ AALTONEN 10L search for massive color octet non-chiral vector particle decaying into $t\bar{t}$ pair with mass in the range 400 GeV $< M < 800$ GeV. See their Fig. 6 for limit in the mass-coupling plane.
- ¹⁷ KHACHATRYAN 10 search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 7$ TeV.
- ¹⁸ AALTONEN 09AC search for new narrow resonance decaying to dijets.
- ¹⁹ CHOUDHURY 07 limit is from the $t\bar{t}$ production cross section measured at CDF.
- ²⁰ DONCHESKI 98 compare α_s derived from low-energy data and that from $\Gamma(Z \rightarrow \text{hadrons})/\Gamma(Z \rightarrow \text{leptons})$.
- ²¹ ABE 97G search for new particle decaying to dijets.
- ²² ABE 95N assume axigluons decaying to quarks in the Standard Model only.
- ²³ ABE 93G assume $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 10$.
- ²⁴ CUYPERS 91 compare α_s measured in T decay and that from R at PEP/PETRA energies.
- ²⁵ ABE 90H assumes $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 5$ ($\Gamma(g_A) = 0.09 m_{g_A}$). For $N = 10$, the excluded region is reduced to 120–150 GeV.
- ²⁶ ROBINETT 89 result demands partial-wave unitarity of $J = 0$ $t\bar{t} \rightarrow t\bar{t}$ scattering amplitude and derives a limit $m_{g_A} > 0.5 m_t$. Assumes $m_t > 56$ GeV.
- ²⁷ ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution. $\Gamma(g_A) < 0.4 m_{g_A}$ assumed. See also BAGGER 88.
- ²⁸ CUYPERS 88 requires $\Gamma(T \rightarrow g g_A) < \Gamma(T \rightarrow g g g)$. A similar result is obtained by DONCHESKI 88.
- ²⁹ DONCHESKI 88B requires $\Gamma(T \rightarrow g q\bar{q})/\Gamma(T \rightarrow g g g) < 0.25$, where the former decay proceeds via axigluon exchange. A more conservative estimate of < 0.5 leads to $m_{g_A} > 21$ GeV.

MASS LIMITS for Color-Octet Scalar Bosons

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
none 600–3400	95	1 SIRUNYAN 18B0 CMS	$pp \rightarrow S_8 X, S_8 \rightarrow g g$	
		2 KHACHATRYAN...15AV CMS	$pp \rightarrow \theta^0 \theta^0 \rightarrow b\bar{b}Zg$	
none 150–287	95	3 AAD 13K ATLS	$pp \rightarrow S_8 S_8 X, S_8 \rightarrow 2j$	
		1 SIRUNYAN 18B0	search for color octet scalar boson produced through gluon fusion process in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes S_{8gg} coupling $k_S^2 = 1/2$.	
		2 KHACHATRYAN 15AV	search for pair productions of neutral color-octet weak-triplet scalar particles (θ^0), decaying to $b\bar{b}$, Zg or γg , in pp collisions at $\sqrt{s} = 8$ TeV. The θ^0 particle is often predicted in coloron (G' , color-octet gauge boson) models and appear in the pp collisions through $G' \rightarrow \theta^0 \theta^0$ decays. Assuming $B(\theta^0 \rightarrow b\bar{b}) = 0.5$, they give limits $m_{\theta^0} > 623$ GeV (426 GeV) for $m_{G'} = 2.3 m_{\theta^0}$ ($m_{G'} = 5 m_{\theta^0}$).	

See key on page 999

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

³AAD 13k search for pair production of color-octet scalar particles in pp collisions at $\sqrt{s} = 7$ TeV. Cross section limits are interpreted as mass limits on scalar partners of a Dirac gluino.

X^0 (Heavy Boson) Searches in Z Decays

Searches for radiative transition of Z to a lighter spin-0 state X^0 decaying to hadrons, a lepton pair, a photon pair, or invisible particles as shown in the comments. The limits are for the product of branching ratios.

- RAINBOLT 19 limits are from $B(Z \rightarrow \ell^+ \ell^- \ell^+ \ell^-)$. See their Figs. 5 and 6 for limits in mass-coupling plane.
- SIRUNYAN 19AZ search for $pp \rightarrow Z \rightarrow X^0 \mu^+ \mu^- \rightarrow \mu^+ \mu^- \mu^+ \mu^-$ events in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits on $\sigma(pp \rightarrow X^0 \mu^+ \mu^-) \cdot B(X^0 \rightarrow \mu^+ \mu^-)$.
- BARATE 98U obtain limits on $B(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \ell \bar{\ell}, q \bar{q}, gg, \gamma\gamma, \nu\bar{\nu})$. See their Fig. 17.
- See Fig. 4 of ACCIARRI 97Q for the upper limit on $B(Z \rightarrow \gamma X^0; E_\gamma > E_{\min})$ as a function of E_{\min} .
- ACTON 93E give $\sigma(e^+ e^- \rightarrow X^0 \gamma) \cdot B(X^0 \rightarrow \gamma\gamma) < 0.4$ pb (95%CL) for $m_{X^0} = 60 \pm 2.5$ GeV. If the process occurs via s-channel γ exchange, the limit translates to $\Gamma(X^0) \cdot B(X^0 \rightarrow \gamma\gamma)^2 < 20$ MeV for $m_{X^0} = 60 \pm 1$ GeV.
- ABREU 92D give $\sigma_Z \cdot B(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < (3-10)$ pb for $m_{X^0} = 10-78$ GeV. A very similar limit is obtained for spin-1 X^0 .
- ADRIANI 92F search for isolated γ in hadronic Z decays. The limit $\sigma_Z \cdot B(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < (2-10)$ pb (95%CL) is given for $m_{X^0} = 25-85$ GeV.
- ACTON 91 searches for $Z \rightarrow Z^* X^0, Z^* \rightarrow e^+ e^-, \mu^+ \mu^-,$ or $\nu\bar{\nu}$. Excludes any new scalar X^0 with $m_{X^0} < 9.5$ GeV/c if it has the same coupling to ZZ^* as the MSM Higgs boson.
- ACTON 91B limits are for $m_{X^0} = 60-85$ GeV.
- ADEVA 91D limits are for $m_{X^0} = 30-89$ GeV.
- ADEVA 91D limits are for $m_{X^0} = 30-86$ GeV.
- AKRAWY 90J give $\Gamma(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < 1.9$ MeV (95%CL) for $m_{X^0} = 32-80$ GeV. We divide by $\Gamma(Z) = 2.5$ GeV to get product of branching ratios. For nonresonant transitions, the limit is $B(Z \rightarrow \gamma q \bar{q}) < 8.2$ MeV assuming three-body phase space distribution.

MASS LIMITS for a Heavy Neutral Boson Coupling to $e^+ e^-$

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
none 55-61		1 ODAKA 89	VNS	$\Gamma(X^0 \rightarrow e^+ e^-) \cdot B(X^0 \rightarrow \text{had.}) \gtrsim 0.2$ MeV
>45	95	2 DERRICK 86	HRS	$\Gamma(X^0 \rightarrow e^+ e^-) = 6$ MeV

>48	95	3 ADEVA 85	MRKJ	$\Gamma(X^0 \rightarrow e^+ e^-) = 4$ MeV
		4 BERGER 85B	PLUT	
none 39.8-45.5		5 ADEVA 84	MRKJ	$\Gamma(X^0 \rightarrow e^+ e^-) = 10$ keV
>47.8	95	5 ADEVA 84	MRKJ	$\Gamma(X^0 \rightarrow e^+ e^-) = 4$ MeV
none 39.8-45.2		5 BEHREND 84c	CELL	
>47	95	5 BEHREND 84c	CELL	$\Gamma(X^0 \rightarrow e^+ e^-) = 4$ MeV

- ODAKA 89 looked for a narrow or wide scalar resonance in $e^+ e^- \rightarrow$ hadrons at $E_{cm} = 55.0-60.8$ GeV.
- DERRICK 86 found no deviation from the Standard Model Bhabha scattering at $E_{cm} = 29$ GeV and set limits on the possible scalar boson $e^+ e^-$ coupling. See their figure 4 for excluded region in the $\Gamma(X^0 \rightarrow e^+ e^-) \cdot m_{X^0}$ plane. Electronic chiral invariance requires a parity doublet of X^0 , in which case the limit applies for $\Gamma(X^0 \rightarrow e^+ e^-) = 3$ MeV.
- ADEVA 85 first limit is from $2\gamma, \mu^+ \mu^-,$ hadrons assuming X^0 is a scalar. Second limit is from $e^+ e^-$ channel. $E_{cm} = 40-47$ GeV. Supersedes ADEVA 84.
- BERGER 85B looked for effect of spin-0 boson exchange in $e^+ e^- \rightarrow e^+ e^-$ and $\mu^+ \mu^-$ at $E_{cm} = 34.7$ GeV. See Fig. 5 for excluded region in the $m_{X^0} - \Gamma(X^0)$ plane.
- ADEVA 84 and BEHREND 84c have $E_{cm} = 39.8-45.5$ GeV. MARK-J searched X^0 in $e^+ e^- \rightarrow$ hadrons, $2\gamma, \mu^+ \mu^-, e^+ e^-$ and CELLO in the same channels plus τ pair. No narrow or broad X^0 is found in the energy range. They also searched for the effect of X^0 with $m_X > E_{cm}$. The second limits are from Bhabha data and for spin-0 singlet.

The same limits apply for $\Gamma(X^0 \rightarrow e^+ e^-) = 2$ MeV if X^0 is a spin-0 doublet. The second limit of BEHREND 84c was read off from their figure 2. The original papers also list limits in other channels.

Search for X^0 Resonance in $e^+ e^-$ Collisions

The limit is for $\Gamma(X^0 \rightarrow e^+ e^-) \cdot B(X^0 \rightarrow f)$, where f is the specified final state. Spin 0 is assumed for X^0 .

Axions (A^0) and Other Very Light Bosons, Searches for

See the related review(s):

[Axions and Other Similar Particles](#)

A^0 (Axion) MASS LIMITS from Astrophysics and Cosmology

These bounds depend on model-dependent assumptions (i.e. — on a combination of axion parameters).

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
••• We do not use the following data for averages, fits, limits, etc. •••			
>0.2	BARROSO 82	ASTR	Standard Axion
>0.25	1 RAFFELT 82	ASTR	Standard Axion
>0.2	2 DICUS 78C	ASTR	Standard Axion
	MIKAEELIAN 78	ASTR	Stellar emission
>0.3	2 SATO 78	ASTR	Standard Axion
>0.2	VYSOTSKII 78	ASTR	Standard Axion

1 Lower bound from 5.5 MeV γ -ray line from the sun.

2 Lower bound from requiring the red giants' stellar evolution not be disrupted by axion emission.

A^0 (Axion) and Other Light Boson (X^0) Searches in Hadron Decays

Limits are for branching ratios.

1 The limit is for $\tau_{X^0} = 10$ ps. See their Fig. 4 for limits in the range of $m_{X^0} = 250-4700$ MeV and $\tau_{X^0} = 0.1-1000$ ps.

2 The limit as a function of m_{X^0} from 0 to 250 MeV is provided in their Fig. 5.

3 The limit is for $m_{X^0} = 216$ MeV and $\tau_{X^0} \leq 10$ ps. See their Fig. 4(c) for limits in the range of $m_{X^0} = 211-354$ MeV and longer lifetimes.

4 WON 16 look for a vector boson coupled to baryon number. Derived limits on $\alpha' < 10^{-3}-10^{-2}$ for $m_{X^0} = 290-520$ MeV at 95% CL. See their Fig. 4 for mass-dependent limits.

5 The limit is for $\tau_{X^0} = 10$ ps and $m_{X^0} = 214-4350$ MeV. See their Fig. 4 for mass- and lifetime-dependent limits.

6 Limits between 2.0×10^{-5} and 1.5×10^{-6} are obtained for $m_{X^0} = 20-100$ MeV (see their Fig. 8). Angular momentum conservation requires that X^0 has spin ≥ 1 .

7 The limit is for $B(\phi \rightarrow \eta X^0) \cdot B(X^0 \rightarrow e^+ e^-)$ and applies to $m_{X^0} = 410$ MeV. It is derived by analyzing $\eta \rightarrow \pi^0 \pi^0 \pi^0$ and $\pi^- \pi^+ \pi^0$. Limits between 1×10^{-6} and 2×10^{-8} are obtained for $m_{X^0} \leq 450$ MeV (see their Fig. 6).

8 ARCHILLI 12 analyzed $\eta \rightarrow \pi^+ \pi^- \pi^0$ decays. Derived limits on $\alpha'/\alpha < 2 \times 10^{-5}$ for $m_{X^0} = 50-420$ MeV at 90% CL. See their Fig. 8 for mass-dependent limits.

9 This limit is for $B(\pi^0 \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow e^+ e^-)$ and applies for $m_{X^0} = 90$ MeV and $\tau_{X^0} \approx 1 \times 10^{-8}$ sec. Limits between 10^{-8} and 2×10^{-15} are obtained for $m_{X^0} = 3-120$ MeV and $\tau_{X^0} = 1 \times 10^{-11}-1$ sec. See their Fig. 3 for limits at different masses and lifetimes.

10 This limit is for $B(\eta \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow e^+ e^-)$ and applies for $m_{X^0} = 100$ MeV and $\tau_{X^0} \approx 6 \times 10^{-9}$ sec. Limits between 10^{-5} and 3×10^{-14} are obtained for $m_{X^0} \lesssim 550$ MeV and $\tau_{X^0} = 10^{-10}-10$ sec. See their Fig. 5 for limits at different mass and lifetime and for η' decays.

11 This limit applies for a mass near 180 MeV. For other masses in the range $m_{X^0} = 150-250$ MeV the limit is less restrictive, but still improves ADLER 02c and ATIYA 93b.

12 ANISIMOVSKY 04 bound is for $m_{X^0} = 0$.

13 ADLER 02c bound is for $m_{X^0} < 60$ MeV. See Fig. 2 for limits at higher masses.

14 The quoted limit is for $m_{X^0} = 0-80$ MeV. See their Fig. 5 for the limit at higher mass. The branching fraction limit assumes pure phase space decay distributions.

15 ALTEGOER 98 looked for X^0 from π^0 decay which penetrate the shielding and convert to π^0 in the external Coulomb field of a nucleus.

16 KITCHING 97 limit is for $B(K^+ \rightarrow \pi^+ X^0) \cdot B(X^0 \rightarrow \gamma\gamma)$ and applies for $m_{X^0} \approx 50$ MeV, $\tau_{X^0} < 10^{-10}$ s. Limits are provided for $0 < m_{X^0} < 100$ MeV, $\tau_{X^0} < 10^{-8}$ s.

17 ADLER 96 looked for a peak in missing-mass distribution. This work is an update of ATIYA 93. The limit is for massless stable X^0 particles and extends to $m_{X^0} = 80$ MeV at the same level. See paper for dependence on finite lifetime.

18 AMSLER 94b and AMSLER 96b looked for a peak in missing-mass distribution.

19 The MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of X^0 decay modes. It applies to $\tau(X^0) > 10^{-23}$ sec.

20 ATIYA 93b looked for a peak in missing mass distribution. The bound applies for stable X^0 of $m_{X^0} = 150-250$ MeV, and the limit becomes stronger (10^{-8}) for $m_{X^0} = 180-240$ MeV.

21 NG 93 studied the production of X^0 via $\gamma\gamma \rightarrow \pi^0 \rightarrow \gamma X^0$ in the early universe at $T \approx 1$ MeV. The bound on extra neutrinos from nucleosynthesis $\Delta N_\nu < 0.3$ (WALKER 91) is employed. It applies to $m_{X^0} \ll 1$ MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier X^0 .

22 ALLIEGRO 92 limit applies for $m_{X^0} = 150-340$ MeV and is the branching ratio times the decay probability. Limit is $< 1.5 \times 10^{-8}$ at 99% CL.

23 ATIYA 92 looked for a peak in missing mass distribution. The limit applies to $m_{X^0} = 0-130$ MeV in the narrow resonance limit. See paper for the dependence on the lifetime. Covariance requires X^0 to be a vector particle.

24 BARABASH 92 is a beam dump experiment that searched for a light Higgs. Limits between 1×10^{-12} and 1×10^{-7} are obtained for $3 < m_{X^0} < 40$ MeV.

25 Limits between 1×10^{-12} and 1 are obtained for $4 < m_{X^0} < 69$ MeV.

26 Limits between 1×10^{-11} and 5×10^{-3} are obtained for $4 < m_{X^0} < 63$ MeV.

27 Limits between 1×10^{-14} and 1 are obtained for $3 < m_{X^0} < 82$ MeV.

28 MEIJERDREES 92 limit applies for $\tau_{X^0} = 10^{-23}-10^{-11}$ sec. Limits between 2×10^{-4} and 4×10^{-6} are obtained for $m_{X^0} = 25-120$ MeV. Angular momentum conservation requires that X^0 has spin ≥ 1 .

29 ATIYA 90b limit is for $B(K^+ \rightarrow \pi^+ X^0) \cdot B(X^0 \rightarrow \gamma\gamma)$ and applies for $m_{X^0} = 50$ MeV, $\tau_{X^0} < 10^{-10}$ s. Limits are also provided for $0 < m_{X^0} < 100$ MeV, $\tau_{X^0} < 10^{-8}$ s.

30 KORENCHENKO 87 limit assumes $m_{A^0} = 1.7$ MeV, $\tau_{A^0} \lesssim 10^{-12}$ s, and $B(A^0 \rightarrow e^+ e^-) = 1$.

31 EICHLER 86 looked for $\pi^+ \rightarrow e^+ \nu A^0$ followed by $A^0 \rightarrow e^+ e^-$. Limits on the branching fraction depend on the mass and lifetime of A^0 . The quoted limits are valid when $\tau(A^0) \gtrsim 3 \times 10^{-10}$ s if the decays are kinematically allowed.

See key on page 999

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

- ³² YAMAZAKI 84 looked for a discrete line in $K^+ \rightarrow \pi^+ X$. Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.
- ³³ ASANO 82 at KEK set limits for $B(K^+ \rightarrow \pi^+ X^0)$ for $m_{X^0} < 100$ MeV as $BR < 4. \times 10^{-8}$ for $\tau(X^0 \rightarrow n\gamma\text{'s}) > 1. \times 10^{-9}$ s, $BR < 1.4 \times 10^{-6}$ for $\tau < 1. \times 10^{-9}$ s.
- ³⁴ ASANO 81B is KEK experiment. Set $B(K^+ \rightarrow \pi^+ X^0) < 3.8 \times 10^{-8}$ at CL = 90%.
- ³⁵ ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 ($3 < m < 40$ MeV) contradicts experimental muon anomalous magnetic moments.

A^0 (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

$< 4.4 \times 10^{-5}$	90	1 BADERT... 02	CNTR	$\alpha\text{-Ps} \rightarrow \gamma X_1 X_2, m_{X_1} + m_{X_2} \leq 900 \text{ keV}$
$< 2 \times 10^{-4}$	90	MAENO 95	CNTR	$\alpha\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} = 850\text{--}1013 \text{ keV}$
$< 3.0 \times 10^{-4}$	90	2 ASAI 94	CNTR	$\alpha\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} = 30\text{--}500 \text{ keV}$
$< 2.8 \times 10^{-5}$	90	3 AKOPYAN 91	CNTR	$\alpha\text{-Ps} \rightarrow A^0 \gamma (A^0 \rightarrow \gamma \gamma), m_{A^0} < 30 \text{ keV}$
$< 1.1 \times 10^{-6}$	90	4 ASAI 91	CNTR	$\alpha\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} < 800 \text{ keV}$
$< 3.8 \times 10^{-4}$	90	GNINENKO 90	CNTR	$\alpha\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} < 30 \text{ keV}$
$< (1\text{--}5) \times 10^{-4}$	95	5 TSUCHIAKI 90	CNTR	$\alpha\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} = 300\text{--}900 \text{ keV}$
$< 6.4 \times 10^{-5}$	90	6 ORITO 89	CNTR	$\alpha\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} < 30 \text{ keV}$
		7 AMALDI 85	CNTR	Ortho-positronium
		8 CARBONI 83	CNTR	Ortho-positronium
1 BADERTSCHER 02 looked for a three-body decay of ortho-positronium into a photon and two penetrating (neutral or milli-charged) particles.				
2 The ASAI 94 limit is based on inclusive photon spectrum and is independent of A^0 decay modes.				
3 The AKOPYAN 91 limit applies for a short-lived A^0 with $\tau_{A^0} < 10^{-13} m_{A^0}$ [keV] s.				
4 ASAI 91 limit translates to $g_{A^0 e^+ e^-}^2 / 4\pi < 1.1 \times 10^{-11}$ (90% CL) for $m_{A^0} < 800$ keV.				
5 The TSUCHIAKI 90 limit is based on inclusive photon spectrum and is independent of A^0 decay modes.				
6 ORITO 89 limit translates to $g_{A^0 e^+ e^-}^2 / 4\pi < 6.2 \times 10^{-10}$. Somewhat more sensitive limits are obtained for larger m_{A^0} : $B < 7.6 \times 10^{-6}$ at 100 keV.				
7 AMALDI 85 set limits $B(A^0 \gamma) / B(\gamma \gamma \gamma) < (1\text{--}5) \times 10^{-6}$ for $m_{A^0} = 900\text{--}100$ keV which are about 1/10 of the CARBONI 83 limits.				
8 CARBONI 83 looked for ortho-positronium $\rightarrow A^0 \gamma$. Set limit for A^0 electron coupling squared, $(g_{e e A^0})^2 / (4\pi) < 6. \times 10^{-10}\text{--}7. \times 10^{-9}$ for m_{A^0} from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from $g\text{--}2$ experiments.				

A^0 (Axion) Search in Photoproduction

• • • We do not use the following data for averages, fits, limits, etc. • • •		
	1 BASSOMPIERRE... 95	$m_{A^0} = 1.8 \pm 0.2 \text{ MeV}$
1 BASSOMPIERRE 95 is an extension of BASSOMPIERRE 93. They looked for a peak in the invariant mass of $e^+ e^-$ pairs in the region $m_{e^+ e^-} = 1.8 \pm 0.2 \text{ MeV}$. They obtained bounds on the production rate A^0 for $\tau(A^0) = 10^{-18}\text{--}10^{-9}$ sec. They also found an excess of events in the range $m_{e^+ e^-} = 2.1\text{--}3.5 \text{ MeV}$.		

A^0 (Axion) Production in Hadron Collisions

Limits are for $\sigma(A^0) / \sigma(\pi^0)$.

1 SIRUNYAN 19Bq look for the pair production of a new light boson decaying into a pair of muons, and set limits on the product of the production cross section times branching fraction to dimuons squared times acceptance over a range of $m_{X^0} = 0.25\text{--}8.5 \text{ GeV}$. See the right panel of their Fig. 1 for mass-dependent limits.					
2 JAIN 07 claims evidence for $A^0 \rightarrow e^+ e^-$ produced in 207Pb collision on nuclear emulsion (Ag/Br) for $m(A^0) = 7 \pm 1$ or $19 \pm 1 \text{ MeV}$ and $\tau(A^0) \leq 10^{-13} \text{ s}$.					
3 AHMAD 97 reports a result of APEX Collaboration which studied positron production in $^{238}\text{U} + ^{232}\text{Ta}$ and $^{238}\text{U} + ^{181}\text{Ta}$ collisions, without requiring a coincident electron. No narrow lines were found for $250 < E_{e^+} < 750 \text{ keV}$.					
4 LEINBERGER 97 (ORANGE Collaboration) at GSI looked for a narrow sum-energy $e^+ e^-$ line at $\sim 635 \text{ keV}$ in $^{238}\text{U} + ^{181}\text{Ta}$ collision. Limits on the production probability for a narrow sum-energy $e^+ e^-$ line are set. See their Table 2.					
5 GANZ 96 (EPOS II Collaboration) has placed upper bounds on the production cross section of $e^+ e^-$ pairs from $^{238}\text{U} + ^{181}\text{Ta}$ and $^{238}\text{U} + ^{232}\text{Th}$ collisions at GSI. See Table 2 for limits both for back-to-back and isotropic configurations of $e^+ e^-$ pairs. These limits rule out the existence of peaks in the $e^+ e^-$ sum-energy distribution, reported by an earlier version of this experiment.					
6 KAMEL 96 looked for $e^+ e^-$ pairs from the collision of ^{32}S (200 GeV/nucleon) and emulsion. No evidence of mass peaks is found in the region of sensitivity $m_{e e} > 2 \text{ MeV}$.					
7 BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of $e^+ e^-$ or $\mu^+ \mu^-$ from the produce A^0 . See Fig. 5 for the excluded region in $m_{A^0}\text{-}x$ plane. For the standard axion, $0.3 < x < 25$ is excluded at 95% CL. If combined with BLUEMLEIN 91, $0.008 < x < 32$ is excluded.					
8 MEIJERDREES 92 give $\Gamma(\pi^- p \rightarrow n A^0) \cdot B(A^0 \rightarrow e^+ e^-) / \Gamma(\pi^- p \rightarrow \text{all}) < 10^{-5}$ (90% CL) for $m_{A^0} = 100 \text{ MeV}$, $\tau_{A^0} = 10^{-11}\text{--}10^{-23} \text{ sec}$. Limits ranging from 2.5×10^{-3} to 10^{-7} are given for $m_{A^0} = 25\text{--}136 \text{ MeV}$.					
9 BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for $A^0 \rightarrow e^+ e^-, 2\gamma$ are found. Fig. 6 gives the excluded region in $m_{A^0}\text{-}x$ plane ($x = \tan\beta = v_2/v_1$). Standard axion is excluded for $0.2 < m_{A^0} < 3.2 \text{ MeV}$ for most $x > 1$, $0.2\text{--}11 \text{ MeV}$ for most $x < 1$.					
10 FAISSNER 89 searched for $A^0 \rightarrow e^+ e^-$ in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass $2m_e\text{--}20 \text{ MeV}$ is excluded. Lower limit on f_{A^0} of $\approx 10^4 \text{ GeV}$ is given for $m_{A^0} = 2m_e\text{--}20 \text{ MeV}$.					
11 DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass $\sim 1.1, \sim 2.1, \text{ and } \sim 9 \text{ MeV}$, lifetimes $10^{-16}\text{--}10^{-15} \text{ s}$ decaying to $e^+ e^-$					

Downloaded from https://academic.oup.com/ptep/article/2020/8/083C01/5891211 by Aix Marseille Universite user on 06 January 2021

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

- and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B. M. Anand, Proc. of the Royal Society of London, Section A **A22** 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with π^0 Dalitz decay. DEBOER 89B is a reply which contests the criticism.
- 12 EL-NADI 88 claim the existence of a neutral particle decaying into e^+e^- with mass 1.60 ± 0.59 MeV, lifetime $(0.15 \pm 0.01) \times 10^{-14}$ s, which is produced in heavy ion interactions with emulsion nuclei at ~ 4 GeV/c/nucleon.
 - 13 FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for $A^0 \rightarrow \gamma\gamma$. A standard axion decaying to 2γ is excluded except for a region $x \lesssim 1$. Lower limit on f_{A^0} of 10^2 – 10^3 GeV is given for $m_{A^0} = 0.1$ –1 MeV.
 - 14 BADIER 86 did not find long-lived A^0 in 300 GeV π^- Beam Dump Experiment that decays into e^+e^- in the mass range $m_{A^0} = (20$ – $200)$ MeV, which excludes the A^0 decay constant $f(A^0)$ in the interval (60–600) GeV. See their figure 6 for excluded region on $f(A^0)$ – m_{A^0} plane.
 - 15 BERGSMÄ 85 look for $A^0 \rightarrow 2\gamma, e^+e^-, \mu^+\mu^-$. First limit above is for $m_{A^0} = 1$ MeV; second is for 200 MeV. See their figure 4 for excluded region on f_{A^0} – m_{A^0} plane, where f_{A^0} is A^0 decay constant. For Peccei-Quinn PECEI 77 $A^0, m_{A^0} < 180$ keV and $\tau > 0.037$ s. (CL = 90%). For the axion of FAISSNER 81B at 250 keV, BERGSMÄ 85 expect 15 events but observe zero.
 - 16 FAISSNER 83 observed 19 $1\text{-}\gamma$ and 12 $2\text{-}\gamma$ events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.
 - 17 FAISSNER 83B extrapolate SIN γ signal to LAMPF ν experimental condition. Resulting 370 γ 's are not at variance with LAMPF upper limit of 450 γ 's. Derived from LAMPF limit that $[d\sigma(A^0)/d\omega \text{ at } 90^\circ] m_{A^0} / \tau_{A^0} < 14 \times 10^{-35} \text{ cm}^2 \text{ sr}^{-1} \text{ MeV ms}^{-1}$. See comment on FRANK 83B.
 - 18 FRANK 83B stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-A0 are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450 γ 's. See comment on FAISSNER 83B.
 - 19 HOFFMAN 83 set CL = 90% limit $d\sigma/dt B(e^+e^-) < 3.5 \times 10^{-32} \text{ cm}^2/\text{GeV}^2$ for $140 < m_{A^0} < 160$ MeV. Limit assumes $\tau(A^0) < 10^{-9}$ s.
 - 20 FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since $2\text{-}\gamma$ peak rate remarkably decreases if iron wall is set in front of the decay region.
 - 21 FAISSNER 81 see excess μe events. Suggest axion interactions.
 - 22 FAISSNER 81B is SIN 590 MeV proton beam dump. Observed 14.5 ± 5.0 events of 2γ decay of long-lived neutral penetrating particle with $m_{2\gamma} \lesssim 1$ MeV. Axion interpretation with η - A^0 mixing gives $m_{A^0} = 250 \pm 25$ keV, $\tau_{(2\gamma)} = (7.3 \pm 3.7) \times 10^{-3}$ s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83B, FRANK 83B, and BERGSMÄ 85. Also see in the next subsection ALEKSEEV 82B, CAVIGNAC 83, and ANANEV 85.
 - 23 KIM 81 analyzed 8 candidates for $A^0 \rightarrow 2\gamma$ obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is $(0.86$ – $5.6) \times 10^{-3}$ s depending on models. Faisner (private communication), says axion production underestimated and mass overestimated. Correct value around 200 keV.
 - 24 FAISSNER 80 is SIN beam dump experiment with 590 MeV protons looking for $A^0 \rightarrow e^+e^-$ decay. Assuming $A^0/\pi^0 = 5.5 \times 10^{-7}$, obtained decay rate limit $20/(A^0 \text{ mass}) \text{ MeV/s}$ (CL = 90%), which is about 10^{-7} below theory and interpreted as upper limit to $m_{A^0} < 2m_{e^-}$.
 - 25 JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events $[\sigma(\text{production})\sigma(\text{interaction}) < 7. \times 10^{-68} \text{ cm}^4, \text{ CL} = 90\%]$. Second limit is from nonobservation of axion decays into 2γ 's or e^+e^- , and for axion mass a few MeV.
 - 26 SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.
 - 27 BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either 2γ or e^+e^- . No signal found. CL = 90% limits for model parameter(s) are given.
 - 28 COTEUS 79 is a beam dump experiment at BNL.
 - 29 DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distributions due to energy lost to weakly interacting particles.
 - 30 BELLOTTI 78 first value comes from search for $A^0 \rightarrow e^+e^-$. Second value comes from search for $A^0 \rightarrow 2\gamma$, assuming mass $< 2m_{e^-}$. For any mass satisfying this, limit is above value $\times (\text{mass}^{-4})$. Third value uses data of PL 60B 401 and quotes $\sigma(\text{production})\sigma(\text{interaction}) < 10^{-67} \text{ cm}^4$.
 - 31 BOSETTI 78B quotes $\sigma(\text{production})\sigma(\text{interaction}) < 2. \times 10^{-67} \text{ cm}^4$.
 - 32 DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.
 - 33 MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).
 - 34 VYSOTSKII 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

A^0 (Axion) Searches in Reactor Experiments

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
1	CHANG 07		Primakoff or Compton
2	ALTMANN 95	CNTR	Reactor; $A^0 \rightarrow e^+e^-$
3	KETOV 86	SPEC	Reactor; $A^0 \rightarrow \gamma\gamma$
4	KOCH 86	SPEC	Reactor; $A^0 \rightarrow \gamma\gamma$
5	DATAR 82	CNTR	Light water reactor
6	VUILLEUMIER 81	CNTR	Reactor; $A^0 \rightarrow 2\gamma$

- 1 CHANG 07 looked for monochromatic photons from Primakoff or Compton conversion of axions from the Kuo-Sheng reactor due to axion coupling to photon or electron, respectively. The search places model-independent limits on the products $G_{A\gamma\gamma}G_{ANN}$ and $G_{Aee}G_{ANN}$ for $m(A^0)$ less than the MeV range.
- 2 ALTMANN 95 looked for A^0 decaying into e^+e^- from the Bugey 5 nuclear reactor. They obtain an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma) \times B(A^0 \rightarrow e^+e^-) < 10^{-16}$ for $m_{A^0} = 1.5$ MeV at 90% CL. The limit is weaker for heavier A^0 . In the case of a standard axion, this limit excludes a mass in the range $2m_e < m_{A^0} < 4.8$ MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances Z^0 in the (m_{X^0}, f_{X^0}) plane.
- 3 KETOV 86 searched for A^0 at the Rovno nuclear power plant. They found an upper limit on the A^0 production probability of $0.8 [100 \text{ keV}/m_{A^0}]^6 \times 10^{-6}$ per fission. In the standard axion model, this corresponds to $m_{A^0} > 150$ keV. Not valid for $m_{A^0} \gtrsim 1$ MeV.
- 4 KOCH 86 searched for $A^0 \rightarrow \gamma\gamma$ at nuclear power reactor Biblis A. They found an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$ (CL=95%). Standard axion with $m_{A^0} = 250$ keV gives 10^{-5} for the ratio. Not valid for $m_{A^0} > 1022$ keV.
- 5 DATAR 82 looked for $A^0 \rightarrow 2\gamma$ in neutron capture ($np \rightarrow dA^0$) at Tarapur 500 MW reactor. Sensitive to sum of $l = 0$ and $l = 1$ amplitudes. With ZEHNDER 81 [$(l = 0) - (l = 1)$] result, assert nonexistence of standard A^0 .
- 6 VUILLEUMIER 81 is at Grenoble reactor. Set limit $m_{A^0} < 280$ keV.

- 1 DERBIN 02 looked for the axion emission in an M1 transition in ^{125m}Te decay. They looked for a possible presence of a shifted energy spectrum in gamma rays due to the undetected axion.
- 2 DEBOER 97C reanalyzed the existent data on Nuclear M1 transitions and find that a 9 MeV boson decaying into e^+e^- would explain the excess of events with large opening angles. See also DEBOER 01 for follow-up experiments.
- 3 TSUNODA 95 looked for axion emission when ^{252}Cf undergoes a spontaneous fission, with the axion decaying into e^+e^- . The bound is for $m_{A^0} = 40$ MeV. It improves to 2.5×10^{-5} for $m_{A^0} = 200$ MeV.
- 4 MINOWA 93 studied chain process, $^{139}\text{Ce} \rightarrow ^{139}\text{La}^*$ by electron capture and M1 transition of $^{139}\text{La}^*$ to the ground state. It does not assume decay modes of A^0 . The bound applies for $m_{A^0} < 166$ keV.
- 5 HICKS 92 bound is applicable for $\tau_{X^0} < 4 \times 10^{-11}$ sec.
- 6 THE ASANUMA 90 limit is for the branching fraction of X^0 emission per ^{241}Am α decay and valid for $\tau_{X^0} < 3 \times 10^{-11}$ s.
- 7 THE DEBOER 90 limit is for the branching ratio $^8\text{Be}^* (18.15 \text{ MeV}, 1^+) \rightarrow ^8\text{Be} A^0, A^0 \rightarrow e^+e^-$ for the mass range $m_{A^0} = 4$ –15 MeV.
- 8 THE BINI 89 limit is for the branching fraction of $^{16}\text{O}^* (6.05 \text{ MeV}, 0^+) \rightarrow ^{16}\text{O} X^0, X^0 \rightarrow e^+e^-$ for $m_{X^0} = 1.5$ –3.1 MeV. $\tau_{X^0} \lesssim 10^{-11}$ s is assumed. The spin-parity of X is restricted to 0^+ or 1^- .
- 9 AVIGNONE 88 looked for the 1115 keV transition $\text{C}^* \rightarrow \text{Cu} A^0$, either from $A^0 \rightarrow 2\gamma$ in-flight decay or from the secondary A^0 interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for $m_{A^0} < 1.1$ MeV.

See key on page 999

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

- ¹⁰DATAR 88 rule out light pseudoscalar particle emission through its decay $A^0 \rightarrow e^+e^-$ in the mass range 1.02–2.5 MeV and lifetime range 10^{-13} – 10^{-8} s. The above limit is for $\tau = 5 \times 10^{-13}$ s and $m = 1.7$ MeV; see the paper for the τ - m dependence of the limit.
- ¹¹The limit is for the branching fraction of $^{16}\text{O}^*(6.05 \text{ MeV}, 0^+) \rightarrow ^{16}\text{O}X^0, X^0 \rightarrow e^+e^-$ against internal pair conversion for $m_{X^0} = 1.7$ MeV and $\tau_{X^0} < 10^{-11}$ s. Similar limits are obtained for $m_{X^0} = 1.3$ – 3.2 MeV. The spin parity of X^0 must be either 0^+ or 1^- . The limit at 1.7 MeV is translated into a limit for the X^0 -nucleon coupling constant: $g_{X^0 NN}^2/4\pi < 2.3 \times 10^{-9}$.
- ¹²The DOEHNER 88 limit is for $m_{A^0} = 1.7$ MeV, $\tau(A^0) < 10^{-10}$ s. Limits less than 10^{-4} are obtained for $m_{A^0} = 1.2$ – 2.2 MeV.
- ¹³SAVAGE 88 looked for A^0 that decays into e^+e^- in the decay of the 9.17 MeV $J^P = 2^+$ state in ^{14}N , 17.64 MeV state $J^P = 1^+$ in ^8Be , and the 18.15 MeV state $J^P = 1^+$ in ^8Be . This experiment constrains the isovector coupling of A^0 to hadrons, if $m_{A^0} = (1.1 \rightarrow 2.2)$ MeV and the isoscalar coupling of A^0 to hadrons, if $m_{A^0} = (1.1 \rightarrow 2.6)$ MeV. Both limits are valid only if $\tau(A^0) \lesssim 1 \times 10^{-11}$ s.
- ¹⁴Limits are for $\Gamma(A^0(1.8 \text{ MeV}))/\Gamma(\pi\text{M}1)$; i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of e^+e^- pairs. Valid for $\tau_{A^0} < 2 \times 10^{-11}$ s. ^6Li isovector decay data strongly disfavor PECCCI 86 model I, whereas the ^{10}B and ^{14}N isoscalar decay data strongly reject PECCCI 86 model II and III.
- ¹⁵SAVAGE 86b looked for A^0 that decays into e^+e^- in the decay of the 9.17 MeV $J^P = 2^+$ state in ^{14}N . Limit on the branching fraction is valid if $\tau_{A^0} \lesssim 1 \times 10^{-11}$ s for $m_{A^0} = (1.1$ – $1.7)$ MeV. This experiment constrains the iso-vector coupling of A^0 to hadrons.
- ¹⁶ANANEV 85 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% masses below 470 keV (Li^* decay) and below $2m_e$ for deuterium* decay.
- ¹⁷CAVAIGNAC 83 at Bugey reactor exclude axion at any $m_{97\text{Nb}^*}$ decay and axion with m_{A^0} between 275 and 288 keV (deuteron* decay).
- ¹⁸ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% mass-ranges $m_{A^0} < 400$ keV (Li^* decay) and 330 keV $< m_{A^0} < 2.2$ MeV. (deuteron* decay).
- ¹⁹LEHMANN 82 obtained $A^0 \rightarrow 2\gamma$ rate $< 6.2 \times 10^{-5}/\text{s}$ (CL = 95%) excluding m_{A^0} between 100 and 1000 keV.
- ²⁰ZEHNDER 82 used Gogsen 2.8GW light-water reactor to check A^0 production. No 2γ peak in Li^* , Nb^* decay (both single p transition) nor in n capture (combined with previous Ba^* negative result) rules out standard A^0 . Set limit $m_{A^0} < 60$ keV for any A^0 .
- ²¹ZEHNDER 81 looked for $\text{Ba}^* \rightarrow A^0\text{Ba}$ transition with $A^0 \rightarrow 2\gamma$. Obtained 2γ coincidence rate $< 2.2 \times 10^{-5}/\text{s}$ (CL = 95%) excluding $m_{A^0} > 160$ keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.
- ²²CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

A^0 (Axion) Limits from Its Electron Coupling

Limits are for $\tau(A^0 \rightarrow e^+e^-)$.

VALUE (s)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
none 4×10^{-16} – 4.5×10^{-12}	90	1 BROSS	91 BDMP $eN \rightarrow eA^0N$ ($A^0 \rightarrow ee$)	
		2 GUO	90 BDMP $eN \rightarrow eA^0N$ ($A^0 \rightarrow ee$)	
		3 BJORKEN	88 CALO $A \rightarrow e^+e^-$ or 2γ

none 1×10^{-14} – 1×10^{-11}	90	6 BROWN	86 BDMP $eN \rightarrow eA^0N$ ($A^0 \rightarrow ee$)	
none 6×10^{-14} – 9×10^{-11}	95	7 DAVIER	86 BDMP $eN \rightarrow eA^0N$ ($A^0 \rightarrow ee$)	
none 3×10^{-13} – 1×10^{-7}	90	8 KONAKA	86 BDMP $eN \rightarrow eA^0N$ ($A^0 \rightarrow ee$)	

- ¹The listed BROSS 91 limit is for $m_{A^0} = 1.14$ MeV. $B(A^0 \rightarrow e^+e^-) = 1$ assumed. Excluded domain in the τ_{A^0} - m_{A^0} plane extends up to $m_{A^0} \approx 7$ MeV (see Fig. 5). Combining with electron g -2 constraint, axions coupling only to e^+e^- ruled out for $m_{A^0} < 4.8$ MeV (90% CL).
- ²GUO 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with g -2 constraint, axions coupling only to e^+e^- are ruled out for $m_{A^0} < 2.7$ MeV (90% CL).
- ³BJORKEN 88 reports limits on axion parameters (f_A, m_A, τ_A) for $m_{A^0} < 200$ MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic electrons.
- ⁴BLINOV 88 assume zero spin, $m = 1.8$ MeV and lifetime $< 5 \times 10^{-12}$ s and find $\Gamma(A^0 \rightarrow \gamma\gamma)B(A^0 \rightarrow e^+e^-) < 2$ eV (CL=90%).
- ⁵Assumes $A^0\gamma\gamma$ coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for $m_{A^0} < 15$ MeV.
- ⁶Uses electrons in hadronic showers from an incident 800 GeV proton beam. Limits for $m_{A^0} < 15$ MeV are shown in their figure 3.
- ⁷ $m_{A^0} = 1.8$ MeV assumed. The excluded domain in the τ_{A^0} - m_{A^0} plane extends up to $m_{A^0} \approx 14$ MeV, see their figure 4.
- ⁸The limits are obtained from their figure 3. Also given is the limit on the $A^0\gamma\gamma$ - $A^0e^+e^-$ coupling plane by assuming Primakoff production.

Search for A^0 (Axion) Resonance in Bhabha Scattering

The limit is for $\Gamma(A^0)[B(A^0 \rightarrow e^+e^-)]^2$.

< 2500	90	MILLS	87 CNTR	$m_{A^0} = 1.8$ MeV
		10 VONWIMMER	87 CNTR	

- ¹HALLIN 92 quote limits on lifetime, 8×10^{-14} – 5×10^{-13} sec depending on mass, assuming $B(A^0 \rightarrow e^+e^-) = 100\%$. They say that TSERTOS 91 overestimated their sensitivity by a factor of 3.
- ²HENDERSON 92c exclude axion with lifetime $\tau_{A^0} = 1.4 \times 10^{-12}$ – 4.0×10^{-10} s, assuming $B(A^0 \rightarrow e^+e^-) = 100\%$. HENDERSON 92c also exclude a vector boson with $\tau = 1.4 \times 10^{-12}$ – 6.0×10^{-10} s.
- ³WU 92 quote limits on lifetime $> 3.3 \times 10^{-13}$ s assuming $B(A^0 \rightarrow e^+e^-) = 100\%$. They say that TSERTOS 89 overestimate the limit by a factor of $\pi/2$. WU 92 also quote a bound for vector boson, $\tau > 8.2 \times 10^{-13}$ s.
- ⁴WIDMANN 91 bound applies exclusively to the case $B(A^0 \rightarrow e^+e^-) = 1$, since the detection efficiency varies substantially as $\Gamma(A^0)_{\text{total}}$ changes. See their Fig. 6.
- ⁵JUDGE 90 excludes an elastic pseudoscalar e^+e^- resonance for 4.5×10^{-13} s $< \tau(A^0) < 7.5 \times 10^{-12}$ s (95% CL) at $m_{A^0} = 1.832$ MeV. Comparable limits can be set for $m_{A^0} = 1.776$ – 1.856 MeV.
- ⁶See also TSERTOS 88b in references.
- ⁷The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88b, footnote 3.
- ⁸VANKLINKEN 88 looked for relatively long-lived resonance ($\tau = 10^{-10}$ – 10^{-12} s). The sensitivity is not sufficient to exclude such a narrow resonance.
- ⁹MAIER 87 obtained limits $R\Gamma \lesssim 60$ eV (100 eV) at $m_{A^0} \approx 1.64$ MeV (1.83 MeV) for energy resolution $\Delta E_{\text{cm}} \approx 3$ keV, where R is the resonance cross section normalized to that of Bhabha scattering, and $\Gamma = \Gamma_{e^+e^-}^2/\Gamma_{\text{total}}$. For a discussion implying that $\Delta E_{\text{cm}} \approx 10$ keV, see TSERTOS 89.
- ¹⁰VONWIMMERSPERG 87 measured Bhabha scattering for $E_{\text{cm}} = 1.37$ – 1.86 MeV and found a possible peak at 1.73 with $\int \sigma dE_{\text{cm}} = 14.5 \pm 6.8$ keV·b. For a comment and a reply, see VANKLINKEN 88b and VONWIMMERSPERG 88. Also see CONNELL 88.

Search for A^0 (Axion) Resonance in $e^+e^- \rightarrow \gamma\gamma$

The limit is for $\Gamma(A^0 \rightarrow e^+e^-)\Gamma(A^0 \rightarrow \gamma\gamma)/\Gamma_{\text{total}}$

< 3.8	95	3 SKALSEY	92 CNTR	$m_{X^0}=1.5$ MeV

- ¹ VO 94 looked for $X^0 \rightarrow \gamma\gamma$ decaying at rest. The precise limits depend on m_{X^0} . See Fig. 2(b) in paper.
² VO 94 looked for $X^0 \rightarrow \gamma\gamma$ decaying in flight.
³ SKALSEY 92 also give limits 4.3 for $m_{X^0}=1.54$ and 7.5 for 1.64 MeV. The spin of X^0 is assumed to be one.

Light Boson (X^0) Search in Nonresonant e^+e^- Annihilation at Rest

Limits are for the ratio of $n\gamma + X^0$ production relative to $\gamma\gamma$.

VALUE (units 10^{-6})	CL%	DOCUMENT ID	TECN	COMMENT

< 0.26	90	5 ADACHI	94 CNTR	$\gamma\gamma X^0, X^0 \rightarrow \gamma\gamma$
< 0.33	90	6 ADACHI	94 CNTR	$\gamma\gamma X^0, X^0 \rightarrow \gamma\gamma$

- ¹ MITSUI 96 looked for a monochromatic γ . The bound applies for a vector X^0 with $C=-1$ and $m_{X^0} < 200$ keV. They derive an upper bound on eX^0 coupling and hence on the branching ratio $B(\rho\text{-Ps} \rightarrow \gamma\gamma X^0) < 6.2 \times 10^{-6}$. The bounds weaken for heavier X^0 .
² SKALSEY 95 looked for a monochromatic γ without an accompanying γ in e^+e^- annihilation. The bound applies for scalar and vector X^0 with $C=-1$ and $m_{X^0}=100-1000$ keV.
³ SKALSEY 95 reinterpreted the bound on γA^0 decay of ρ -Ps by ASA1 91 where 3% of delayed annihilations are not from 3S_1 states. The bound applies for scalar and vector X^0 with $C=-1$ and $m_{X^0}=0-800$ keV.
⁴ ADACHI 94 looked for a peak in the $\gamma\gamma$ invariant mass distribution in $\gamma\gamma\gamma\gamma$ production from e^+e^- annihilation. The bound applies for $m_{X^0}=70-800$ keV.
⁵ ADACHI 94 looked for a peak in the missing-mass distribution in $\gamma\gamma$ channel, using $\gamma\gamma\gamma\gamma$ production from e^+e^- annihilation. The bound applies for $m_{X^0} < 800$ keV.
⁶ ADACHI 94 looked for a peak in the missing mass distribution in $\gamma\gamma\gamma$ channel, using $\gamma\gamma\gamma\gamma$ production from e^+e^- annihilation. The bound applies for $m_{X^0}=200-900$ keV.

Searches for Goldstone Bosons (X^0)

(Including Horizontal Bosons and Majorons.) Limits are for branching ratios.

- ¹ BAYES 15 limits are the average over $m_{X^0}=13-80$ MeV for the isotropic decay distribution of positrons. See their Fig. 4 and Table II for the mass-dependent limits as well as the dependence on the decay anisotropy. In particular, they find a limit $< 58 \times 10^{-6}$ at 90% CL for massless familons and for the same asymmetry as normal muon decay, a case not covered by JODIDIO 86.
² LATTANZI 13 use WMAP 9 year data as well as X-ray and γ -ray observations to derive limits on decaying majoron dark matter. A limit on the decay width $\Gamma(X^0 \rightarrow \nu\bar{\nu}) < 6.4 \times 10^{-19} \text{ s}^{-1}$ at 95% CL is found if majorons make up all of the dark matter.
³ LESSA 07 consider decays of the form Meson $\rightarrow \ell\nu$ Majoron and $\ell \rightarrow \ell'\nu\bar{\nu}$ Majoron and use existing data to derive limits on the neutrino-Majoron Yukawa couplings $g_{\alpha\beta}$ ($\alpha, \beta = e, \mu, \tau$). Their best limits are $|g_{e\alpha}|^2 < 5.5 \times 10^{-6}$, $|g_{\mu\alpha}|^2 < 4.5 \times 10^{-5}$, $|g_{\tau\alpha}|^2 < 5.5 \times 10^{-2}$ at CL = 90%.
⁴ DIAZ 98 studied models of spontaneously broken lepton number with both singlet and triplet Higgses. They obtain limits on the parameter space from invisible decay $Z \rightarrow H^0 A^0 \rightarrow X^0 X^0 X^0 X^0$ and $e^+e^- \rightarrow Z H^0$ with $H^0 \rightarrow X^0 X^0$.
⁵ BOBRAKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (arion). A limit

- $x_e^2 < 2 \times 10^{-4}$ (95%CL) is found for the effective anomalous magneton parametrized as $x_e(G_F/8\pi\sqrt{2})^{1/2}$.
⁶ ALBRECHT 90E limits are for $B(\tau \rightarrow \ell X^0)/B(\tau \rightarrow \ell\nu\bar{\nu})$. Valid for $m_{X^0} < 100$ MeV. The limits rise to 7.1% (for μ), 5.0% (for e) for $m_{X^0}=500$ MeV.
⁷ ATIYA 90 limit is for $m_{X^0}=0$. The limit $B < 1 \times 10^{-8}$ holds for $m_{X^0} < 95$ MeV. For the reduction of the limit due to finite lifetime of X^0 , see their Fig. 3.
⁸ BALKE 88 limits are for $B(\mu^+ \rightarrow e^+ X^0)$. Valid for $m_{X^0} < 80$ MeV and $\tau_{X^0} > 10^{-8}$ sec.
⁹ BOLTON 88 limit corresponds to $F > 3.1 \times 10^9$ GeV, which does not depend on the chirality property of the coupling.
¹⁰ CHANDA 88 find $v_T < 10$ MeV for the weak-triplet Higgs vacuum expectation value in Gelmini-Roncadelli model, and $v_S > 5.8 \times 10^6$ GeV in the singlet Majoron model.
¹¹ CHOI 88 used the observed neutrino flux from the supernova SN 1987A to exclude the neutrino Majoron Yukawa coupling h in the range $2 \times 10^{-5} < h < 3 \times 10^{-4}$ for the interaction $L_{\text{int}} = \frac{1}{2} i h \bar{\nu}_L \gamma_5 \psi_\nu \phi_X$. For several families of neutrinos, the limit applies for $(\Sigma h_i^2)^{1/4}$.
¹² PICCIOTTO 88 limit applies when $m_{X^0} < 55$ MeV and $\tau_{X^0} > 2$ ns, and it decreases to 4×10^{-7} at $m_{X^0}=125$ MeV, beyond which no limit is obtained.
¹³ GOLDMAN 87 limit corresponds to $F > 2.9 \times 10^9$ GeV for the family symmetry breaking scale from the Lagrangian $L_{\text{int}} = (1/F) \bar{\psi}_\mu \gamma^\mu (a + b\gamma_5) \psi_e \theta_\mu \phi_{X^0}$ with $a^2 + b^2 = 1$. This is not as sensitive as the limit $F > 9.9 \times 10^9$ GeV derived from the search for $\mu^+ \rightarrow e^+ X^0$ by JODIDIO 86, but does not depend on the chirality property of the coupling.
¹⁴ Limits are for $\Gamma(\mu \rightarrow e X^0)/\Gamma(\mu \rightarrow e\nu\bar{\nu})$. Valid when $m_{X^0}=0-93.4, 98.1-103.5$ MeV.
¹⁵ EICHLER 86 looked for $\mu^+ \rightarrow e^+ X^0$ followed by $X^0 \rightarrow e^+e^-$. Limits on the branching fraction depend on the mass and lifetime of X^0 . The quoted limits are valid when $\tau_{X^0} \lesssim 3 \times 10^{-10}$ s if the decays are kinematically allowed.
¹⁶ JODIDIO 86 corresponds to $F > 9.9 \times 10^9$ GeV for the family symmetry breaking scale with the parity-conserving effective Lagrangian $L_{\text{int}} = (1/F) \bar{\psi}_\mu \gamma^\mu \psi_e \theta_\mu \phi_{X^0}$.
¹⁷ BALTRUSAITIS 85 search for light Goldstone boson (X^0) of broken U(1). CL = 95% limits are $B(\tau \rightarrow \mu^+ X^0)/B(\tau \rightarrow \mu^+ \nu\bar{\nu}) < 0.125$ and $B(\tau \rightarrow e^+ X^0)/B(\tau \rightarrow e^+ \nu\bar{\nu}) < 0.04$. Inferred limit for the symmetry breaking scale is $m > 3000$ TeV.
¹⁸ The primordial heavy neutrino must decay into ν and familon, f_A , early so that the red-shifted decay products are below critical density, see their table. In addition, $K \rightarrow \pi f_A$ and $\mu \rightarrow e f_A$ are unseen. Combining these excludes $m_{\text{heavy}\nu}$ between 5×10^{-5} and 5×10^{-4} MeV (μ decay) and $m_{\text{heavy}\nu}$ between 5×10^{-5} and 0.1 MeV (K -decay).

Majoron Searches in Neutrinoless Double β Decay

Limits are for the half-life of neutrinoless $\beta\beta$ decay with a Majoron emission.

No experiment currently claims any such evidence. Only the best or comparable limits for each isotope are reported.

- ¹ BERNATOWICZ 92 studied double- β decays of ¹²⁸Te and ¹³⁰Te, and found the ratio $\tau(130\text{Te})/\tau(128\text{Te}) = (3.52 \pm 0.11) \times 10^{-4}$ in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of ¹²⁸Te of $(7.7 \pm 0.4) \times 10^{24}$ year. We calculated 90% CL limit as $(7.7-1.28 \times 0.4=7.2) \times 10^{24}$.

See key on page 999

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

- ² ARNOLD 19 uses the NEMO-3 tracking calorimeter to determine limits for the Majoron emitting double beta decay, with spectral index $n = 3$. The limit corresponds to the range of the g_{ee} coupling of 0.013–0.035; depending on the nuclear matrix elements used.
- ³ ARNOLD 18 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{ee} \rangle < 3.2\text{--}8.0 \times 10^{-5}$; the range corresponds to different nuclear matrix element calculations.
- ⁴ AGOSTINI 15A analyze a 20.3 kg yr of data set of the GERDA calorimeter to determine $g_{\nu\chi} < 3.4\text{--}8.7 \times 10^{-5}$ on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.
- ⁵ ARNOLD 15 use the NEMO-3 tracking calorimeter with 3.43 kg yr exposure to determine the limit on Majoron emission. The limit corresponds to $g_{\nu\chi} < 1.6\text{--}3.0 \times 10^{-4}$. The spread reflects different nuclear matrix elements. Supersedes ARNOLD 06.
- ⁶ ALBERT 14A utilize 100 kg yr of exposure of the EXO-200 tracking calorimeter to place a limit on the $g_{\nu\chi} < 0.8\text{--}1.7 \times 10^{-5}$ on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.
- ⁷ GANDO 12 use the KamLAND-Zen detector to obtain the limit on the $0\nu\chi$ decay with Majoron emission. It implies that the coupling constant $g_{\nu\chi} < 0.8\text{--}1.6 \times 10^{-5}$ depending on the nuclear matrix elements used.
- ⁸ ARNOLD 11 use the NEMO-3 detector to obtain the reported limit on Majoron emission. It implies that the coupling constant $g_{\nu\chi} < 0.6\text{--}1.6 \times 10^{-4}$ depending on the nuclear matrix element used. Supersedes ARNOLD 03.
- ⁹ ARGYRIADES 10 use the NEMO-3 tracking detector and ⁹⁶Zr to derive the reported limit. No limit for the Majoron electron coupling is given.
- ¹⁰ ARGYRIADES 09 use ¹⁵⁰Nd data taken with the NEMO-3 tracking detector. The reported limit corresponds to $\langle g_{\nu\chi} \rangle < 1.7\text{--}3.0 \times 10^{-4}$ using a range of nuclear matrix elements that include the effect of nuclear deformation.
- ¹¹ ARNOLD 06 use ¹⁰⁰Mo data taken with the NEMO-3 tracking detector. The reported limit corresponds to $\langle g_{\nu\chi} \rangle < (0.4\text{--}1.8) \times 10^{-4}$ using a range of matrix element calculations. Superseded by ARNOLD 15.
- ¹² NEMO-3 tracking calorimeter is used in ARNOLD 06. Reported half-life limit for ⁸²Se corresponds to $\langle g_{\nu\chi} \rangle < (0.66\text{--}1.9) \times 10^{-4}$ using a range of matrix element calculations. Supersedes ARNOLD 04.
- ¹³ ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{\nu\chi} \rangle < (0.5\text{--}0.9)10^{-4}$ using the matrix elements of SIMKOVIĆ 99, STOICA 01 and CIVITARESE 03. Superseded by ARNOLD 06.
- ¹⁴ ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{\nu\chi} \rangle < (0.7\text{--}1.6)10^{-4}$ using the matrix elements of SIMKOVIĆ 99, STOICA 01 and CIVITARESE 03.
- ¹⁵ Supersedes ALESSANDRELLO 00. Array of TeO₂ crystals in high resolution cryogenic calorimeter. Some enriched in ¹³⁰Te. Derive $\langle g_{\nu\chi} \rangle < 17\text{--}33 \times 10^{-5}$ depending on matrix element.
- ¹⁶ Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search.
- ¹⁷ Limit for the $0\nu\chi$ decay with Majoron emission of ¹¹⁶Cd using enriched CdWO₄ scintillators. $\langle g_{\nu\chi} \rangle < 4.6\text{--}8.1 \times 10^{-5}$ depending on the matrix element. Supersedes DANEVICH 00.
- ¹⁸ Limit for the $0\nu 2\chi$ decay of ¹¹⁶Cd. Supersedes DANEVICH 00.
- ¹⁹ BERNABEI 02b obtain limit for $0\nu\chi$ decay with Majoron emission of ¹³⁶Xe using liquid Xe scintillation detector. They derive $\langle g_{\nu\chi} \rangle < 2.0\text{--}3.0 \times 10^{-5}$ with several nuclear matrix elements.
- ²⁰ Replaces TANAKA 93. FUSHIMI 02 derive half-life limit for the $0\nu\chi$ decay by means of tracking calorimeter ELEGANT V. Considering various matrix element calculations, a range of limits for the Majoron-neutrino coupling is given: $\langle g_{\nu\chi} \rangle < (6.3\text{--}360) \times 10^{-5}$.
- ²¹ ASHITKOV 01 result for $0\nu\chi$ of ¹⁰⁰Mo is less stringent than ARNOLD 00.
- ²² DANEVICH 01 obtain limit for the $0\nu\chi$ decay with Majoron emission of ¹⁶⁰Gd using Gd₂SiO₅:Ce crystal scintillators.
- ²³ DANEVICH 01 obtain limit for the $0\nu 2\chi$ decay with 2 Majoron emission of ¹⁶⁰Gd.
- ²⁴ ARNOLD 00 reports limit for the $0\nu\chi$ decay with Majoron emission derived from tracking calorimeter NEMO 2. Using ⁸²Se source: $\langle g_{\nu\chi} \rangle < 1.6 \times 10^{-4}$. Matrix element from GUENTHER 96.
- ²⁵ Using ⁹⁶Zr source: $\langle g_{\nu\chi} \rangle < 2.6 \times 10^{-4}$. Matrix element from ARNOLD 99.
- ²⁶ ARNOLD 00 reports limit for the $0\nu 2\chi$ decay with two Majoron emission derived from tracking calorimeter NEMO 2.
- ²⁷ ARNOLD 98 determine the limit for $0\nu\chi$ decay with Majoron emission of ⁸²Se using the NEMO-2 tracking detector. They derive $\langle g_{\nu\chi} \rangle < 2.3\text{--}4.3 \times 10^{-4}$ with several nuclear matrix elements.
- ²⁸ LUESCHER 98 report a limit for the 0ν decay with Majoron emission of ¹³⁶Xe using Xe TPC. This result is more stringent than BARABASH 89. Using the matrix elements of ENGEL 88, they obtain a limit on $\langle g_{\nu\chi} \rangle$ of 2.0×10^{-4} .
- ²⁹ See Table 1 in GUENTHER 96 for limits on the Majoron coupling in different models.

- ¹ PALOMBA 19 used the LIGO O2 dataset to derive limits on nearly monochromatic gravitational waves emitted by boson clouds formed around a stellar-mass black hole. They exclude boson masses in a range of 1.1×10^{-13} and 4×10^{-13} eV for high initial black hole spin, and 1.2×10^{-13} and 1.8×10^{-13} eV for moderate spin. See their Figs. 2 and 3 for limits based on various values of black hole initial spin, boson cloud age, and distance.
- ² CHANG 18 update axion bremsstrahlung emission rates in nucleon-nucleon collisions, shifting the excluded mass range to higher values. They rule out the hadronic axion with mass up to a few hundred eV, closing the hadronic axion window. See their Fig. 11 for results based on several different choices of the temperature and density profile of the proto-neutron star.
- ³ ARCHIDIACONO 13A is analogous to HANNESTAD 05A. The limit is based on the CMB temperature power spectrum of the Planck data, the CMB polarization from the WMAP 9-yr data, the matter power spectrum from SDSS-DR7, and the local Hubble parameter measurement by the Carnegie Hubble program.
- ⁴ CADAMURO 11 use the deuterium abundance to show that the m_{A0} range 0.7 eV – 300 keV is excluded for axions, complementing HANNESTAD 10.
- ⁵ DERBIN 11A look for solar axions produced by Compton and bremsstrahlung processes, in the resonant excitation of ¹⁶⁹Tm, constraining the axion-electron × axion nucleon couplings.
- ⁶ ANDRIAMONJE 10 search for solar axions produced from ⁷Li (478 keV) and D(p,γ)³He (5.5 MeV) nuclear transitions. They show limits on the axion-photon coupling for two reference values of the axion-nucleon coupling for $m_A < 100$ eV.
- ⁷ This is an update of HANNESTAD 08 including 7 years of WMAP data.
- ⁸ ANDRIAMONJE 09 look for solar axions produced from the thermally excited 14.4 keV level of ⁵⁷Fe. They show limits on the axion-nucleon × axion-photon coupling assuming $m_A < 0.03$ eV.
- ⁹ DERBIN 09A look for Primakoff-produced solar axions in the resonant excitation of ¹⁶⁹Tm, constraining the axion-photon × axion-nucleon couplings.
- ¹⁰ KEKEZ 09 look at axio-electric effect of solar axions in HPGe detectors. The one-loop axion-electron coupling for hadronic axions is used.
- ¹¹ This is an update of HANNESTAD 07 including 5 years of WMAP data.
- ¹² This is an update of HANNESTAD 05A with new cosmological data, notably WMAP (3 years) and baryon acoustic oscillations (BAO). Lyman- α data are left out, in contrast to HANNESTAD 05A and MELCHIORRI 07A, because it is argued that systematic errors are large. It uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component.
- ¹³ MELCHIORRI 07A is analogous to HANNESTAD 05A, with updated cosmological data, notably WMAP (3 years). Uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component. Leaving out Lyman- α data, a conservative limit is 1.4 eV.
- ¹⁴ HANNESTAD 05A puts an upper limit on the mass of hadronic axion because in this mass range it would have been thermalized and contribute to the hot dark matter component of the universe. The limit is based on the CMB anisotropy from WMAP, SDSS large

Invisible A^0 (Axion) MASS LIMITS from Astrophysics and Cosmology

$v_1 = v_2$ is usually assumed ($v_j =$ vacuum expectation values). For a review of these limits, see RAFFELT 91 and TURNER 90. In the comment lines below, D and K refer to DFSZ and KSVZ axion types, discussed in the above minireview.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

- scale structure, Lyman α , and the prior Hubble parameter from HST Key Project. A χ^2 statistic is used. Neutrinos are assumed not to contribute to hot dark matter.
- 15 MORIO 98 points out that a KSVZ axion of this mass range (see CHANG 93) can be a viable hot dark matter of Universe, as long as the model-dependent $g_{A\gamma}$ is accidentally small enough as originally emphasized by KAPLAN 85; see Fig. 1.
- 16 BORISOV 97 bound is on the axion-electron coupling $g_{ae} < 1 \times 10^{-13}$ from the photo-production of axions off of magnetic fields in the outer layers of neutron stars.
- 17 KACHELRIESS 97 bound is on the axion-electron coupling $g_{ae} < 1 \times 10^{-10}$ from the production of axions in strongly magnetized neutron stars. The authors also quote a stronger limit, $g_{ae} < 9 \times 10^{-13}$ which is strongly dependent on the strength of the magnetic field in white dwarfs.
- 18 KEIL 97 uses new measurements of the axial-vector coupling strength of nucleons, as well as a reanalysis of many-body effects and pion-emission processes in the core of the neutron star, to update limits on the invisible-axion mass.
- 19 RAFFELT 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red giant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).
- 20 ALTHERR 94 bound is on the axion-electron coupling $g_{ae} < 1.5 \times 10^{-13}$, from energy loss via axion emission.
- 21 CHANG 93 updates ENGEL 90 bound with the Kaplan-Manohar ambiguity in $z=m_u/m_d$ (see the Note on the Quark Masses in the Quark Particle Listings). It leaves the window $f_A = 3 \times 10^5 - 3 \times 10^6$ GeV open. The constraint from Big-Bang Nucleosynthesis is satisfied in this window as well.
- 22 BERSHADY 91 searched for a line at wave length from 3100–8300 Å expected from 2 γ decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.
- 23 KIM 91c argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an *upperbound* rather than a lowerbound.
- 24 RAFFELT 91b argue that previous SN1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.
- 25 RESSELL 91 uses absence of any intracuster line emission to set limit.
- 26 ENGEL 90 rule out $10^{-10} \lesssim g_{AN} \lesssim 10^{-3}$, which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to $2.5 \times 10^{-3} \text{ eV} \lesssim m_{A^0} \lesssim 2.5 \times 10^4 \text{ eV}$. The constraint is loose in the middle of the range, i.e. for $g_{AN} \sim 10^{-6}$.
- 27 RAFFELT 90d is a re-analysis of DEARBORN 86.
- 28 The region $m_{A^0} \gtrsim 2 \text{ eV}$ is also allowed.
- 29 ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.
- 30 MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2–4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 88b.
- 31 RAFFELT 88b derives a limit for the energy generation rate by exotic processes in helium-burning stars $\epsilon < 100 \text{ erg g}^{-1} \text{ s}^{-1}$, which gives a firmer basis for the axion limits based on red giant cooling.
- 32 RAFFELT 87 also gives a limit $g_{A\gamma} < 1 \times 10^{-10} \text{ GeV}^{-1}$.
- 33 DEARBORN 86 also gives a limit $g_{A\gamma} < 1.4 \times 10^{-11} \text{ GeV}^{-1}$.
- 34 RAFFELT 86 gives a limit $g_{A\gamma} < 1.1 \times 10^{-10} \text{ GeV}^{-1}$ from red giants and $< 2.4 \times 10^{-9} \text{ GeV}^{-1}$ from the sun.
- 35 KAPLAN 85 says $m_{A^0} < 23 \text{ eV}$ is allowed for a special choice of model parameters.
- 36 FUKUGITA 82 gives a limit $g_{A\gamma} < 2.3 \times 10^{-10} \text{ GeV}^{-1}$.

Search for Relic Invisible Axions

Limits are for $[G_{A\gamma\gamma}/m_{A^0}]^2 \rho_A$ where $G_{A\gamma\gamma}$ denotes the axion two-photon coupling,

$$L_{\text{int}} = -\frac{G_{A\gamma\gamma}}{4} \phi_A F_{\mu\nu} \tilde{F}^{\mu\nu} = G_{A\gamma\gamma} \phi_A \mathbf{E} \cdot \mathbf{B}, \text{ and } \rho_A \text{ is the axion energy density near the earth.}$$

- 1 ALESINI 19 used a superconducting resonant cavity made of NbTi to increase the quality factor. The limit applies to a mass range of 0.2 neV around $m_{A^0} = 37.5 \mu\text{eV}$.
- 2 FUJITA 19 look for photon birefringence under the oscillating axion background using the polarimetric imaging observation of a protoplanetary disk, AB Aur. See their Fig. 2 for a more conservative limit taking account of possible systematic effects.
- 3 OUELLET 19a look for the axion-induced oscillating magnetic field generated by a toroidal magnetic field. The quoted limit applies at $m_{A^0} = 8 \text{ neV}$. See their Fig. 3 for the mass-dependent limits.
- 4 BOUTAN 18 use a small high frequency cavity installed above the main ADMX cavity to look for heavier axion dark matter. See their Fig. 4 for mass-dependent limits.
- 5 DU 18 is analogous to DUFFY 06. They upgraded a dilution refrigerator to reduce the system noise. The quoted limit is around $m_{A^0} = 2.69 \mu\text{eV}$ for the boosted Maxwellian axion line shape. See Fig. 4 for their mass-dependent limits.
- 6 ZHONG 18 is analogous to BRUBAKER 17. The quoted limit applies at $m_{A^0} = 23.76 \mu\text{eV}$. See Fig. 4 for their mass-dependent limits.
- 7 BRANCA 17 look for modulations of the fine-structure constant and the electron mass due to moduli dark matter by using the cryogenic resonant-mass AURIGA detector. The limit on the assumed dilatonic coupling implies $G_{S\gamma\gamma} < 1.5 \times 10^{-24} \text{ GeV}^{-1}$ for the scalar to two-photon coupling. See Fig. 5 for the mass-dependent limits.
- 8 BRUBAKER 17 used a microwave cavity detector at the Yale Wright Laboratory to search for dark matter axions. See Fig. 3 for the mass-dependent limits.
- 9 CHOI 17 used a microwave cavity detector with toroidal geometry. See Fig. 4 for their mass-dependent limits.
- 10 HOSKINS 16 is analogous to DUFFY 06. See Fig. 12 for mass-dependent limits in terms of the local dark matter density.
- 11 BECK 13 argues that dark-matter axions passing through Earth may generate a small observable signal in resonant S/N/S Josephson junctions. A measurement by HOFFMANN 04 [Physical Review B70 1805 03 (2004)] is interpreted in terms of subdominant dark matter axions with $m_{A^0} = 0.11 \text{ meV}$.
- 12 HOSKINS 11 is analogous to DUFFY 06. See Fig. 4 for the mass-dependent limit in terms of the local density.
- 13 ASZTALOS 10 used the upgraded detector of ASZTALOS 04 to search for halo axions. See their Fig. 5 for the m_{A^0} dependence of the limit.
- 14 DUFFY 06 used the upgraded detector of ASZTALOS 04, while assuming a smaller velocity dispersion than the isothermal model as in Eq. (8) of their paper. See Fig. 10 of their paper on the axion mass dependence of the limit.
- 15 ASZTALOS 04 looked for a conversion of halo axions to microwave photons in magnetic field. At 90% CL, the KSVZ axion cannot have a local halo density more than 0.45 GeV/cm^3 in the quoted mass range. See Fig. 7 of their paper on the axion mass dependence of the limit.
- 16 KIM 98 calculated the axion-to-photon couplings for various axion models and compared them to the HAGMANN 90 bounds. This analysis demonstrates a strong model dependence of $G_{A\gamma\gamma}$ and hence the bound from relic axion search.
- 17 HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.
- 18 WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagnetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with $[G_{A\gamma\gamma}/m_{A^0}]^2 = 2 \times 10^{-14} \text{ MeV}^{-4}$ (the three generation DFSZ model) and $\rho_A = 300 \text{ MeV/cm}^3$ that makes up galactic halos gives $(G_{A\gamma\gamma}/m_{A^0})^2 \rho_A = 4 \times 10^{-44}$. Note that our definition of $G_{A\gamma\gamma}$ is $(1/4\pi)$ smaller than that of WUENSCH 89.

Invisible A^0 (Axion) Limits from Photon Coupling

Limits are for the modulus of the axion-two-photon coupling $G_{A\gamma\gamma}$ defined by

$$L = -G_{A\gamma\gamma} \phi_A \mathbf{E} \cdot \mathbf{B}. \text{ For scalars } S^0 \text{ the limit is on the coupling constant in } L = G_{S\gamma\gamma} \phi_S (\mathbf{E}^2 - \mathbf{B}^2). \text{ The relation between } G_{A\gamma\gamma} \text{ and } m_{A^0} \text{ is not used unless stated otherwise, i.e., many of these bounds apply to low-mass axion-like particles (ALPs), not to QCD axions.}$$

$<3.6 \times 10^{-9}$	99.7	66	LAZARUS	92		$m_{A^0} < 0.03$ eV
$<7.7 \times 10^{-9}$	99.7	66	LAZARUS	92		$m_{A^0} = 0.03\text{--}0.11$ eV
$<7.7 \times 10^{-7}$	99	67	RUOSO	92		$m_{A^0} < 10^{-3}$ eV
$<2.5 \times 10^{-6}$		68	SEMERTZIDIS	90		$m_{A^0} < 7 \times 10^{-4}$ eV

- ¹ ALONI 19 used the data collected by the PRIMEX experiment to derive a limit based on a data-driven method. See their Fig. 2 for mass-dependent limits.
- ² CAPUTO 19 look for an oscillating variation of the polarization angle of the pulsar J0437-4715, where they assume the local axion energy density $\rho_A = 0.3$ GeV/cm³. See their Fig. 2 for mass-dependent limits for 5×10^{-24} eV $\leq m_{A^0} \leq 2 \times 10^{-19}$ eV.
- ³ FEDDERKE 19 look for a uniform reduction of the CMB polarization at large scales, which is induced by the oscillating axion background during CMB decoupling. The quoted limit is based on the assumption that axions make up all of the dark matter. See their Fig. 3 for mass-dependent limits for $m_{A^0} = 10^{-22}\text{--}10^{-19}$ eV.
- ⁴ IVANOV 19 look for the axion-induced periodic changes in the polarization angle of parsec-scale jets in active galactic nuclei observed by the MOJAVE program, where they use the axion energy density $\rho_A = 20$ GeV/cm³. See their Fig. 6 for mass-dependent limits for 5×10^{-23} eV $\leq m_{A^0} \leq 1.2 \times 10^{-21}$ eV.
- ⁵ LIANG 19 look for spectral irregularities in the spectrum of 10 bright H.E.S.S. sources in the Galactic plane, assuming photon-ALP mixing in the Galactic magnetic fields. See their Fig. 2 for mass-dependent limits with different Galactic magnetic field models.
- ⁶ FORTIN 18 studied the conversion of axion-like particles produced in the core of a magnetar to hard X-rays in the magnetosphere. See their Fig. 5 for mass-dependent limits with different values of the magnetar core temperature.
- ⁷ YAMAJI 18 search for axions with an x-ray LSW at Spring-8, using the Laue-case conversion in a silicon crystal. They also obtain $G_{A\gamma\gamma} < 4.2 \times 10^{-9}$ GeV⁻¹ for $m_{A^0} < 10$ eV. See their Fig. 5 for mass-dependent limits.
- ⁸ ZHANG 18 look for spectral irregularities in the spectrum of PKS 2155-304 measured by Fermi-LAT, assuming photon-ALP mixing in the intercluster and Galactic magnetic fields. See their Figs. 2 and 3 for mass-dependent limits with different values of the intercluster magnetic field parameters.
- ⁹ ADE 17 look for cosmic birefringence from axion-like particles using CMB polarization data taken by the BICEP2 and Keck Array experiments. They set a limit $G_{A\gamma\gamma} H_I < 7.2 \times 10^{-2}$ at 95%CL for $m_{A^0} < 10^{-28}$ eV, where H_I is the Hubble parameter during inflation.
- ¹⁰ ANASTASSOPOULOS 17 looked for solar axions by the CAST axion helioscope in the vacuum phase, and supersedes ANDRIAMONJE 07.

- ¹¹ DOLAN 17 update existing limits on $G_{A\gamma\gamma}$ for axion-like particles. See their Fig. 2 for mass-dependent limits.
- ¹² INADA 17 search for axions with an x-ray LSW at Spring-8. See their Fig. 4 for mass-dependent limits.
- ¹³ KOHRI 17 attributed to axion-photon oscillations the excess of cosmic infrared background observed by the CIBER experiment. See their Fig. 5 for the region preferred by their scenario.
- ¹⁴ MARSH 17 is similar to WOUTERS 13, using Chandra observations of M87. See their Fig. 6 for mass-dependent limits.
- ¹⁵ TIWARI 17 use observed limits of the cosmic distance-duality relation to constrain the photon-ALP mixing based on 3D simulations of the magnetic field configuration. The quoted value is for the averaged magnetic field of 1nG with a coherent length of 1 Mpc. See their Fig. 5 for mass-dependent limits.
- ¹⁶ AJELLO 16 look for irregularities in the energy spectrum of the NGC1275 measured by Fermi LAT, assuming photon-ALP mixing in the intra-cluster and Galactic magnetic fields. See their Fig. 2 for mass-dependent limits.
- ¹⁷ DELLA-VALLE 16 look for the birefringence induced by axion-like particles. See their Fig. 14 for mass-dependent limits.
- ¹⁸ DELLA-VALLE 16 look for the dichroism induced by axion-like particles. See their Fig. 14 for mass-dependent limits.
- ¹⁹ JAECKEL 16 use the LEP data of $Z \rightarrow 2\gamma$ and $Z \rightarrow 3\gamma$ to constrain the ALP production via $e^+e^- \rightarrow Z \rightarrow A^0\gamma$ ($A^0 \rightarrow \gamma\gamma$), assuming the ALP coupling with two hypercharge bosons. See their Fig. 4 for mass-dependent limits.
- ²⁰ LEEFER 16 derived limits by using radio-frequency spectroscopy of dysprosium and atomic clock measurements. See their Fig. 1 for mass-dependent limits as well as limits on Yukawa-type couplings of the scalar to the electron and nucleons.
- ²¹ ANASTASSOPOULOS 15 search for solar chameleons with CAST and derived limits on the chameleon coupling to photons and matter. See their Fig. 12 for the exclusion region.
- ²² ARIK 15 is analogous to ARIK 09, and search for solar axions for m_{A^0} around 0.2 and 0.4 eV. See their Figs. 1 and 3 for the mass-dependent limits.
- ²³ Based on OSQAR photon regeneration experiment. See their Fig. 6 for mass-dependent limits on scalar and pseudoscalar bosons.
- ²⁴ BRAX 15 derived limits on conformal and disformal couplings of a scalar to photons by searching for a chaotic absorption pattern in the X-ray and UV bands of the Hydra A galaxy cluster and a BL lac object, respectively. See their Fig. 8.
- ²⁵ HASEBE 15 look for an axion via a four-wave mixing process at quasi-parallel colliding laser beams. They also derived limits on a scalar coupling to photons $G_{S\gamma\gamma} < 2.62 \times 10^{-4}$ GeV⁻¹ at $m_{S^0} = 0.15$ eV. See their Figs. 11 and 12 for mass-dependent limits.
- ²⁶ MILLEA 15 is similar to CADAMURO 12, including the Planck data and the latest inferences of primordial deuterium abundance. See their Fig. 3 for mass-dependent limits.
- ²⁷ VANTILBURG 15 look for harmonic variations in the dysprosium transition frequency data, induced by coherent oscillations of the fine-structure constant due to dilaton-like dark matter, and set the limits, $G_{S\gamma\gamma} < 6 \times 10^{-27}$ GeV⁻¹ at $m_{S^0} = 6 \times 10^{-23}$ eV. See their Fig. 4 for mass-dependent limits between $1 \times 10^{-24} < m_{S^0} < 1 \times 10^{-15}$ eV.
- ²⁸ VINYOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations. See their Fig. 9.
- ²⁹ ARIK 14 is similar to ARIK 11. See their Fig. 2 for mass-dependent limits.
- ³⁰ AYALA 14 derived the limit from the helium-burning lifetime of horizontal-branch stars based on number counts in globular clusters.
- ³¹ DELLA-VALLE 14 use the new PVLAS apparatus to set a limit on vacuum magnetic birefringence induced by axion-like particles. See their Fig. 6 for the mass-dependent limits.
- ³² EJLLI 14 set limits on a product of primordial magnetic field and the axion mass using CMB distortion induced by resonant axion production from CMB photons. See their Fig. 1 for limits applying specifically to the DFSZ and KSVZ axion models.
- ³³ PUGNAT 14 is analogous to EHRET 10. See their Fig. 5 for mass-dependent limits on scalar and pseudoscalar bosons.
- ³⁴ REESMAN 14 derive limits by requiring effects of axion-photon interconversion on gamma-ray spectra from distant blazars to be no larger than errors in the best-fit optical depth based on a certain extragalactic background light model. See their Fig. 5 for mass-dependent limits.
- ³⁵ ABRAMOWSKI 13A look for irregularities in the energy spectrum of the BL Lac object PKS 2155-304 measured by H.E.S.S. The limits depend on assumed magnetic field around the source. See their Fig. 7 for mass-dependent limits.
- ³⁶ ARMENGAUD 13 is analogous to AVIGNONE 98. See Fig. 6 for the limit.
- ³⁷ BETZ 13 performed a microwave-based light shining through the wall experiment. See their Fig. 13 for mass-dependent limits.
- ³⁸ FRIEDLAND 13 derived the limit by considering blue-loop suppression of the evolution of red giants with 7-12 solar masses.
- ³⁹ MEYER 13 attributed to axion-photon oscillations the observed excess of very high-energy γ -rays with respect to predictions based on extragalactic background light models. See their Fig. 4 for mass-dependent lower limits for various magnetic field configurations.
- ⁴⁰ WOUTERS 13 look for irregularities in the X-ray spectrum of the Hydra cluster observed by Chandra. See their Fig. 4 for mass-dependent limits.
- ⁴¹ CADAMURO 12 derived cosmological limits on $G_{A\gamma\gamma}$ for axion-like particles. See their Fig. 1 for mass-dependent limits.
- ⁴² PAYEZ 12 derive limits from polarization measurements of quasar light (see their Fig. 3). The limits depend on assumed magnetic field strength in galaxy clusters. The limits depend on assumed magnetic field and electron density in the local galaxy supercluster.
- ⁴³ ARIK 11 search for solar axions using ³He buffer gas in CAST, continuing from the ⁴He version of ARIK 09. See Fig. 2 for the exact mass-dependent limits.
- ⁴⁴ ALPS is a photon regeneration experiment. See their Fig. 4 for mass-dependent limits on scalar and pseudoscalar bosons.
- ⁴⁵ AHMED 09A is analogous to AVIGNONE 98.
- ⁴⁶ ARIK 09 is the ⁴He filling version of the CAST axion helioscope in analogy to INOUE 02 and INOUE 08. See their Fig. 7 for mass-dependent limits.
- ⁴⁷ CHOU 09 use the GammeV apparatus in the afterglow mode to search for chameleons, (pseudo)scalar bosons with a mass depending on the environment. For pseudoscalars they exclude at 3 σ the range 2.6×10^{-7} GeV⁻¹ $< G_{A\gamma\gamma} < 4.2 \times 10^{-6}$ GeV⁻¹ for vacuum m_{A^0} roughly below 6 meV for density scaling index exceeding 0.8.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

- ⁴⁸ GONDOLO 09 use the all-flavor measured solar neutrino flux to constrain solar interior temperature and thus energy losses.
- ⁴⁹ LIPSS photon regeneration experiment, assuming scalar particle S^0 . See Fig. 4 for mass-dependent limits.
- ⁵⁰ CHOU 08 perform a variable-baseline photon regeneration experiment. See their Fig. 3 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06.
- ⁵¹ FOCHE 08 is an update of ROBILLIARD 07. See their Fig. 12 for mass-dependent limits.
- ⁵² INOUE 08 is an extension of INOUE 02 to larger axion masses, using the Tokyo axion helioscope. See their Fig. 4 for mass-dependent limits.
- ⁵³ ZAVATTINI 08 is an upgrade of ZAVATTINI 06, see their Fig. 8 for mass-dependent limits. They now exclude the parameter range where ZAVATTINI 06 had seen a positive signature.
- ⁵⁴ ANDRIAMONJE 07 looked for Primakoff conversion of solar axions in 9T superconducting magnet into X-rays. Supersedes ZIOUTAS 05.
- ⁵⁵ ROBILLIARD 07 perform a photon regeneration experiment with a pulsed laser and pulsed magnetic field. See their Fig. 4 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06 with a CL exceeding 99.9%.
- ⁵⁶ ZAVATTINI 06 propagate a laser beam in a magnetic field and observe dichroism and birefringence effects that could be attributed to an axion-like particle. This result is now excluded by ROBILLIARD 07, ZAVATTINI 08, and CHOU 08.
- ⁵⁷ INOUE 02 looked for Primakoff conversion of solar axions in 4T superconducting magnet into X-ray.
- ⁵⁸ MORALES 02b looked for the coherent conversion of solar axions to photons via the Primakoff effect in Germanium detector.
- ⁵⁹ BERNABEL 01b looked for Primakoff coherent conversion of solar axions into photons via Bragg scattering in NaI crystal in DAMA dark matter detector.
- ⁶⁰ ASTIER 00b looked for production of axions from the interaction of high-energy photons with the horn magnetic field and their subsequent re-conversion to photons via the interaction with the NOMAD dipole magnetic field.
- ⁶¹ MASSO 00 studied limits on axion-proton coupling using the induced axion-photon coupling through the proton loop and CAMERON 93 bound on the axion-photon coupling using optical rotation. They obtained the bound $g_{p\gamma}^2/4\pi < 1.7 \times 10^{-9}$ for the coupling $g_{p\gamma}^2 P^0 A$.
- ⁶² AVIGNONE 98 result is based on the coherent conversion of solar axions to photons via the Primakoff effect in a single crystal germanium detector.
- ⁶³ Based on the conversion of solar axions to X-rays in a strong laboratory magnetic field.
- ⁶⁴ Experiment based on proposal by MAIANI 86.
- ⁶⁵ Experiment based on proposal by VANBIBBER 87.
- ⁶⁶ LAZARUS 92 experiment is based on proposal found in VANBIBBER 89.
- ⁶⁷ RUOSO 92 experiment is based on the proposal by VANBIBBER 87.
- ⁶⁸ SEMERTZIDIS 90 experiment is based on the proposal of MAIANI 86. The limit is obtained by taking the noise amplitude as the upper limit. Limits extend to $m_{A^0} = 4 \times 10^{-3}$ where $G_{A\gamma\gamma} < 1 \times 10^{-4}$ GeV $^{-1}$.

Limit on Invisible A^0 (Axion) Electron Coupling

The limit is for $g_{Aee} \phi_A \bar{\psi}(\gamma_5)\psi$, or equivalently, the dipole-dipole potential

$$-\frac{g_{Aee}^2}{16\pi m_e^2} ((\sigma_1 \cdot \sigma_2) - 3(\sigma_1 \cdot \mathbf{n})(\sigma_2 \cdot \mathbf{n}))/r^3 \text{ where } \mathbf{n} = \mathbf{r}/r \text{ and the sign of the potential was corrected based on DAIDO 17.}$$

¹ ADHIKARI 19B is analogous to LIU 17A.

² APRILE 19D is analogous to APRILE 17B, but they use only ionization signals. The quoted limit applies to $m_{A^0} = 0.7$ keV. See their Fig. 5(e) for mass-dependent limits.

³ DESSERT 19 used the Suzaku observations of a magnetic white dwarf (RE J0317-853) to look for X-ray signatures converted from axions in the surrounding magnetic fields. They obtained the limit, $g_{Aee} \cdot G_{A\gamma\gamma} < 1.6 \times 10^{-24}$ GeV $^{-1}$ at 95%CL for $m_{A^0} \lesssim 10^{-5}$ eV. See their Fig. 2 for mass-dependent limits.

⁴ TERRANO 19 look for the axion-induced oscillating magnetic field acting on the electron spin, using data taken with a rotating torsion pendulum containing polarized electrons. The quoted limit applies to $m_{A^0} = 10^{-23}-10^{-18}$ eV and assumes a local axion dark matter density, $\rho_A = 0.45$ GeV/cm 3 . See their Fig. 5 for mass-dependent limits.

⁵ ABE 18F is an update of ABE 14F. The quoted limit applies to $m_{A^0} = 60$ keV. See their Fig. 5 for mass-dependent limits.

⁶ ARMENGAUD 18 is analogous to LIU 17A.

⁷ ARMENGAUD 18 is analogous to AHMED 09A. See the left panel of Fig. 5 for mass-dependent limits.

⁸ CRESCINI 18 look for collective excitations of the electron spins caused by dark matter axions. The quoted limit assumes the local dark matter density, $\rho_A = 0.45$ GeV/c 3 .

⁹ FICEK 18 use the measurements of the hyperfine structure of antiprotonic helium to constrain a dipole-dipole potential between electron and antiproton. See their Fig. 3 for limits on various spin- and velocity-dependent potentials.

¹⁰ ABGRALL 17 is analogous to AHMED 09A using the MAJORANA DEMONSTRATOR. See their Fig. 2 for limits between 6 keV $< m_{A^0} < 97$ keV.

¹¹ AKERIB 17B is analogous to LIU 17A.

¹² AKERIB 17B is analogous to AHMED 09A. See their Fig. 7 for mass-dependent limits.

¹³ APRILE 17B is analogous to AHMED 09A. They found a bug in their code and needed to correct the limits in Fig. 7 of APRILE 14B. See their Fig. 1 for the corrected limits between 1 keV $< m_{A^0} < 40$ keV.

¹⁴ FICEK 17 look for spin-dependent interactions between electrons by comparing precision spectroscopic measurements in ^4He with theoretical calculations. See their Fig. 1 for limits up to $m_{A^0} = 10$ keV.

¹⁵ FU 17A is analogous to LIU 17A. See their Fig. 3 for mass-dependent limits.

¹⁶ FU 17A is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.

¹⁷ LIU 17A is analogous to AHMED 09A. See their Fig. 9 for limits between 0.25 keV $< m_{A^0} < 20$ keV.

¹⁸ LIU 17A look for solar axions produced from Compton, bremsstrahlung, atomic-recombination and deexcitation channels, and set a limit for $m_{A^0} < 1$ keV.

¹⁹ LUO 17 use a recent measurement of the dipole-dipole interaction between two iron atoms at the nanometer scale and set a limit for $m_{A^0} < 1$ keV. See their Fig. 3 for mass-dependent limits.

²⁰ BATTICH 16 is analogous to CORSICO 16 and used the pulsating DB white dwarf PG 1351+489.

²¹ CORSICO 16 studied the cooling rate of the pulsating DA white dwarf L19-2 based on an asteroseismic model.

²² YOON 16 look for solar axions with the axio-electric effect in CsI(Tl) crystals and set a limit for $m_{A^0} < 1$ keV.

²³ TERRANO 15 used a torsion pendulum and rotating attractor with 20-pole electron-spin distributions. See their Fig. 4 for a mass-dependent limit up to $m_{A^0} = 500 \mu\text{eV}$.

²⁴ ABE 14F set limits on the axioelectric effect in the XMAS detector assuming the pseudoscalar constitutes all the local dark matter. See their Fig. 3 for limits between $m_{A^0} = 40-120$ keV.

²⁵ APRILE 14B look for solar axions using the XENON100 detector.

²⁶ APRILE 14B is analogous to AHMED 09A. Their Fig. 7 was later found to be incorrect due to a bug in their code. See Fig. 1 in APRILE 17B for the corrected limits.

²⁷ DERBIN 14 is an update of DERBIN 13 with a BGO scintillating bolometer. See their Fig. 3 for mass-dependent limits.

²⁸ MILLER-BERTOLAMI 14 studied the impact of axion emission on white dwarf cooling in a self-consistent way.

²⁹ ABE 13D is analogous to DERBIN 12, using the XMAS detector.

³⁰ ARMENGAUD 13 is similar to AALSETH 11. See their Fig. 10 for limits between 3 keV $< m_{A^0} < 100$ keV.

³¹ ARMENGAUD 13 is similar to DERBIN 12, and take account of axio-recombination and axio-deexcitation effects. See their Fig. 12 for mass-dependent limits.

³² BARTH 13 search for solar axions produced by axion-electron coupling, and obtained the limit, $g_{Aee} \cdot G_{A\gamma\gamma} < 8.1 \times 10^{-23}$ GeV $^{-1}$ at 95%CL.

³³ DERBIN 13 looked for 5.5 MeV solar axions produced in $p\bar{d} \rightarrow ^3\text{He} A^0$ in a BGO detector through the axioelectric effect. See their Fig. 4 for mass-dependent limits.

³⁴ HECKEL 13 studied the influence of 2 or 4 stationary sources each containing 6.0×10^{24} polarized electrons, on a rotating torsion pendulum containing 9.8×10^{24} polarized electrons. See their Fig. 4 for mass-dependent limits.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

35 VIAUX 13A constrain axion emission using the observed brightness of the tip of the red-giant branch in the globular cluster M5.
 36 CORSICO 12 attributed the excessive cooling rate of the pulsating white dwarf R548 to emission of axions with $g_{Aee} \simeq 4.8 \times 10^{-13}$.
 37 DERBIN 12 look for solar axions with the axio-electric effect in a Si(Li) detector. The solar production is based on Compton and bremsstrahlung processes.
 38 AALSETH 11 is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.
 39 AHMED 09A assume keV-mass pseudoscalars are the local dark matter and constrain the axio-electric effect in the CDMS detector. See their Fig. 5 for mass-dependent limits.
 40 DAVOUDIASL 09 use geophysical constraints on Earth cooling by axion emission.
 41 These experiments measured induced magnetization of a bulk material by the spin-dependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor. The sign of the limit set by CHUI 93 is opposite to that of the axion-mediated dipole-dipole potential.
 42 These experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either of them. The limits reflect the corrected sign of the dipole-dipole potential.
 43 WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.

Invisible A^0 (Axion) Limits from Nucleon Coupling

Limits are for the axion mass in eV.

		30 ADELBERGER 07		Test of Newton's law

1 LEINSON 19 is analogous to BEZNOGOV 18, but estimating the axion luminosity based on the Tolman's analytic solution to the Einstein equations of spherical fluids in hydrostatic equilibrium. The dimensionless axion-neutron coupling is constrained as $g_{ANN} < 1.0 \times 10^{-10}$.
 2 LLOYD 19 is analogous to BERENJI 16. They highlight that the limit obtained with this technique strongly depends on the assumed NS core temperature.
 3 SMORRA 19 look for spin-precession effects from ultra-light axion dark matter in the \bar{p} spin-flip resonance data. Assuming $\rho_A = 0.4 \text{ GeV/cm}^3$, they constrain the dimensionless axion-antiproton coupling as $g_{A\bar{p}p} < 2-9$ at 95% CL for $m_{A^0} = 2 \times 10^{-23}-4 \times 10^{-17} \text{ eV}$. See the right panel of their Fig. 3.
 4 WU 19 look for axion-induced time-oscillating features of the NMR spectrum of acetonitrile- d_3 . Assuming $C_p = C_n$ and $\rho_A = 0.4 \text{ GeV/cm}^3$, they constrain the dimensionless axion-nucleon coupling as $g_{ANN} < 6 \times 10^{-5}$ for $m_{A^0} = 10^{-21}-1.3 \times 10^{-17} \text{ eV}$. Note that the limits for $m_{A^0} < 10^{-21} \text{ eV}$ in their Fig. 3(a) should be weaker than those for heavier masses. See ADELBERGER 19 and WU 19c on this issue.
 5 AKHMATOV 18 is an update of GAVRILYUK 15.
 6 ARMENGAUD 18 is analogous to ALESSANDRIA 13. The quoted limit assumes the DFSZ axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.
 7 BEZNOGOV 18 constrain the axion-neutron coupling by assuming that thermal evolution of the hot neutron star HESS J1731-347 is dominated by the lowest possible neutrino emission. The quoted limit assumes the KSVZ axion with the effective Peccei-Quinn charge of the neutron $C_n = -0.02$. The dimensionless axion-neutron coupling is constrained as $g_{ANN} < 2.8 \times 10^{-10}$.
 8 GAVRILYUK 18 look for the resonant excitation of ^{83}Kr (9.4 keV) by solar axions produced via the Primakoff effect. The mass bound assumes $m_H/m_d = 0.56$ and $S = 0.5$.
 9 HAMAGUCHI 18 studied the axion emission from the neutron star in Cassiopeia A based on the minimal cooling scenario which explains the observed rapid cooling rate. The quoted limit corresponds to $f_A > 5 \times 10^8 \text{ GeV}$ obtained for the KSVZ axion with $C_p = -0.47$ and $C_n = -0.02$.

10 ABEL 17 look for a time-oscillating neutron EDM and an axion-wind spin-precession effect respectively induced by axion dark matter couplings to gluons and nucleons. See their Fig. 4 for limits in the range of $m_{A^0} = 10^{-24}-10^{-17} \text{ eV}$.
 11 ABGRALL 17 limit assumes the hadronic axion model used in ALESSANDRIA 13. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.
 12 FU 17A look for the 14.4 keV ^{57}Fe solar axions. The limit assumes the DFSZ axion model. See their Fig. 3 for mass-dependent limits on the axion-electron coupling. Notice that in this figure the DFSZ and KSVZ lines should be interchanged.
 13 KLIMCHITSKAYA 17A use the differential measurement of the Casimir force between a Ni-coated sphere and Au and Ni sectors of the structured disc to constrain the axion coupling to nucleons for $2.61 \text{ meV} < m_{A^0} < 0.9 \text{ eV}$. See their Figs. 1 and 2 for mass dependent limits.
 14 LIU 17 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 6(b) for the limit on product of axion couplings to electrons and nucleons.
 15 BERENJI 16 used the Fermi LAT observations of neutron stars to look for photons from axion decay. They assume the effective Peccei-Quinn charge of the neutron $C_n = 0.1$ and a neutron-star core temperature of 20 MeV.
 16 GAVRILYUK 15 look for solar axions emitted by the M1 transition of ^{83}Kr (9.4 keV). The mass bound assumes $m_H/m_d = 0.56$ and $S = 0.5$.
 17 KLIMCHITSKAYA 15 use the measurement of differential forces between a test mass and rotating source masses of Au and Si to constrain the force due to two-axion exchange for $1.7 \times 10^{-3} < m_{A^0} < 0.9 \text{ eV}$. See their Figs. 1 and 2 for mass dependent limits.
 18 BEZERRA 14 use the measurement of the thermal Casimir-Polder force between a Bose-Einstein condensate of ^{87}Rb atoms and a SiO_2 plate to constrain the force mediated by exchange of two pseudoscalars for $0.1 \text{ meV} < m_{A^0} < 0.3 \text{ eV}$. See their Fig. 2 for the mass-dependent limit on pseudoscalar coupling to nucleons.
 19 BEZERRA 14A is analogous to BEZERRA 14. They use the measurement of the Casimir pressure between two Au-coated plates to constrain pseudoscalar coupling to nucleons for $1 \times 10^{-3} \text{ eV} < m_{A^0} < 15 \text{ eV}$. See their Figs. 1 and 2 for the mass-dependent limit.
 20 BEZERRA 14B is analogous to BEZERRA 14. BEZERRA 14B use the measurement of the normal and lateral Casimir forces between sinusoidally corrugated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for $1 \text{ eV} < m_{A^0} < 20 \text{ eV}$. See their Figs. 1-3 for mass-dependent limits.
 21 BEZERRA 14C is analogous to BEZERRA 14. They use the measurement of the gradient of the Casimir force between Au- and Ni-coated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for $3 \times 10^{-5} \text{ eV} < m_{A^0} < 1 \text{ eV}$. See their Figs. 1, 3, and 4 for the mass-dependent limits.
 22 BLUM 14 studied effects of an oscillating strong CP phase induced by axion dark matter on the primordial ^4He abundance. See their Fig. 1 for mass-dependent limits.
 23 LEINSON 14 attributes the excessive cooling rate of the neutron star in Cassiopeia A to axion emission from the superfluid core, and found $C_n^2 m_{A^0}^2 \simeq 5.7 \times 10^{-6} \text{ eV}^2$, where C_n is the effective Peccei-Quinn charge of the neutron.
 24 ALESSANDRIA 13 used the CUORE experiment to look for 14.4 keV solar axions produced from the M1 transition of thermally excited ^{57}Fe nuclei in the solar core, using the axio-electric effect. The limit assumes the hadronic axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.
 25 ARMENGAUD 13 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 8 for the limit on product of axion couplings to electrons and nucleons.
 26 BELLINI 12 looked for solar axions emitted by the M1 transition of $^7\text{Li}^*$ (478 keV) after the electron capture of ^7Be , using the resonant excitation ^7Li in the LiF crystal. The mass bound assumes $m_H/m_d = 0.55$, $m_H/m_S = 0.029$, and the flavor-singlet axial vector matrix element $S = 0.4$.
 27 BELLINI 12B looked for 5.5 MeV solar axions produced in the $pd \rightarrow ^3\text{He} A^0$. The limit assumes the hadronic axion model. See their Figs. 6 and 7 for mass-dependent limits on product of axion couplings to photons, electrons, and nucleons.
 28 DERBIN 11 looked for solar axions emitted by the M1 transition of thermally excited ^{57}Fe nuclei in the Sun, using their possible resonant capture on ^{57}Fe in the laboratory. The mass bound assumes $m_H/m_d = 0.56$ and the flavor-singlet axial vector matrix element $S = 3F - D \simeq 0.5$.
 29 BELLINI 08 consider solar axions emitted in the M1 transition of $^7\text{Li}^*$ (478 keV) and look for a peak at 478 keV in the energy spectra of the Counting Test Facility (CTF), a Borexino prototype. For $m_{A^0} < 450 \text{ keV}$ they find mass-dependent limits on products of axion couplings to photons, electrons, and nucleons.
 30 ADELBERGER 07 use precision tests of Newton's law to constrain a force contribution from the exchange of two pseudoscalars. See their Fig. 5 for limits on the pseudoscalar coupling to nucleons, relevant for m_{A^0} below about 1 meV.

Axion Limits from T-violating Medium-Range Forces

The limit is for the coupling $g = g_p g_s$ in a T-violating potential between nucleons or nucleon and electron of the form $V = \frac{g\hbar^2}{8\pi m_p} (\boldsymbol{\sigma} \cdot \boldsymbol{r}) \left(\frac{1}{r^2} + \frac{1}{\lambda r} \right) e^{-r/\lambda}$, where g_p and g_s are dimensionless scalar and pseudoscalar coupling constants and $\lambda = \hbar/(m_A c)$ is the range of the force.

1	DZUBA	18	used atomic EDM measurements to derive limits on the product of the pseudoscalar coupling to nucleon and the scalar coupling to electron, which improved on the laboratory bounds for $m_{A^0} > 0.01 \text{ eV}$. See their Fig. 1 for mass-dependent limits.	$<5 \times 10^{-12}$	95	11	CORTINA-GIL	19	NA62	$m_{\gamma} = 60\text{--}110 \text{ MeV}$
2	STADNIK	18	used atomic and molecular EDM experiments to derive limits on the product of the pseudoscalar couplings to electron and the scalar coupling to nucleon and electron. See their Fig. 2 for mass-dependent limits, which improved on the laboratory bounds for $m_{A^0} > 0.01 \text{ eV}$.	$<4.4 \times 10^{-4}$	90	12	DANILOV	19	TEXO	$m_{\gamma} = 20 \text{ eV} - 1 \text{ MeV}$
3	CRESCINI	17	use the QUAX- $g_p g_s$ experiment to look for variation of a paramagnetic GSO crystal magnetization when rotating lead disks are positioned near the crystal, and find $g = g_p g_s^N < 4.3 \times 10^{-30}$ for $\lambda = 0.1\text{--}0.2 \text{ m}$ at 95% CL. See their Fig. 6 for limits as a function of λ .	$<3 \times 10^{-5}$	95	13	HOCHBERG	19		$m_{\gamma} = 0.8\text{--}4 \text{ eV}$
4	AFACH	15	look for a change of spin precession frequency of ultracold neutrons when a magnetic field with opposite directions is applied, and find $g < 2.2 \times 10^{-27} (\text{m}/\lambda)^2$ at 95% CL for $1 \mu\text{m} < \lambda < 5 \text{ mm}$. See their Fig. 3 for their limits.	$<1 \times 10^{-11}$	95	14	KOPYLOV	19	CNTR	$m_{\gamma} = 9\text{--}40 \text{ eV}$
5	STADNIK	15	studied proton and neutron spin contributions for nuclei and derive the limits $g < 10^{-28}\text{--}10^{-23}$ for $\lambda > 3 \times 10^{-4} \text{ m}$ using the data of TULLNEY 13. See their Figs. 1 and 2 for λ -dependent limits.	$<1.5 \times 10^{-9}$		15	KOVETZ	19	COSM	$m_{\gamma} = 10^{-23}\text{--}10^{-13} \text{ eV}$
6	TERRANO	15	used a torsion pendulum and rotating attractor, and derived a restrictive limit on the product of the pseudoscalar coupling to electron and the scalar coupling to nucleons, $g < 9 \times 10^{-29}\text{--}5 \times 10^{-26}$ for $m_{A^0} < 1.5\text{--}400 \mu\text{eV}$. See their Fig. 5 for mass-dependent limits.	$<3 \times 10^{-14}$	95	16	NGUYEN	19	WDMX	$m_{\gamma} = 6 \text{ neV} - 2.07 \mu\text{eV}$
7	BULATOWICZ	13	looked for NMR frequency shifts in polarized ^{129}Xe and ^{131}Xe when a zirconia rod is positioned near the NMR cell, and find $g < 1 \times 10^{-19}\text{--}1 \times 10^{-24}$ for $\lambda = 0.01\text{--}1 \text{ cm}$. See their Fig. 4 for their limits.	$<4.5 \times 10^{-14}$	90	17	ABE	18F	XMAS	$m_{\gamma} = 40\text{--}120 \text{ keV}$
8	CHU	13	look for a shift of the spin precession frequency of polarized ^3He in the presence of an unpolarized mass, in analogy to YUDIN 96. See Fig. 3 for limits on g in the approximate m_{A^0} range $0.02\text{--}2 \text{ meV}$.	$<2.5 \times 10^{-3}$	95	18	ADRIAN	18	HPS	$m_{\gamma} = 19\text{--}81 \text{ MeV}$
9	TULLNEY	13	look for a shift of the precession frequency difference between the colocated ^3He and ^{129}Xe in the presence an unpolarized mass, and derive limits $g < 3 \times 10^{-29}\text{--}2 \times 10^{-22}$ for $\lambda > 3 \times 10^{-4} \text{ m}$. See their Fig. 3 for λ -dependent limits.	$<4.4 \times 10^{-4}$	90	19	ANASTASI	18B	KLOE	$m_{\gamma} = 519\text{--}987 \text{ MeV}$
10	RAFFELT	12	show that the pseudoscalar couplings to electron and nucleon and the scalar coupling to nucleon are individually constrained by stellar energy-loss arguments and searches for anomalous monopole-monopole forces, together providing restrictive constraints on g . See their Figs. 2 and 3 for results.	$<4 \times 10^{-15}$	90	20	ARMENGAUD	18	EDE3	$m_{\gamma} = 0.8\text{--}500 \text{ keV}$
11	HOEDL	11	use a novel torsion pendulum to study the force by the polarized electrons of an external magnet. In their Fig. 3 they show restrictive limits on g in the approximate m_{A^0} range $0.03\text{--}10 \text{ meV}$.	$<1.8 \times 10^{-5}$	90	21	BANERJEE	18	NA64	$m_{\gamma} = 1\text{--}23 \text{ MeV}$
12	PETUKHOV	10	use spin relaxation of polarized ^3He and find $g < 3 \times 10^{-23} (\text{cm}/\lambda)^2$ at 95% CL for the force range $\lambda = 10^{-4}\text{--}1 \text{ cm}$.	$<1 \times 10^{-8}$	90	22	BANERJEE	18A	NA64	$m_{\gamma} = 1\text{--}100 \text{ MeV}$
13	SEREBROV	10	use spin precession of ultracold neutrons close to bulk matter and find $g < 2 \times 10^{-21} (\text{cm}/\lambda)^2$ at 95% CL for the force range $\lambda = 10^{-4}\text{--}1 \text{ cm}$.	$<3.1 \times 10^{-14}$	90	23	KNIRCK	18		$m_{\gamma} = 0.67\text{--}0.92 \text{ MeV}$
14	IGNATOVICH	09	use data on depolarization of ultracold neutrons in material traps. They show λ -dependent limits in their Fig. 1.	$<3 \times 10^{-4}$	90	24	ABGRALL	17	HPGE	$m_{\gamma} = 11.8 \text{ keV}$
15	SEREBROV	09	uses data on depolarization of ultracold neutrons stored in material traps and finds $g < 2.96 \times 10^{-21} (\text{cm}/\lambda)^2$ for the force range $\lambda = 10^{-3}\text{--}1 \text{ cm}$ and $g < 3.9 \times 10^{-22} (\text{cm}/\lambda)^2$ for $\lambda = 10^{-4}\text{--}10^{-3} \text{ cm}$, each time at 95% CL, significantly improving on BAESSLER 07.	$<6 \times 10^{-4}$	90	25	ABLIKIM	17AA	BES3	$m_{\gamma} = 1.5\text{--}3.4 \text{ GeV}$
16	BAESSLER	07	use the observation of quantum states of ultracold neutrons in the Earth's gravitational field to constrain g for an interaction range $1 \mu\text{m}\text{--}a \text{ few mm}$. See their Fig. 3 for results.	$<7 \times 10^{-15}$	90	26	ANGLOHER	17	CRES	$m_{\gamma} = 0.3\text{--}0.7 \text{ keV}$
17	HECKEL	06	studied the influence of unpolarized bulk matter, including the laboratory's surroundings or the Sun, on a torsion pendulum containing about 9×10^{22} polarized electrons. See their Fig. 4 for limits on g as a function of interaction range.	$<1.2 \times 10^{-4}$	90	27	BANERJEE	17	NA64	$m_{\gamma} = 0.002\text{--}0.4 \text{ GeV}$
18	NI	99	searched for a T -violating medium-range force acting on paramagnetic Tb F ₃ salt. See their Fig. 1 for the result.	$<2 \times 10^{-11}$	90	28	CHANG	17	ASTR	$m_{\gamma} = 15 \text{ MeV}$
19	POSPELOV	98	studied the possible contribution of T -violating Medium-Range Force to the neutron electric dipole moment, which is possible when axion interactions violate CP. The size of the force among nucleons must be smaller than gravity by a factor of $2 \times 10^{-10} (1 \text{ cm}/\lambda_A)$, where $\lambda_A = \hbar/m_A c$.	$<4.5 \times 10^{-3}$	90	29	DUBININA	17	EMUL	$m_{\gamma} = 1.1\text{--}24 \text{ MeV}$
20	YUDIN	96	compared the precession frequencies of atomic ^{199}Hg and Cs when a large mass is positioned near the cells, relative to an applied magnetic field. See Fig. 3 for their limits.	$<4 \times 10^{-4}$	90	30	LEES	17E	BABR	$m_{\gamma} = 4.7 \text{ GeV}$
21	RITTER	93	studied the influence of bulk mass with polarized electrons on an unpolarized torsion pendulum, providing limits in the interaction range from 1 to 100 cm.	$<4 \times 10^{-4}$	90	31	AAD	16AG	ATLS	$m_{\gamma} = 0.1\text{--}2 \text{ GeV}$
22	VENEMA	92	looked for an effect of Earth's gravity on nuclear spin-precession frequencies of ^{199}Hg and ^{201}Hg atoms.	$<4.4 \times 10^{-4}$	90	32	ANASTASI	16	KLOE	$m_{\gamma} = 527\text{--}987 \text{ MeV}$
23	WINELAND	91	looked for an effect of bulk matter with aligned electron spins on atomic hyperfine resonances in stored $^9\text{Be}^+$ ions using nuclear magnetic resonance.	$<1.7 \times 10^{-6}$	95	33	KHACHATRY...	16	CMS	$m_{\gamma} = 2 \text{ GeV}$
				$<4 \times 10^{-2}$	95	34	AAD	15CD	ATLS	$m_{\gamma} = 15\text{--}55 \text{ GeV}$
				$<1.4 \times 10^{-3}$	90	35	ADARE	15		$m_{\gamma} = 30\text{--}90 \text{ MeV}$
				$<1.7 \times 10^{-3}$	90	36	AN	15A		$m_{\gamma} = 12 \text{ eV} - 40 \text{ keV}$
				$<4.2 \times 10^{-4}$	90	37	ANASTASI	15	KLOE	$m_{\gamma} = 2m_{\mu} - 1 \text{ GeV}$
				$<3 \times 10^{-13}$		38	ANASTASI	15A	KLOE	$m_{\gamma} = 5\text{--}320 \text{ MeV}$
				$<6 \times 10^{-12}$		39	BATLEY	15A	NA48	$m_{\gamma} = 36 \text{ MeV}$
				$<2.3 \times 10^{-13}$	99.7	40	JAEGLE	15	BELL	$m_{\gamma} = 0.1\text{--}3.5 \text{ GeV}$
				$<2 \times 10^{-13}$		41	KAZANAS	15	ASTR	$m_{\gamma} = 2m_e - 100 \text{ MeV}$
				$<1.8 \times 10^{-3}$		42	SUZUKI	15		$m_{\gamma} = 1.9\text{--}4.3 \text{ eV}$
				$<9.0 \times 10^{-4}$		43	VINYOLES	15	ASTR	$m_{\gamma} = 8 \text{ eV}$
				$<1.3 \times 10^{-7}$	95	44	ABE	14F	XMAS	$m_{\gamma} = 40\text{--}120 \text{ keV}$

Hidden Photons: Kinetic Mixing Parameter Limits

Limits are on the kinetic mixing parameter χ which is defined by the Lagrangian

$$L = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} - \frac{1}{4} F'_{\mu\nu} F'^{\mu\nu} - \frac{\chi}{2} F_{\mu\nu} F'^{\mu\nu} + \frac{m^2}{2} A'_\mu A'^\mu,$$

where A_μ and A'_μ are the photon and hidden-photon fields with field strengths $F_{\mu\nu}$ and $F'_{\mu\nu}$, respectively, and $m_{\gamma'}$ is the hidden-photon mass.

Gauge & Higgs Boson Particle Listings
Axions (A^0) and Other Very Light Bosons

- <1 $\times 10^{-3}$ 90 64 ABRAHAMY... 11 $m_{\gamma'}$ = 175–250 MeV
- <9 $\times 10^{-8}$ 95 65 BLUEMLEIN 11 BDMP $m_{\gamma'}$ = 70 MeV
- <1 $\times 10^{-7}$ 66 BJORKEN 09 BDMP $m_{\gamma'}$ = 2–400 MeV
- <5 $\times 10^{-9}$ 67 BJORKEN 09 ASTR $m_{\gamma'}$ = 2–50 MeV
- 1 AAIJ 20c look for hidden photons produced from the pp collision in the decay channel $\gamma' \rightarrow \mu^+ \mu^-$. For prompt decaying hidden photons, limits at the level of 10^{-4} – 10^{-3} are obtained for $m_{\gamma'} = 0.214$ –30 GeV. See their Fig. 2 for mass-dependent limits.
- 2 AAIJ 20c look for hidden photons produced from the pp collision in the decay channel $\gamma' \rightarrow \mu^+ \mu^-$. For hidden photons with lifetimes of order ps, limits at the level of 10^{-5} are obtained for $m_{\gamma'} = 218$ –315 MeV. See their Fig. 4 for mass-dependent limits.
- 3 AABOUD 19g look for $h \rightarrow \gamma' \gamma'$ ($\gamma' \rightarrow \mu^+ \mu^-$) and exclude a kinetic mixing around 10^{-9} – 10^{-8} for $B(h \rightarrow \gamma' \gamma') = 0.01$ and 0.1. See their Fig. 9 for mass-dependent limits.
- 4 ABLIKIM 19a look for $J/\psi \rightarrow \gamma' \eta$ ($\gamma' \rightarrow e^+ e^-$). Limits between 6×10^{-3} and 5×10^{-2} are obtained (see their Fig. 8).
- 5 ABLIKIM 19h look for $J/\psi \rightarrow \gamma' \eta'$ ($\gamma' \rightarrow e^+ e^-$). Limits between 3.4×10^{-3} and 2.6×10^{-2} are obtained. See their Fig. 5 for mass-dependent limits.
- 6 AGUILAR-AREVALO 19a look for the absorption signal of hidden photon dark matter by using a CCD. The quoted limit applies to $m_{\gamma'} = 17$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm³ is assumed. See their Fig. 4 for mass-dependent limits.
- 7 APRILE 19d is analogous to ABE 14f. The quoted limit applies to $m_{\gamma'} = 0.7$ keV. See their Fig. 5(f) for mass-dependent limits.
- 8 BANERJEE 19 is an update of BANERJEE 18a. The quoted limit is at $m_{\gamma'} = 1$ MeV. See their Fig. 3 for mass-dependent limits.
- 9 BHONAH 19 examine heating of Galactic Center gas clouds by hidden photon dark matter. The quoted limit applies to $m_{\gamma'} \simeq 10$ – 12 eV. See their Fig. 2 for mass-dependent limits.
- 10 BRUN 19 is analogous to SUZUKI 15. The limit is derived under an assumption that hidden photons constitute the local dark matter density $\rho_{\gamma'} = 0.3$ GeV/cm³.
- 11 CORTINA-GIL 19 look for an invisible hidden photon in the reaction $K^+ \rightarrow \pi^+ \pi^0$ ($\pi^0 \rightarrow \gamma \gamma'$). The quoted limit applies to $m_{\gamma'} = 62.5$ –65 MeV. See their Figs. 6 and 7 for mass-dependent limits.
- 12 DANILOV 19 examined the hidden photon production in nuclear reactors, correctly taking account of the effective photon mass in the reactor and detector. The limit gets weaker for $m_{\gamma'}$ less than the effective photon mass in proportion to $1/m_{\gamma'}^2$. See their Fig. 1 for mass-dependent limits.
- 13 HOCHBERG 19 look for the absorption signal of hidden photon dark matter by using superconducting-nanowire single-photon detectors. The quoted limit applies to $m_{\gamma'} \simeq 1$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm³ is assumed. See their Fig. 4 for mass-dependent limits.
- 14 KOPYLOV 19 look for hidden-photon dark matter using a counter with an aluminum cathode and derive limits assuming it constitute all the local dark matter. The quoted limit applies to $m_{\gamma'} = 12$ eV. See their Fig. 7 for mass-dependent limits.
- 15 KOVETZ 19 examine heating of the early Universe plasma by hidden photon dark matter, and derive the limits by requiring that the cosmic mean 21 cm brightness temperature relative to the CMB temperature satisfy $T_{21} > -100$ mK. The quoted limit applies to $m_{\gamma'} \simeq 2 \times 10^{-14}$ eV. See their Fig. 3 for mass-dependent limits.
- 16 NGUYEN 19 look for hidden photon dark matter with a resonant cavity, and set limits $\sim 10^{-12}$ for $m_{\gamma'} = 0.2$ – $2.07 \mu\text{eV}$. The quoted limit applies to $m_{\gamma'} = 1.3 \mu\text{eV}$. The local density $\rho_{\gamma'} = 0.3$ GeV/cm³ is assumed. See their Fig. 19 for mass-dependent limits.
- 17 ABE 18f is an update of ABE 14f. The quoted limit applies to $m_{\gamma'} \simeq 40$ keV. See their Fig. 5 for mass-dependent limits.
- 18 ADRIAN 18 look for a hidden photon resonance in the reaction $e^- Z \rightarrow e^- Z \gamma'$ ($\gamma' \rightarrow e^+ e^-$). The quoted limit applies to $m_{\gamma'} = 40$ MeV. See their Fig. 4 for mass-dependent limits.
- 19 ANASTASI 18b look for a hidden photon resonance in the reaction $e^+ e^- \rightarrow \gamma' \gamma'$ ($\gamma' \rightarrow \mu^+ \mu^-$). The quoted limit is obtained by combining the result of ANASTASI 16 and it applies to $m_{\gamma'} \simeq 519$ –987 MeV. See their Fig. 9 for mass-dependent limits.
- 20 ARMENGAUD 18 is analogous to ABE 14f. The quoted limits applies to $m_{\gamma'} = 1.6$ keV. See the right panel of Fig. 5 for mass-dependent limits.
- 21 BANERJEE 18 look for hidden photons produced in the reaction $e^- Z \rightarrow e^- Z \gamma'$ ($\gamma' \rightarrow e^+ e^-$), and exclude $9.2 \times 10^{-5} \lesssim \chi \lesssim 1 \times 10^{-2}$ for $m_{\gamma'} = 1$ –23 MeV. They also set a limit on the electron coupling to a 16.7 MeV gauge boson suggested by the ATOMKI (KRASNAHORKAY 16) experiment. See their Fig. 3 for mass-dependent limits.
- 22 BANERJEE 18a look for invisible decays of hidden photons produced in the reaction $e^- Z \rightarrow e^- Z \gamma'$. The quoted limit is at $m_{\gamma'} = 1$ MeV. See their Fig. 15 for mass-dependent limits.
- 23 KNIRCK 18 is analogous to SUZUKI 15. See their Fig. 5 for mass-dependent limits.
- 24 ABRALL 17 is analogous to ABE 14f using the MAJORANA DEMONSTRATOR. See their Fig. 3 for limits between 6 keV $< m_{\gamma'} < 97$ keV.
- 25 ABLIKIM 17aa look for $e^+ e^- \rightarrow \gamma \gamma'$ ($\gamma' \rightarrow e^+ e^-$ or $\mu^+ \mu^-$). Limits between 10^{-3} and 10^{-4} are obtained (see their Fig. 3).
- 26 ANGLÖHER 17 is analogous to ABE 14f. The quoted limit is at $m_{\gamma'} = 0.7$ keV. See their Fig. 8 for mass-dependent limits.
- 27 BANERJEE 17 look for invisible decays of hidden photons produced in the reaction $e^- Z \rightarrow e^- Z \gamma'$. The quoted limit applies to $m_{\gamma'} = 2$ MeV. See their Fig. 3 for mass-dependent limits.
- 28 CHANG 17 examine the hidden photon emission from SN1987A, including the effects of finite temperature and density on χ and obtain limits χ ($m_{\gamma'}/\text{MeV}$) $\lesssim 3 \times 10^{-9}$ for $m_{\gamma'} < 15$ MeV and $\chi \lesssim 10^{-9}$ for $m_{\gamma'} = 15$ –120 MeV.
- 29 DUBININA 17 look for $\mu^+ \rightarrow e^+ \bar{\nu}_\mu \nu_e \gamma'$ ($\gamma' \rightarrow e^+ e^-$) in a nuclear photoemulsion. The quoted limit applies to $m_{\gamma'} = 1.1$ MeV. Limits between 4.5×10^{-3} and 10^{-2} are obtained (see their Fig. 3).
- 30 LEES 17e look for invisible decays of hidden photons produced in the reaction $e^+ e^- \rightarrow \gamma \gamma'$. See their Fig. 5 for limits in the mass range $m_{\gamma'} \leq 8$ GeV.
- 31 AAD 16ag look for hidden photons promptly decaying into collimated electrons and/or muons, assuming that they are produced in the cascade decays of squarks or the Higgs boson. See their Fig. 10 and Fig.13 for their limits on the cross section times branching fractions.
- 32 ANASTASI 16 look for the decay $\gamma' \rightarrow \pi^+ \pi^-$ in the reaction $e^+ e^- \rightarrow \gamma \gamma'$. Limits between 4.3×10^{-3} and 4.4×10^{-4} are obtained for $527 < m_{\gamma'} < 987$ MeV (see their Fig. 9).
- 33 KHACHATRYAN 16 look for $\gamma' \rightarrow \mu^+ \mu^-$ in a dark SUSY scenario where the SM-like Higgs boson decays into a pair of the visible lightest neutralinos with mass 10 GeV, both of which decay into γ' and a hidden neutralino with mass 1 GeV. See the right panel in their Fig. 2.
- 34 AAD 15cd look for $H \rightarrow Z \gamma' \rightarrow 4\ell$ with the ATLAS detector at LHC and find $\chi < 4$ – 17×10^{-2} for $m_{\gamma'} = 15$ –55 GeV. See their Fig. 6.
- 35 ADARE 15 look for a hidden photon in $\pi^0, \eta^0 \rightarrow \gamma e^+ e^-$ at the PHENIX experiment. See their Fig. 4 for mass-dependent limits.
- 36 AN 15a derived limits from the absence of ionization signals in the XENON10 and XENON100 experiments, assuming hidden photons constitute all the local dark matter. Their best limit is $\chi < 1.3 \times 10^{-15}$ at $m_{\gamma'} = 18$ eV. See their Fig. 1 for mass-dependent limits.
- 37 ANASTASI 15 look for a production of a hidden photon and a hidden Higgs boson with the KLOE detector at DAΦNE, where the hidden photon decays into a pair of muons and the hidden Higgs boson lighter than $m_{\gamma'}$ escape detection. See their Figs. 6 and 7 for mass-dependent limits on a product of the hidden fine structure constant and the kinetic mixing.
- 38 ANASTASI 15a look for the decay $\gamma' \rightarrow e^+ e^-$ in the reaction $e^+ e^- \rightarrow e^+ e^- \gamma$. Limits between 1.7×10^{-3} and 1×10^{-2} are obtained for $m_{\gamma'} = 5$ –320 MeV (see their Fig. 7).
- 39 BATLEY 15a look for $\pi^0 \rightarrow \gamma \gamma'$ ($\gamma' \rightarrow e^+ e^-$) at the NA48/2 experiment. Limits between 4.2×10^{-4} and 8.8×10^{-3} are obtained for $m_{\gamma'} = 9$ –120 MeV (see their Fig. 4).
- 40 JAEGLER 15 look for the decay $\gamma' \rightarrow e^+ e^-, \mu^+ \mu^-,$ or $\pi^+ \pi^-$ in the dark Higgsstrahlung channel, $e^+ e^- \rightarrow \gamma' H'$ ($H' \rightarrow \gamma' \gamma'$) at the BELLE experiment. They set limits on a product of the branching fraction and the Born cross section as well as a product of the hidden fine structure constant and the kinetic mixing. See their Figs. 3 and 4.
- 41 KAZANAS 15 set limits by studying the decay of hidden photons $\gamma' \rightarrow e^+ e^-$ inside and near the progenitor star of SN1987A. See their Fig. 6 for mass-dependent limits.
- 42 SUZUKI 15 looked for hidden-photon dark matter with a dish antenna and derived limits assuming they constitute all the local dark matter. Their limits are $\chi < 6 \times 10^{-12}$ for $m_{\gamma'} = 1.9$ –4.3 eV. See their Fig. 7 for mass-dependent limits.
- 43 VINOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations, and set the limits $\chi m_{\gamma'} < 1.8 \times 10^{-12}$ eV for $m_{\gamma'} = 3 \times 10^{-5}$ –8 eV. See their Fig. 11.
- 44 ABE 14f look for the photoelectric-like interaction in the XMASS detector assuming the hidden photon constitutes all the local dark matter. Limits between 2×10^{-13} and 1×10^{-12} are obtained, where the relation $\chi^2 = \alpha'/\alpha$ is used to translate the original bound on the ratio of the hidden and EM fine-structure constants. See their Fig. 3 for mass-dependent limits.
- 45 AGA KISHIEV 14 look for hidden photons $\gamma' \rightarrow e^+ e^-$ at the HADES experiment, and set limits on χ for $m_{\gamma'} = 0.02$ –0.6 GeV. See their Fig. 5 for mass-dependent limits.
- 46 BABUSCI 14 look for the decay $\gamma' \rightarrow \mu^+ \mu^-$ in the reaction $e^+ e^- \rightarrow \mu^+ \mu^- \gamma$. Limits between 4×10^{-3} and 9.0×10^{-4} are obtained for 520 MeV $< m_{\gamma'} < 980$ MeV (see their Fig. 7).
- 47 BATELL 14 derived limits from the electron beam dump experiment at SLAC (E-137) by searching for events with recoil electrons by sub-GeV dark matter produced from the decay of the hidden photon. Limits at the level of 10^{-4} – 10^{-1} are obtained for $m_{\gamma'} = 10^{-3}$ –1 GeV, depending on the dark matter mass and the hidden gauge coupling (see their Fig. 2).
- 48 BLUEMLEIN 14 analyzed the beam dump data taken at the U-70 accelerator to look for γ' -bremsstrahlung and the subsequent decay into muon pairs and hadrons. See their Fig. 4 for mass-dependent excluded region.
- 49 FRADETTE 14 studied effects of decay of relic hidden photons on BBN and CMB to set constraints on very small values of the kinetic mixing. See their Figs. 4 and 7 for mass-dependent excluded regions.
- 50 LEES 14l look for hidden photons in the reaction $e^+ e^- \rightarrow \gamma \gamma'$ ($\gamma' \rightarrow e^+ e^-, \mu^+ \mu^-$). Limits at the level of 10^{-4} – 10^{-3} are obtained for 0.02 GeV $< m_{\gamma'} < 10.2$ GeV. See their Fig. 4 for mass-dependent limits.
- 51 MERKEL 14 look for $\gamma' \rightarrow e^+ e^-$ at the A1 experiment at the Mainz Microtron (MAMI). See their Fig. 3 for mass-dependent limits.
- 52 AN 13b examined the stellar production of hidden photons, correcting an important error of the production rate of the longitudinal mode which now dominates. See their Fig. 2 for mass-dependent limits based on solar energy loss.
- 53 AN 13c use the solar flux of hidden photons to set a limit on the atomic ionization rate in the XENON10 experiment. They find $\chi m_{\gamma'} < 3 \times 10^{-12}$ eV for $m_{\gamma'} < 1$ eV. See their Fig. 2 for mass-dependent limits.
- 54 DIAMOND 13 analyzed the beam dump data taken at the SLAC millicharge experiment to constrain a hidden photon invisibly decaying into lighter long-lived particles, which undergo elastic scattering off nuclei in the detector. Limits between 8×10^{-4} – 2×10^{-2}

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

- are obtained. The quoted limit is applied when the dark gauge coupling is set equal to the electromagnetic coupling. See their Fig. 4 for mass-dependent limits.
- 55** GNINENKO 13 used the data taken at the SINDRUM experiment to constrain the decay, $\pi^0 \rightarrow \gamma\gamma (\gamma \rightarrow e^+e^-)$ to derive limits. See their Fig. 2 for their mass-dependent excluded region.
- 56** HORVAT 13 look for hidden-photo-electric effect in HPGe detectors induced by solar hidden photons. See their Fig. 3 for mass-dependent limits.
- 57** INADA 13 search for hidden photons using an intense X-ray beamline at SPRING-8. See their Fig. 4 for mass-dependent limits.
- 58** MIZUMOTO 13 look for solar hidden photons. See their Fig. 5 for mass-dependent limits.
- 59** PARKER 13 look for hidden photons using a cryogenic resonant microwave cavity. See their Fig. 5 for mass-dependent limits.
- 60** PARKER 13 derived a limit for the hidden photon CDM with a randomly oriented hidden photon field.
- 61** REDONDO 13 examined the solar emission of hidden photons including the enhancement factor for the longitudinal mode pointed out by AN 13b, and also updated stellar-energy loss arguments. See their Fig. 3 for mass-dependent limits, including a review of the currently best limits from other arguments.
- 62** GNINENKO 12a obtained bounds on $B(\pi^0 \rightarrow \gamma\gamma) \cdot B(\gamma \rightarrow e^+e^-)$ from the NOMAD and PS191 neutrino experiments, and derived limits between $8 \times 10^{-8} - 2 \times 10^{-4}$. See their Fig. 4 for mass-dependent excluded regions.
- 63** GNINENKO 12b used the data taken at the CHARM experiment to constrain the decay, $\eta(\gamma) \rightarrow \gamma\gamma (\gamma \rightarrow e^+e^-)$, and derived limits between $1 \times 10^{-7} - 1 \times 10^{-4}$. See their Fig. 4 for mass-dependent excluded region.
- 64** ABRAHAMYAN 11 look for $\gamma \rightarrow e^+e^-$ in the electron-nucleon fixed-target experiment at the Jefferson Laboratory (APEX). See their Fig. 5 for mass-dependent limits.
- 65** BLUEMLEIN 11 analyzed the beam dump data taken at the U-70 accelerator to look for $\pi^0 \rightarrow \gamma\gamma (\gamma \rightarrow e^+e^-)$. See their Fig. 5 for mass-dependent limits.
- 67** BJORKEN 09 analyzed the beam dump data taken at E137, E141, and E774 to constrain a hidden photon produced by bremsstrahlung, subsequently decaying into e^+e^- , and derived limits between 10^{-7} and 10^{-2} . See their Fig. 1 for mass-dependent excluded region.
- 67** BJORKEN 09 required the energy loss in the γ' emission from the core of SN1987A not to exceed 10^{53} erg/s, and derived limits between 5×10^{-9} and 2×10^{-6} . See their Fig. 1 for mass-dependent excluded region.

J = 1/2

e MASS (atomic mass units u)

The primary determination of an electron's mass comes from measuring the ratio of the mass to that of a nucleus...

Table with columns: VALUE (10^-6 u), DOCUMENT ID, TECN, COMMENT. Includes data for MOHR 16, MOHR 12, MOHR 08, MOHR 05, BEIER 02, MOHR 99, FARNHAM 95, COHEN 87.

1 BEIER 02 compares Larmor frequency of the electron bound in a 12C5+ ion with the cyclotron frequency of a single trapped 12C5+ ion.

e MASS

2010 CODATA (MOHR 12) gives the conversion factor from u (atomic mass units, see the above datablock) to MeV as 931.494 061 (21).

Table with columns: VALUE (MeV), DOCUMENT ID, TECN, COMMENT. Includes data for MOHR 16, MOHR 12, MOHR 08, MOHR 05, BEIER 02, MOHR 99, FARNHAM 95, COHEN 87, COHEN 73.

1 Converted to MeV using the 1998 CODATA value of the conversion constant, 931.494013 ± 0.000037 MeV/u.

(me+ - me-) / maverage

A test of CPT invariance.

Table with columns: VALUE, CL%, DOCUMENT ID, TECN, COMMENT. Includes data for FEE 93, DOLGOV 14, CHU 84.

1 FEE 93 value is obtained under the assumption that the positronium Rydberg constant is exactly half the hydrogen one.

|qe+ + qe-|/e

A test of CPT invariance. See also similar tests involving the proton.

Table with columns: VALUE, DOCUMENT ID, TECN, COMMENT. Includes data for HUGHES 92, SCHAEFER 95, MUELLER 92.

1 HUGHES 92 uses recent measurements of Rydberg-energy and cyclotron-frequency ratios.

e MAGNETIC MOMENT ANOMALY

me/μB - 1 = (g-2)/2

Table with columns: VALUE (units 10^-6), DOCUMENT ID, TECN, CHG, COMMENT. Includes data for MOHR 16, MOHR 12, HANNEKE 08, MOHR 08, ODOM 06, MOHR 05, MOHR 99, COHEN 87, VANDYCK 87, VANDYCK 87.

1 MOHR 08 average is dominated by ODOM 06. 2 Superseded by HANNEKE 08 per private communication with Gerald Gabrielse.

(ge+ - ge-) / gaverage

A test of CPT invariance.

Table with columns: VALUE (units 10^-12), CL%, DOCUMENT ID, TECN, COMMENT. Includes data for VANDYCK 87, VASSERMAN 87, SCHWINBERG 81.

1 VANDYCK 87 measured (g-/g+)-1 and we converted it. 2 VASSERMAN 87 measured (g+ - g-)/(g-2). We multiplied by (g-2)/g = 1.2 x 10^-3.

e ELECTRIC DIPOLE MOMENT (d)

A nonzero value is forbidden by both T invariance and P invariance.

Table with columns: VALUE (10^-28 ecm), CL%, DOCUMENT ID, TECN, COMMENT. Includes data for ANDREEV 18, CAIRNCROSS 17, BARON 14, ECKEL 12, HUDSON 11, REGAN 02, COMMINI 94, ABDULLAH 90, CHO 89, MURTHY 89, LAMOREAUX 87, SANDARS 75, PLAYER 70, WEISSKOPF 68.

1 ANDREEV 18 gives a measurement corresponding to this limit as (4.3 ± 3.1 ± 2.6) x 10^-30 ecm. 2 CAIRNCROSS 17 gives a measurement corresponding to this limit as (0.09 ± 0.77 ± 0.17) x 10^-28 ecm.

e- MEAN LIFE / BRANCHING FRACTION

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review D45 S1 (1992), p. VI.10).

Most of these experiments are one of three kinds: Attempts to observe (a) the 255.5 keV gamma ray produced in e- -> nu_e gamma, (b) the (K) shell x-ray produced when an electron decays without additional energy deposit...

Note that we use the mean life rather than the half life, which is often reported.

e -> nu_e gamma and astrophysical limits

Table with columns: VALUE (yr), CL%, DOCUMENT ID, TECN, COMMENT. Includes data for AGOSTINI 15B, BORX.

μ MASS (atomic mass units u)

The muon's mass is obtained from the muon-electron mass ratio as determined from the measurement of Zeeman transition frequencies in muonium (μ^+e^- atom). Since the electron's mass is most accurately known in u, the muon's mass is also most accurately known in u. The conversion factor to MeV has approximately the same relative uncertainty as the mass of the muon in u. In this datablock we give the result in u, and in the following datablock in MeV.

VALUE (u)	DOCUMENT ID	TECN	COMMENT
0.1134289257 ± 0.0000000025	MOHR	16	RVUE 2014 CODATA value

 Muon Anomalous Magnetic Moment

μ MAGNETIC MOMENT ANOMALY

The parity-violating decay of muons in a storage ring is observed. The difference frequency ω_3 between the muon spin precession and the orbital angular frequency ($e/m_\mu c$)(B) is measured, as is the free proton NMR frequency ω_p , thus determining the ratio $R = \omega_3/\omega_p$. Given the magnetic moment ratio $\lambda = \mu_\mu/\mu_p$ (from hyperfine structure in muonium), $(g-2)/2 = R/(\lambda-R)$.

$$\mu_\mu / (e\hbar/2m_\mu) - 1 = (g_\mu - 2)/2$$

0.8 ± 4.3	BAILEY	78	CNTR -	Storage ring

¹ This is the combination of the two BENNETT 09 measurements quoted here separately for μ^+ and μ^- . The result is also presented as a measurement of $(0.0 \pm 0.9) \times 10^{-19}$ e cm.
² Also reported as the limit of $|d(\mu^+)| < 2.1 \times 10^{-19}$ e cm at 95% CL.
³ Also reported as the limit of $|d(\mu^-)| < 1.5 \times 10^{-19}$ e cm at 95% CL.
⁴ This is the combination of the two BAILEY 78 results quoted here separately for μ^+ and μ^- . BAILEY 78 uses the convention $d = 1/2 \cdot (d_{\mu^+} - d_{\mu^-})$ and reports 3.7 ± 3.4 . We convert their result to use the same convention as BENNETT 09.

MUON-ELECTRON CHARGE RATIO ANOMALY $q_{\mu^+}/q_{e^-} + 1$

VALUE	DOCUMENT ID	TECN	CHG	COMMENT
(1.1 ± 2.1) × 10⁻⁹	¹ MEYER	00	CNTR +	1s-2s muonium interval
¹ MEYER 00 measure the 1s-2s muonium interval, and then interpret the result in terms of muon-electron charge ratio q_{μ^+}/q_{e^-} .				

μ^- DECAY MODES

μ^+ modes are charge conjugates of the modes below.

Mode	Fraction (Γ_i/Γ)	Confidence level
Γ_1 $e^- \bar{\nu}_e \nu_\mu$	≈ 100%	
Γ_2 $e^- \bar{\nu}_e \nu_\mu \gamma$	[a] $(6.0 \pm 0.5) \times 10^{-8}$	
Γ_3 $e^- \bar{\nu}_e \nu_\mu e^+ e^-$	[b] $(3.4 \pm 0.4) \times 10^{-5}$	

Lepton Family number (LF) violating modes

Γ_i	Mode	LF	Value	%	90%
Γ_4	$e^- \nu_e \bar{\nu}_\mu$	LF	[c] < 1.2	%	90%
Γ_5	$e^- \gamma$	LF	< 4.2	$\times 10^{-13}$	90%
Γ_6	$e^- e^+ e^-$	LF	< 1.0	$\times 10^{-12}$	90%
Γ_7	$e^- 2\gamma$	LF	< 7.2	$\times 10^{-11}$	90%

[a] This only includes events with energy of $e > 45$ MeV and energy of $\gamma > 40$ MeV. Since the $e^- \bar{\nu}_e \nu_\mu$ and $e^- \bar{\nu}_e \nu_\mu \gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.

[b] See the Particle Listings below for the energy limits used in this measurement.

[c] A test of additive vs. multiplicative lepton family number conservation.

μ^- BRANCHING RATIOS

$\Gamma(e^- \bar{\nu}_e \nu_\mu \gamma) / \Gamma_{\text{total}}$	Γ_2/Γ

< 1.7×10^{-10}	90		⁴ AHMAD 88	TPC		TRIUMF

¹ This limit assumes a giant resonance excitation of the daughter Ca nucleus (mean energy and width both 20 MeV).

² KAULARD 98 obtained these same limits using the unified classical analysis of FELDMAN 98.

³ This limit assumes the daughter Ca nucleus is left in the ground state. However, the probability of this is unknown.

⁴ Assuming a giant-resonance-excitation model.

LIMIT ON MUONIUM \rightarrow ANTIMUONIUM CONVERSION

Forbidden by lepton family number conservation.

$R_g = G_C / G_F$

The effective Lagrangian for the $\mu^+ e^- \rightarrow \mu^- e^+$ conversion is assumed to be

$$\mathcal{L} = 2^{-1/2} G_C [\bar{\nu}_\mu \gamma_\lambda (1 - \gamma_5) \psi_e] [\bar{\psi}_\mu \gamma_\lambda (1 - \gamma_5) \psi_e] + \text{h.c.}$$

The experimental result is then an upper limit on G_C / G_F , where G_F is the Fermi coupling constant.

VALUE	CL%	EVTS	DOCUMENT ID	TECN	CHG	COMMENT

τ

$$J = \frac{1}{2}$$

τ discovery paper was PERL 75. $e^+e^- \rightarrow \tau^+\tau^-$ cross-section threshold behavior and magnitude are consistent with pointlike spin-1/2 Dirac particle. BRANDELİK 78 ruled out pointlike spin-0 or spin-1 particle. FELDMAN 78 ruled out $J = 3/2$. KIRKBY 79 also ruled out $J = \text{integer}$, $J = 3/2$.

- 1 ABLIKIM 14D fit $\sigma(e^+e^- \rightarrow \tau^+\tau^-)$ at different energies near threshold.
- 2 AUBERT 09AK and BELOUS 07 fit τ pseudomass spectrum in $\tau \rightarrow \pi^+\pi^-\nu_\tau$ decays. Result assumes $m_{\nu_\tau} = 0$.
- 3 ABBIENDI 00A fit τ pseudomass spectrum in $\tau \rightarrow \pi^\pm \leq 2\pi^0\nu_\tau$ and $\tau \rightarrow \pi^\pm\pi^+\pi^- \leq 1\pi^0\nu_\tau$ decays. Result assumes $m_{\nu_\tau} = 0$.
- 4 BAI 96 fit $\sigma(e^+e^- \rightarrow \tau^+\tau^-)$ at different energies near threshold.
- 5 ALBRECHT 92M fit τ pseudomass spectrum in $\tau^- \rightarrow 2\pi^-\pi^+\nu_\tau$ decays. Result assumes $m_{\nu_\tau} = 0$.
- 6 BACINO 78B value comes from $e^\pm X^\mp$ threshold. Published mass 1782 MeV increased by 1 MeV using the high precision $\psi(2S)$ mass measurement of ZHOLENTZ 80 to eliminate the absolute SPEAR energy calibration uncertainty.
- 7 BALEST 93 fit spectra of minimum kinematically allowed τ mass in events of the type $e^+e^- \rightarrow \tau^+\tau^- \rightarrow (\pi^+n\pi^0\nu_\tau)(\pi^-m\pi^0\nu_\tau)$ $n \leq 2, m \leq 2, 1 \leq n+m \leq 3$. If $m_{\nu_\tau} \neq 0$, result increases by $(m_{\nu_\tau}^2/1100)$ MeV.
- 8 BAI 92 fit $\sigma(e^+e^- \rightarrow \tau^+\tau^-)$ near threshold using $e\mu$ events.

$(m_{\tau^+} - m_{\tau^-})/m_{\text{average}}$

A test of CPT invariance.

The charged particle here can be e, μ, or hadron. In many analyses, the sum of the topological branching fractions (1, 3, and 5 prongs) is constrained to be unity. Since the 5-prong fraction is very small, the measured 1-prong and 3-prong fractions are highly correlated and cannot be treated as independent quantities in our overall fit. We arbitrarily choose to use the 3-prong fraction in our fit, and leave the 1-prong fraction out. We do, however, use these 1-prong measurements in our average below.

1 Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, ALBRECHT 95c, ALBRECHT 93g, and ALBRECHT 94e. ALBRECHT 98 use tau pair events of the type $\tau^- \tau^+ \rightarrow (\ell^- \bar{\nu}_\ell \nu_\tau)(\pi^+ \pi^0 \bar{\nu}_\tau)$, and their charged conjugates.
 2 ABE 97o assume $\eta = 0$ in their fit. Letting η vary in the fit gives a ρ value of $0.69 \pm 0.13 \pm 0.05$.
 3 Value is from a simultaneous fit for the ρ and η decay parameters to the lepton energy spectrum. Not independent of ALBRECHT 90E $\rho(e \text{ or } \mu)$ value which assumes $\eta = 0$. Result is strongly correlated with ALBRECHT 95c.
 4 Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95c, ALBRECHT 93g, and ALBRECHT 94e.

$\rho(e)$ PARAMETER

(V-A) theory predicts $\rho = 0.75$.

Heavy Charged Lepton Searches

Charged Heavy Lepton MASS LIMITS

Sequential Charged Heavy Lepton (L^\pm) MASS LIMITS

These experiments assumed that a fourth generation L^\pm decayed to a fourth generation ν_L (or L^0) where ν_L was stable, or that L^\pm decays to a light ν_L via mixing.

See the "Quark and Lepton Compositeness, Searches for" Listings for limits on radiatively decaying excited leptons, i.e. $\ell^* \rightarrow \ell\gamma$. See the "WIMPs and other Particle Searches" section for heavy charged particle search limits in which the charged particle could be a lepton.

- ACCIARRI 96G assumes LEP result that the associated neutral heavy lepton mass > 40 GeV.
- The AHMED 94 limits are from a search for neutral and charged sequential heavy leptons at HERA via the decay channels $L^- \rightarrow e\gamma$, $L^- \rightarrow \nu W^-$, $L^- \rightarrow eZ$; and $L^0 \rightarrow \nu\gamma$, $L^0 \rightarrow e^- W^+$, $L^- \rightarrow \nu Z$, where the W decays to $\ell\nu_\ell$, or to jets, and Z decays to $\ell^+ \ell^-$ or jets.
- RILES 90 limits were the result of a special analysis of the data in the case where the mass difference $m_{L^-} - m_{L^0}$ was allowed to be quite small, where L^0 denotes the neutrino into which the sequential charged lepton decays. With a slightly reduced m_{L^\pm} range, the mass difference extends to about 4 GeV.
- STOKER 89 (Mark II at PEP) gives bounds on charged heavy lepton (L^\pm) mass for the generalized case in which the corresponding neutral heavy lepton (L^0) in the SU(2) doublet is not of negligible mass.
- ABE 88 search for L^+ and $L^- \rightarrow$ hadrons looking for acoplanar jets. The bound is valid for $m_\nu < 10$ GeV.
- ADACHI 88B search for hadronic decays giving acoplanar events with large missing energy. $E_{cm}^{ee} = 52$ GeV.
- Assumes associated neutrino is approximately massless.
- ADEVA 85 analyze one-isolated-muon data and sensitive to $\tau < 10$ nanosec. Assume B(lepton) = 0.30. $E_{cm} = 40-47$ GeV.
- BARTEL 83 limit is from PETRA e^+e^- experiment with average $E_{cm} = 34.2$ GeV.
- BERGER 81B is DESY DORIS and PETRA experiment. Looking for $e^+e^- \rightarrow L^+L^-$.
- BRANDELIK 81 is DESY-PETRA experiment. Looking for $e^+e^- \rightarrow L^+L^-$.
- AZIMOV 80 estimated probabilities for $M+N$ type events in $e^+e^- \rightarrow L^+L^-$ deducing semi-hadronic decay multiplicities of L from e^+e^- annihilation data at $E_{cm} = (2/3)m_L$. Obtained above limit comparing these with e^+e^- data (BRANDELIK 80).
- BARBER 80B looked for $e^+e^- \rightarrow L^+L^-$, $L \rightarrow \nu_\ell^+ X$ with MARK-J at DESY-PETRA.
- ROTHER 69 examines previous data on μ pair production and π and K decays.

Stable Charged Heavy Lepton (L^\pm) MASS LIMITS

VALUE (GeV)	CL%	DOCUMENT ID	TECN
>102.6	95	ACHARD	01B L3

Neutrino Properties

NEUTRINO PROPERTIES

Revised August 2019 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

The Neutrino Properties Listings concern measurements of various properties of neutrinos. Nearly all of the measurements, so far only limits, actually concern superpositions of the mass eigenstates ν_i , which are in turn related to the weak eigenstates ν_ℓ , via the neutrino mixing matrix

$$|\nu_\ell\rangle = \sum_i U_{\ell i} |\nu_i\rangle.$$

In the analogous case of quark mixing via the CKM matrix, the smallness of the off-diagonal terms (small mixing angles) permits a “dominant eigenstate” approximation. However, the results of neutrino oscillation searches show that the mixing matrix contains two large mixing angles and a third angle that is not exceedingly small. We cannot therefore associate any particular state $|\nu_i\rangle$ with any particular lepton label e, μ or τ . Nevertheless, note that in the standard labeling the $|\nu_1\rangle$ has the largest $|\nu_e\rangle$ component ($\sim 2/3$), $|\nu_2\rangle$ contains $\sim 1/3$ of the $|\nu_e\rangle$ component and $|\nu_3\rangle$ contains only a small $\sim 2.5\%$ $|\nu_e\rangle$ component.

Neutrinos are produced in weak decays with a definite lepton flavor, and are typically detected by the charged current weak interaction again associated with a specific lepton flavor. Hence, the listings for the neutrino mass that follow are separated into the three associated charged lepton categories. Other properties (mean lifetime, magnetic moment, charge and charge radius) are no longer separated this way. If needed, the associated lepton flavor is reported in the footnotes.

Measured quantities (mass-squared, magnetic moments, mean lifetimes, *etc.*) all depend upon the mixing parameters $|U_{\ell i}|^2$, but to some extent also on experimental conditions (e.g., on energy resolution). Many of these observables, in particular

mass-squared, cannot distinguish between Dirac and Majorana neutrinos and are unaffected by CP phases.

Direct neutrino mass measurements are usually based on the analysis of the kinematics of charged particles (leptons, pions) emitted together with neutrinos (flavor states) in various weak decays. The most sensitive neutrino mass measurement to date, involving electron type antineutrinos, is based on fitting the shape of the beta spectrum. The quantity $m_{\nu_e}^{2(eff)} = \sum_i |U_{ei}|^2 m_{\nu_i}^2$ is determined or constrained, where the sum is over all mass eigenvalues m_{ν_i} that are too close together to be resolved experimentally. (The quantity $m_{\nu_e}^{eff} \equiv \sqrt{m_{\nu_e}^{2(eff)}}$ is often denoted $\langle m_\beta \rangle$ in the literature.) If the energy resolution is better than $\Delta m_{ij}^2 \equiv m_{\nu_i}^2 - m_{\nu_j}^2$, the corresponding heavier m_{ν_i} and mixing parameter could be determined by fitting the resulting spectral anomaly (step or kink).

The dependence of m_{ν_e} on the mass of the lightest neutrino is shown in Fig. 14.11 of the *Neutrino Masses, Mixing, and Oscillations* review. In the case of inverted ordering there is a minimum possible value of $m_{\nu_e}^{eff}$, approximately $\sqrt{(\Delta m_{32}^2)} \sim 50$ meV. If $m_{\nu_e}^{eff}$ is found to be larger than this value, it is impossible, based on this information only, to decide which ordering is realized in nature. On the other hand, if the $m_{\nu_e}^{eff}$ is less than ~ 50 meV, only the normal mass ordering is possible.

A limit on $m_{\nu_e}^{2(eff)}$ implies an upper limit on the minimum value m_{min}^2 of $m_{\nu_i}^2$, independent of the mixing parameters U_{ei} : $m_{min}^2 \leq m_{\nu_e}^{2(eff)}$. However, if and when the value of $m_{\nu_e}^{2(eff)}$ is determined then its combination with the results derived from neutrino oscillations that give us the values of the neutrino mass-squared differences $\Delta m_{ij}^2 \equiv m_i^2 - m_j^2$, including eventually also their signs, and the mixing parameters $|U_{ei}|^2$, the individual neutrino mass squares $m_{\nu_j}^2 = m_{\nu_e}^{2(eff)} - \sum_i |U_{ei}|^2 \Delta m_{ij}^2$ can be determined.

So far solar, reactor, atmospheric and accelerator neutrino oscillation experiments can be consistently described using three active neutrino flavors, i.e. two mass splittings and three mixing angles. However, several experiments with radioactive sources, reactors, and accelerators imply the possible existence of one or more non-interacting, i.e. sterile, neutrino species that might be observable since they couple, albeit weakly, to the flavor neutrinos $|\nu_l\rangle$. In that case, the neutrino mixing matrix would be $n \times n$ unitary matrix with $n > 3$.

Combined three neutrino analyses determine the squared mass differences and all three mixing angles to within reasonable accuracy. For given $|\Delta m_{ij}^2|$ a limit on $m_{\nu_e}^{2(eff)}$ from beta decay defines an upper limit on the maximum value m_{max} of m_{ν_i} : $m_{max}^2 \leq m_{\nu_e}^{2(eff)} + \sum_{i < j} |\Delta m_{ij}^2|$. The analysis of the low energy beta decay of tritium, combined with the oscillation results, thus limits *all* active neutrino masses. Traditionally, experimental neutrino mass limits obtained from pion decay $\pi^+ \rightarrow \mu^+ + \nu_\mu$ or the shape of the spectrum of decay products of the τ lepton did not distinguish between flavor and mass eigenstates. These results are reported as limits of the μ and τ based neutrino

Lepton Particle Listings

Neutrino Properties

mass. After the determination of the $|\Delta m_{ij}^2|$'s and the mixing angles θ_{ij} , the corresponding neutrino mass limits are no longer competitive with those derived from low energy beta decays.

The spread of arrival times of the neutrinos from SN1987A, coupled with the measured neutrino energies, provided a time-of-flight limit on a quantity similar to $\langle m_{\beta} \rangle \equiv \sqrt{m_{\nu_e}^{2(eff)}}$. This statement, clothed in various degrees of sophistication, has been the basis for a very large number of papers. The resulting limits, however, are no longer comparable with the limits from tritium beta decay.

Constraint, or eventually a value, of the sum of the neutrino masses m_{tot} can be determined from the analysis of the cosmic microwave background anisotropy, combined with the galaxy redshift surveys and other data. These limits are reported in a separate table (Sum of Neutrino Masses, m_{tot}). Obviously, m_{tot} represents an upper limit for all m_i values. Note that many reported m_{tot} limits are considerably more stringent than the listed $m_{\nu_e}^{eff}$ limits. Discussion concerning the model dependence of the m_{tot} limit is continuing.

\overline{m} MASS (electron based)

Those limits given below are for the square root of $m_{\nu_e}^{2(eff)} \equiv \sum_i |U_{ei}|^2 m_{\nu_i}^2$. Limits that come from the kinematics of ${}^3\text{H}\beta\text{-}\overline{m}$ decay are the square roots of the limits for $m_{\nu_e}^{2(eff)}$. Obtained from the measurements reported in the Listings for " \overline{m} Mass Squared," below.

¹ AKER 19 report a neutrino mass limit, derived from the first month of data collected by the KATRIN tritium endpoint experiment. The analysis of the electron kinematics shows no evidence for neutrino mass.

² ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002 (some of the earlier runs were rejected), using a windowless gaseous tritium source. The fitted value of m_{ν} , based on the method of Feldman and Cousins, is obtained from the upper limit of the fit for m_{ν}^2 . Previous analysis problems were resolved by careful monitoring of the tritium gas column density. Supersedes LOBASHEV 99 and BELESEV 95.

³ PAGLIAROLI 10 is critical of the likelihood method used by LOREDO 02.

⁴ KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Various sources of systematic uncertainties have been identified and quantified. The background has been reduced compared to the initial running period. A spectral anomaly at the endpoint, reported in LOBASHEV 99, was not observed.

⁵ ARNABOLDI 03A *et al.* report kinematical neutrino mass limit using β -decay of ${}^{187}\text{Re}$. Bolometric AgReO_4 micro-calorimeters are used. Mass bound is substantially weaker than those derived from tritium β -decays but has different systematic uncertainties.

⁶ LOREDO 02 updates LOREDO 89.

⁷ LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. This limit depends on phenomenological fit parameters used to derive their best fit to m_{ν}^2 , making an unambiguous interpretation difficult. See the footnote under " \overline{m} Mass Squared."

⁸ WEINHEIMER 99 presents two analyses which exclude the spectral anomaly and result in an acceptable m_{ν}^2 . We report the most conservative limit, but the other is nearly the same. See the footnote under " \overline{m} Mass Squared."

⁹ BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. A fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly) plus a monochromatic line 7–15 eV below the endpoint yields $m_{\nu}^2 = -4.1 \pm 10.9 \text{ eV}^2$, leading to this Bayesian limit.

¹⁰ CHING 95 quotes results previously given by SUN 93; no experimental details are given. A possible explanation for consistently negative values of m_{ν}^2 is given.

¹¹ HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. Bayesian limit calculated from the weighted mean $m_{\nu}^2 = 221 \pm 4244 \text{ eV}^2$ from the two runs listed below.

¹² STOEFL 95 (LLNL) result is the Bayesian limit obtained from the m_{ν}^2 errors given below but with m_{ν}^2 set equal to 0. The anomalous endpoint accumulation leads to a value of m_{ν}^2 which is negative by more than 5 standard deviations.

¹³ WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.

¹⁴ HOLZSCHUH 92B (Zurich) result is obtained from the measurement $m_{\nu}^2 = -24 \pm 48 \pm 61$ (1σ errors), in eV^2 , using the PDG prescription for conversion to a limit in m_{ν} .

¹⁵ KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid. This result is the Bayesian limit obtained from the m_{ν}^2 limit with the errors combined in quadrature. This was also done in ROBERTSON 91, although the authors report a different procedure.

¹⁶ ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_{ν} lies between 17 and 40 eV. However, the probability of a positive m^2 is only 3% if statistical and systematic error are combined in quadrature.

¹⁷ See also comment in BORIS 87B and erratum in BORIS 88.

\overline{m}^2 MASS SQUARED (electron based)

Given troubling systematics which result in improbably negative estimates of $m_{\nu_e}^{2(eff)} \equiv \sum_i |U_{ei}|^2 m_{\nu_i}^2$, in many experiments, we use only KRAUS 05, LOBASHEV 99, and AKER 19 for our average.

¹ AKER 19 use the first month of data collected by the KATRIN experiment to determine m_{ν}^2 . The result is consistent with a neutrino mass of zero and is used to place a limit on m_{ν} .

² ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002, using a windowless gaseous tritium source. The analysis does not use the two additional fit parameters (see LOBASHEV 99) for a step-like structure near the endpoint. Using only the runs where the tritium gas column density was carefully monitored the need for such parameters was eliminated. Supersedes LOBASHEV 99 and BELESEV 95.

³ KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Problems with significantly negative squared neutrino masses, observed in some earlier experiments, have been resolved in this work.

⁴ LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. The data were corrected for electron trapping effects in the source, eliminating the dependence of the fitted neutrino mass on the fit interval. The analysis assuming a pure beta spectrum yields significantly negative fitted $m_{\nu}^2 \approx -(20-10) \text{ eV}^2$. This problem is attributed to a discrete spectral anomaly of about 6×10^{-11} intensity with a time-dependent energy of 5–15 eV below the endpoint. The data analysis accounts for this anomaly by introducing two extra phenomenological fit parameters resulting in a best fit of $m_{\nu}^2 = -1.9 \pm 3.4 \pm 2.2 \text{ eV}^2$ which is used to derive a neutrino mass limit. However, the introduction of phenomenological fit parameters which are correlated with the derived m_{ν}^2 limit makes unambiguous interpretation of this result difficult.

See key on page 999

Lepton Particle Listings Neutrino Properties

- ⁵ WEINHEIMER 99 is a continuation of the work reported in WEINHEIMER 93. Using a lower temperature of the frozen tritium source eliminated the dewetting of the T_2 film, which introduced a dependence of the fitted neutrino mass on the fit interval in the earlier work. An indication for a spectral anomaly reported in LOBASHEV 99 has been seen, but its time dependence does not agree with LOBASHEV 99. Two analyses, which exclude the spectral anomaly either by choice of the analysis interval or by using a particular data set which does not exhibit the anomaly, result in acceptable m_ν^2 fits and are used to derive the neutrino mass limit published by the authors. We list the most conservative of the two.
- ⁶ BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. This value comes from a fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly), including the effects of an apparent peak 7–15 eV below the endpoint.
- ⁷ HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. They quote measurements from two data sets.
- ⁸ STOEFFL 95 (LLNL) uses a gaseous source of molecular tritium. An anomalous pileup of events at the endpoint leads to the negative value for m_ν^2 . The authors acknowledge that “the negative value for the best fit of m_ν^2 has no physical meaning” and discuss possible explanations for this effect.
- ⁹ SUN 93 uses a tritiated hydrocarbon source. See also CHING 95.
- ¹⁰ WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
- ¹¹ HOLZSCHUH 92B (Zurich) source is a monolayer of tritiated hydrocarbon.
- ¹² KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid.
- ¹³ ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_ν lies between 17 and 40 eV. However, the probability of a positive m_ν^2 is only 3% if statistical and systematic error are combined in quadrature.

ν MASS (electron based)

These are measurement of m_ν (in contrast to $m_{\overline{\nu}}$ given above). The masses can be different for a Dirac neutrino in the absence of CPT invariance. The possible distinction between ν and $\overline{\nu}$ properties is usually ignored elsewhere in these Listings.

ν MASS (muon based)

Limits given below are for the square root of $m_{\nu\mu}^{2(\text{eff})} \equiv \sum_i |U_{\nu\mu i}|^2 m_{\nu_i}^2$.

In some of the COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

OUR EVALUATION is based on OUR AVERAGE for the π^+ mass and the ASSAMAGAN 96 value for the muon momentum for the π^+ decay at rest. The limit is calculated using the unified classical analysis of FELDMAN 98 for a Gaussian distribution near a physical boundary. WARNING: since $m_{\nu\mu}^{2(\text{eff})}$ is calculated from the differences of large numbers, it and the corresponding limits are extraordinarily sensitive to small changes in the pion mass, the decay muon momentum, and their errors. For example, the limits obtained using JECKELMANN 94, LENZ 98, and the weighted averages are 0.15, 0.29, and 0.19 MeV, respectively.

VALUE (MeV)	CL%	DOCUMENT ID	TECN	COMMENT

- ¹ ASSAMAGAN 96 measurement of p_μ from $\pi^+ \rightarrow \mu^+ \nu$ at rest combined with JECKELMANN 94 Solution B pion mass yields $m_\nu^2 = -0.016 \pm 0.023$ with corresponding Bayesian limit listed above. If Solution A is used, $m_\nu^2 = -0.143 \pm 0.024$ MeV². Replaces ASSAMAGAN 94.
- ² DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below T_{QCD} for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits.
- ³ ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, ~ 1 s.
- ⁴ Assumes neutrino lifetime >1 s. For Dirac neutrinos only. See also ENQVIST 93.

⁵ ANDERHUB 82 kinematics is insensitive to the pion mass.

ν MASS (tau based)

The limits given below are the square roots of limits for $m_{\nu\tau}^{2(\text{eff})} \equiv \sum_i |U_{\nu\tau i}|^2 m_{\nu_i}^2$.

In some of the ASTR and COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

- ¹ BARATE 98F result based on kinematics of 2939 $\tau^- \rightarrow 2\pi^- \pi^+ \nu_\tau$ and 52 $\tau^- \rightarrow 3\pi^- 2\pi^+ (\pi^0) \nu_\tau$ decays. If possible 2.5% excited a_1 decay is included in 3-prong sample analysis, limit increases to 19.2 MeV.
- ² ATHANAS 00 bound comes from analysis of $\tau^- \rightarrow \pi^- \pi^+ \pi^- \pi^0 \nu_\tau$ decays.
- ³ ACKERSTAFF 98T use $\tau^- \rightarrow 5\pi^\pm \nu_\tau$ decays to obtain a limit of 43.2 MeV (95%CL). They combine this with ALEXANDER 96M value using $\tau^- \rightarrow 3h^\pm \nu_\tau$ decays to obtain quoted limit.
- ⁴ AMMAR 98 limit comes from analysis of $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$ and $\tau^- \rightarrow 2\pi^- \pi^+ 2\pi^0 \nu_\tau$ decay modes.
- ⁵ ANASTASSOV 97 derive limit by comparing their m_τ measurement (which depends on m_{ν_τ}) to BAI 96 m_τ threshold measurement.
- ⁶ FIELDS 97 limit for a Dirac neutrino. For a Majorana neutrino the mass region < 0.93 or > 31 MeV is excluded. These bounds assume $N_\nu < 4$ from nucleosynthesis; a wider excluded region occurs with a smaller N_ν upper limit.
- ⁷ SWAIN 97 derive their limit from the Standard Model relationships between the tau mass, lifetime, branching fractions for $\tau^- \rightarrow e^- \overline{\nu}_e \nu_\tau, \tau^- \rightarrow \mu^- \overline{\nu}_\mu \nu_\tau, \tau^- \rightarrow \pi^- \nu_\tau$, and $\tau^- \rightarrow K^- \nu_\tau$, and the muon mass and lifetime by assuming lepton universality and using world average values. Limit is reduced to 48 MeV when the CLEO τ mass measurement (BALEST 93) is included; see CLEO’s more recent m_{ν_τ} limit (ANASTASSOV 97). Consideration of mixing with a fourth generation heavy neutrino yields $\sin^2 \theta_L < 0.016$ (95%CL).
- ⁸ ALEXANDER 96M bound comes from analyses of $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$ and $\tau^- \rightarrow h^- h^- h^+ \nu_\tau$ decays.
- ⁹ BOTTINO 96 assumes three generations of neutrinos with mixing, finds consistency with massless neutrinos with no mixing based on 1995 data for masses, lifetimes, and leptonic partial widths.
- ¹⁰ HANNESTAD 96C limit is on the mass of a Majorana neutrino. This bound assumes $N_\nu < 4$ from nucleosynthesis. A wider excluded region occurs with a smaller N_ν upper limit. This paper is the corrected version of HANNESTAD 96; see the erratum: HANNESTAD 96B.
- ¹¹ SOBIE 96 derive their limit from the Standard Model relationship between the tau mass, lifetime, and leptonic branching fraction, and the muon mass and lifetime, by assuming lepton universality and using world average values.
- ¹² BUSKULIC 95H bound comes from a two-dimensional fit of the visible energy and invariant mass distribution of $\tau^- \rightarrow 5\pi (\pi^0) \nu_\tau$ decays. Replaced by BARATE 98F.
- ¹³ DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below T_{QCD} for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits. DOLGOV 96 argues that a possible window near 20 MeV is excluded.
- ¹⁴ SIGL 95 exclude massive Dirac or Majorana neutrinos with lifetimes between 10^{-3} and 10^8 seconds if the decay products are predominantly γ or $e^+ e^-$.
- ¹⁵ DODELSON 94 calculate constraints on ν_τ mass and lifetime from nucleosynthesis for 4 generic decay modes. Limits depend strongly on decay mode. Quoted limit is valid for

Lepton Particle Listings

Neutrino Properties

all decay modes of Majorana neutrinos with lifetime greater than about 300s. For Dirac neutrinos limits change to < 0.3 or > 33 .

¹⁶ KAWASAKI 94 excluded region is for Majorana neutrino with lifetime > 1000 s. Other limits are given as a function of ν_τ lifetime for decays of the type $\nu_\tau \rightarrow \nu_\mu \phi$ where ϕ is a Nambu-Goldstone boson.

¹⁷ PERES 94 used PDG 92 values for parameters to obtain a value consistent with mixing. Reexamination by BOTTINO 96 which included radiative corrections and 1995 PDG parameters resulted in two allowed regions, $m_3 < 70$ MeV and 140 MeV $m_3 < 149$ MeV.

¹⁸ CINABRO 93 bound comes from analysis of $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$ and $\tau^- \rightarrow 2\pi^- \pi^+ 2\pi^0 \nu_\tau$ decay modes.

¹⁹ DOLGOV 93 assumes neutrino lifetime > 100 s. For Majorana neutrinos, the low mass limit is 0.5 MeV. KAWANO 92 points out that these bounds can be overcome for a Dirac neutrino if it possesses a magnetic moment. See also DOLGOV 96.

²⁰ ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, ~ 1 s.

²¹ ALBRECHT 92M reports measurement of a slightly lower τ mass, which has the effect of reducing the ν_τ mass reported in ALBRECHT 88B. Bound is from analysis of $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$ mode.

²² Assumes neutrino lifetime > 1 s. For Dirac neutrinos. See also ENQVIST 93.

²³ KOLB 91 exclusion region is for Dirac neutrino with lifetime > 1 s; other limits are given.

Revised September 2019 by K.A. Olive (University of Minnesota).

Neutrinos decouple from thermal equilibrium in the early universe at temperatures $\mathcal{O}(1)$ MeV. The limits on low mass ($m_\nu \lesssim 1$ MeV) neutrinos apply to m_{tot} given by

$$m_{\text{tot}} = \sum_{\nu} m_{\nu} .$$

Stable neutrinos in this mass range decouple from the thermal bath while still relativistic and make a contribution to the total energy density of the Universe which is given by

$$\rho_{\nu} = m_{\text{tot}} n_{\nu} \simeq m_{\text{tot}} (3/11) (3.045/3)^{3/4} n_{\gamma} ,$$

where the factor $3/11$ is the ratio of (light) neutrinos to photons and the factor $(3.045/3)^{3/4}$ corrects for the fact that the effective number of neutrinos in the standard model is 3.045 when taking into account e^+e^- annihilation during neutrino decoupling. Writing $\Omega_{\nu} = \rho_{\nu}/\rho_c$, where ρ_c is the critical energy density of the Universe, and using $n_{\gamma} = 410.7 \text{ cm}^{-3}$, we have

$$\Omega_{\nu} h^2 \simeq m_{\text{tot}} / (93 \text{ eV}) .$$

While an upper limit to the matter density of $\Omega_m h^2 < 0.12$ would constrain $m_{\text{tot}} < 11$ eV, much stronger constraints are obtained from a combination of observations of the CMB, the amplitude of density fluctuations on smaller scales from the clustering of galaxies and the Lyman- α forest, baryon acoustic oscillations, and new Hubble parameter data. These combine to give an upper limit of around 0.15 eV, and may, in the near future, be able to provide a lower bound on the sum of the neutrino masses. The current lower bound of $m_{\text{tot}} > 0.06$ eV implies a lower limit of $\Omega_{\nu} h^2 > 6 \times 10^{-4}$. See our review on "Neutrinos in Cosmology" for more details.

SUM OF THE NEUTRINO MASSES, m_{tot}

This is a sum of the neutrino masses, m_{tot} , as defined in the above note, of effectively stable neutrinos, i.e. those with mean lifetimes on cosmological scales. When necessary, we have generalized the results reported so they apply to m_{tot} . For other limits, see SZALAY 76, VYSOTSKY 77, BERNSTEIN 81, FREESE 84, SCHRAMM 84, and COWSIK 85. For more information see a note on "Neutrinos in Cosmology" in this Review.

¹ LOUREIRO 19 combines data from large scale structure, cosmic microwave background, type Ia supernovae and big bang nucleosynthesis using physically motivated neutrino mass models.

² UPADHYE 19 uses the shape of the BOSS redshift-space galaxy power spectrum in combination with the CMB, and supernovae data. Limit weakens to < 0.54 eV if the dark energy equation of state is allowed to vary.

³ CHOUDHURY 18 combines 2015 Planck CMB temperature data, information from the optical depth to reionization from Planck 2016 intermediate results together with baryon acoustic oscillation data from BOSS, MGS, and 6dFGS as well as supernovae Type Ia data from the Pantheon Sample. The limit is strengthened to 0.118 eV when high- l CMB polarization data is also included.

⁴ SIMPSON 17 uses a combination of laboratory and cosmological measurements to determine the light neutrino masses and argue that there is strong evidence for the normal mass ordering.

⁵ Combines temperature anisotropies of the CMB from Planck with data on baryon acoustic oscillations and the optical depth to reionization. Limit is strengthened to 0.118 when high multipole polarization data is included. Updates GIUSARMA 16.

⁶ Constrains the total mass of neutrinos using the Lyman-alpha forest power spectrum with BOSS (mid-resolution), XQ-100 (high-resolution) and CMB. Without the CMB data, the limit relaxes to 0.8 eV. Supersedes PALANQUE-DELABROUILLE 15A.

⁷ Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation and Planck cluster data.

⁸ Constrains the total mass of neutrinos from BAO data from SDSS-III/BOSS combined with CMB data from Planck. Limit quoted for normal mass hierarchy. The limit for the inverted mass hierarchy is 0.20 eV and for the degenerate mass hierarchy it is 0.15 eV.

⁹ ROSSI 15 sets limits on the sum of neutrino masses using BOSS Lyman alpha forest data combined with Planck CMB data and baryon acoustic oscillations.

- 10 Constrains the total mass of neutrinos from Planck CMB data along with WMAP polarization, high L, and BAO data.
- 11 Finite neutrino mass fit to resolve discrepancy between CMB and lensing measurements.
- 12 Fit to the total mass of neutrinos from BOSS data along with WMAP CMB data and data from other BAO constraints and weak lensing.
- 13 Fit to the total mass of neutrinos from Planck CMB data along with BAO.
- 14 Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation data from BOSS and HST data on the Hubble parameter.
- 15 Fit based on the SPT-SZ survey combined with CMB, BAO, and H_0 data.
- 16 Constrains the total mass of neutrinos (marginalizing over the effective number of neutrino species) from CMB, CMB lensing, BAO, and galaxy clustering data.
- 17 Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation data from BOSS, 6dFGS, SDSS, WiggleZ data on the galaxy power spectrum, and HST data on the Hubble parameter. The limit is increased to 0.25 eV if a lower bound to the sum of neutrino masses of 0.04 eV is assumed.
- 18 Constrains the total mass of neutrinos from observational Hubble parameter data with seven-year WMAP data and the most recent estimate of H_0 .
- 19 Constrains the total mass of neutrinos from the CFHTLS combined with seven-year WMAP data and a prior on the Hubble parameter. Limit is relaxed to 0.41 eV when small scales affected by non-linearities are removed.
- 20 Constrains the total mass of neutrinos from the Sloan Digital Sky Survey and the five-year WMAP data.
- 21 Constrains the total mass of neutrinos from the 7-year WMAP data including SDSS and HST data. Limit relaxes to 1.19 eV when CMB data is used alone. Supersedes HANNESTAD 06.
- 22 Constrains the total mass of neutrinos from a combination of CMB data, a recent measurement of H_0 (SHOES), and baryon acoustic oscillation data from SDSS.
- 23 Constrains the total mass of neutrinos from SDSS MegaZ LRG DR7 galaxy clustering data combined with CMB, HST, supernovae and baryon acoustic oscillation data. Limit relaxes to 0.47 eV when the equation of state parameter, $w \neq 1$.
- 24 Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to 0.54 eV when supernovae and baryon acoustic oscillation observations are included. Assumes Λ CDM model.
- 25 Constrains the total mass of neutrinos from five-year WMAP data. Limit improves to 0.67 eV when supernovae and baryon acoustic oscillation observations are included. Limits quoted assume the Λ CDM model. Supersedes SPERGEL 07.
- 26 Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to $0.03 < \Sigma m_\nu < 0.54$ eV when supernovae and baryon acoustic oscillation observations are included. The slight preference for massive neutrinos at the two-sigma level disappears when systematic errors are taken into account. Assumes Λ CDM model.
- 27 Constrains the total mass of neutrinos from recent Chandra X-ray observations of galaxy clusters when combined with CMB, supernovae, and baryon acoustic oscillation measurements. Assumes flat universe and constant dark-energy equation of state, w .
- 28 Constrains the total mass of neutrinos from recent CMB and SOSS LRG power spectrum data along with bias mass relations from SDSS, DEEP2, and Lyman-Break Galaxies. It assumes Λ CDM model. Limit degrades to 0.59 eV in a more general w CDM model.
- 29 Constrains the total mass of neutrinos from neutrino oscillation experiments and cosmological data. The most conservative limit uses only WMAP three-year data, while the most stringent limit includes CMB, large-scale structure, supernova, and Lyman-alpha data.
- 30 Constrains the total mass of neutrinos from recent CMB, large scale structure, SN1a, and baryon acoustic oscillation data. The limit relaxes to 1.75 when WMAP data alone is used with no prior. Paper shows results with several combinations of data sets. Supersedes KRISTIANSEN 06.
- 31 Constrains the total mass of neutrinos from the CMB and the large scale structure data. The most conservative limit is obtained when generic initial conditions are allowed.
- 32 Constrains the total mass of neutrinos from recent CMB, large scale structure, Lyman-alpha forest, and SN1a data.
- 33 Constrains the total mass of neutrinos from recent CMB and large scale structure data. See also GOOBAR 06. Superseded by HANNESTAD 10.
- 34 Constrains the total mass of neutrinos from the CMB and the final 2dF Galaxy Redshift Survey.
- 35 Constrains the total mass of neutrinos from the CMB experiments alone, assuming Λ CDM Universe. FUKUGITA 06 show that this result is unchanged by the 3-year WMAP data.
- 36 Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey and the 2dF galaxy redshift survey, WMAP and 27 other CMB experiments and measurements by the HST Key project.
- 37 Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey, the 2dF galaxy redshift survey, WMAP and ACBAR. The limit is strengthened to 0.6 eV when measurements by the HST Key project and supernovae data are included.
- 38 Constrains the fractional contribution of neutrinos to the total matter density in the Universe from WMAP data combined with other CMB measurements, the 2dFGRS data, and Lyman α data. The limit does not noticeably change if the Lyman α data are not used.
- 39 LEVVIS 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB, HST Key project, 2dF galaxy redshift survey, supernovae type Ia, and BBN.
- 40 WANG 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB and other cosmological data sets such as galaxy clustering and the Lyman α forest.
- 41 FUKUGITA 00 is a limit on neutrino masses from structure formation. The constraint is based on the clustering scale σ_8 and the COBE normalization and leads to a conservative limit of 0.9 eV assuming 3 nearly degenerate neutrinos. The quoted limit is on the sum of the light neutrino masses.

42 CROFT 99 result based on the power spectrum of the Ly α forest. If $\Omega_{\text{matter}} < 0.5$, the limit is improved to $m_\nu < 2.4 (\Omega_{\text{matter}}/0.17-1)$ eV.

Limits on MASSES of Light Stable Right-Handed ν (with necessarily suppressed interaction strengths)

VALUE (eV)	DOCUMENT ID	TECN	COMMENT
<100-200	1 OLIVE	82	COSM Dirac ν
<200-2000	1 OLIVE	82	COSM Majorana ν

<1 x 10 ⁻¹³		11 BERNSTEIN	63	ASTR solar energy losses

¹ CAPRINI 05 limit derived from the lack of a charge asymmetry in the universe. Limit assumes that charge asymmetries between particles are not anti-correlated.

² DELLA-VALLE 16 obtain a limit on the charge of neutrinos valid for masses of less than 10 MeV. For heavier neutrinos the limit increases as a power of mass, reaching 10⁻⁶ e for $m = 100$ MeV.

³ CHEN 14A use the Multi-Configuration RPPA method to analyze reactor $\bar{\nu}_e$ scattering on Ge atoms with 300 eV recoil energy threshold to obtain this limit.

⁴ STUDENIKIN 14 uses the limit on μ_ν from BEDA 13 and the 2.8 keV threshold of the electron recoil energy to obtain this limit.

⁵ GNINENKO 07 use limit on $\bar{\nu}_e$ magnetic moment from LI 03b to derive this result. The limit is considerably weaker than the limits on the charge of ν_e and $\bar{\nu}_e$ from various astrophysics considerations.

⁶ This RAFFELT 99 limit applies to all neutrino flavors which are light enough (<5 keV) to be emitted from globular-cluster red giants.

⁷ This RAFFELT 99 limit is derived from the helioseismological limit on a new energy-loss channel of the Sun, and applies to all neutrino flavors which are light enough (<1 keV) to be emitted from the sun.

⁸ BABU 94 use COOPER-SARKAR 92 limit on ν magnetic moment to derive quoted result. It applies to ν_τ .

⁹ DAVIDSON 91 use data from early SLAC electron beam dump experiment to derive charge limit as a function of neutrino mass. It applies to ν_τ .

¹⁰ Exact BARBIELLINI 87 limit depends on assumptions about the intergalactic or galactic magnetic fields and about the direct distance and time through the field. It applies to ν_e .

¹¹ The limit applies to all flavors.

ν (MEAN LIFE) / MASS

Measures $[\sum |U_{ej}|^2 \Gamma_j m_j]^{-1}$, where the sum is over mass eigenstates which cannot be resolved experimentally. Some of the limits constrain the radiative decay and are based on the limit of the corresponding photon flux. Other apply to the decay of a heavier neutrino into the lighter one and a Majoron or other invisible particle. Many of these limits apply to any ν within the indicated mass range.

Limits on the radiative decay are either directly based on the limits of the corresponding photon flux, or are derived from the limits on the neutrino magnetic moments. In the later case the transition rate for $\nu_i \rightarrow \nu_j + \gamma$

is constrained by $\Gamma_{ij} = \frac{1}{\tau_{ij}} = \frac{(m_i^2 - m_j^2)^3}{m_i^3} \mu_{ij}^2$ where μ_{ij} is the neutrino transition moment in the mass eigenstates basis. Typically, the limits on lifetime based on the magnetic moments are many orders of magnitude more restrictive than limits based on the nonobservation of photons.

1 KRAKAUER 91 quotes the limit $\tau/m_{\nu_1} > (0.75a^2 + 21.65a + 26.3) \text{ s/eV}$, where a is a parameter describing the asymmetry in the neutrino decay defined as $dN_{\nu_1}/d\cos\theta = (1/2)(1 + a\cos\theta)$. The parameter $a = 0$ for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).

2 RAFFELT 85 limit on the radiative decay is from solar x - and γ -ray fluxes. Limit depends on ν flux from pp , now established from GALLEX and SAGE to be > 0.5 of expectation.

3 REINES 74 looked for ν of nonzero mass decaying radiatively to a neutral of lesser mass $+\gamma$. Used liquid scintillator detector near fission reactor. Finds lab lifetime 6×10^7 s or more. Above value of (mean life)/mass assumes average effective neutrino energy of 0.2 MeV. To obtain the limit 6×10^7 s REINES 74 assumed that the full $\bar{\nu}_e$ reactor flux could be responsible for yielding decays with photon energies in the interval 0.1 MeV – 0.5 MeV. This represents some overestimate so their lower limit is an over-estimate of the lab lifetime (VOGEL 84). If so, OBERAUER 87 may be comparable or better.

4 AHARMIM 19 quotes the limit τ/m_{ν_2} for invisible nonradiative decay of ν_2 . They obtained this result by analyzing the entire SNO dataset, allowing for the decay of ν_2 which would cause an energy-dependent distortion of the survival probability of electron-type solar neutrinos.

5 AHARMIM 19 quotes the limit τ/m_{ν_2} for invisible nonradiative decay of ν_2 . They obtained this result by combining the τ/m_{ν_2} measurements from SNO and other solar neutrino experiments (Super-Kamiokande, KamLAND, and Borexino ^{8B} results; Borexino and KamLAND ^{7Be} results; the combined gallium interaction rate from GNO, GALLEX, and SAGE; and the chlorine interaction rate from Homestake). The quoted limit at 99% CL is $> 1.04 \times 10^{-3}$.

6 ESCUDERO 19 sets limits on invisible neutrino decays using Planck 2018 data of $\tau > 1.3$ – 0.3×10^9 s at 95% C.L. Values in the range $\tau = 2$ – 16×10^9 s are preferred at 95% C.L. when Planck polarization data is included. Limits scale as $(m_\nu/0.05 \text{ eV})^3$.

7 CECCHINI 11 search for radiative decays of solar neutrinos into visible photons during the 2006 total solar eclipse. The range of (mean life)/mass values corresponds to a range of ν_1 masses between 10^{-4} and 0.1 eV.

8 MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the maximum allowed distortion of the CMB spectrum as measured by the COBE/FIRAS. For the decay $\nu_2 \rightarrow \nu_1$ the lifetime limit is $\lesssim 4 \times 10^{20}$ s for $m_{min} \lesssim 0.14$ eV. For transition with the $|\Delta m_{31}|$ mass difference the lifetime limit is $\sim 2 \times 10^{19}$ s for $m_{min} \lesssim 0.14$ eV and $\sim 5 \times 10^{20}$ s for $m_{min} \gtrsim 0.14$ eV.

9 MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the cosmic infrared background (CIB) using the Spitzer Observatory data. For transition with the $|\Delta m_{31}|$ mass difference they obtain the lifetime limit $\sim 10^{20}$ s for $m_{min} \lesssim 0.14$ eV.

10 WONG 07 use their limit on the neutrino magnetic moment together with the assumed experimental value of $\Delta m_{13}^2 \sim 2 \times 10^{-3} \text{ eV}^2$ to obtain $\tau_{13}/m_1^3 > 3.2 \times 10^{27} \text{ s/eV}^3$ for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for τ_{23} and τ_{21} .

11 XIN 05 search for the γ from radiative decay of ν_e produced by the electron capture on ⁵¹Cr. No events were seen and the limit on τ/m_ν was derived. This is a weaker limit on the decay of ν_e than KRAKAUER 91.

12 XIN 05 use their limit on the neutrino magnetic moment of ν_e together with the assumed experimental value of $\Delta m_{1,3}^2 \sim 2 \times 10^{-3} \text{ eV}^2$ to obtain $\tau_{13}/m_1^3 > 1 \times 10^{23} \text{ s/eV}^3$ for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for τ_{23} and τ_{21} . Again, this limit is specific for ν_e .

13 AHARMIM 04 obtained these results from the solar $\bar{\nu}_e$ flux limit set by the SNO measurement assuming ν_2 decay through nonradiative process $\nu_2 \rightarrow \bar{\nu}_1 X$, where X is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.

14 CECCHINI 04 obtained this bound through the observations performed on the occasion of the 21 June 2001 total solar eclipse, looking for visible photons from radiative decays of solar neutrinos. Limit is a τ/m_{ν_2} in $\nu_2 \rightarrow \nu_1 \gamma$. Limit ranges from ~ 100 to 10^7 s/eV for $0.01 < m_{\nu_1} < 0.1 \text{ eV}$.

15 EGUCHI 04 obtained these results from the solar $\bar{\nu}_e$ flux limit set by the KamLAND measurement assuming ν_2 decay through nonradiative process $\nu_2 \rightarrow \bar{\nu}_1 X$, where X is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.

16 The ratio of the lifetime over the mass derived by BANDYOPADHYAY 03 is for ν_2 . They obtained this result using the following solar-neutrino data: total rates measured in Cl and Ga experiments, the Super-Kamiokande's zenith-angle spectra, and SNO's day and night spectra. They assumed that ν_1 is the lowest mass, stable or nearly stable neutrino state and ν_2 decays through nonradiative Majoron emission process, $\nu_2 \rightarrow \bar{\nu}_1 + J$, or through nonradiative process with all the final state particles being sterile. The best fit is obtained in the region of the LMA solution.

17 DERBIN 02B (also BACK 03b) obtained this bound for the radiative decay from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). The laboratory gamma spectrum is given as $dN_\gamma/d\cos\theta = (1/2)(1 + \alpha\cos\theta)$ with $\alpha=0$ for a Majorana neutrino, and α varying to -1 to 1 for a Dirac neutrino. The listed bound is for the case of $\alpha=0$. The most conservative bound $1.5 \times 10^{13} \text{ s eV}^{-1}$ is obtained for the case of $\alpha=-1$.

18 The ratio of the lifetime over the mass derived by JOSHIPURA 02B is for ν_2 . They obtained this result from the total rates measured in all solar neutrino experiments. They assumed that ν_1 is the lowest mass, stable or nearly stable neutrino state and ν_2 decays through nonradiative process like Majoron emission decay, $\nu_2 \rightarrow \nu'_1 + J$ where ν'_1 state is sterile. The exact limit depends on the specific solution of the solar neutrino problem. The quoted limit is for the LMA solution.

19 DOLGOV 99 places limits in the (Majorana) τ -associated ν mass-lifetime plane based on nucleosynthesis. Results would be considerably modified if neutrino oscillations exist.

20 BILLER 98 use the observed TeV γ -ray spectra to set limits on the mean life of any radiatively decaying neutrino between 0.05 and 1 eV. Curve shows $\tau_\nu/B_\gamma > 0.15 \times 10^{21}$ s at 0.05 eV, $> 1.2 \times 10^{21}$ s at 0.17 eV, $> 3 \times 10^{21}$ s at 1 eV, where B_γ is the branching ratio to photons.

21 BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.

22 Limit on the radiative decay based on nonobservation of γ 's in coincidence with ν 's from SN 1987A.

23 DODELSON 92 range is for wrong-helicity keV mass Dirac ν 's from the core of neutron star in SN 1987A decaying to ν 's that would have interacted in KAM2 or LMB detectors.

24 GRANEK 91 considers heavy neutrino decays to $\gamma\nu_L$ and $3\nu_L$, where $m_{\nu_1} < 100$ keV. Lifetime is calculated as a function of heavy neutrino mass, branching ratio into $\gamma\nu_L$, and m_{ν_1} .

25 KRAKAUER 91 quotes the limit for ν_e , $\tau/m_\nu > (0.3a^2 + 9.8a + 15.9) \text{ s/eV}$, where a is a parameter describing the asymmetry in the radiative neutrino decay defined as $dN_\gamma/d\cos\theta = (1/2)(1 + a\cos\theta)$ $a = 0$ for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).

26 WALKER 90 uses SN 1987A γ flux limits after 289 days.

27 CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.

28 RAFFELT 89 uses KYULDJIEV 84 to obtain $\tau m^3 > 3 \times 10^{18} \text{ s eV}^3$ (based on $\bar{\nu}_e e^-$ cross sections). The bound for the radiative decay is not valid if electric and magnetic transition moments are equal for Dirac neutrinos.

See key on page 999

Lepton Particle Listings Neutrino Properties

- ²⁹ RAFFELT 89B analyze stellar evolution and exclude the region $3 \times 10^{12} < \tau m^3 < 3 \times 10^{21} \text{ s eV}^3$.
- ³⁰ Model-dependent theoretical analysis of SN1987A neutrinos. Quoted limit is for $[\sum_j |U_{\ell j}|^2 \Gamma_j m_j]^{-1}$, where $\ell = \mu, \tau$. Limit is $3.3 \times 10^{14} \text{ s/eV}$ for $\ell = e$.
- ³¹ OBERAUER 87 looks for photons and e^+e^- pairs from radiative decays of reactor neutrinos.
- ³² BINETRUY 84 finds $\tau < 10^8 \text{ s}$ for neutrinos in a radiation-dominated universe.
- ³³ These experiments look for $\nu_k \rightarrow \nu_j \gamma$ or $\bar{\nu}_k \rightarrow \bar{\nu}_j \gamma$.
- ³⁴ STECKER 80 limit based on UV background; result given is $\tau > 4 \times 10^{22} \text{ s}$ at $m_\nu = 20 \text{ eV}$.
- ³⁵ FALK 78 finds lifetime constraints based on supernova energetics.
- ³⁶ COWSIK 77 considers variety of scenarios. For neutrinos produced in the big bang, present limits on optical photon flux require $\tau > 10^{23} \text{ s}$ for $m_\nu \sim 1 \text{ eV}$. See also COWSIK 79 and GOLDMAN 79.

ν MAGNETIC MOMENT

The coupling of neutrinos to an electromagnetic field is characterized by a 3×3 matrix λ of the magnetic (μ) and electric (d) dipole moments ($\lambda = \mu - id$). For Majorana neutrinos the matrix λ is antisymmetric and only transition moments are allowed, while for Dirac neutrinos λ is a general 3×3 matrix. In the standard electroweak theory extended to include neutrino masses (see FUJIKAWA 80) $\mu_\nu = 3eG_F m_\nu / (8\pi^2 \sqrt{2}) = 3.2 \times 10^{-19} (m_\nu/\text{eV}) \mu_B$, i.e. it is unobservably small given the known small neutrino masses. In more general models there is no longer a proportionality between neutrino mass and its magnetic moment, even though only massive neutrinos have nonvanishing magnetic moments without fine tuning.

Laboratory bounds on λ are obtained via elastic ν - e scattering, where the scattered neutrino is not observed. The combinations of matrix elements of λ that are constrained by various experiments depend on the initial neutrino flavor and on its propagation between source and detector (e.g., solar ν_e and reactor $\bar{\nu}_e$ do not constrain the same combinations). The listings below therefore identify the initial neutrino flavor.

Other limits, e.g. from various stellar cooling processes, apply to all neutrino flavors. Analogous flavor independent, but weaker, limits are obtained from the analysis of $e^+e^- \rightarrow \nu\bar{\nu}\gamma$ collider experiments.

- ¹ AGOSTINI 17A obtained this limit using the shape of the recoil electron energy spectrum from the Borexino Phase-II 1291.5 live days of solar neutrino data and the constraints on the sum of the solar neutrino fluxes from the radiochemical gallium experiments SAGE, Gallex, and GNO. Without radiochemical constraints, the 90% C.L. limit of $< 4.0 \times 10^{-11} \mu_B$ is obtained.
- ² BEDA 13 report $\bar{\nu}_e e^-$ scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.5 and 55 keV. Supersedes BEDA 07. Supersedes BEDA 10. This is the most stringent limit on the magnetic moment of reactor $\bar{\nu}_e$.
- ³ AUERBACH 01 limit is based on the LSND ν_e and ν_μ electron scattering measurements. The limit is slightly more stringent than KRAKAUER 90.
- ⁴ SCHWIENHORST 01 quote an experimental sensitivity of 4.9×10^{-7} .
- ⁵ ARCEO-DIAZ 15 constrains the neutrino magnetic moment from observation of the tip of the red giant branch in the globular cluster ω -Centauri.
- ⁶ CORSICO 14 constrains the neutrino magnetic moment from observations of white dwarf pulsations.
- ⁷ MILLER-BERTOLAMI 14B constrains the neutrino magnetic moment from observations of the white dwarf luminosity function of the Galactic disk.
- ⁸ VIAUX 13A constrains the neutrino magnetic moment from observations of the globular cluster M5.
- ⁹ BEDA 10 report $\bar{\nu}_e e^-$ scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.9 and 45 keV. Supersedes BEDA 07. Supersedes by BEDA 13.
- ¹⁰ DENIZ 10 observe reactor $\bar{\nu}_e$ scattering with recoil kinetic energies 3-8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on $\bar{\nu}_e$ magnetic moment.
- ¹¹ KUZNETSOV 09 obtain a limit on the flavor averaged magnetic moment of Dirac neutrinos from the time averaged neutrino signal of SN1987A. Improves and supersedes the analysis of BARBIERI 88 and AYALA 99.
- ¹² ARPESELLA 08A obtained this limit using the shape of the recoil electron energy spectrum from the Borexino 192 live days of solar neutrino data.
- ¹³ BEDA 07 performed search for electromagnetic $\bar{\nu}_e$ - e scattering at Kalininskaya nuclear reactor. A Ge detector with active and passive shield was used and the electron recoil spectrum between 3.0 and 61.3 keV analyzed. Supersedes by BEDA 10.
- ¹⁴ WONG 07 performed search for non-standard $\bar{\nu}_e$ - e scattering at the Kuo-Sheng nuclear reactor. Ge detector equipped with active anti-Compton shield is used. Most stringent laboratory limit on magnetic moment of reactor $\bar{\nu}_e$. Supersedes LI 03B.
- ¹⁵ DARAKTCHIEVA 05 present the final analysis of the search for non-standard $\bar{\nu}_e$ - e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction of both the kinetic energy above 700 keV and scattering angle of the recoil electron, by use of TPC. Most stringent laboratory limit on magnetic moment. Supersedes DARAKTCHIEVA 03.
- ¹⁶ XIN 05 evaluated the ν_e flux at the Kuo-Sheng nuclear reactor and searched for non-standard ν_e - e scattering. Ge detector equipped with active anti-Compton shield was used. This laboratory limit on magnetic moment is considerably less stringent than the limits for reactor $\bar{\nu}_e$, but is specific to ν_e .
- ¹⁷ GRIFOLS 04 obtained this bound using the SNO data of the solar ^8B neutrino flux measured with deuteron breakup. This bound applies to $\mu_{\text{eff}} = (\mu_{21}^2 + \mu_{22}^2 + \mu_{23}^2)^{1/2}$.
- ¹⁸ LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 days of solar neutrino data. Neutrinos are assumed to have only diagonal magnetic moments, $\mu_{\nu 1} = \mu_{\nu 2}$. This limit corresponds to the oscillation parameters in the vacuum oscillation region.
- ¹⁹ LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 live-day solar neutrino data, by limiting the oscillation parameter region in the LMA region allowed by solar neutrino experiments plus KamLAND. $\mu_{\nu 1} = \mu_{\nu 2}$ is assumed. In the LMA region, the same limit would be obtained even if neutrinos have off-diagonal magnetic moments.
- ²⁰ BACK 03B obtained this bound from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). Standard Solar Model flux was assumed. This μ_ν can be different from the reactor μ_ν in certain oscillation scenarios (see BEACOM 99).
- ²¹ DARAKTCHIEVA 03 searched for non-standard $\bar{\nu}_e$ - e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction by use of TPC. Supersedes by DARAKTCHIEVA 05.
- ²² LI 03B used Ge detector in active shield near nuclear reactor to test for nonstandard $\bar{\nu}_e$ - e scattering.
- ²³ GRIMUS 02 obtain stringent bounds on all Majorana neutrino transition moments from a simultaneous fit of LMA-MSW oscillation parameters and transition moments to global

Lepton Particle Listings

Neutrino Properties

solar neutrino data + reactor data. Using only solar neutrino data, a 90% CL bound of $6.3 \times 10^{-10} \mu_B$ is obtained.

²⁴ TANIMOTO 00 combined $e^+ e^- \rightarrow \nu \bar{\nu} \gamma$ data from VENUS, TOPAZ, and AMY.

²⁵ AYALA 99 improves the limit of BARBIERI 88.

²⁶ BEACOM 99 obtain the limit using the shape, but not the absolute magnitude which is affected by oscillations, of the solar neutrino spectrum obtained by Superkamiokande (825 days). This μ_ν can be different from the reactor μ_ν in certain oscillation scenarios.

²⁷ RAFFELT 99 is an update of RAFFELT 90. This limit applies to all neutrino flavors which are light enough (< 5 keV) to be emitted from globular-cluster red giants. This limit pertains equally to electric dipole moments and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.

²⁸ RAFFELT 99 is essentially an update of BERNSTEIN 63, but is derived from the helioseismological limit on a new energy-loss channel of the Sun. This limit applies to all neutrino flavors which are light enough (< 1 keV) to be emitted from the Sun. This limit pertains equally to electric dipole and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.

²⁹ ACCIARRI 97q result applies to both direct and transition magnetic moments and for $q^2=0$.

³⁰ ELMFORS 97 calculate the rate of depolarization in a plasma for neutrinos with a magnetic moment and use the constraints from a big-bang nucleosynthesis on additional degrees of freedom.

³¹ Applies to absolute value of magnetic moment.

³² DERBIN 93 determine the cross section for 0.6–2.0 MeV electron energy as $(1.28 \pm 0.63) \times \sigma_{\text{weak}}$. However, the (reactor on - reactor off)/(reactor off) is only $\sim 1/100$.

³³ COOPER-SARKAR 92 assume $f_{D_s}/f_\pi = 2$ and D_s, \bar{D}_s production cross section = $2.6 \mu\text{b}$ to calculate ν flux.

³⁴ VIDYAKIN 92 limit is from a $e\bar{\nu}$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2 \theta_{WW} = 0.23$ as input.

³⁵ DORENBOSCH 91 corrects an incorrect statement in DORENBOSCH 89 that the ν magnetic moment is $< 1 \times 10^{-9}$ at the 95%CL. DORENBOSCH 89 measures both ν_μ e and $\bar{\nu}$ e elastic scattering and assume $\mu(\nu) = \mu(\bar{\nu})$.

³⁶ KRAKAUER 90 experiment fully reported in ALLEN 93.

³⁷ RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives $< 1.4 \times 10^{-12}$. Limit at 95%CL obtained from δM_C .

³⁸ Significant dependence on details of stellar models.

³⁹ FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by $\mu < 10^{-16} [10^{-9} G/B_0]$ where B_0 is the present-day intergalactic field strength.

⁴⁰ GROTCHE 88 combined data from MAC, ASP, CELLO, and Mark J.

⁴¹ For $m_\nu = 8\text{--}200$ eV. NUSSINOV 87 examines transition magnetic moments for $\nu_\mu \rightarrow \nu_e$ and obtain $< 3 \times 10^{-15}$ for $m_\nu > 16$ eV and $< 6 \times 10^{-14}$ for $m_\nu > 4$ eV.

⁴² We obtain above limit from SUTHERLAND 76 using their limit $f < 1/3$.

⁴³ KIM 74 is a theoretical analysis of $\bar{\nu}_\mu$ reaction data.

³ Based on analysis of CCFR 98 results. Limit is on $\langle r_{\bar{\nu}_e}^2 \rangle + \langle r_{\nu_\mu}^2 \rangle$. The CHARM II and E734 at BNL results are reanalyzed, and weaker bounds on the charge radius squared than previously published are obtained. The NuTeV result is discussed; when tentatively interpreted as ν_μ charge radius it implies $\langle r_{\bar{\nu}_e}^2 \rangle + \langle r_{\nu_\mu}^2 \rangle = (4.20 \pm 1.64) \times 10^{-33} \text{ cm}^2$.

⁴ Results of LEP-2 are interpreted as limits on the axial-vector charge radius squared of a Majorana ν_τ . Slightly weaker limits for both vector and axial-vector charge radius squared are obtained for the Dirac case, and somewhat weaker limits are obtained from the analysis of lower energy data (LEP-1.5 and TRISTAN).

⁵ AUERBACH 01 measure $\nu_e e$ elastic scattering with LSND detector. The cross section agrees with the Standard Model expectation, including the charge and neutral current interference. The 90% CL applies to the range shown.

⁶ VIDYAKIN 92 limit is from a $e\bar{\nu}$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2 \theta_{WW} = 0.23$ as input.

⁷ Result is obtained from reanalysis given in ALLEN 91, followed by our reduction to obtain 1σ errors.

⁸ GRIFOLS 89b sets a limit of $\langle r^2 \rangle < 0.2 \times 10^{-32} \text{ cm}^2$ for right-handed neutrinos.

NEUTRINO CHARGE RADIUS SQUARED

We report limits on the so-called neutrino charge radius squared. While the straight-forward definition of a neutrino charge radius has been proven to be gauge-dependent and, hence, unphysical (LEE 77c), there have been recent attempts to define a physically observable neutrino charge radius (BERNABEU 00, BERNABEU 02). The issue is still controversial (FUJIKAWA 03, BERNABEU 03). A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

¹ DENIZ 10 observe reactor $\bar{\nu}_e e$ scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on $\bar{\nu}_e$ charge radius.

² CADEDU 18 use the data of the COHERENT experiment, AKIMOV 18. The limit is $\langle r_{\nu_\mu}^2 \rangle$ for ν_μ obtained from the time-dependent data. Weaker limits were obtained for charge radii of ν_e and for transition charge radii. The published value was divided by 2 to conform to the convention of this table.

Lepton Particle Listings

Neutrino Properties, Number of Neutrino Types

Table listing neutrino properties and experiments. Columns include experiment names (e.g., GRIMUS, JOSHIPURA, LEWIS), neutrino types (e.g., NP B648 376, PL D66 113008), and associated institutions or collaborations (e.g., W. Grimus et al., A.S. Josphipura, E. Masso, S. Mohanty).

Number of Neutrino Types

The neutrinos referred to in this section are those of the Standard SU(2) x U(1) Electroweak Model possibly extended to allow nonzero neutrino masses. Light neutrinos are those with m < mZ/2. The limits are on the number of neutrino mass eigenstates, including nu1, nu2, and nu3.

THE NUMBER OF LIGHT NEUTRINO TYPES FROM COLLIDER EXPERIMENTS

Revised June 2020 by C.-J. Lin (LBNL). Written by D. Karlen (University of Victoria and TRIUMF).

The most precise measurements of the number of light neutrino types, Nnu, come from studies of Z production in e+e- collisions. The invisible partial width, Gamma_inv, is determined by subtracting the measured visible partial widths, corresponding to Z decays into quarks and charged leptons, from the total Z width. The invisible width is assumed to be due to Nnu light neutrino species each contributing the neutrino partial width Gamma_nu as given by the Standard Model. In order to reduce the model dependence, the Standard Model value for the ratio of the neutrino to charged leptonic partial widths, (Gamma_nu/Gamma_l)_SM = 1.991 +/- 0.001, is used instead of (Gamma_nu)_SM to determine the number of light neutrino types:

N_nu = Gamma_inv / Gamma_l * (Gamma_l / Gamma_nu)_SM

The combined result from the four LEP experiments is N_nu = 2.984 +/- 0.008 [1]. Recent analyses applied corrections to the LEP result [1] by including the effect of correlated luminosity systematics and also using an improved Bhabha cross section calculation [2,3] to obtain N_nu = 2.9963 +/- 0.0074.

In the past, when only small samples of Z decays had been recorded by the LEP experiments and by the Mark II at SLC, the uncertainty in N_nu was reduced by using Standard Model fits to the measured hadronic cross sections at several center-of-mass energies near the Z resonance. Since this method is

Lepton Particle Listings

Number of Neutrino Types

much more dependent on the Standard Model, the approach described above is favored.

Before SLC and LEP, limits on the number of neutrino generations were placed by experiments at lower-energy e^+e^- colliders by measuring the cross section of the process $e^+e^- \rightarrow \nu\bar{\nu}\gamma$. The ASP, CELLO, MAC, MARK J, and VENUS experiments observed a total of 3.9 events above background [4], leading to a 95% CL limit of $N_\nu < 4.8$. This process has a much larger cross section at center-of-mass energies near the Z mass and has been measured at LEP by the ALEPH, DELPHI, L3, and OPAL experiments [5]. These experiments have observed several thousand such events, and the combined result is $N_\nu = 3.00 \pm 0.08$. The same process has also been measured by the LEP experiments at much higher center-of-mass energies, between 130 and 208 GeV, in searches for new physics [6]. Combined with the lower energy data, the result is $N_\nu = 2.92 \pm 0.05$.

Experiments at $p\bar{p}$ colliders also placed limits on N_ν by determining the total Z width from the observed ratio of $W^\pm \rightarrow \ell^\pm\nu$ to $Z \rightarrow \ell^+\ell^-$ events [7]. This involved a calculation that assumed Standard Model values for the total W width and the ratio of W and Z leptonic partial widths, and used an estimate of the ratio of Z to W production cross sections. Now that the Z width is very precisely known from the LEP experiments, the approach is now one of those used to determine the W width.

¹ Uses Planck Data combined with an independent standard measure of distance to the sound horizon to set a limit on the total number of neutrinos. Only CMB and early-time information are used.

² ROSSI 15 sets limits on the number of neutrino types using BOSS Lyman alpha forest data combined with Planck CMB data and baryon acoustic oscillations.

³ Fit to the number of neutrino degrees of freedom from Planck CMB data along with WMAP polarization, high L, and BAO data.

⁴ Fit to the number of neutrinos degrees of freedom from Planck CMB data along with BAO, shear and cluster data.

⁵ Fit based on the SPT-SZ survey combined with CMB, BAO, and H_0 data.

⁶ Constrains the number of neutrino degrees of freedom (marginalizing over the total mass) from CMB, CMB lensing, BAO, and galaxy clustering data.

⁷ Limit on the number of light neutrino types from observational Hubble parameter data with seven-year WMAP data, SPT, and the most recent estimate of H_0 . Best fit is 3.45 ± 0.65 .

See key on page 999

Lepton Particle Listings

Number of Neutrino Types, Double- β Decay

- ⁸ Limit on the number of light neutrino types from the CFHTLS combined with seven-year WMAP data and a prior on the Hubble parameter. Best fit is $4.17^{+1.62}_{-1.26}$. Limit is relaxed to $3.98^{+2.02}_{-1.20}$ when small scales affected by non-linearities are removed.
- ⁹ Constrains the number of neutrino types from recent CMB and large scale structure data. No priors on other cosmological parameters are used.
- ¹⁰ Constrains the number of neutrino types from recent CMB, large scale structure, Lyman-alpha forest, and SN1a data. The slight preference for $N_\nu > 3$ comes mostly from the Lyman-alpha forest data.
- ¹¹ Constrains the number of neutrino types from recent CMB and large scale structure data. See also HAMANN 07.
- ¹² Limit on the number of neutrino types based on ⁴He and D/H abundance assuming a baryon density fixed to the WMAP data. Limit relaxes to 4.6 if D/H is not used or to 5.8 if only D/H and the CMB are used. See also CYBURT 01 and CYBURT 03.
- ¹³ Limit on the number of neutrino types based on combination of WMAP data and big-bang nucleosynthesis. The limit from WMAP data alone is 8.3. See also KNELLER 01. $N_\nu \geq 3$ is assumed to compute the limit.
- ¹⁴ 95% confidence level range on the number of neutrino flavors from WMAP data combined with other CMB measurements, the 2dGRS data, and HST data.
- ¹⁵ SHVARTSMAN 69 limit inferred from his equations.

Double- β Decay

OMITTED FROM SUMMARY TABLE
NEUTRINOLESS DOUBLE- β DECAY

Revised August 2019 by A. Piepke (University of Alabama) and P. Vogel (Caltech).

Observation of neutrinoless double-beta ($0\nu\beta\beta$) decay would signal violation of total lepton number conservation. The process can be mediated by an exchange of a light Majorana neutrino, or by an exchange of other particles. However, the existence of $0\nu\beta\beta$ -decay requires a nonvanishing Majorana neutrino mass, no matter what the actual mechanism is. As long as only a limit on the lifetime is available, limits on the effective Majorana neutrino mass, on the lepton-number violating right-handed current or other possible mechanisms mediating $0\nu\beta\beta$ decay can be obtained, independently of the actual mechanism, by assuming that one of these “new physics” possibilities dominates. These limits are listed in the Double- β Decay Listings of the experimental measurements.

In the following we assume that the exchange of light Majorana neutrinos ($m_{\nu_i} \leq 10$ MeV) contributes dominantly to the decay rate. Besides a dependence on the phase space ($G^{0\nu}$) and the nuclear matrix element ($M^{0\nu}$), the observable $0\nu\beta\beta$ -decay rate is proportional then to the square of the effective Majorana mass m_{ee} , $(T_{1/2}^{0\nu})^{-1} = G^{0\nu} \cdot |M^{0\nu}|^2 \cdot m_{ee}^2$, with $m_{ee}^2 = |\sum_i U_{ei}^2 m_{\nu_i}|^2$. The sum contains, in general, complex CP-phases in U_{ei}^2 , i.e., cancellations may occur. For three neutrino flavors there are two physical phases for Majorana neutrinos (η_1, η_2) and one for Dirac neutrinos (δ_{CP}). The relevant Majorana phases affect only processes to which lepton-number changing amplitudes contribute. Given the general 3×3 mixing matrix for Majorana neutrinos, one can construct other analogous lepton number violating quantities, $m_{\ell\ell'} = \sum_i U_{ei} U_{\ell'i} m_{\nu_i}$ (ℓ or $\ell' \neq e$). However, these are currently much less constrained than m_{ee} .

Nuclear structure calculations are needed to deduce m_{ee} from the decay rate. While $G^{0\nu}$ can be calculated accurately, the computation of $M^{0\nu}$ is subject to uncertainty. Comparing different nuclear model evaluations indicates a factor ~ 2 -3 spread in the calculated nuclear matrix elements. Nuclear structure calculation consistently overestimate Gamow-Teller (axial current) matrix elements. This inability of the nuclear models to reproduce Gamow-Teller decay rates is often parametrized in form of a modified coupling constant g_A . Many nuclear theorists interpret this shortcoming as evidence that important physics is missing in the modeling of weak nuclear transitions. It is not clear how these observed uncertainties impact $0\nu\beta\beta$ -matrix elements. Nevertheless, this constitutes an additional element of uncertainty. Recent work, [1] shows how the discrepancy between experimental and theoretical axial current matrix elements might be resolved. However, application of this approach to the $0\nu\beta\beta$ decay remains to be accomplished. The particle physics quantities to be determined are thus nuclear model-dependent, so the half-life measurements are listed first. Where possible, we reference the nuclear matrix elements used in the subsequent analysis. Since rates for the conventional $2\nu\beta\beta$ decay serve to constrain the nuclear theory models, results for this process are also given.

Lepton Particle Listings

Double- β Decay

Oscillation experiments utilizing atmospheric, accelerator, solar, and reactor produced neutrinos and anti-neutrinos show that at least some neutrinos are massive. However, so far the inverted mass ordering (i.e., whether $\Delta m_{31}^2 < 0$) is disfavored only by 2-3 σ compared to the normal mass ordering (when $\Delta m_{31}^2 > 0$), while the absolute neutrino mass values or the properties of neutrinos under CPT-conjugation (Dirac or Majorana) remain undetermined. All confirmed oscillation experiments can be consistently described using three interacting neutrino species with two mass splittings and three mixing angles. (For values of the mixing angles and mass square differences see the corresponding tables.)

Based on the 3-neutrino analysis:

$m_{ee}^2 = |\cos^2 \theta_{13} \cos^2 \theta_{12} m_1 + e^{2i(\eta_2 - \eta_1)} \cos^2 \theta_{13} \sin^2 \theta_{12} m_2 + e^{-2i(\eta_1 + \delta_{CP})} \sin^2 \theta_{13} m_3|^2$, valid for both mass orderings. Given the present knowledge of the neutrino oscillation parameters one can derive a relation between the effective Majorana mass and the mass of the lightest neutrino, as illustrated in Figure 14.11 in the Neutrino Masses, Mixing and Oscillations review. The three mass orderings allowed by the oscillation data: normal ($m_1 < m_2 \ll m_3$), inverted ($m_3 \ll m_1 < m_2$), and degenerate ($m_1 \approx m_2 \approx m_3$), result in different projections. The width of the colored bands reflects the uncertainty introduced by the unknown Majorana and Dirac phases as well as the experimental errors of the oscillation parameters. The latter causes only minor broadening of the bands. Because of the overlap of the different mass scenarios, a measurement of m_{ee} would not reveal which mass ordering is applicable, provided the value of m_{ee} is in the overlapping range.

Analogous plots depict the relation of m_{ee} with the summed neutrino mass $m_{tot} = m_1 + m_2 + m_3$, constrained by observational cosmology, and m_{ee} as a function of the average mass $m_{\nu_e}^{eff} = [\sum |U_{ei}|^2 m_{\nu_i}^2]^{1/2}$ determined through the analysis of the electron energy distribution in low energy beta decays. (See Fig. 1 of [2].) The oscillation data thus allow to test whether observed values of m_{ee} and m_{tot} or $m_{\nu_e}^{eff}$ are consistent within the 3 neutrino framework. The rather large intrinsic width of the $\beta\beta$ -decay constraints essentially does not allow to positively identify the mass ordering, and thus the sign of Δm_{31}^2 , even in combination with these other observables. Naturally, if a value of $0 < m_{ee} \leq 0.01$ eV is ever established, then the normal mass ordering becomes the only possible scenario.

It should be noted that systematic uncertainties of the nuclear matrix elements and possible quenching of the axial current matrix elements are sometimes not folded into the mass limits reported by $\beta\beta$ -decay experiments. Taking this additional uncertainty into account would further widen the projections. The plots are based on a 3-neutrino analysis. If it turns out that additional, i.e. sterile light neutrinos exist, the allowed regions would be modified substantially.

If neutrinoless double-beta decay is observed, it will be possible to fix a range of absolute values of the masses m_{ν_i} . Unlike the direct neutrino mass measurements, however, a limit

on m_{ee} does not allow one to constrain the individual mass values m_{ν_i} even when the mass differences Δm_{ij}^2 are known.

Neutrino oscillation data imply the existence of a lower limit ~ 0.014 eV for the Majorana neutrino mass for the inverted mass ordering pattern, while m_{ee} could, by fine tuning, vanish in the case of the normal mass ordering. Several new double-beta searches have been proposed to probe the interesting m_{ee} mass range, with the prospect of full coverage of the inverted mass ordering region within the next decade.

The $0\nu\beta\beta$ decay mechanism discussed so far is not the only way in which the decay can occur. Numerous other possible scenarios have been proposed, however, all of them requiring new physics. It will be a challenging task to decide which mechanism was responsible once $0\nu\beta\beta$ decay is observed. LHC experiments may reveal corresponding signatures for new physics of lepton number violation. If lepton-number violating right-handed weak current interactions exist, its strength can be characterized by the phenomenological coupling constants η and λ (η describes the coupling between the right-handed lepton current and left-handed quark current while λ describes the coupling when both currents are right-handed). The $0\nu\beta\beta$ decay rate then depends on $\langle \eta \rangle = \eta \sum_i U_{ei} V_{ei}$ and $\langle \lambda \rangle = \lambda \sum_i U_{ei} V_{ei}$ that vanish for massless or unmixed neutrinos (V_{ij} is a matrix analogous to U_{ij} but describing the mixing with the hypothetical right-handed neutrinos). The observation of the single electron spectra could, in principle, allow to distinguish this mechanism of $0\nu\beta\beta$ from the light Majorana neutrino exchange driven mode. The limits on $\langle \eta \rangle$ and $\langle \lambda \rangle$ are listed in a separate table. The reader is cautioned that a number of earlier experiments did not distinguish between η and λ . In addition, see the section on Majoron searches for additional limits set by these experiments.

Half-life 0ν double- β decay

In most cases the transitions $(Z,A) \rightarrow (Z+2,A) + 2e^-$ to the 0^+ ground state of the final nucleus are listed. We also list transitions that decrease the nuclear charge ($2e^+$, e^+ CC and double EC) and transitions to an excited state of the final nucleus (0^+_i , 2^+ , and 2^+_i). In the following Listings only the best or comparable limits for the half-lives of each transition are reported and only those with about $T_{1/2} > 10^{23}$ years that are relevant for particle physics.

1 AGOSTINI 19 use 82.4 kg-yr of data, collected by the GERDA experiment, to search for the 0ν ββ decay of ⁷⁶Ge. High resolution Ge-calorimeters, made from isotopically enriched Ge, are used. A median sensitivity of 1.1 × 10²⁶ yr is reported. Supersedes AGOSTINI 18.

2 ALDUINO 19 use the combined data of the CUORICINO and CUORE-0 experiments to place a lower limit on the half life of the 0ν ββ decay of ¹³⁰Te to the first excited 0⁺ state of ¹³⁰Xe. Supersedes ANDREOTTI 12.

3 ALENKOV 19 report the 0ν ββ decay half-life limit based on the 52.1 kg-d exposure of ¹⁰⁰Mo, of a cryogenic dual heat and light detector in the Yangyang underground laboratory. The median sensitivity is 1.1 × 10²³ years.

4 ALVIS 19 use the MAJORANA Demonstrator with enriched in ⁷⁶Ge detectors to set this limit on 0ν ββ half-life of ⁷⁶Ge. The exposure is 26.0 kg yr. The sensitivity is 4.8 × 10²⁵ yr.

5 ANTON 19 uses the complete dataset of the EXO-200 detector to search for the 0ν ββ decay. The exposure is 234.1 kg yr. The median sensitivity is 5.0 × 10²⁵ yr. Supersedes ALBERT 18 and ALBERT 14B.

6 AZZOLINI 19 use the CPID-0 scintillating cryogenic bolometer to set this limit on 0ν ββ half-life of ⁸²Se. The exposure is 5.29 kg yr. The sensitivity is 5 × 10²⁴ yr.

7 NI 19 use the PandaX-II dual phase TPC at CJPL to search for the 0ν ββ decay of ¹³⁶Xe. The half-life limit 2.4 × 10²³ yr is obtained from 22.2 kg yr exposure with a sensitivity of 1.9 × 10²³ yr.

8 AALSETH 18 uses the MAJORANA Demonstrator to search for the 0ν ββ decay. The exposure is 9.95 kg-year. The median sensitivity is 2.1 × 10²⁵ yr.

9 AGOSTINI 18 uses the GERDA detector to search for the 0ν ββ decay. The exposure is 46.7 kg-year. The median sensitivity is 5.8 × 10²⁵ yr. Supersedes AGOSTINI 17.

10 ALBERT 18 uses the EXO-200 detector to search for the 0ν ββ decay. The exposure is 177.6 kg-year. The median sensitivity is 3.7 × 10²⁵ years.

11 ALDUINO 18 uses the CUORE detector to search for the 0ν ββ decay of ¹³⁰Te. The exposure is 86.3 kg-year of natural TeO₂ corresponding to 24.0 kg-year for ¹³⁰Te. The median sensitivity is 0.7 × 10²⁵ yr. The limit is obtained combining the new data from CUORE with those of CUORE0 (9.8 kg-year of ¹³⁰Te) and Cuoricino (19.8 kg-year of ¹³⁰Te).

12 ARNOLD 18 use the NEMO-3 tracking detector to place a limit on the 0ν ββ decay of ⁸²Se. This is a slightly weaker limit than in BARABASH 11A, using the same detector. Supersedes ARNOLD 05A.

13 AZZOLINI 18 uses CUPID-0 detector, a novel scintillating cryogenic calorimeter, operated in the LNGS. This results replaces BARABASH 11A (NEMO-3) as the most stringent limit on the 0ν ββ-decay of ⁸²Se.

14 AZZOLINI 18A data collected by CUPID-0 based on scintillating bolometers is used to derive a new most stringent limit on the 0ν ββ-decay of ⁸²Se to the 0₁⁺ state of ⁸²Kr.

15 BARABASH 18 use 1.162 kg of ¹¹⁶CdWO₄ scintillating crystals to obtain this limit. Supersedes DANEVICH 03 with analogous source and is more sensitive than ARNOLD 17.

16 AGOSTINI 17 result corresponds to data collected with GERDA phase 1 and first release of phase 2 for a total of 343 mol-yr exposure. Supersedes AGOSTINI 13A. The median sensitivity is 4.0 10²⁵ yr.

17 ALBERT 17C uses the EXO-200 detector that contains 19.098 ± 0.014% admixture of ¹³⁴Xe to search for the 0ν and 2ν ββ decay modes. The exposure is 29.6 kg-year. The median sensitivity is 1.9 × 10²¹ years.

18 ARNOLD 17 use the NEMO-3 tracking calorimeter, containing 410 g of enriched ¹¹⁶Cd exposed for 5.26 yr, to determine the half-life limit. Supersedes BARABASH 11A.

19 ALDUINO 16 report result obtained with 9.8 kg y of data collected with the CUORE-0 bolometer, combined with data from the CUORICINO. Supersedes ALFONSO 15.

20 ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter (¹³⁶Xe 89.5 kg yr) to place a limit on the 0ν ββ-decay into the first excited state of the daughter nuclide.

21 ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter (¹³⁶Xe 89.5 kg yr) to place a limit on the 0ν ββ-decay into the second excited state of the daughter nuclide.

22 ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter (¹³⁶Xe 89.5 kg yr) to place a limit on the 0ν ββ-decay into the third excited state of the daughter nuclide.

23 GANDO 16 use the KamLAND detector to search for the 0ν decay of ¹³⁶Xe. With a significant background reduction, the combination of results of the first (270.7 days) and the second phase (263.8 days) of the experiment leads to about six fold improvement over the previous limit. Supersedes GANDO 13A. The sensitivity is 5.6 10²⁵ yr.

24 ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the limit of 0ν ββ-half life of ¹⁰⁰Mo. Supersedes ARNOLD 2005A and BARABASH 11A.

25 ALBERT 14b use 100 kg yr of exposure of the EXO-200 tracking calorimeter to place a lower limit on the 0ν ββ-half life of ¹³⁶Xe. Supersedes AUGER 12.

26 ANDREOTTI 12 use high resolution TeO₂ bolometric calorimeter to search for the 0ν ββ decay of ¹³⁰Te leading to the excited 0₁⁺ state at 1793.5 keV.

27 BARABASH 11A use the NEMO-3 detector to measure 2ν ββ rates and place limits on 0ν ββ half lives for various nuclides. Supersedes ARNOLD 05A, ARNOLD 04, ARNOLD 98, and ELLIOTT 92.

28 Supersedes ARNABOLDI 04. Bolometric TeO₂ detector array CUORICINO is used for high resolution search for 0ν ββ decay. The half-life limit is derived from 3.09 kg yr ¹³⁰Te exposure.

29 UMEHARA 08 use CaF₂ scintillation calorimeter to search for double beta decay of ⁴⁸Ca. Limit is significantly more stringent than quoted sensitivity: 18 × 10²¹ years.

30 Limit on 0ν-decay to the first excited 0₁⁺-state of daughter nucleus using NEMO-3 tracking calorimeter. Supersedes DASSIE 95.

31 Limit on 0ν-decay to the first excited 2⁺-state of daughter nucleus using NEMO-3 tracking calorimeter.

32 NEMO-3 tracking calorimeter is used in ARNOLD 05A to place limit on 0ν ββ half-life of ⁸²Se. Detector contains 0.93 kg of enriched ⁸²Se. Supersedes ARNOLD 04.

33 Supersedes ALESSANDRELLO 00. Array of TeO₂ crystals in high resolution cryogenic calorimeter. Some enriched in ¹²⁸Te. Ground state to ground state decay.

34 Limit on 0ν ββ decay of ¹¹⁶Cd using enriched CdWO₄ scintillators. Supersedes DANEVICH 00.

35 AALSETH 02b limit is based on 117 mol-yr of data using enriched Ge detectors. Background reduction by means of pulse shape analysis is applied to part of the data set. Reported limit is slightly less restrictive than that in KLAPDOR-KLEINGROTHAUS 01. However, it excludes part of the allowed half-life range reported in KLAPDOR-KLEINGROTHAUS 01B for the same nuclide. The analysis has been criticized in KLAPDOR-KLEINGROTHAUS 04B. The criticism was addressed and disputed in AALSETH 04.

36 KLAPDOR-KLEINGROTHAUS 01 is a continuation of the work published in BAUDIS 99. Isotopically enriched Ge detectors are used in calorimetric measurement. The most stringent bound is derived from the data set in which pulse-shape analysis has been used to reduce background. Exposure time is 35.5 kg y. Supersedes BAUDIS 99 as most stringent result.

Half-life measurements of the two-neutrino double-β decay

The measured half-life values for the transitions (Z,A) → (Z+2,A) + 2e⁻ + 2ν̄_e to the 0⁺ ground state of the final nucleus are listed. We also list the transitions to an excited state of the final nucleus (0_i⁺, etc.). We report only the measurements with the smallest (or comparable) uncertainty for each transition.

$\langle m_{ee} \rangle$, The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double- β Decay

$\langle m_{ee} \rangle = |\sum U_{ei}^2 m_{\nu_i}|$, $i = 1, 2, 3$. It is assumed that ν_i are Majorana particles and that the transition is dominated by the known (light) neutrinos. Note that U_{ei}^2 and not $|U_{ei}|^2$ occur in the sum, and that consequently cancellations are possible. The experiments obtain the limits on $\langle m_{\nu} \rangle$ from the measured ones on $T_{1/2}$ using a range of nuclear matrix elements (NME), which is reflected in the spread of $\langle m_{\nu} \rangle$. Different experiments may choose different NME. All assume $g_A = 1.27$. In the following Listings, only the best or comparable limits for each isotope are reported. When not mentioned explicitly the transition is between ground states, but transitions between excited states are also reported.

• • • We do not use the following data for averages, fits, limits, etc. • • •

- AGOSTINI 19 use 82.4 kg-yr of data collected by the isotopically enriched ⁷⁶Ge detectors of the GERDA experiment to derive an upper limit for $\langle m_{\beta\beta} \rangle$. The range reflects the variability of the theoretically calculated nuclear matrix elements. Supersedes AGOSTINI 18.
- ALENKOV 19 report the range of the effective masses $\langle m_{\beta\beta} \rangle$ corresponding to the $0\nu\beta\beta$ decay half-life limit. It is based on the 52.1 kg-d exposure of ¹⁰⁰Mo, in the Yangyang underground laboratory. The median sensitivity is 1.1×10^{23} years. The range of $\langle m_{\beta\beta} \rangle$ reflects the uncertainty of nuclear matrix elements.
- ALVIS 19 use the MAJORANA Demonstrator with enriched in ⁷⁶Ge detectors to set this limit. The exposure is 26.0 kg yr. The sensitivity is 4.8×10^{25} yr.
- ANTON 19 uses the complete dataset of the EXO-200 experiment to obtain these limits. The spread reflect the uncertainty in the nuclear matrix elements. Supersedes ALBERT 18 and ALBERT 14B.
- AZZOLINI 19 use the CPID-0 scintillating cryogenic bolometer to set this limit. The exposure is 5.29 kg yr. The sensitivity is 5×10^{24} yr.
- NI 19 use the PandaX-II dual phase TPC at CJPL to search for the $0\nu\beta\beta$ decay of ¹³⁶Xe with 22.2 kg yr exposure. The range in the $m_{\beta\beta}$ limit of 1.3–3.5 eV reflects the range of the calculated nuclear matrix elements. The sensitivity is 1.9×10^{23} yr.
- AALSETH 18 uses the MAJORANA Demonstrator detector to establish this limit.
- AGOSTINI 18 uses the GERDA detector to establish this limit.
- ALBERT 18 uses the EXO-200 experiment to obtain this limit.
- ALDUINO 18 use the combined data of CUORE, CUORE0, and Cuoricino to obtain this limit.
- ARNOLD 18 use the NEMO-3 tracking detector to constrain the $0\nu\beta\beta$ decay of ⁸²Se. The limit on $\langle m_{\beta\beta} \rangle$ is obtained assuming light neutrino exchange; the range reflects different calculations of the nuclear matrix elements. This is a somewhat weaker limit than in BARABASH 11A using the same detector.
- AZZOLINI 18 uses data collected by the CUPID-0 scintillating cryogenic calorimeter, operated in the LNGS, to derive a range of limits on $\langle m_{\nu} \rangle$. The reported range reflects the spread of the nuclear matrix element calculations considered in this work. Use $g_A = 1.269$.
- BARABASH 18 use 1.162 kg of ¹¹⁶CdWO₄ scintillating crystals to obtain these limits. The spread reflects the estimated uncertainty in the nuclear matrix element. Supersedes DANEVICH 03.
- AGOSTINI 17 is based on 343 mol yr of data from GERDA phase 1 and phase 2 first part and the corresponding limit on $T_{1/2}$ using the different nuclear matrix elements mentioned by the authors. Supersedes AGOSTINI 13A.
- ARNOLD 17 utilize NEMO-3 data, taken with enriched ¹¹⁶Cd to limit the effective Majorana neutrino mass. The reported range results from the use of different nuclear matrix elements. Supersedes BARABASH 11A.
- ALDUINO 16 place a limit on the effective Majorana neutrino mass using the combined data of the CUORE-0 and CUORICINO experiments. The range reflects the authors' evaluation of the variability of the nuclear matrix elements. Supersedes ALFONSO 15.
- ARNOLD 16A limit is derived from data taken with the NEMO-3 detector and ¹⁵⁰Nd. A range of nuclear matrix elements that include the effect of nuclear deformation have been used. Supersedes ARGYRIADES 09.
- GANDO 16 result is based on the 2016 KamLAND-Zen half-life limit. The stated range reflects different nuclear matrix elements, an unquenched $g_A = 1.27$ is used. Supersedes GANDO 13A.
- ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the neutrino mass limit based on the $0\nu\beta\beta$ -half life of ¹⁰⁰Mo. The spread range reflects different nuclear matrix elements. Supersedes ARNOLD 14 and BARABASH 11A.
- ALBERT 14B is based on 100 kg yr of exposure of the EXO-200 tracking calorimeter. The mass range reflects the nuclear matrix element calculations. Supersedes AUGER 12.
- BARABASH 11A limit is based on NEMO-3 data for ⁸²Se. The reported range reflects different nuclear matrix elements. Supersedes ARNOLD 05A and ARNOLD 04.
- ARGYRIADES 10 use ⁹⁶Zr and the NEMO-3 tracking detector to obtain the reported mass limit. The range reflects the fluctuation of the nuclear matrix elements considered.

See key on page 999

Lepton Particle Listings
Double-β Decay, Neutrino Mixing

- 23 Limit was obtained using CaF2 scintillation calorimeter to search for double beta decay of 48Ca. Reported range of limits reflects spread of QRPA and SM matrix element calculations used. Supersedes OGAWA 04.
24 Supersedes ARNABOLDI 04. Reported range of limits due to use of different nuclear matrix element calculations.
25 Supersedes ARNABOLDI 03. Reported range of limits due to use of different nuclear matrix element calculations.
26 Limit for $\langle m_{\nu} \rangle$ is based on the nuclear matrix elements of STAUDT 90 and ARNOLD 96. Supersedes DANEVICH 00.
27 KLAPDOR-KLEINGROTHAUS 01 uses the calculation by STAUDT 90. Using several other models in the literature could worsen the limit up to 1.2eV. This is the most stringent experimental bound on m_{ν}. It supersedes BAUDIS 99B.

Limits on Lepton-Number Violating (V+A) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later. $\langle \lambda \rangle = \lambda \sum U_{ej} V_{ej}$ and $\langle \eta \rangle = \eta \sum U_{ej} V_{ej}$, where the sum is over the number of neutrino generations. This sum vanishes for massless or unmixed neutrinos. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

Table with columns: $\langle \lambda \rangle (10^{-6})$, CL%, $\langle \eta \rangle (10^{-8})$, CL%, ISOTOPE, METHOD, DOCUMENT ID. Contains data for various isotopes like 82Se, 116Cd, 100Mo, 76Ge, 130Te, 116CdWO4, 100Mo, 76Ge, 136Xe, 128Te.

- 1 ARNOLD 18 use the NEMO03 tracking detector, with 0.93 kg of 82Se mass and 5.25 y exposure to obtain the limits for the hypothetical right-handed currents. Supersedes ARNOLD 05A.
2 BARABASH 18 use 1.162 kg of 116CdWO4 scintillating crystals to obtain this limits for the hypothetical right-handed currents in the 0νββ decay of 116Cd.
3 ARNOLD 14 is based on 34.7 kg yr of exposure of the NEMO-3 tracking calorimeter. The reported range limit on $\langle \lambda \rangle$ and $\langle \eta \rangle$ reflects the nuclear matrix element uncertainty in 100Mo.
4 ARNOLD 07 use NEMO-3 half life limit for 0ν-decay of 100Mo to the first excited 2+ state of daughter nucleus to limit the right-right handed admixture of weak currents $\langle \lambda \rangle$. This limit is not competitive when compared to the decay to the ground state.
5 Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim 6σ statistical evidence for observation of 0ν-decay. Authors use matrix element of MUTO 89 to determine $\langle \lambda \rangle$ and $\langle \eta \rangle$. Uncertainty of nuclear matrix element is not reflected in stated errors.
6 ARNOLD 05A derive limit for $\langle \lambda \rangle$ based on 100 Mo data collected with NEMO-3 detector. No limit for $\langle \eta \rangle$ is given. Supersedes ARNOLD 04.
7 ARNOLD 05A derive limit for $\langle \lambda \rangle$ based on 82Se data collected with NEMO-3 detector. No limit for $\langle \eta \rangle$ is given. Supersedes ARNOLD 04.
8 ARNOLD 04 use the matrix elements of SUHONEN 94 to obtain a limit for $\langle \lambda \rangle$, no limit for $\langle \eta \rangle$ is given. This limit is more stringent than the limit in EJIRI 01 for the same nucleus.
9 ARNOLD 04 use the matrix elements of TOMODA 91 and SUHONEN 91 to obtain a limit for $\langle \lambda \rangle$, no limit for $\langle \eta \rangle$ is given.
10 Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.
11 Limits for $\langle \lambda \rangle$ and $\langle \eta \rangle$ are based on nuclear matrix elements of STAUDT 90. Supersedes DANEVICH 00.
12 The range of the reported $\langle \lambda \rangle$ and $\langle \eta \rangle$ values reflects the spread of the nuclear matrix elements. On axis value assuming $\langle m_{\nu} \rangle = 0$ and $\langle \lambda \rangle = \langle \eta \rangle = 0$, respectively.
13 GUENTHER 97 limits use the matrix elements of STAUDT 90. Supersedes BALYSH 95 and BALYSH 92.
14 VUILLEUMIER 93 uses the matrix elements of MUTO 89. Based on a half-life limit 2.6 × 1023 y at 90%CL.
15 BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the 0ν width, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on η. Further details of the experiment are given in BERNATOWICZ 93.

Table with columns: Author, Year, Reference, Collaboration. Lists various authors and their contributions to the field, including collaborations like NEMO-3, CUORICINO, MAJORANA, GERDA, etc.

Neutrino Mixing

With the possible exceptions of "short-baseline anomalies," such as LSND, all neutrino data can be described within the framework of a 3×3 mixing matrix between the mass eigenstates ν1, ν2, and ν3, leading to the flavor eigenstates νe, νμ, and ντ, as described in the review "Neutrino masses, mixing and oscillations."

The Listings are divided in the following sections:

(A) Neutrino fluxes and event ratios: shows measurements which correspond to various oscillation tests for Accelerator, Reactor, Atmospheric, and Solar neutrino experiments. Typically, ratios involve a measurement in a realm sensitive to oscillations compared to one for which no oscillation effect is expected.

Double-β Decay REFERENCES

Table with columns: Author, Year, Reference, Collaboration. Lists references for double-beta decay studies.

Lepton Particle Listings

Neutrino Mixing

(B) Neutrino mixing parameters: shows measurements of $\sin^2(\theta_{12})$, $\sin^2(\theta_{23})$, $\sin^2(\theta_{13})$, Δm_{21}^2 , Δm_{32}^2 , and δ_{CP} as extracted from the measured data in the quoted publications in the frame of the three-neutrino mixing scheme. The quoted averages are not the result of a global fit, as in the review "Neutrino masses, mixing, and oscillations," and, as a consequence, might slightly differ from them. In some cases, measurements depend on the mass order (normal when $\Delta m_{32}^2 > 0$ or inverted when $\Delta m_{32}^2 < 0$) or octant of θ_{23} (lower when $\theta_{23} < 45^\circ$ or upper when $\theta_{23} > 45^\circ$).

(C) Other neutrino mixing results:

The LSND anomaly [AGUILAR 01], reported a signal which is consistent with $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ oscillations. In a three neutrino framework, this would be a measurement of θ_{12} and Δm_{21}^2 . This does not appear to be consistent with the interpretation of other neutrino data. It has been interpreted as evidence for a 4th "sterile" neutrino. The following listings include results which might be relevant towards understanding this observation. They include searches for $\nu_\mu \rightarrow \nu_e$, $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$, sterile neutrino oscillations, and others.

(A) Neutrino fluxes and event ratios

Events (observed/expected) from accelerator ν_μ experiments.

Some neutrino oscillation experiments compare the flux in two or more detectors. This is usually quoted as the ratio of the event rate in the far detector to the expected rate based on an extrapolation from the near detector in the absence of oscillations.

VALUE	DOCUMENT ID	TECN	COMMENT
• • •	We do not use the following data for averages, fits, limits, etc. • • •		
1.01 ± 0.10	1 ABE	14B T2K	ν_e rate in T2K near detect.
0.71 ± 0.08	2 AHN	06A K2K	K2K to Super-K
0.64 ± 0.05	3 MICHAEL	06 MINS	All charged current events
0.71 $^{+0.08}_{-0.09}$	4 ALIU	05 K2K	KEK to Super-K
0.70 $^{+0.10}_{-0.11}$	5 AHN	03 K2K	KEK to Super-K

- ¹ The rate of ν_e from μ decay was measured to be 0.68 ± 0.30 compared to the predicted flux. From K decay 1.10 ± 0.14 compared to the predicted flux.
- ² Based on the observation of 112 events when $158.1^{+9.2}_{-8.6}$ were expected without oscillations. Including not only the number of events but also the shape of the energy distribution, the evidence for oscillation is at the level of about 4.3σ . Supersedes ALIU 05.
- ³ This ratio is based on the observation of 215 events compared to an expectation of 336 ± 14 without oscillations. See also ADAMSON 08.
- ⁴ This ratio is based on the observation of 107 events at the far detector 250 km away from KEK, and an expectation of 151^{+12}_{-10} .
- ⁵ This ratio is based on the observation of 56 events with an expectation of $80.1^{+6.2}_{-5.4}$.

Events (observed/expected) from reactor $\bar{\nu}_e$ experiments.

The quoted values are the ratios of the measured reactor $\bar{\nu}_e$ event rate at the quoted distances, and the rate expected without oscillations. The expected rate is based on the experimental data for the most significant reactor fuels (^{235}U , ^{239}Pu , ^{241}Pu) and on calculations for ^{238}U .

A recent re-evaluation of the spectral conversion of electron to $\bar{\nu}_e$ in MUELLER 11 results in an upward shift of the reactor $\bar{\nu}_e$ spectrum by 3% and, thus, might require revisions to the ratios listed in this table.

- ¹ ADEY 19 present a re-analysis of 1230 days of Daya Bay near detector data with reduced systematic uncertainties on the neutron detection efficiency. Note that ADEY 19 report the measured to predicted antineutrino ratio using the reactor model of MUELLER 11 (Huber-Mueller model). The ratio using the older ILL-Vogel model is $1.001 \pm 0.015 \pm 0.027$.
- ² AN 16 use 217 days of data (338k events) to determine the neutrino flux ratio relative to the prediction of Mueller-Huber and ILL-Vogel models (see AN 16 for details). The reported flux ratios were corrected for θ_{13} oscillation effect. The flux measurement is consistent with results from previous short-baseline reactor experiments. The measured inverse beta decay yield is $(1.55 \pm 0.04) \times 10^{-18} \text{ cm}^2/(\text{GW day})$ or $\sigma_f = (5.92 \pm 0.14) \times 10^{-43} \text{ cm}^2/\text{fission}$. About 4σ excess of events was observed in the 4–6 MeV prompt energy region.
- ³ DENIZ 10 observe reactor $\bar{\nu}_e e$ scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate is consistent with the Standard Model prediction, leading to a constraint on $\sin^2 \theta_{W} = 0.251 \pm 0.031(\text{stat}) \pm 0.024(\text{sys})$.
- ⁴ Updated result of KamLAND, including the data used in EGUCHI 03. Note that the survival probabilities for different periods are not directly comparable because the effective baseline varies with power output of the reactor sources involved, and there were large variations in the reactor power production in Japan in 2003.
- ⁵ EGUCHI 03 observe reactor neutrino disappearance at ~ 180 km baseline to various Japanese nuclear power reactors.
- ⁶ BOEHM 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors.
- ⁷ APOLLONIO 99, APOLLONIO 98 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use $\bar{\nu}_e p \rightarrow e^+ n$ in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98. See also APOLLONIO 03 for detailed description.
- ⁸ GREENWOOD 96 search for neutrino oscillations at 18 m and 24 m from the reactor at Savannah River.
- ⁹ DECLAIS 94 result based on integral measurement of neutrons only. Result is ratio of measured cross section to that expected in standard V-A theory. Replaced by ACHKAR 95.
- ¹⁰ KWON 81 represents an analysis of a larger set of data from the same experiment as BOEHM 80.

Atmospheric neutrinos

Neutrinos and antineutrinos produced in the atmosphere induce μ -like and e -like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as μ/e . It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The "ratio of the ratios" of experimental to theoretical μ/e , $R(\mu/e)$, or that of experimental to theoretical μ/total , $R(\mu/\text{total})$ with $\text{total} = \mu + e$, is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions. In addition, the measured "up-down asymmetry" for μ ($N_{up}(\mu)/N_{down}(\mu)$) or e ($N_{up}(e)/N_{down}(e)$) is reported. The expected "up-down asymmetry" is nearly unity if there is no neutrino oscillation.

$R(\mu/e) = (\text{Measured Ratio } \mu/e) / (\text{Expected Ratio } \mu/e)$

- ¹ ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring e -like events with $0.1 \text{ GeV}/c < p_e$ and μ -like events $0.2 \text{ GeV}/c < p_\mu$, both having a visible energy $< 1.33 \text{ GeV}$. These criteria match the definition used by FUKUDA 94.
- ² ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring events with visible energy $> 1.33 \text{ GeV}$ and partially-contained events. All partially-contained events are classified as μ -like.
- ³ SANCHEZ 03 result is based on an exposure of 5.9 kton yr, and updates ALLISON 99 result. The analyzed data sample consists of fully-contained e -flavor and μ -flavor events having lepton momentum $> 0.3 \text{ GeV}/c$.
- ⁴ FUKUDA 96B studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.
- ⁵ DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90B. This ratio is for the contained and semicontained events. DAUM 95

See key on page 999

Lepton Particle Listings

Neutrino Mixing

also report $R(\mu/e) = 0.99 \pm 0.13 \pm 0.08$ for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.

⁶FUKUDA 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained e -like events with $0.1 < p_e < 1.33$ GeV/c and fully-contained μ -like events with $0.2 < p_\mu < 1.5$ GeV/c.

⁷FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy > 1.33 GeV and partially contained μ -like events.

⁸BECKER-SZENDY 92B reports the fraction of nonshowering events (mostly muons from atmospheric neutrinos) as $0.36 \pm 0.02 \pm 0.02$, as compared with expected fraction $0.51 \pm 0.01 \pm 0.05$. After cutting the energy range to the Kamiokande limits, BEIER 92 finds $R(\mu/e)$ very close to the Kamiokande value.

$R(\nu_\mu) = (\text{Measured Flux of } \nu_\mu) / (\text{Expected Flux of } \nu_\mu)$

¹ADAMSON 06 uses a measurement of 107 total neutrinos compared to an expected rate of 127 ± 13 without oscillations.

²AMBROSIO 01 result is based on the upward through-going muon tracks with $E_\mu > 1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The first error is the statistical error, the second is the systematic error, dominated by the theoretical error in the predicted flux.

³AMBROSIO 00 result is based on the upgoing partially contained event sample. It came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

⁴AMBROSIO 00 result is based on the combined samples of downgoing partially contained events and upgoing stopping events. These two subsamples could not be distinguished due to the lack of timing information. The result came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

⁵AMBROSIO 98 result is for all nadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of ± 0.13 . With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields $\sin^2 2\theta = 1.0$ and $\Delta(m^2) \sim$ a few times 10^{-3} eV². However, the fit to the observed zenith distribution gives a maximum probability for χ^2 of only 5% for the best oscillation hypothesis.

⁶CASPER 91 correlates showering/nonshowering signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowering ($\approx \nu_\mu$ induced) fraction is $0.41 \pm 0.03 \pm 0.02$, as compared with expected 0.51 ± 0.05 (syst).

⁷AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define $\rho = (\text{measured number of } \nu_e) / (\text{measured number of } \nu_\mu)$. They report $\rho(\text{measured}) = \rho(\text{expected}) = 0.96 \pm \frac{0.32}{0.28}$.

⁸From this data BOLIEV 81 obtain the limit $\Delta(m^2) \leq 6 \times 10^{-3}$ eV² for maximal mixing, $\nu_\mu \leftrightarrow \nu_\mu$ type oscillation.

$R(\mu/\text{total}) = (\text{Measured Ratio } \mu/\text{total}) / (\text{Expected Ratio } \mu/\text{total})$

¹ADAMSON 12B reports the atmospheric neutrino results obtained with MINOS far detector in 2,553 live days (an exposure of 37.9 kton-yr). This result is obtained with a sample of high resolution contained-vertex muons. The quoted error is statistical only.

²ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring μ -like events with visible energy > 1.33 GeV and partially-contained events.

All partially-contained events are classified as μ -like. Upward-going events are those with $-1 < \cos(\text{zenith angle}) < -0.2$ and downward-going events are those with $0.2 < \cos(\text{zenith angle}) < 1$. The μ -like up-down ratio for the multi-GeV data deviates from 1 (the expectation for no atmospheric ν_μ oscillations) by more than 12 standard deviations.

$N_{\text{up}}(e) / N_{\text{down}}(e)$

¹ADAMSON 12B reports the atmospheric neutrino results obtained with MINOS far detector in 2,553 live days (an exposure of 37.9 kton-yr). The muon charge ratio $N(\mu^+) / N(\mu^-)$ represents the $\overline{\nu}_\mu / \nu_\mu$ ratio. As far as the same oscillation parameters are used for ν_s and $\overline{\nu}_s$, the expected $\overline{\nu}_\mu / \nu_\mu$ ratio is almost entirely independent of any input oscillations.

²This result is obtained with a charge-separated sample of high resolution contained-vertex muons.

³This result is obtained with a charge-separated sample of high resolution neutrino-induced rock-muons.

⁴The charge-separated samples of high resolution contained-vertex muons and neutrino-induced rock-muons are combined to obtain this result which is consistent with unity.

⁵ADAMSON 07 result is obtained with the MINOS far detector in 854.24 live days, based on neutrino-induced upward-going and horizontal muons. This result is consistent with CP T conservation.

⁶ADAMSON 06 result is obtained with the MINOS far detector with an exposure of 4.54 kton yr, based on contained events. The expected ratio is calculated by assuming the same oscillation parameters for neutrinos and antineutrinos.

Solar neutrinos

Solar neutrinos are produced by thermonuclear fusion reactions in the Sun. Radiochemical experiments measure particular combinations of fluxes from various neutrino-producing reactions, whereas water-Cherenkov experiments mainly measure a flux of neutrinos from decay of ⁸B. Solar neutrino fluxes are composed of all active neutrino species, ν_e , ν_μ , and ν_τ . In addition, some other mechanisms may cause antineutrino components in solar neutrino fluxes. Each measurement method is sensitive to

Lepton Particle Listings

Neutrino Mixing

a particular component or a combination of components of solar neutrino fluxes.

ν_e Capture Rates from Radiochemical Experiments

1 SNU (Solar Neutrino Unit) = 10^{-36} captures per atom per second.

VALUE (SNU)	DOCUMENT ID	TECN	COMMENT

2.56 ± 0.16 ± 0.16	⁷ CLEVELAND	98 HOME	³⁷ Cl \rightarrow ³⁷ Ar

- ¹ KAETHER 10 reports the reanalysis results of a complete GALLEX data (GALLEX I+II+III+IV, reported in HAMPEL 99) based on the event selection with a new pulse shape analysis, which provides a better background reduction than the rise time analysis adopted in HAMPEL 99.
- ² Combined result of GALLEX I+II+III+IV reanalysis and GNO I+II+III (ALTMANN 05).
- ³ ABDURASHITOV 09 reports a combined analysis of 168 extractions of the SAGE solar neutrino experiment during the period January 1990 through December 2007, and updates the ABDURASHITOV 02 result. The data are consistent with the assumption that the solar neutrino production rate is constant in time. Note that a $\sim 15\%$ systematic uncertainty in the overall normalization may be added to the ABDURASHITOV 09 result, because calibration experiments for gallium solar neutrino measurements using intense ⁵¹Cr (twice by GALLEX and once by SAGE) and ³⁷Ar (by SAGE) result in an average ratio of 0.87 ± 0.05 of the observed to calculated rates.
- ⁴ ALTMANN 05 reports the complete result from the GNO solar neutrino experiment (GNO I+II+III), which is the successor project of GALLEX. Experimental technique of GNO is essentially the same as that of GALLEX. The run data cover the period 20 May 1998 through 9 April 2003.
- ⁵ Combined result of GALLEX I+II+III+IV (HAMPEL 99) and GNO I+II+III.
- ⁶ HAMPEL 99 report the combined result for GALLEX I+II+III+IV (65 runs in total), which update the HAMPEL 96 result. The GALLEX IV result (12 runs) is $118.4 \pm 17.8 \pm 6.6$ SNU. (HAMPEL 99 discuss the consistency of partial results with the mean.) The GALLEX experimental program has been completed with these runs. The total run data cover the period 14 May 1991 through 23 January 1997. A total of 300 ⁷¹Ge events were observed. Note that a $\sim 15\%$ systematic uncertainty in the overall normalization may be added to the HAMPEL 99 result, because calibration experiments for gallium solar neutrino measurements using intense ⁵¹Cr (twice by GALLEX and once by SAGE) and ³⁷Ar (by SAGE) result in an average ratio of 0.87 ± 0.05 of the observed to calculated rates.
- ⁷ CLEVELAND 98 is a detailed report of the ³⁷Cl experiment at the Homestake Mine. The average solar neutrino-induced ³⁷Ar production rate from 108 runs between 1970 and 1994 updates the DAVIS 89 result.

ϕ_{ES} (⁸B)

⁸B solar-neutrino flux measured via νe elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to ν_μ, ν_τ due to the cross-section difference, $\sigma(\nu_{\mu,\tau} e) \sim 0.16\sigma(\nu_e e)$. If the ⁸B solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is ~ 0.16 times of ν_e .

- ¹ ANDERSON 19 reports this result from the $\nu_e e$ elastic scattering rate using a 69.2 kton-day (or 114.7 days) of exposure from May through December, 2017 during the SNO+ detector's water commissioning phase. The events over the reconstructed electron kinetic energy range of 5–15 MeV were analyzed.
- ² AGOSTINI 18B obtained this result from the $\nu_e e$ elastic scattering rate over the period between January 2008 and December 2016.
- ³ ABE 16C reports the combined results of the four phases of the Super-Kamiokande average flux measurements. Here the revised Super-Kamiokande-III result is used.
- ⁴ ABE 16C reports the Super-Kamiokande-IV results for 1664 live days from September 2008 to February 2014. The analysis threshold is total electron energy of 4.0 MeV.
- ⁵ ABE 16C revised the Super-Kamiokande-III average flux value reported in ABE 11. Super-Kamiokande-III results are for 548 live days from August 4, 2006 to August 18, 2008. The analysis threshold is 5.0 MeV, but the event sample in the 5.0–6.5 MeV total electron energy range has a total live time of 298 days.
- ⁶ ABE 11 recalculated the Super-Kamiokande-II results using ⁸B spectrum of WINTER 06A.
- ⁷ ABE 11 recalculated the Super-Kamiokande-I results using ⁸B spectrum of WINTER 06A.
- ⁸ ABE 11B use a 123 kton-day exposure of the KamLAND liquid scintillation detector to measure the ⁸B solar neutrino flux. They utilize $\nu - e$ elastic scattering above a reconstructed-energy threshold of 5.5 MeV, corresponding to 5 MeV electron recoil energy. 299 electron recoil candidate events are reported, of which 157 ± 23.6 are assigned to background.
- ⁹ BELLINI 10A reports the Borexino result with 3 MeV energy threshold for scattered electrons. The data correspond to 345.3 live days with a target mass of 100 t, between July 15, 2007 and August 23, 2009.
- ¹⁰ AHARMIM 08 reports the results from SNO Phase III measurement using an array of ³He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ⁸B shape.
- ¹¹ CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the average flux is 7 MeV.
- ¹² HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).
- ¹³ AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the ⁸B energy spectrum was not constrained. In the other method, the constraint of an undistorted ⁸B energy spectrum was added for comparison with AHMAD 02 results.
- ¹⁴ AHMAD 02 reports the ⁸B solar-neutrino flux measured via νe elastic scattering above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results.
- ¹⁵ AHMAD 01 reports the ⁸B solar-neutrino flux measured via νe elastic scattering above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.
- ¹⁶ FUKUDA 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold $E_e > 9.3$ MeV (first 449 days), > 7.5 MeV (middle 794 days), and > 7.0 MeV (last 836 days). These results update the HIRATA 90 result for the average ⁸B solar-neutrino flux and HIRATA 91 result for the day-night variation in the ⁸B solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.

ϕ_{CC} (⁸B)

⁸B solar-neutrino flux measured with charged-current reaction which is sensitive exclusively to ν_e .

¹AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the ⁸B flux mostly comes from the NC signal, however, CC contribution is included in the fit.

²AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with a "binned-histogram unconstrained fit" where binned probability distribution functions of the neutrino signal observables were used without any model constraints on the shape of the neutrino spectrum.

³AHARMIM 08 reports the results from SNO Phase III measurement using an array of ³He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ⁸B shape.

⁴AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the ⁸B energy spectrum was not constrained. In the other method, the constraint of an undistorted ⁸B energy spectrum was added for comparison with AHMAD 02 results.

⁵AHMAD 02 reports the first SNO result of the ⁸B solar-neutrino flux measured with the neutral-current reaction on deuterium, $\nu_e d \rightarrow np\nu_e$, above the neutral-current reaction threshold of 2.2 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001. The complete description of the SNO Phase I data set is given in AHARMIM 07.

$\phi_{\nu_\mu+\nu_\tau}$ (⁸B)

¹ANDERSON 19 reports this result from the measured $\nu_e e$ elastic scattering rate using a 69.2 kton-day (or 114.7 days) of exposure from May through December, 2017 during the SNO+ detector's water commissioning phase, assuming the neutrino mixing parameters given in PDG 16 and a standard solar model given in BAHCALL 05.

²AGOSTINI 18B obtained this result from the measured $\nu_e e$ elastic scattering rate over the period between January 2008 and December 2016, assuming the MSW-LMA oscillation parameters derived by ESTEBAN 17. Assuming a high-metallicity standard solar model, the electron neutrino survival probability for the ⁸B solar neutrino is calculated to be 0.37 ± 0.08.

³AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the ⁸B flux mostly comes from the NC signal, however, CC contribution is included in the fit.

⁴AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with the assumption of unitarity, which relates the NC, CC, and ES rates. The data were fit with the free parameters directly describing the total ⁸B neutrino flux and the energy-dependent ν_e survival probability.

⁵AHARMIM 08 reports the results from SNO Phase III measurement using an array of ³He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17

$\phi_{CC}(pp)$

(B) Three-neutrino mixing parameters

THREE-NEUTRINO MIXING PARAMETERS

Updated July 2019 by M. Goodman (ANL).

Introduction and Notation: With the exception of possible short-baseline anomalies (such as LSND), current accelerator, reactor, solar and atmospheric neutrino data can be described within the framework of a 3×3 mixing matrix between the flavor states ν_e, ν_μ and ν_τ and mass eigenstates ν_1, ν_2 and ν_3 . (See equation 14.34 of the review “Neutrino Mass, Mixing and Oscillations” by M.C. Gonzalez-Garcia and M. Yokoyama.) Whether or not this is the ultimately correct framework, it is currently widely used to parametrize neutrino mixing data and to plan new experiments.

The mass differences are called $\Delta m_{21}^2 \equiv m_2^2 - m_1^2$ and $\Delta m_{32}^2 \equiv m_3^2 - m_2^2$. Until recently, we assumed

$$\Delta m_{32}^2 \sim \Delta m_{31}^2. \tag{1}$$

But the experimental error is comparable to the difference $\Delta m_{31}^2 - \Delta m_{32}^2 = \Delta m_{21}^2$, so we quote them separately when appropriate. The measurements made by ν_μ disappearance at accelerators and by ν_e disappearance at reactors are slightly different mixtures of Δm_{32}^2 and Δm_{31}^2 . The angles are labeled θ_{12}, θ_{23} and θ_{13} . The CP violating phase is called δ_{CP} .

The familiar two neutrino form for oscillations is

$$P(\nu_a \rightarrow \nu_b; a \neq b) = \sin^2(2\theta) \sin^2(\Delta m^2 L/4E). \tag{2}$$

Despite the fact that the mixing angles have been measured to be much larger than in the quark sector, the two neutrino form is often a very good approximation and is used in many situations.

The angles appear in the equations below in many forms. They often appear as $\sin^2(2\theta)$. The listings currently now use $\sin^2(\theta)$ because this distinguishes the octant, i.e. whether θ_{23} is larger or smaller than 45° .

Accelerator neutrino experiments: Ignoring Δm_{21}^2 , CP violation, and matter effects, the equations for the probability of appearance in an accelerator oscillation experiment are:

$$P(\nu_\mu \rightarrow \nu_\tau) = \sin^2(2\theta_{23}) \cos^4(\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \tag{3}$$

$$P(\nu_\mu \rightarrow \nu_e) = \sin^2(2\theta_{13}) \sin^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E) \tag{4}$$

$$P(\nu_e \rightarrow \nu_\mu) = \sin^2(2\theta_{13}) \sin^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E) \tag{5}$$

$$P(\nu_e \rightarrow \nu_\tau) = \sin^2(2\theta_{13}) \cos^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E). \tag{6}$$

Current and future long-baseline accelerator experiments are studying non-zero θ_{13} through $P(\nu_\mu \rightarrow \nu_e)$. Including the CP terms and low mass scale, the equation for neutrino oscillation in vacuum is:

$$\begin{aligned} P(\nu_\mu \rightarrow \nu_e) &= P1 + P2 + P3 + P4 \\ P1 &= \sin^2(\theta_{23}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \\ P2 &= \cos^2(\theta_{23}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{21}^2 L/4E) \\ P3 &= -/+ J \sin(\delta_{CP}) \sin(\Delta m_{32}^2 L/4E) \\ P4 &= J \cos(\delta_{CP}) \cos(\Delta m_{32}^2 L/4E) \end{aligned} \tag{7}$$

where

$$\begin{aligned} J &= \cos(\theta_{13}) \sin(2\theta_{12}) \sin(2\theta_{13}) \sin(2\theta_{23}) \times \\ &\sin(\Delta m_{32}^2 L/4E) \sin(\Delta m_{21}^2 L/4E) \end{aligned} \tag{8}$$

and the sign in P3 is negative for neutrinos and positive for anti-neutrinos respectively. For most new long-baseline accelerator experiments, P2 can safely be neglected. Also, depending on the distance and the mass order, matter effects need to be included.

Reactor neutrino experiments: Nuclear reactors are prolific sources of $\bar{\nu}_e$ with an energy near 4 MeV. The oscillation probability can be expressed

$$\begin{aligned} P(\bar{\nu}_e \rightarrow \bar{\nu}_e) &= 1 - \cos^4(\theta_{13}) \sin^2(2\theta_{12}) \sin^2(\Delta m_{21}^2 L/4E) \\ &\quad - \cos^2(\theta_{12}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{31}^2 L/4E) \\ &\quad - \sin^2(\theta_{12}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \end{aligned} \tag{9}$$

not using the approximation in Eq. (1). For short distances ($L < 5 \text{ km}$) we can ignore the second term on the right and can reimpose approximation Eq. (1). This takes the familiar two neutrino form with θ_{13} and Δm_{32}^2 :

$$P(\bar{\nu}_e \rightarrow \bar{\nu}_e) = 1 - \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E). \tag{10}$$

Lepton Particle Listings

Neutrino Mixing

Solar and Atmospheric neutrino experiments: Solar neutrino experiments are sensitive to ν_e disappearance and have allowed the measurement of θ_{12} and Δm_{21}^2 . They are also sensitive to θ_{13} . We identify $\Delta m_{\odot}^2 = \Delta m_{21}^2$ and $\theta_{\odot} = \theta_{12}$.

Atmospheric neutrino experiments are primarily sensitive to ν_{μ} disappearance through $\nu_{\mu} \rightarrow \nu_{\tau}$ oscillations, and have allowed the measurement of θ_{23} and Δm_{32}^2 . We identify $\Delta m_A^2 = \Delta m_{32}^2$ and $\theta_A = \theta_{23}$. Despite the large ν_e component of the atmospheric neutrino flux, it is difficult to measure Δm_{21}^2 effects. This is because of a cancellation between $\nu_{\mu} \rightarrow \nu_e$ and $\nu_e \rightarrow \nu_{\mu}$ together with the fact that the ratio of ν_{μ} and ν_e atmospheric fluxes, which arise from sequential π and μ decay, is near 2.

Oscillation Parameter Listings: In Section (B) we encode the three mixing angles θ_{12} , θ_{23} , θ_{13} , δ_{CP} , and two mass squared differences Δm_{21}^2 and Δm_{32}^2 . Our knowledge of θ_{12} and Δm_{21}^2 comes from the KamLAND reactor neutrino experiment together with solar neutrino experiments. Our knowledge of θ_{23} and Δm_{32}^2 comes from atmospheric, reactor and long-baseline accelerator neutrino experiments. For the earlier experiments, we identified the large mass splitting as Δm_{32}^2 . Now that $\sigma(\Delta m_{32}^2) \approx \Delta m_{21}^2$, some experiments report separate values for the two mass orders. Results on θ_{13} come from reactor antineutrino disappearance experiments. There are also results from long-baseline accelerator experiments looking for ν_e appearance. The interpretation of both kinds of results depends on Δm_{32}^2 , and the accelerator results also depend on the mass order, θ_{23} and the CP violating phase δ_{CP} .

Accelerator and atmospheric experiments have some sensitivity to the CP violation phase δ_{CP} through Eq. (7). Note that P3 depends on the sign of Δm_{32}^2 so the sensitivity depends on the mass order. For non-maximal θ_{23} mixing, it also depends on the octant of θ_{23} , i.e. whether $\theta_{23} > \pi/4$ or $\theta_{23} < \pi/4$.

 $\sin^2(\theta_{12})$

If an experiment reports $\sin^2(2\theta_{12})$ we convert the value to $\sin^2(\theta_{12})$.

¹ ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using all solar data and KamLAND data. *CPT* invariance is assumed.

² ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using Super-Kamiokande (I+II+III+IV) and SNO data.

³ ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, by combining the four phases of the Super-Kamiokande solar data.

⁴ ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using the Super-Kamiokande-IV data.

⁵ FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

⁶ GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $0.304^{+0.013}_{-0.012}$ for normal and $0.305^{+0.012}_{-0.013}$ for inverted mass ordering.

⁷ AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

⁸ AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active ^8B neutrino flux and energy-dependent ν_e survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and ^7Be (BELLINI 11A) rates, and ^8B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVEN 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

⁹ AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.45 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data.

¹⁰ AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.45 \times 10^{-3} \text{ eV}^2$, using global solar neutrino and KamLAND (GANDO 11) data. *CPT* invariance is assumed.

¹¹ GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming *CPT* invariance. Supersedes GANDO 11.

¹² GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming *CPT* invariance. Supersedes GANDO 11.

¹³ GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

¹⁴ ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, GALLEX/GNO, SAGE, and KamLAND data. *CPT* invariance is assumed.

¹⁵ ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, GALLEX/GNO, and SAGE data.

Lepton Particle Listings

Neutrino Mixing

- ¹⁶ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4 \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and CPT invariance are assumed.
- ¹⁷ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4 \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.
- ¹⁸ BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^8B flux was left free. CPT invariance is assumed.
- ¹⁹ BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^8B flux was left free.
- ²⁰ GAND0 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GAND0 13.
- ²¹ GAND0 11 obtain this result with three-neutrino fit using the KamLAND data only. Superseded by GAND0 13.
- ²² AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).
- ²³ AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.
- ²⁴ AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.
- ²⁵ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.
- ²⁶ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data.
- ²⁷ ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for Δm_{21}^2 and $\tan^2 \theta_{12}$, using KamLAND data only. Superseded by GAND0 11.
- ²⁸ ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO χ^2 -map, and solar flux data. CPT invariance is assumed. Superseded by GAND0 11.
- ²⁹ The result given by AHARMIM 08 is $\theta = (34.4^{+1.3}_{-1.2})^\circ$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). CPT invariance is assumed.
- ³⁰ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using SK ν_e data, CC data from other solar neutrino experiments, and KamLAND data (ARAKI 05). CPT invariance is assumed.
- ³¹ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. CPT invariance is assumed.
- ³² HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.
- ³³ The result given by AHARMIM 05A is $\theta = (33.9 \pm 1.6)^\circ$. This result is obtained by a two-neutrino oscillation analysis using SNO pure deuterium and salt phase data, SK ν_e data, Cl and Ga CC data, and KamLAND data (ARAKI 05). CPT invariance is assumed. AHARMIM 05A also quotes $\theta = (33.9^{+2.4}_{-2.2})^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.86^{+0.05}_{-0.06}$.
- ³⁴ AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes $\tan^2 \theta = 0.45^{+0.09}_{-0.08}$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.86^{+0.05}_{-0.07}$.
- ³⁵ ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. CPT invariance is assumed. The 1σ error shown here is translated from the number provided by the KamLAND collaboration, $\tan^2 \theta = 0.40^{+0.07}_{-0.05}$. The corresponding number quoted in ARAKI 05 is $\tan^2 \theta = 0.40^{+0.10}_{-0.07}$ ($\sin^2 2\theta = 0.82 \pm 0.07$), which envelops the 68% CL two-dimensional region.
- ³⁶ The result given by AHMED 04A is $\theta = (32.5^{+1.7}_{-1.6})^\circ$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). CPT invariance is assumed. AHMED 04A also quotes $\theta = (32.5^{+2.4}_{-2.3})^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.82 \pm 0.06$.
- ³⁷ AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is $\Delta(m^2) = 6.5 \times 10^{-5} \text{ eV}^2$, $\tan^2 \theta = 0.40$ ($\sin^2 2\theta = 0.82$).
- ³⁸ The result given by SMY 04 is $\tan^2 \theta = 0.44 \pm 0.08$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). CPT invariance is assumed.
- ³⁹ SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The 1σ errors are read from Fig. 6(a) of SMY 04.

⁴⁰ SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The 1σ errors are read from Fig. 6(a) of SMY 04.

⁴¹ AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$ and $\tan \theta = 0.34$ ($\sin^2 2\theta = 0.76$).

⁴² FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$ and $\tan^2 \theta = 0.38$ ($\sin^2 2\theta = 0.80$).

¹ GAND0 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming CPT invariance. Supersedes GAND0 11.

² ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using all solar data and KamLAND data. CPT invariance is assumed.

Lepton Particle Listings

Neutrino Mixing

- ³ ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using Super-Kamiokande (I+II+III+IV) and SNO data.
- ⁴ ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, by combining the four phases of the Super-Kamiokande solar data.
- ⁵ ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using the Super-Kamiokande-IV data.
- ⁶ FORERO 14 performs a global fit to Δm_{21}^2 using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.
- ⁷ GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(7.50^{+0.19}_{-0.17}) \times 10^{-5} \text{ eV}^2$ for normal and $(7.50^{+0.18}_{-0.17}) \times 10^{-5} \text{ eV}^2$ for inverted mass ordering.
- ⁸ AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.
- ⁹ AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active ^8B neutrino flux and energy-dependent ν_e survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and ^7Be (BELLINI 11A) rates, and ^8B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08), and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.
- ¹⁰ AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.45 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data.
- ¹¹ AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.45 \times 10^{-3} \text{ eV}^2$, using global solar neutrino and KamLAND data (GANDO 11). *CPT* invariance is assumed.
- ¹² GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming *CPT* invariance. Supersedes GANDO 11.
- ¹³ GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.
- ¹⁴ ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, GALLEX/GNO, SAGE, and KamLAND data. *CPT* invariance is assumed.
- ¹⁵ ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, GALLEX/GNO, and SAGE data.
- ¹⁶ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4 \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and *CPT* invariance are assumed.
- ¹⁷ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4 \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.
- ¹⁸ BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^8B flux was left free. *CPT* invariance is assumed.
- ¹⁹ BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^8B flux was left free.
- ²⁰ GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.
- ²¹ GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Supersedes ABE 08a.
- ²² AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08a), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).
- ²³ AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08a). *CPT* invariance is assumed.
- ²⁴ AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.
- ²⁵ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data and KamLAND data (ABE 08a). *CPT* invariance is assumed.
- ²⁶ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data.
- ²⁷ ABE 08a obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for Δm_{21}^2 and $\tan^2\theta_{12}$, using KamLAND data only. Superseded by GANDO 11.
- ²⁸ ABE 08a obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO χ^2 -map, and solar flux data. *CPT* invariance is assumed. Superseded by GANDO 11.
- ²⁹ AHARMIM 08 obtained this result by a two-neutrino oscillation analysis using all solar neutrino data including those of Borexino (ARPESELLA 08a) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08a). *CPT* invariance is assumed.
- ³⁰ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed.
- ³¹ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02b), and KamLAND (ARAKI 05) experiments. *CPT* invariance is assumed.
- ³² HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data.
- ³³ HOSAKA 06 obtained this result from the consistency between the observed and expected day-night flux asymmetry amplitude. The listed 68% CL range is derived from the 1σ boundary of the amplitude fit to the data. Oscillation parameters are constrained to be in the LMA region. The mixing angle is fixed at $\tan^2\theta = 0.44$ because the fit depends only very weakly on it.
- ³⁴ AHARMIM 05a obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed. AHARMIM 05a also quotes $\Delta(m^2) = (8.0^{+0.6}_{-0.4}) \times 10^{-5} \text{ eV}^2$ as the error enveloping the 68% CL two-dimensional region.
- ³⁵ AHARMIM 05a obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05a. AHARMIM 05a also quotes $\Delta(m^2) = (6.5^{+4.4}_{-2.3}) \times 10^{-5} \text{ eV}^2$ as the error enveloping the 68% CL two-dimensional region.
- ³⁶ ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. *CPT* invariance is assumed. The 1σ error shown here is provided by the KamLAND collaboration. The error quoted in ARAKI 05, $\Delta(m^2) = (7.9^{+0.6}_{-0.5}) \times 10^{-5}$, envelops the 68% CL two-dimensional region.
- ³⁷ AHMED 04a obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04a also quotes $\Delta(m^2) = (7.1^{+1.2}_{-0.6}) \times 10^{-5} \text{ eV}^2$ as the error enveloping the 68% CL two-dimensional region.
- ³⁸ AHMED 04a obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04a. The best-fit point is $\Delta(m^2) = 6.5 \times 10^{-5} \text{ eV}^2$, $\tan^2\theta = 0.40$ ($\sin^2 2\theta = 0.82$).
- ³⁹ SMY 04 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.
- ⁴⁰ SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The 1σ errors are read from Fig. 6(a) of SMY 04.
- ⁴¹ SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data. The 1σ errors are read from Fig. 6(a) of SMY 04.
- ⁴² AHMAD 02b obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02b. The best fit point is $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$ and $\tan\theta = 0.34$ ($\sin^2 2\theta = 0.76$).
- ⁴³ FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$ and $\tan^2\theta = 0.38$ ($\sin^2 2\theta = 0.80$).

 $\sin^2(\theta_{23})$

The reported limits below correspond to the projection onto the $\sin^2(\theta_{23})$ axis of the 90% CL contours in the $\sin^2(\theta_{23}) - \Delta m_{32}^2$ plane presented by the authors. Unless otherwise specified, the limits are 90% CL and the reported uncertainties are 68% CL.

If an experiment reports $\sin^2(2\theta_{23})$ we convert the value to $\sin^2(\theta_{23})$.

Neutrino Mixing

0.49	+0.30 -0.28	AGAFONOVA	19	OPER	0.24 to 0.76	⁵³ HATAKEYAMA 98	KAMI	Kamiokande	1 ACERO 19 is based on a sample size of 12.33×10^{20} protons on target. The fit combines both antineutrino and neutrino data to extract the oscillation parameters. The results favor the normal mass ordering by 1.9σ and θ_{23} values in octant II by 1.6σ . Supersedes ACERO 18.		
0.50	+0.20 -0.19	⁹ ALBERT	19	ANTR	Atmospheric ν , deep sea telescope	0.20 to 0.80	⁵⁴ FUKUDA	94	KAMI	Kamiokande	2 Errors are from normal mass ordering and θ_{13} octant II fits.
0.587	+0.036 -0.069	¹⁰ ABE	18B	SKAM	3ν osc: normal mass ordering, θ_{13} free						3 AARTSEN 18A uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 18A also reports the best fit result for the inverted mass ordering as $\Delta m_{32}^2 = -2.32 \times 10^{-3} \text{ eV}^2$ and $\sin^2(\theta_{23}) = 0.51$. Uncertainties for the inverted mass ordering fits were not provided. Supersedes AARTSEN 15A.
0.551	+0.044 -0.075	¹⁰ ABE	18B	SKAM	3ν osc: inverted mass ordering, θ_{13} free						4 ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, Δm_{21}^2 , $\sin^2(\theta_{23})$, and δ , while the solar parameters and $\sin^2(\theta_{13})$ are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$, $\sin^2(\theta_{12}) = 0.304 \pm 0.014$, and $\sin^2(\theta_{13}) = 0.0219 \pm 0.0012$.
0.56	± 0.04	¹¹ ACERO	18	NOVA	Normal mass order; octant II for θ_{23}						5 ABE 18g data prefers normal mass ordering is with a posterior probability of 87%. Supersedes ABE 17F.
0.47	± 0.04	¹¹ ACERO	18	NOVA	Normal mass order; octant I for θ_{23}						6 ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the ν_μ disappearance and ν_e appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions. The best fit is for first θ_{23} octant and inverted mass ordering.
0.547	+0.020 -0.030	DE-SALAS	18	FIT	Normal mass ordering, global fit						7 AARTSEN 20 uses the data taken between May 2012 and April 2014 with the low-energy subdetector DeepCore of the IceCube neutrino telescope. The reconstructed energy range is between 4 (5) and 90 (80) GeV for the main (confirmatory) analysis. Though the observed best-fit is in the lower octant for both mass orderings, a substantial range of $\sin^2(\theta_{23}) > 0.5$ is still compatible with the observed data for both mass orderings.
0.551	+0.018 -0.030	DE-SALAS	18	FIT	Inverted mass order, global fit						8 AARTSEN 19c uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy sub-detector DeepCore of the IceCube neutrino telescope. AARTSEN 19c adopts looser event selection criteria to prioritize the efficiency of selecting neutrino events, different from tighter event selection criteria which closely follow the criteria used by AARTSEN 18A to measure the ν_μ disappearance.
0.532	+0.061 -0.087	¹² ABE	17A	T2K	Normal mass ordering						9 ALBERT 19 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2016 (2830 days of total live time). Supersedes ADRIAN-MARTINEZ 12.
0.534	+0.061 -0.087	¹² ABE	17A	T2K	Inverted mass ordering						10 ABE 18b uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm_{21}^2 , $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and δ , while the solar parameters are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ and $\sin^2\theta_{12} = 0.304 \pm 0.014$.
0.51	+0.08 -0.07	ABE	17C	T2K	Normal mass ordering with neutrinos						11 ACERO 18 performs a joint fit to the data for ν_μ disappearance and ν_e appearance. The overall best fit favors normal mass ordering and θ_{23} in octant II. No 1σ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.
0.42	+0.25 -0.07	ABE	17C	T2K	Normal mass ordering with antineutrinos						12 Errors are from the projections of the 68% contour on 2D plot of Δm^2 versus $\sin^2(\theta_{23})$. ABE 17f supersedes ABE 17A. Superseded by ABE 18g.
0.52	+0.075 -0.09	ABE	17C	T2K	normal mass ordering with neutrinos and antineutrinos						13 Superseded by ACERO 18.
0.55	+0.05 -0.09	¹² ABE	17F	T2K	Normal mass ordering						14 ABE 16d reports oscillation results using $\bar{\nu}_\mu$ disappearance in an off-axis beam.
0.55	+0.05 -0.08	¹² ABE	17F	T2K	Inverted mass ordering						15 ADAMSON 16A obtains $\sin^2(\theta_{23})$ in the 68% C.L. range [0.38, 0.65] ([0.37, 0.64]), with two statistically degenerate best-fit values of 0.44 and 0.59 (0.44 and 0.59) for normal (inverted) mass ordering. Superseded by ADAMSON 17A.
0.404	+0.022 -0.030	¹³ ADAMSON	17A	NOVA	Normal mass ordering; octant I for θ_{23}						16 AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Superseded by AARTSEN 18A.
0.624	+0.022 -0.030	¹³ ADAMSON	17A	NOVA	Normal mass ordering; octant II for θ_{23}						17 ABE 14 results are based on ν_μ disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. Superseded by ABE 17A.
0.398	+0.030 -0.022	¹³ ADAMSON	17A	NOVA	Inverted mass ordering; octant I for θ_{23}						18 FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.
0.618	+0.022 -0.030	¹³ ADAMSON	17A	NOVA	Inverted mass ordering; octant II for θ_{23}						19 GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 0.433–0.496 or 0.530–0.594 for normal and 0.514–0.612 for inverted mass ordering.
0.45	+0.19 -0.07	¹⁴ ABE	16D	T2K	3ν osc; normal mass ordering; $\bar{\nu}$ beam						20 AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.
0.38	to 0.65	¹⁵ ADAMSON	16A	NOVA	normal mass ordering						21 The best fit value is $\sin^2(\theta_{23}) = 0.514 \pm 0.082$. Superseded by ABE 14.
0.37	to 0.64	¹⁵ ADAMSON	16A	NOVA	Inverted mass ordering						22 ADAMSON 13B obtained this result from ν_μ and $\bar{\nu}_\mu$ disappearance using ν_μ (10.71×10^{20} POT) and $\bar{\nu}_\mu$ (3.36×10^{20} POT) beams, and atmospheric (37.88kton-years) data from MINOS. The fit assumed two-flavor neutrino hypothesis and identical ν_μ and $\bar{\nu}_\mu$ oscillation parameters. Superseded by ADAMSON 14.
0.53	+0.09 -0.12	¹⁶ AARTSEN	15A	ICCB	Normal mass ordering						23 ABE 12a obtained this result by a two-neutrino oscillation analysis. The best-fit point is $\sin^2(2\theta_{23}) = 0.98$.
0.51	+0.09 -0.11	¹⁶ AARTSEN	15A	ICCB	Inverted mass ordering						24 ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos. The best fit value is $\sin^2(2\theta_{23}) = 0.95^{+0.10}_{-0.11} \pm 0.01$.
0.514	+0.055 -0.056	¹⁷ ABE	14	T2K	3ν osc.; normal mass ordering						25 ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.
0.511	+0.055	¹⁷ ABE	14	T2K	3ν osc.; inverted mass ordering						26 The best fit point is $\Delta m^2 = 0.0019 \text{ eV}^2$ and $\sin^2 2\theta = 0.99$. The 90% single-parameter confidence interval at the best fit point is $\sin^2 2\theta > 0.86$.
0.567	+0.032 -0.128	¹⁸ FORERO	14	FIT	Normal mass ordering						27 The data are separated into pure samples of ν_s and $\bar{\nu}_s$, and separate oscillation parameters for ν_s and $\bar{\nu}_s$ are fit to the data. The best fit point is $(\Delta m^2, \sin^2 2\theta) = (0.0022 \text{ eV}^2, 0.99)$ and $(\Delta \bar{m}^2, \sin^2 2\bar{\theta}) = (0.0016 \text{ eV}^2, 1.00)$. The quoted result is taken from the

Neutrino Mixing

- 90% C.L. contour in the $(\Delta m^2, \sin^2 2\theta)$ plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.
- ²⁸ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time). Superseded by ALBERT 19.
- ²⁹ABE 11c obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data. ABE 11c also reported results under a two-neutrino disappearance model with separate mixing parameters between ν and $\bar{\nu}$, and obtained $\sin^2 2\theta > 0.93$ for ν and $\sin^2 2\theta > 0.83$ for $\bar{\nu}$ at 90% C.L.
- ³⁰ADAMSON 11b obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with 1.71×10^{20} protons on target. This result is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.
- ³¹WENDELL 10 obtained this result ($\sin^2 \theta_{23} = 0.407\text{--}0.583$) by a three-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data, assuming $\theta_{13} = 0$ but including the solar oscillation parameters Δm_{21}^2 and $\sin^2 \theta_{12}$ in the fit.
- ³²WENDELL 10 obtained this result ($\sin^2 \theta_{23} = 0.43\text{--}0.61$) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2 = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06a result.
- ³³WENDELL 10 obtained this result ($\sin^2 \theta_{23} = 0.44\text{--}0.63$) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2 = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06a result.
- ³⁴ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- ³⁵Supersedes ALIU 05.
- ³⁶MICHAEL 06 best fit is for maximal mixing. See also ADAMSON 08.
- ³⁷The best fit is for maximal mixing.
- ³⁸ALLISON 05 result is based upon atmospheric neutrino interactions including upward-stopping muons, with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017 \text{ eV}^2$ and $\sin^2(2\theta) = 0.97$.
- ³⁹ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period.
- ⁴⁰AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$, N_{low} and N_{high} , and the numbers of InDown + UpStop and InUp events. Here, N_{low} and N_{high} are the number of events with reconstructed neutrino energies $< 30 \text{ GeV}$ and $> 130 \text{ GeV}$, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for maximal mixing.
- ⁴¹ASHIE 04 obtained this result from the $L(\text{flight length})/E(\text{estimated neutrino energy})$ distribution of ν_μ disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data.
- ⁴²There are several islands of allowed region from this K2K analysis, extending to high values of Δm^2 . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for maximal mixing.
- ⁴³AMBROSIO 03 obtained this result on the basis of the ratio $R = N_{low}/N_{high}$, where N_{low} and N_{high} are the number of upward through-going muon events with reconstructed neutrino energy $< 30 \text{ GeV}$ and $> 130 \text{ GeV}$, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits.
- ⁴⁴AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is to maximal mixing.
- ⁴⁵SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection μ flavor sample while the e -flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is $\sin^2(2\theta) = 0.97$.
- ⁴⁶AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits. The best fit is for maximal mixing.
- ⁴⁷AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$. See the previous footnote.
- ⁴⁸FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_\mu > 1.6 \text{ GeV}$, the observed flux is $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is $\sin^2(2\theta) = 0.95$.
- ⁴⁹FUKUDA 99b obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. This is compared to the expected flux of $(0.73 \pm 0.16 (\text{theoretical error})) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is to maximal mixing.
- ⁵⁰FUKUDA 99d obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is to maximal mixing.
- ⁵¹FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for maximal mixing.
- ⁵²HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_\mu > 1.6 \text{ GeV}$, the observed flux of upward through-going muons is $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times$

$10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. This is compared to the expected flux of $(2.46 \pm 0.54 (\text{theoretical error})) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is for maximal mixing.

- ⁵³HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is $\sin^2(2\theta) = 0.95$.

- ⁵⁴FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for maximal mixing.

 Δm_{32}^2

The sign of Δm_{32}^2 is not known at this time. If given, values are shown separately for the normal and inverted mass ordering. Unless otherwise specified, the ranges below correspond to the projection onto the Δm_{32}^2 axis of the 90% CL contours in the $\sin^2(2\theta_{23}) - \Delta m_{32}^2$ plane presented by the authors. If uncertainties are reported with the value, they correspond to one standard deviation uncertainty.

1 ACERO 19 is based on a sample size of 12.33×10^{20} protons on target. The fit combines both antineutrino and neutrino data to extract the oscillation parameters. The results favor the normal mass ordering by 1.9σ and θ_{23} values in octant II by 1.6σ . Supersedes ACERO 18.

2 AARTSEN 18A uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 18A also reports the best fit values for the inverted mass ordering as $\Delta m_{32}^2 = -2.32 \times 10^{-3} \text{ eV}^2$ and $\sin^2(\theta_{23}) = 0.51$. Uncertainties for the inverted mass ordering fits were not provided. Supersedes AARTSEN 15A.

3 ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, Δm_{32}^2 , $\sin^2(\theta_{23})$, and δ , while the solar parameters and $\sin^2(\theta_{13})$ are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$, $\sin^2(\theta_{12}) = 0.304 \pm 0.014$, and $\sin^2(\theta_{13}) = 0.0219 \pm 0.0012$.

4 ABE 18C data prefers normal ordering with a posterior probability of 87%. Supersedes ABE 17F.

5 ABE 18C reports $\Delta m_{13}^2 = (2.432 \pm 0.070) \times 10^{-3} \text{ eV}^2$ for inverted mass ordering. We convert to Δm_{32}^2 using PDG 18 value of $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$.

6 ADEY 18A reports results from analysis of 1958 days of data taking with the Daya-Bay experiment, with $3.9 \times 10^6 \bar{\nu}_e$ candidates. The fit to the data gives $\Delta m_{ee}^2 = (2.522^{+0.068}_{-0.070}) \times 10^{-3} \text{ eV}^2$. Solar oscillation parameters are fixed in the analysis using the global averages, $\sin^2(\theta_{12}) = 0.307^{+0.013}_{-0.012}$, $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$, from PDG 18. Supersedes AN 17A.

7 BAK 18 reports results of the RENO experiment using about 2200 live-days of data taken with detectors placed at 410.6 and 1445.7 m from reactors of the Hanbit Nuclear Power Plant. We convert the results to Δm_{32}^2 using the PDG 18 values of $\sin^2\theta_{12} = 0.307^{+0.013}_{-0.012}$ and $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$. Supersedes SEO 18.

8 ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the analysis combines the ν_μ disappearance and ν_e appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions.

9 AARTSEN 19C uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy sub-detector DeepCore of the IceCube neutrino telescope. AARTSEN 19C adopts looser event selection criteria to prioritize the efficiency of selecting neutrino events, different from tighter event selection criteria which closely follow the criteria used by AARTSEN 18A to measure the ν_μ disappearance.

10 ALBERT 19 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2016 (2830 days of total live time). Supersedes ADRIAN-MARTINEZ 12.

11 ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm_{32}^2 , $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and δ , while the solar parameters are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ and $\sin^2\theta_{12} = 0.304 \pm 0.014$.

12 ACERO 18 performs a joint fit to the data for ν_μ disappearance and ν_e appearance. The overall best fit favors normal mass ordering and θ_{23} in octant II. No 1σ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.

13 The error for octant I is taken from the result for octant II.

14 AGAFONOVA 18 assumes maximal θ_{23} mixing.

15 SEO 18 reports result of the RENO experiment from a rate and shape analysis of 500 days of data. A simultaneous fit to θ_{13} and Δm_{ee}^2 yields $\Delta m_{ee}^2 = (2.62^{+0.21+0.12}_{-0.23-0.13}) \times 10^{-3} \text{ eV}^2$. We convert the results to Δm_{32}^2 using the PDG 18 values of $\sin^2\theta_{12}$ and Δm_{21}^2 . SEO 18 is a detailed description of the results published in CHOI 16, which it supersedes. Superseded by BAK 18.

16 ABE 17F confidence intervals are obtained using a frequentist analysis including θ_{13} constraint from reactor experiments. Bayesian intervals based on Markov Chain Monte Carlo method are also provided by the authors. Superseded by ABE 18C.

17 Superseded by ACERO 18.

18 AN 17A report results from combined rate and spectral shape analysis of 1230 days of data taken with the Daya Bay reactor experiment. The data set contains more than 2.5×10^6 inverse beta-decay events with neutron capture on Gd. The fit to the data gives $\Delta_{ee}^2 = (2.50 \pm 0.06 \pm 0.06) \times 10^{-3} \text{ eV}^2$. Superseded by ADEY 18A.

19 ABE 16D reports oscillation results using $\bar{\nu}_\mu$ disappearance in an off-axis beam.

20 Superseded by ADAMSON 17A.

21 CHOI 16 reports result of the RENO experiment from a rate and shape analysis of 500 days of data. A simultaneous fit to θ_{13} and Δm_{ee}^2 yields $\Delta m_{ee}^2 = (2.62^{+0.21+0.12}_{-0.23-0.13}) \times 10^{-3} \text{ eV}^2$. We convert the results to Δm_{32}^2 using PDG 18 values of $\sin^2(\theta_{12})$ and Δm_{21}^2 .

22 AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurements with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Superseded by AARTSEN 18A.

23 AGAFONOVA 15A result is based on $5 \nu_\mu \rightarrow \nu_\tau$ appearance candidates with an expected background of 0.25 ± 0.05 events. The best fit is for $\Delta m_{32}^2 = 3.3 \times 10^{-3} \text{ eV}^2$.

24 AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine prompt energy spectra. The results correspond to the exposure of $6.9 \times 10^5 \text{ GW}_{th}\text{-ton-days}$. They derive $\Delta m_{ee}^2 = (2.42 \pm 0.11) \times 10^{-3} \text{ eV}^2$. Assuming the normal (inverted) ordering, the fitted $\Delta m_{32}^2 = (2.37 \pm 0.11) \times 10^{-3} ((2.47 \pm 0.11) \times 10^{-3}) \text{ eV}^2$. Superseded by AN 17A.

25 ABE 14 results are based on ν_μ disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. In ABE 14 the inverted mass ordering result is reported as $\Delta m_{13}^2 = (2.48 \pm 0.10) \times 10^{-3} \text{ eV}^2$ which we converted to Δm_{32}^2 by adding PDG 14 value of $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$. Superseded by ABE 17C.

26 AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine prompt energy spectra and derive $\Delta m_{ee}^2 = (2.59^{+0.19}_{-0.20}) \times 10^{-3} \text{ eV}^2$. Assuming the normal (inverted) ordering, the fitted $\Delta m_{32}^2 = (2.54^{+0.19}_{-0.20}) \times 10^{-3} ((2.64^{+0.19}_{-0.20}) \times 10^{-3}) \text{ eV}^2$. Superseded by AN 15.

27 FORERO 14 performs a global fit to Δm_{31}^2 using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

28 GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(2.460 \pm 0.046) \times 10^{-3} \text{ eV}^2$ for normal and $(2.445^{+0.047}_{-0.045}) \times 10^{-3} \text{ eV}^2$ for inverted mass ordering.

29 The value for normal mass ordering is actually a measurement of Δm_{31}^2 which differs from Δm_{32}^2 by a much smaller value of Δm_{21}^2 .

30 AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.

Lepton Particle Listings

Neutrino Mixing

- ³¹ Based on the observation of 58 ν_μ events with 205 ± 17 (syst) expected in the absence of neutrino oscillations. Superseded by ABE 14.
- ³² ADAMSON 13B obtained this result from ν_μ and $\bar{\nu}_\mu$ disappearance using ν_μ (10.71×10^{20} POT) and $\bar{\nu}_\mu$ (3.36×10^{20} POT) beams, and atmospheric (37.88 kton-years) data from MINOS. The fit assumed two-flavor neutrino hypothesis and identical ν_μ and $\bar{\nu}_\mu$ oscillation parameters.
- ³³ ABE 12A obtained this result by a two-neutrino oscillation analysis. The best-fit point is $\Delta m_{32}^2 = 2.65 \times 10^{-3} \text{ eV}^2$.
- ³⁴ ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos.
- ³⁵ ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.
- ³⁶ The 90% single-parameter confidence interval at the best fit point is $\Delta m^2 = 0.0019 \pm 0.0004 \text{ eV}^2$.
- ³⁷ The data are separated into pure samples of ν_s and $\bar{\nu}_s$, and separate oscillation parameters for ν_s and $\bar{\nu}_s$ are fit to the data. The best fit point is $(\Delta m^2, \sin^2 2\theta) = (0.0022 \text{ eV}^2, 0.99)$ and $(\Delta \bar{m}^2, \sin^2 2\bar{\theta}) = (0.0016 \text{ eV}^2, 1.00)$. The quoted result is taken from the 90% C.L. contour in the $(\Delta m^2, \sin^2 2\theta)$ plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.
- ³⁸ ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time). Superseded by ALBERT 19
- ³⁹ ABE 11c obtained this result by a two-neutrino oscillation analysis with separate mixing parameters between neutrinos and antineutrinos, using the Super-Kamiokande-I+II+III atmospheric neutrino data. The corresponding 90% CL neutrino oscillation parameter range obtained from this analysis is $\Delta m^2 = 1.7\text{--}3.0 \times 10^{-3} \text{ eV}^2$.
- ⁴⁰ ADAMSON 11B obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with 1.71×10^{20} protons on target. This result is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.
- ⁴¹ ADAMSON 11c obtains this result based on a study of antineutrinos in a neutrino beam and assumes maximal mixing in the two-flavor approximation.
- ⁴² WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2 = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- ⁴³ ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- ⁴⁴ The best fit in the physical region is for $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$.
- ⁴⁵ Supersedes ALIU 05.
- ⁴⁶ MICHAEL 06 best fit is $2.74 \times 10^{-3} \text{ eV}^2$. See also ADAMSON 08.
- ⁴⁷ ALLISON 05 result is based on an atmospheric neutrino observation with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017 \text{ eV}^2$ and $\sin^2 2\theta = 0.97$.
- ⁴⁸ ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period. The best fit is for $\Delta m^2 = 2.1 \times 10^{-3} \text{ eV}^2$.
- ⁴⁹ AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$, N_{low} and N_{high} , and the numbers of InDown + UpStop and InUp events. Here, N_{low} and N_{high} are the number of events with reconstructed neutrino energies $< 30 \text{ GeV}$ and $> 130 \text{ GeV}$, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for $\Delta m^2 = 2.3 \times 10^{-3} \text{ eV}^2$.
- ⁵⁰ ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of ν_μ disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data. The best fit is for $\Delta m^2 = 2.4 \times 10^{-3} \text{ eV}^2$.
- ⁵¹ There are several islands of allowed region from this K2K analysis, extending to high values of Δm^2 . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$.
- ⁵² AMBROSIO 03 obtained this result on the basis of the ratio $R = N_{low}/N_{high}$, where N_{low} and N_{high} are the number of upward through-going muon events with reconstructed neutrino energy $< 30 \text{ GeV}$ and $> 130 \text{ GeV}$, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3} \text{ eV}^2$.
- ⁵³ AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3} \text{ eV}^2$.
- ⁵⁴ SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection μ flavor sample while the e -flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is for $\Delta m^2 = 5.2 \times 10^{-3} \text{ eV}^2$.
- ⁵⁵ AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.
- ⁵⁶ AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$. See the previous footnote.
- ⁵⁷ FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_\mu > 1.6 \text{ GeV}$, the observed flux is $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is for $\Delta m^2 = 5.9 \times 10^{-3} \text{ eV}^2$.

- ⁵⁸ FUKUDA 99b obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. This is compared to the expected flux of $(0.73 \pm 0.16 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is for $\Delta m^2 = 3.9 \times 10^{-3} \text{ eV}^2$.
- ⁵⁹ FUKUDA 99d obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is for $\Delta m^2 = 3.1 \times 10^{-3} \text{ eV}^2$.
- ⁶⁰ FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for $\Delta m^2 = 2.2 \times 10^{-3} \text{ eV}^2$.
- ⁶¹ HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_\mu > 1.6 \text{ GeV}$, the observed flux of upward through-going muons is $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. This is compared to the expected flux of $(2.46 \pm 0.54 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is for $\Delta m^2 = 2.2 \times 10^{-3} \text{ eV}^2$.
- ⁶² HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is for $\Delta m^2 = 13 \times 10^{-3} \text{ eV}^2$.
- ⁶³ FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for $\Delta m^2 = 16 \times 10^{-3} \text{ eV}^2$.

$\sin^2(\theta_{13})$

At present time direct measurements of $\sin^2(\theta_{13})$ are derived from the reactor $\bar{\nu}_e$ disappearance at distances corresponding to the Δm_{32}^2 value, i.e. $L \sim 1\text{km}$. Alternatively, limits can also be obtained from the analysis of the solar neutrino data and accelerator-based $\nu_\mu \rightarrow \nu_e$ experiments.

If an experiment reports $\sin^2(2\theta_{13})$ we convert the value to $\sin^2(\theta_{13})$.

- 1 ADEY 18A reports results from analysis of 1958 days of data taking with the Daya-Bay experiment, with 3.9×10^6 $\bar{\nu}_e$ candidates. The fit to the data gives $\Delta m_{ee}^2 = (2.522 \pm 0.068 \pm 0.070) \times 10^{-3} \text{ eV}^2$. Solar oscillation parameters are fixed in the analysis using the global averages, $\sin^2(\theta_{12}) = 0.307^{+0.013}_{-0.012}$, $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$, from PDG 18. Supersedes AN 17A.
- 2 BAK 18 reports results of the RENO experiment using about 2200 live-days of data taken with detectors placed at 410.6 and 1445.7 m from reactors of the Hanbit Nuclear Power Plant. Supersedes SEO 18.
- 3 ABE 16B uses 455.57 live days of data from a detector 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2\theta_{13})$. This analysis uses 7.15 reactor-off days for constraining backgrounds. A rate and shape analysis is performed on combined neutron captures on H and Gd. Supersedes ABE 14H and ABE 13C.
- 4 AN 16A uses data from the eight antineutrino detectors (404 days) and six antineutrino detectors (217 days) runs to determine the mixing parameter $\sin^2(2\theta_{13})$ using the neutron capture on H only. Supersedes AN 14B.
- 5 ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm_{32}^2 , $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and δ , while the solar parameters are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ and $\sin^2\theta_{12} = 0.304 \pm 0.014$.
- 6 AGAFONOVA 18A reports $\sin^2(2\theta_{13}) < 0.43$ at 90% C.L. The result on the sterile neutrino search in the context of 3+1 model is also reported. A 90% C.L. upper limit on $\sin^2(2\theta_{\mu e}) = 0.021$ for $\Delta m_{41}^2 \geq 0.1 \text{ eV}^2$ is set.
- 7 SEO 18 reports results of the RENO experiment using about 500 days of data, performing a rate and shape analysis. Compared to AHN 12, a significant reduction of the systematic uncertainties is reported. A 3% excess of events near 5 MeV of the prompt energy is observed. SEO 18 is a detailed description of the results published in CHOI 16, which it supersedes. Supersedes by BAK 18.
- 8 Using T2K data only. For inverted mass ordering, all values of θ_{13} are ruled out at 68% CL.
- 9 AN 17A reports results from combined rate and spectral shape analysis of 1230 days of data taken with the Daya Bay reactor experiment. The data set contains more than 2.5×10^6 inverse beta-decay events with neutron capture on Gd. A simultaneous fit to θ_{13} and Δm_{ee}^2 is performed. Supersedes by ADEY 18A.
- 10 CHOI 16 reports results of the RENO experiment using about 500 days of data, performing a rate and shape analysis. Compared to AHN 12, a significant reduction of the systematic uncertainties is reported. A 3% excess of events near 5 MeV of the prompt energy is observed. Supersedes AHN 12.
- 11 AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine the mixing angle θ_{13} using the $\bar{\nu}_e$ observed interaction rates with neutron capture on Gd and energy spectra. The result corresponds to the exposure of $6.9 \times 10^5 \text{ GW}_{th}$ -ton-days. Supersedes by AN 17A.
- 12 ABE 14A uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2\theta_{13})$. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A "rate-modulation" analysis is performed. Supersedes ABE 12B.

- 13 ABE 14C result is for ν_e appearance and assumes $\Delta m_{32}^2 = 2.4 \times 10^{-3} \text{ eV}^2$, $\sin^2(\theta_{23}) = 0.5$, and $\delta = 0$.
- 14 ABE 14H uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2\theta_{13})$. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A rate and shape analysis is performed. Superseded by ABE 16B.
- 15 AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine the mixing angle θ_{13} using the $\bar{\nu}_e$ observed interaction rates with neutron capture on Gd and energy spectra. Supersedes AN 13 and superseded by AN 15.
- 16 AN 14B uses six identical anti-neutrino detectors with flux-weighted baselines of ~ 500 m and ~ 1.6 km to six power reactors. This rate analysis uses a 217-day data set and neutron capture on protons (not Gd) only. $\Delta m_{31}^2 = 2.32 \times 10^{-3} \text{ eV}^2$ is assumed. Superseded by AN 16A.
- 17 FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.
- 18 GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(2.18^{+0.10}_{-0.11}) \times 10^{-2} \text{ eV}^2$ for normal and $(2.19^{+0.12}_{-0.10}) \times 10^{-2} \text{ eV}^2$ for inverted mass ordering.
- 19 ABE 13C uses delayed neutron capture on hydrogen instead of on Gd used previously. The physical volume is thus three times larger. The fit is based on the rate and shape analysis as in ABE 12B. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 16B.
- 20 ABE 13E assumes maximal θ_{23} mixing and CP phase $\delta = 0$.
- 21 ADAMSON 13A results obtained from ν_e appearance, assuming $\delta = 0$, and $\sin^2(2\theta_{23}) = 0.957$.
- 22 AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.45 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data. AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active ^8B neutrino flux and energy-dependent ν_e survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and ^7Be (BELLINI 11A) rates, and ^8B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra. AHARMIM 13 also reported a result combining global solar and KamLAND data, which is $\sin^2(2\theta_{13}) = (9.1^{+2.9}_{-3.1}) \times 10^{-2}$.
- 23 AN 13 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 498 and 555 m) and the remaining three at the far hall (at the flux averaged distance of 1628 m from all six reactor cores) to determine the $\bar{\nu}_e$ interaction rate ratios. Superseded by AN 14.
- 24 ABE 12 determines the $\bar{\nu}_e$ interaction rate in a single detector, located 1050 m from the cores of two reactors. A rate and shape analysis is performed. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations. The value of $\Delta m_{31}^2 = 2.4 \times 10^{-3} \text{ eV}^2$ is used in the analysis. Superseded by ABE 12B.
- 25 ABE 12B determines the neutrino mixing angle θ_{13} using a single detector, located 1050 m from the cores of two reactors. This result is based on a spectral shape and rate analysis. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 14A.
- 26 AHN 12 uses two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99 m from six reactor cores, to determine the mixing angle θ_{13} . This rate-only analysis excludes the no-oscillation hypothesis at 4.9 standard deviations. The value of $\Delta m_{31}^2 = (2.32^{+0.12}_{-0.08}) \times 10^{-3} \text{ eV}^2$ was assumed in the analysis. Superseded by CHOI 16.
- 27 AN 12 uses six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle θ_{13} using the $\bar{\nu}_e$ observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 5.2 standard deviations. The value of $\Delta m_{31}^2 = (2.32^{+0.12}_{-0.08}) \times 10^{-3} \text{ eV}^2$ was assumed in the analysis. Superseded by AN 13.
- 28 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4 \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. This result implies an upper bound of $\sin^2\theta_{13} < 0.059$ (95% CL) or $\sin^2\theta_{13} < 0.22$ (95% CL). The normal neutrino mass ordering and CPT invariance are assumed.
- 29 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4 \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.
- 30 The quoted limit is for $\Delta m_{32}^2 = 2.4 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the normal mass ordering. For other values of δ , the 68% region spans from 0.03 to 0.25, and the 90% region from 0.02 to 0.32.
- 31 The quoted limit is for $\Delta m_{32}^2 = 2.4 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the inverted mass ordering. For other values of δ , the 68% region spans from 0.04 to 0.30, and the 90% region from 0.02 to 0.39.
- 32 The quoted limit is for $\Delta m_{32}^2 = 2.32 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the normal mass ordering. For other values of δ , the 68% region spans from 0.02 to 0.12, and the 90% region from 0 to 0.16.
- 33 The quoted limit is for $\Delta m_{32}^2 = 2.32 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the inverted mass ordering. For other values of δ , the 68% region spans from 0.02 to 0.16, and the 90% region from 0 to 0.21.
- 34 FOGLI 11 obtained this result from an analysis using the atmospheric, accelerator long baseline, CHOOZ, solar, and KamLAND data. Recently, MUELLER 11 suggested an

Lepton Particle Listings

Neutrino Mixing

- average increase of about 3.5% in normalization of the reactor $\bar{\nu}_e$ fluxes, and using these fluxes, the fitted result becomes 0.10 ± 0.03 .
- ³⁵ GANDO 11 report $\sin^2\theta_{13} = 0.020 \pm 0.016$. This result was obtained with three-neutrino fit using the KamLAND + solar data.
- ³⁶ GANDO 11 report $\sin^2\theta_{13} = 0.032 \pm 0.037$. This result was obtained with three-neutrino fit using the KamLAND data only.
- ³⁷ This result corresponds to the limit of <0.12 at 90% CL for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ , the 90% CL region spans from 0 to 0.16.
- ³⁸ This result corresponds to the limit of <0.20 at 90% CL for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ , the 90% CL region spans from 0 to 0.21.
- ³⁹ AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), CL (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08a), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).
- ⁴⁰ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data and KamLAND data (ABE 08a). *CPT* invariance is assumed. This result implies an upper bound of $\sin^2\theta_{13} < 0.057$ (95% CL) or $\sin^2 2\theta_{13} < 0.22$ (95% CL).
- ⁴¹ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data.
- ⁴² WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2 = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06a result.
- ⁴³ The quoted limit is for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ , the 68% CL region spans from 0.02 to 0.26.
- ⁴⁴ The quoted limit is for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ , the 68% CL region spans from 0.04 to 0.34.
- ⁴⁵ FOGLI 08 obtained this result from a global analysis of all neutrino oscillation data, that is, solar + KamLAND + atmospheric + accelerator long baseline + CHOOZ.
- ⁴⁶ FOGLI 08 obtained this result from an analysis using the solar and KamLAND neutrino oscillation data.
- ⁴⁷ FOGLI 08 obtained this result from an analysis using the atmospheric, accelerator long baseline, and CHOOZ neutrino oscillation data.
- ⁴⁸ YAMAMOTO 06 searched for $\nu_\mu \rightarrow \nu_e$ appearance. Assumes $2 \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$. The quoted limit is for $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the one- σ low value for AHN 06a. For the AHN 06a best fit value of $2.8 \times 10^{-3} \text{ eV}^2$, the $\sin^2(2\theta_{13})$ limit is < 0.26 . Supersedes AHN 04.
- ⁴⁹ AHN 04 searched for $\nu_\mu \rightarrow \nu_e$ appearance. Assuming $2 \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$, a limit on $\sin^2(2\theta_{\mu e})$ is converted to a limit on $\sin^2(2\theta_{13})$. The quoted limit is for $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the one- σ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3} \text{ eV}^2$, the $\sin^2(2\theta_{13})$ limit is < 0.30 .
- ⁵⁰ The quoted limit is for $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the 1- σ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3} \text{ eV}^2$, the $\sin^2 2\theta_{13}$ limit is < 0.19 . In this range, the θ_{13} limit is larger for lower values of Δm_{32}^2 , and smaller for higher values of Δm_{32}^2 .
- ⁵¹ The quoted limit is for $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the 1- σ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3} \text{ eV}^2$, the $\sin^2 2\theta_{13}$ limit is < 0.23 .
- ⁵² The quoted limit is for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the central value for ADAMSON 08. For the ADAMSON 08 1- σ low value of $2.30 \times 10^{-3} \text{ eV}^2$, the $\sin^2 2\theta_{13}$ limit is < 0.16 . See also APOLLONIO 03 for a detailed description of the experiment.

CP violating phase

δ , CP violating phase

Measurements of δ come from atmospheric and accelerator experiments looking at ν_e appearance. We encode values between 0 and 2π , though it is equivalent to use $-\pi$ to π .

- ¹ ACERO 19 is based on a sample size of 1.33×10^{20} protons on target with combined antineutrino and neutrino data. Supersedes ACERO 18.
- ² ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, Δm_{32}^2 , $\sin^2\theta_{23}$, and δ , while the solar parameters and $\sin^2\theta_{13}$ are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$, $\sin^2\theta_{12} = 0.304 \pm 0.014$, and $\sin^2\theta_{13} = 0.0219 \pm 0.0012$.
- ³ ABE 18G confidence intervals are marginalized over both mass orderings. Normal order preferred with a posterior probability of 87%. The 1-sigma result for normal mass ordering used in the average was provided by the experiment via private communications. Supersedes ABE 17F.
- ⁴ ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm_{32}^2 , $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and δ , while the solar parameters are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ and $\sin^2\theta_{12} = 0.304 \pm 0.014$.
- ⁵ ACERO 18 performs a joint fit to the data for ν_μ disappearance and ν_e appearance. The overall best fit favors normal mass ordering and θ_{23} in octant II. No 1σ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.
- ⁶ ABE 17F confidence intervals are obtained using a frequentist analysis including θ_{13} constraint from reactor experiments. Bayesian intervals based on Markov Chain Monte Carlo method are also provided by the authors. Superseded by ABE 18G.
- ⁷ Errors are projections of 68% C.L. curve of δ_{CP} vs. $\sin^2\theta_{23}$.
- ⁸ ADAMSON 16 result is based on a data sample with 2.74×10^{20} protons on target. The likelihood-based analysis observed 6 ν_e events with an expected background of 0.99 ± 0.11 events.
- ⁹ ADAMSON 14 result is based on three-flavor formalism and $\theta_{23} > \pi/4$. Likelihood as a function of δ is also shown for the other three combinations of hierarchy and θ_{23} octants; all values of δ are allowed at 90% C.L.
- ¹⁰ GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 1.24–1.94 for normal and 1.15–1.77 for inverted mass ordering.
- ¹¹ ADAMSON 13A result is based on ν_e appearance in MINOS and the calculated $\sin^2(2\theta_{23}) = 0.957$, $\theta_{23} > \pi/4$, and normal mass hierarchy. Likelihood as a function of δ is also shown for the other three combinations of hierarchy and θ_{23} octants; all values of δ are allowed at 90% C.L.

(C) Other neutrino mixing results

The LSND collaboration reported in AGUILAR 01 a signal which is consistent with $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ oscillations. In a three neutrino framework, this would be a measurement of θ_{12} and Δm_{21}^2 . This does not appear to be consistent with most of the other neutrino data. The following listings include results from $\nu_\mu \rightarrow \nu_e$, $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ appearance and ν_μ , $\bar{\nu}_\mu$, ν_e , and $\bar{\nu}_e$ disappearance experiments, and searches for *CPT* violation.

See key on page 999

- 1 AGUILAR-AREVALO 18c result is based on $\nu_\mu \rightarrow \nu_e$ appearance of 460.5 ± 99.0 events; The best fit value is $\Delta m^2 = 0.041$ eV².
- 2 AGUILAR-AREVALO 13A result is based on $\nu_\mu \rightarrow \nu_e$ appearance of 162.0 ± 47.8 events; marginally compatible with twoneutrino oscillations. The best fit value is $\Delta m^2 = 3.14$ eV².
- 3 MAHN 12 is a combined spectral fit of MiniBooNE and SciBooNE neutrino data with the range of Δm^2 up to 25 eV². The best limit is 0.04 at 7 eV².
- 4 AGUILAR 01 is the final analysis of the LSND full data set. Search is made for the $\nu_\mu \rightarrow \nu_e$ oscillations using ν_μ from π^+ decay in flight by observing beam-on electron events from $\nu_e C \rightarrow e^- X$. Present analysis results in 8.1 ± 12.2 ± 1.7 excess events in the 60 < E_e < 200 MeV energy range, corresponding to oscillation probability of 0.10 ± 0.16 ± 0.04%. This is consistent, though less significant, with the previous result of ATHANASSOPOULOS 98, which it supersedes. The present analysis uses selection criteria developed for the decay at rest region, and is less effective in removing the background above 60 MeV than ATHANASSOPOULOS 98.
- 5 ATHANASSOPOULOS 98 is a search for the $\nu_\mu \rightarrow \nu_e$ oscillations using ν_μ from π^+ decay in flight. The 40 observed beam-on electron events are consistent with $\nu_e C \rightarrow e^- X$; the expected background is 21.9 ± 2.1. Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability (0.26 ± 0.10 ± 0.05)%. Although the significance is only 2.3 σ , this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ oscillations from μ^+ decay at rest. See also ATHANASSOPOULOS 98b.
- 6 LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

- 1 AGUILAR-AREVALO 18c result is based on $\nu_\mu \rightarrow \nu_e$ appearance of 460.5 ± 99.0 events; The best fit value is $\sin^2(2\theta) = 0.92$. The quoted limit for the two-neutrino mixing angle θ is valid above $\Delta m^2 = 0.59$ eV².
- 2 AGUILAR-AREVALO 13A result is based on $\nu_\mu \rightarrow \nu_e$ appearance of 162.0 ± 47.8 events; marginally compatible with two neutrino oscillations. The best fit value is $\sin^2(2\theta) = 0.002$.
- 3 ANTONELLO 13 use the ICARUS T600 detector at LNGS and ~ 20 GeV beam of ν_μ from CERN 730 km away to search for an excess of ν_e events. Two events are found with 3.7 ± 0.6 expected from conventional sources. This result excludes some parts of the parameter space expected by LSND. Superseded by ANTONELLO 13A.
- 4 Based on four events with a background of 6.4 ± 0.9 from conventional sources with an average energy of 20 GeV and 730 km from the source of ν_μ .
- 5 MAHN 12 is a combined fit of MiniBooNE and SciBooNE neutrino data.
- 6 The limit is $\sin^2 2\theta < 0.9 \times 10^{-3}$ at $\Delta m^2 = 2$ eV². That value of Δm^2 corresponds to the smallest mixing angle consistent with the reported signal from LSND in AGUILAR 01.
- 7 The limit becomes $\sin^2 2\theta < 0.15$ at $\Delta m^2 = 2.8 \times 10^{-3}$ eV², the best-fit value of the ν_μ disappearance analysis in K2K.
- 8 AGUILAR 01 is the final analysis of the LSND full data set of the search for the $\nu_\mu \rightarrow \nu_e$ oscillations. See footnote in preceding table for further details.
- 9 ATHANASSOPOULOS 98 report (0.26 ± 0.10 ± 0.05)% for the oscillation probability; the value of $\sin^2 2\theta$ for large Δm^2 is deduced from this probability. See footnote in

preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate $\sin^2 2\theta$ and Δm^2 . See also ATHANASSOPOULOS 98b.

- 10 LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.
- 11 VILAIN 94c limit derived by combining the ν_μ and $\bar{\nu}_\mu$ data assuming CP conservation.

- 1 Based on $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ appearance of 78.4 ± 28.5 events. The best fit values are $\Delta m^2 = 0.043$ eV² and $\sin^2 2\theta = 0.88$.
- 2 CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.
- 3 This value is for a two neutrino oscillation analysis for excess antineutrino events with E_ν > 475 MeV. The best fit is at 0.07. The allowed region is consistent with LSND reported by AGUILAR 01. Supersedes AGUILAR-AREVALO 09b.
- 4 This value is for a two neutrino oscillation analysis for excess antineutrino events with E_ν > 200 MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. The best fit value is 0.007 for $\Delta(m^2) = 4.4$ eV².
- 5 ARMBRUSTER 02 is the final analysis of the KARMEN 2 data for 17.7 m distance from the ISIS stopped pion and muon neutrino source. It is a search for $\bar{\nu}_e$, detected by the inverse β -decay reaction on protons and ¹²C. 15 candidate events are observed, and 15.8 ± 0.5 background events are expected, hence no oscillation signal is detected. The results exclude large regions of the parameter area favored by the LSND experiment.
- 6 AGUILAR 01 is the final analysis of the LSND full data set. It is a search for $\bar{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly for π^+ decay at rest. $\bar{\nu}_e$ are detected through $\bar{\nu}_e p \rightarrow e^+ n$ (20 < E_{e+} < 60 MeV) in delayed coincidence with $np \rightarrow d\gamma$. Authors observe 87.9 ± 22.4 ± 6.0 total excess events. The observation is attributed to $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ oscillations with the oscillation probability of 0.264 ± 0.067 ± 0.045%, consistent with the previously published result. Taking into account all constraints, the most favored allowed region of oscillation parameters is a band of $\Delta(m^2)$ from 0.2-2.0 eV². Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.
- 7 ATHANASSOPOULOS 96 is a search for $\bar{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly from π^+ decay at rest. $\bar{\nu}_e$ could come from either $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ or $\nu_e \rightarrow \bar{\nu}_e$; our entry assumes the first interpretation. They are detected through $\bar{\nu}_e p \rightarrow e^+ n$ (20 MeV < E_{e+} < 60 MeV) in delayed coincidence with $np \rightarrow d\gamma$. Authors observe 51 ± 20 ± 8 total excess events over an estimated background 12.5 ± 2.9. ATHANASSOPOULOS 96b is a shorter version of this paper.
- 8 ATHANASSOPOULOS 95 error corresponds to the 1.6 σ band in the plot. The expected background is 2.7 ± 0.4 events. Corresponds to an oscillation probability of (0.34 ± 0.20 ± 0.18 ± 0.07)%. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.
- 9 HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ and obtains only upper limits.
- 10 FREEDMAN 93 is a search at LAMPF for $\bar{\nu}_e$ generated from any of the three neutrino types $\nu_\mu, \bar{\nu}_\mu$, and ν_e which come from the beam stop. The $\bar{\nu}_e$'s would be detected by the reaction $\bar{\nu}_e p \rightarrow e^+ n$. FREEDMAN 93 replaces DURKIN 88.

Lepton Particle Listings

Neutrino Mixing

¹ ANTONELLO 13a obtained the limit by assuming $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ oscillation from the $\sim 2\%$ of $\bar{\nu}_\mu$ events contamination in the CNGS beam.

² CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

³ This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 475$ MeV. At 90% CL there is no solution at high $\Delta(m^2)$. The best fit is at maximal mixing. The allowed region is consistent with LSND reported by AGUILAR 01. Supersedes AGUILAR-AREVALO 09b.

⁴ This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 200$ MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. At 90% CL there is no solution at high $\Delta(m^2)$. The best fit value is 0.007 for $\Delta(m^2) = 4.4 \text{ eV}^2$.

⁵ This result is inconclusive with respect to small amplitude mixing suggested by LSND.

⁶ ARMBRUSTER 02 is the final analysis of the KARMEN2 data. See footnote in the preceding table for further details, and the paper for the exclusion plot.

⁷ AGUILAR 01 is the final analysis of the LSND full data set. The deduced oscillation probability is $0.264 \pm 0.067 \pm 0.045\%$; the value of $\sin^2 2\theta$ for large $\Delta(m^2)$ is twice this probability (although these values are excluded by other constraints). See footnote in preceding table for further details, and the paper for a plot showing allowed regions. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

⁸ ATHANASSOPOULOS 96 reports $(0.31 \pm 0.12 \pm 0.05)\%$ for the oscillation probability; the value of $\sin^2 2\theta$ for large $\Delta(m^2)$ should be twice this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions.

⁹ ATHANASSOPOULOS 95 error corresponds to the 1.6σ band in the plot. The expected background is 2.7 ± 0.4 events. Corresponds to an oscillation probability of $(0.34^{+0.20}_{-0.18} \pm 0.07)\%$. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

¹⁰ HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion than the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ and obtains only upper limits.

¹ SEREBROV 19 searches for $\bar{\nu}_e \rightarrow \bar{\nu}_s$ oscillations with baseline 6–12 m with SM-3 research reactor that uses highly enriched ²³⁵U fuel. The spectrum is well described by the $1/L^2$ dependence. However, the shape differs from the theoretical expectations, with the best fit corresponding to $\Delta m_{41}^2 = 7.34 \pm 0.1 \text{ eV}^2$ and $\sin^2(2\theta_{14}) = 0.39 \pm 0.12$ at 3σ significance.

² ALEKSEEV 18 searches for $\bar{\nu}_e \rightarrow \bar{\nu}_s$ oscillations using the DANSS detector at 10.7, 11.2, and 12.7 m from the 3.1 GW_{th} power reactor. The DANSS detector is highly segmented and moveable; the positions are changed usually 3 times a week. The analysis is based on the ratio of the events at top and bottom position; the middle position is used for checks of consistency. The best fit point is at $\Delta m_{41}^2 = 1.4 \text{ eV}^2$ and $\sin^2(2\theta_{14}) = 0.05$ with $\Delta\chi^2 = 13.1$ (statistical errors only) compared to the fit with 3 active neutrinos only. The quoted limit of 0.01 for $\sin^2(2\theta_{14})$ corresponds to $\Delta m_{41}^2 \sim 1.0 \text{ eV}^2$.

³ ALMAZAN 18 searches for the $\bar{\nu}_e \rightarrow \bar{\nu}_s$ oscillations with baseline from 9.4 to 11.1 m from the ILL research reactor with highly enriched ²³⁵U fuel. The STEREO detector consists of six separated cells with Gd loaded scintillator, with 15 m water equivalent overburden. The detected rate is $396.3 \pm 4.7 \bar{\nu}_e/\text{day}$ with signal to background ratio of about 0.9. The reported results corresponds to 66 days of reactor-on. The analysis uses the relative rates normalized to the cell number 1. No indication of the oscillation to the sterile neutrinos is found, the stated limit on $\sin^2(2\theta_{14})$ correspond to $\Delta m_{41}^2 \sim 3.5 \text{ eV}^2$ where the exclusion is maximal.

⁴ ASHENFELTER 18 searches for the $\bar{\nu}_e \rightarrow \bar{\nu}_s$ oscillations at baseline from 6.7 to 9.2 m from the 85 MW research reactor with pure ²³⁵U core. The segmented 4 ton ⁶Li-doped liquid scintillator is operated with about 1 m water equivalent overburden and recorded 25461 ± 283 IBD events. No indication of oscillations into sterile neutrinos was observed. The stated limit for $\sin^2(2\theta_{14})$ is for $\Delta m_{41}^2 \sim 2 \text{ eV}^2$ where the sensitivity is maximal.

⁵ SEREBROV 18A searches for the $\bar{\nu}_e \rightarrow \bar{\nu}_s$ oscillation with baseline 6–12 m from the core of the SM-3 research reactor that uses highly enriched ²³⁵U. They find that oscillations with $\Delta m_{41}^2 \sim 0.7-0.8 \text{ eV}^2$ and $\sin^2(2\theta_{14}) \sim 0.10-0.15$ give better fit to the L and E dependence than the no oscillation scenario. The significance of this is about 2 σ .

⁶ AARTSEN 17B uses three years of upward-going atmospheric neutrino data in the energy range of 10–60 GeV to constrain their disappearance into light sterile neutrinos. The reported limit $\sin^2\theta_{24} < 0.11$ at 90% C.L. is for $\Delta m_{41}^2 = 1.0 \text{ eV}^2$. We convert the result to $\sin^2 2\theta_{24}$ for the listing. AARTSEN 17B also reports $\cos^2\theta_{24} \cdot \sin^2\theta_{34} < 0.15$ at 90% C.L. for $\Delta m_{41}^2 = 1.0 \text{ eV}^2$.

⁷ ABDURASHITOV 17 use the Troitsk nu-mass experiment to search for sterile neutrinos with mass 0.1 - 2 keV. We convert the reported limit from $U_{e4}^2 < 0.002$ to $\sin^2 2\theta_{14} < 0.008$ assume $U_{e4} \sim \sin\theta_{14}$. The stated limit corresponds to the smallest U_{e4}^2 . The exclusion curve begins at U_{e4}^2 of 0.02 for $m_4 = 0.1 \text{ keV}$.

⁸ KO 17 reports on short baseline reactor oscillation search ($\bar{\nu}_e \rightarrow \bar{\nu}_s$), motivated by the so-called "reactor antineutrino anomaly". The experiment is conducted at 23.7 m from the core of unit 5 of the Hanbit Nuclear Power Complex in Korea. The reported limited on $\sin^2(2\theta_{41})$ for sterile neutrinos was determined using the reactor antineutrino spectrum determined by the Daya Bay experiment for Δm_{41}^2 around 0.55 eV^2 where the sensitivity is maximal. A fraction of the parameter space derived from the "reactor antineutrino anomaly" is excluded by this work. Compared to reactor models an event excess is observed at about 5 MeV, in agreement with other experiments.

⁹ AARTSEN 16 use one year of upward-going atmospheric muon neutrino data in the energy range of 320 GeV to 20 TeV to constrain their disappearance into light sterile neutrinos. Sterile neutrinos are expected to produce distinctive zenith distribution for these energies for $0.01 \leq \Delta m^2 \leq 10 \text{ eV}^2$. The stated limit is for $\sin^2 2\theta_{24}$ at Δm^2 around 0.3 eV^2 .

¹⁰ ADAMSON 16b combine the results of AN 16B, ADAMSON 16C, and Bugey-3 reactor experiments to constrain ν_μ to ν_e mixing through oscillations into light sterile neutrinos. The stated limit for $\sin^2 2\theta_{\mu e}$ is at $|\Delta m_{41}^2| = 1.2 \text{ eV}^2$.

¹¹ ADAMSON 16c use the NuMI beam and exposure of 10.56×10^{20} protons on target to search for the oscillation of ν_μ dominated beam into light sterile neutrinos with detectors at 1.04 and 735 km. The reported limit $\sin^2(\theta_{24}) < 0.022$ at 95% C.L. is for $|\Delta m_{41}^2| = 0.5 \text{ eV}^2$. We convert the result to $\sin^2(2\theta_{24})$ for the listing.

¹² AN 16B utilize 621 days of data to place limits on the $\bar{\nu}_e$ disappearance into a light sterile neutrino. The stated limit corresponds to the smallest $\sin^2(2\theta_{14})$ at $|\Delta m_{41}^2| \sim 3 \times 10^{-2} \text{ eV}^2$ (obtained from Figure 3 in AN 16B). The exclusion curve begins at $|\Delta m_{41}^2| \sim 1.5 \times 10^{-4} \text{ eV}^2$ and extends to $\sim 0.25 \text{ eV}^2$. The analysis assumes $\sin^2(2\theta_{12})$

See key on page 999

Lepton Particle Listings
Neutrino Mixing

= 0.846 ± 0.021, Δm₂₁² = (7.53 ± 0.18) × 10⁻⁵ eV², and |Δm₃₂²| = (2.44 ± 0.06) × 10⁻³ eV².

¹³AMBROSIO 01 tested the pure 2-flavor ν_μ → ν_ς hypothesis using matter effects which change the shape of the zenith-angle distribution of upward through-going muons. With maximum mixing and Δm² around 0.0024 eV², the ν_μ → ν_ς oscillation is disfavored with 99% confidence level with respect to the ν_μ → ν_τ hypothesis.

¹⁴FUKUDA 00 tested the pure 2-flavor ν_μ → ν_ς hypothesis using three complementary atmospheric-neutrino data samples. With this hypothesis, zenith-angle distributions are expected to show characteristic behavior due to neutral currents and matter effects. In the Δm² and sin²2θ region preferred by the Super-Kamiokande data, the ν_μ → ν_ς hypothesis is rejected at the 99% confidence level, while the ν_μ → ν_τ hypothesis consistently fits all of the data sample.

CPT tests

(Δm₂₁² - Δm₂₁²)

Table with columns: VALUE (10⁻⁴ eV²), CL%, DOCUMENT ID, TECN, COMMENT. Row 1: <math>-0.11 <math>

¹DEGOUVEA 05 obtained this bound at the 3σ CL from the KamLAND (ARAKI 05) and solar neutrino data.

(Δm₃₂² - Δm₃₂²)

Table with columns: VALUE (10⁻³ eV²), CL%, DOCUMENT ID, TECN, COMMENT. Row 1: <math>-0.12 <math>

• • • We do not use the following data for averages, fits, limits, etc. • • •

Table with columns: VALUE, CL%, DOCUMENT ID, TECN, COMMENT. Row 1: <math>0.6 <math>

¹ADAMSON 13B quotes this difference as a negative of our convention.

²The quoted result is the single-parameter 90% C.L. interval determined from the 90% C.L. contour in the (Δm², Δm²) plane, which is obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.

Heavy Neutral Leptons, Searches for

OMITTED FROM SUMMARY TABLE

We define searches for Heavy Neutral Leptons (HNLs) as searches for Dirac or Majorana fermions with sterile neutrino quantum numbers, that are heavy enough to not disrupt the simplest Big Bang Nucleosynthesis bounds and/or unstable on cosmological timescales: Typically HNLs have mass \sim MeV or higher.

Searches for these particles generically set bounds on the mixing between the HNL and the active neutrinos, as parametrized by the extended 3×4 PMNS matrix elements $U_{\ell X}$ (see the "Neutrino mass, mixing and oscillations" review) where $\ell = e, \mu$ or τ , and we denote the HNL as ν_X . While many measurements may be interpreted to place bounds on various combinations of these matrix elements, we quote below limits only for those cases in which one matrix element is assumed to be much larger than the other two, i.e. $|U_{\ell X}| \gg |U_{\ell' X}|$ for $\ell' \neq \ell$.

Experimental searches make use of various different strategies, including e.g. resonance searches in missing mass decay distributions or specific final states, searches for lepton number violating decays, and trilepton signatures. The resulting bounds on $U_{\ell X}$ are typically dependent on the HNL mass. The quoted limits below are either the best limit near an experimental kinematic threshold, or a characteristic value in the mass range of the experimental sensitivity.

Limits on heavy neutral lepton mixing parameters

Limits on $|U_{eX}|^2$

14 PARK 16 BELL $m_{\nu_X} \sim 0.2-1.4$ GeV

- Limit from prompt lepton number violating trilepton search.
- $K^+ \rightarrow e^+ \nu_X$, with ν_X decay through U_{eX} . ABE 19B also considers bounds on $|U_{\ell X} U_{\ell' X}|$ for combinations of lepton flavors in the ν_X decay final state.
- Searches for a Majorana Heavy Neutral Lepton producing a $\pi^- e^+$ resonance in the same sign dilepton decay $D \rightarrow K \pi^- e^+ e^+$.
- Search for $\pi^+ \rightarrow e^+ \nu_X$.
- Search for $K^+ \rightarrow e^+ \nu_X$.
- Search for prompt ν_X decay signatures.
- Search for displaced ν_X decay signatures.
- Searches for K or $\pi \rightarrow e^+ \nu_X, \nu_X \rightarrow e^+ e^- \nu_e$ using a beam dump experiment at the 70 GeV Serpukhov proton synchrotron. BARANOV 93 also considers limits for $|U_{eX} U_{\mu X}|$ from K or $\pi \rightarrow \mu^+ \nu_X, \nu_X \rightarrow e^+ e^- \nu_e$.
- $\pi^+ \rightarrow e^+ \nu_X$, with ν_X decay through U_{eX} .
- BERNARDI 88 also considers bounds on $|U_{eX} U_{\mu X}|$.
- $K^+ \rightarrow e^+ \nu_X$, with ν_X decay through U_{eX} .
- $D^+ \rightarrow e^+ \nu_X$, with $\nu_X \rightarrow e^- \ell^+ \nu_{\ell}$.
- $D^+ \rightarrow e^+ \nu_X$, with $\nu_X \rightarrow e^- \ell^+ \nu_{\ell}$ or $\nu_X \rightarrow e^- \pi^+$.
- PARK 16 quotes an approximate limit $B(B^+ \rightarrow e^+ \nu_X) < 3 \times 10^{-6}$ in the mass range $m_{\nu_X} \sim 0.2-1.4$ GeV.

Limits on $|U_{\mu X}|^2$

Quoted limits are either the best limit near the kinematic threshold of the experiment, or a characteristic value in the mass range of the experimental sensitivity

Light Quarks (*u*, *d*, *s*)

OMITTED FROM SUMMARY TABLE

u-QUARK MASS

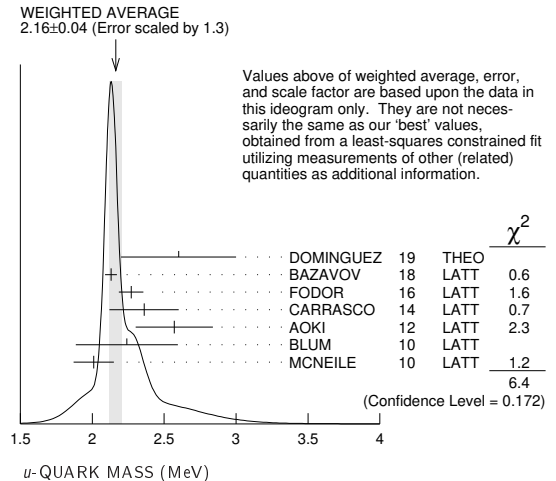

The *u*-, *d*-, and *s*-quark masses are estimates of so-called “current-quark masses,” in a mass-independent subtraction scheme such as \overline{MS} . The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of *d* and *u* masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the *u* quark could be essentially massless. The *s*-quark mass is estimated from SU(3) splittings in hadron masses.

We have normalized the \overline{MS} masses at a renormalization scale of $\mu = 2$ GeV. Results quoted in the literature at $\mu = 1$ GeV have been rescaled by dividing by 1.35. The values of “Our Evaluation” were determined in part via Figures 1 and 2.

- DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.
- BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
- FODOR 16 is a lattice simulation with $N_f = 2 + 1$ dynamical flavors and includes partially quenched QED effects.
- CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The *u* and *d* quark masses are obtained separately by using the *K* meson mass splittings and lattice results for the electromagnetic contributions.
- AOKI 12 is a lattice computation using $1 + 1 + 1$ dynamical quark flavors.
- BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use $2+1$ dynamical quark flavors.
- DAVIES 10 and MCNEILE 10 determine $\bar{m}_c(\mu)/\bar{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $N_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses.

- Mass m_u is obtained from this using the value of m_c from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratios, m_s/\bar{m} and m_u/m_d .
- DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed. The individual m_u , m_d values are obtained using the lattice determination of the average mass m_{ud} and of the ratio m_s/m_{ud} and the value of $Q = (m_s^2 - m_{ud}^2) / (m_d^2 - m_u^2)$ as determined from $\eta \rightarrow 3\pi$ decays.
 - BAZAVOV 10 is a lattice computation using $2+1$ dynamical quark flavors.
 - DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order α_s^4 .
 - DEANDREA 08 determine $m_u - m_d$ from $\eta \rightarrow 3\pi^0$, and combine with the PDG 06 lattice average value of $m_u + m_d = 7.6 \pm 1.6$ to determine m_u and m_d .
 - BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
 - JAMIN 06 determine $m_u(2 \text{ GeV})$ by combining the value of m_s obtained from the spectral function for the scalar $K\pi$ form factor with other determinations of the quark mass ratios.
 - MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate *u* and *d* quarks. Perturbative corrections were included at NNLO order. The quark masses m_u and m_d were determined from their $(m_u + m_d)/2$ measurement and AUBIN 04A m_u/m_d value.
 - NARISON 06 uses sum rules for $e^+ e^- \rightarrow$ hadrons to order α_s^3 to determine m_s combined with other determinations of the quark mass ratios.
 - AUBIN 04A employ a partially quenched lattice calculation of the pseudoscalar meson masses.

d-QUARK MASS

See the comment for the *u* quark above.

We have normalized the \overline{MS} masses at a renormalization scale of $\mu = 2$ GeV. Results quoted in the literature at $\mu = 1$ GeV have been rescaled by dividing by 1.35. The values of “Our Evaluation” were determined in part via Figures 1 and 2.

Quark Particle Listings

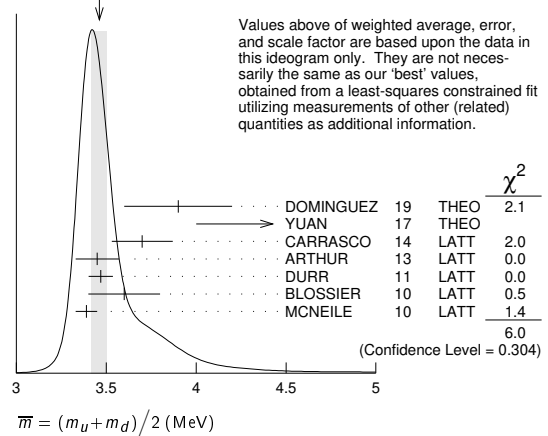

Light Quarks (*u, d, s*)

- ¹ DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.
- ² BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
- ³ FODOR 16 is a lattice simulation with $N_f = 2 + 1$ dynamical flavors and includes partially quenched QED effects.
- ⁴ CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The u and d quark masses are obtained separately by using the K meson mass splittings and lattice results for the electromagnetic contributions.
- ⁵ AOKI 12 is a lattice computation using $1 + 1 + 1$ dynamical quark flavors.
- ⁶ BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use $2+1$ dynamical quark flavors.
- ⁷ DAVIES 10 and MCNEILE 10 determine $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $N_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass m_d is obtained from this using the value of m_c from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratios, m_s/\overline{m} and m_u/m_d .
- ⁸ DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed. The individual m_u, m_d values are obtained using the lattice determination of the average mass m_{ud} and of the ratio m_s/m_{ud} and the value of $Q = (m_s^2 - m_{ud}^2) / (m_d^2 - m_u^2)$ as determined from $\eta \rightarrow 3\pi$ decays.
- ⁹ BAZAVOV 10 is a lattice computation using $2+1$ dynamical quark flavors.
- ¹⁰ DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order α_s^4 .
- ¹¹ DEANDREA 08 determine $m_u - m_d$ from $\eta \rightarrow 3\pi^0$, and combine with the PDG 06 lattice average value of $m_u + m_d = 7.6 \pm 1.6$ to determine m_u and m_d .
- ¹² BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- ¹³ JAMIN 06 determine $m_d(2 \text{ GeV})$ by combining the value of m_s obtained from the spectral function for the scalar $K\pi$ form factor with other determinations of the quark mass ratios.
- ¹⁴ MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate u and d quarks. Perturbative corrections were included at NNLO order. The quark masses m_u and m_d were determined from their $(m_u + m_d)/2$ measurement and AUBIN 04A m_u/m_d value.
- ¹⁵ NARISON 06 uses sum rules for $e^+ e^- \rightarrow \text{hadrons}$ to order α_s^3 to determine m_s combined with other determinations of the quark mass ratios.
- ¹⁶ AUBIN 04A perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with continuum estimate of electromagnetic effects in the kaon masses, and one-loop perturbative renormalization constant.

- ¹ DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.
- ² YUAN 17 determine \overline{m} using QCD sum rules in the isospin $I=0$ scalar channel. At the end of the "Numerical Results" section of YUAN 17 the authors discuss the significance of their larger value of the light quark mass compared to previous determinations.
- ³ CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The u and d quark masses are obtained separately by using the K meson mass splittings and lattice results for the electromagnetic contributions.
- ⁴ ARTHUR 13 is a lattice computation using $2+1$ dynamical domain wall fermions. Masses at $\mu = 3$ GeV have been converted to $\mu = 2$ GeV using conversion factors given in their paper.
- ⁵ DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- ⁶ BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f=2$ dynamical twisted-mass Wilson fermions.
- ⁷ DAVIES 10 and MCNEILE 10 determine $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $N_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass \overline{m} is obtained from this using the value of m_c from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratio, m_s/\overline{m} .
- ⁸ AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using $N_f = 2 + 1$ dynamical flavors of domain wall fermions.
- ⁹ DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order α_s^4 .
- ¹⁰ ALLTON 08 use a lattice computation of the π, K , and Ω masses with $2+1$ dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- ¹¹ BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
- ¹² DOMINGUEZ-CLARIMON 08B obtain an inequality from sum rules for the scalar two-point correlator.
- ¹³ ISHIKAWA 08 use a lattice computation of the light meson spectrum with $2+1$ dynamical flavors of $C(a)$ improved Wilson quarks, and one-loop perturbative renormalization.
- ¹⁴ NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.
- ¹⁵ BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- ¹⁶ GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization, to obtain $\overline{m}(2 \text{ GeV}) = 4.08 \pm 0.25 \pm 0.19 \pm 0.23$ MeV, where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
- ¹⁷ GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization.

See key on page 999

Quark Particle Listings

Light Quarks (*u, d, s*)

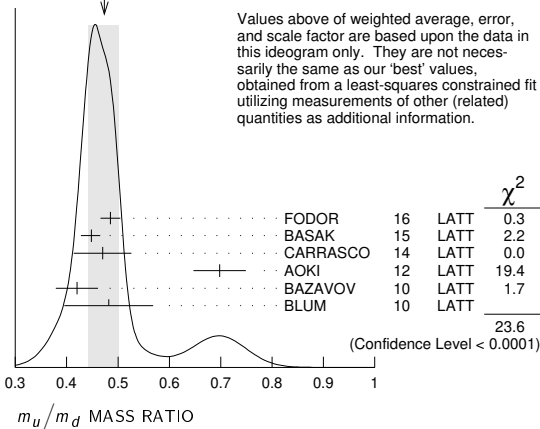

- ¹⁸ MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate *u* and *d* quarks. Perturbative corrections were included at NNLO order.
- ¹⁹ NARISON 06 uses sum rules for $e^+e^- \rightarrow$ hadrons to order α_s^3 to determine m_s combined with other determinations of the quark mass ratios.
- ²⁰ AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
- ²¹ AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory.
- ²² The errors given in AOKI 03b were $+0.046$
 -0.069 . We changed them to ± 0.3 for calculating the overall best values. AOKI 03b uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the $O(a)$ improved Wilson action.
- ²³ BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses $O(a)$ improved Wilson action and nonperturbative renormalization.
- ²⁴ CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.

- ¹ BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
- ² LYTLE 18 combined with CHAKRABORTY 2015 determine $\overline{m}_s(3 \text{ GeV}) = 84.78 \pm 0.65$ MeV from a lattice simulation with $n_f = 2+1+1$ flavors. They also determine the quoted value $\overline{m}_s(2 \text{ GeV})$ for $n_f = 4$ dynamical flavors.
- ³ ANANTHANARAYAN 16 determine $\overline{m}_s(2 \text{ GeV}) = 106.70 \pm 9.36$ MeV and 74.47 ± 7.77 MeV from fits to ALEPH and OPAL τ decay data, respectively. We have used the weighted average of the two.
- ⁴ CARRASCO 14 is a lattice QCD computation of light quark masses using 2 + 1 + 1 dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The *u* and *d* quark masses are obtained separately by using the *K* meson mass splittings and lattice results for the electromagnetic contributions.
- ⁵ ARTHUR 13 is a lattice computation using 2+1 dynamical domain wall fermions. Masses at $\mu = 3$ GeV have been converted to $\mu = 2$ GeV using conversion factors given in their paper.
- ⁶ BODENSTEIN 13 determines m_s from QCD finite energy sum rules, and the perturbative computation of the pseudoscalar correlator to five-loop order.
- ⁷ FRITZSCH 12 determine m_s using a lattice computation with $N_f = 2$ dynamical flavors.
- ⁸ DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- ⁹ CHAKRABORTY 15 is a lattice QCD computation that determines m_c and m_c/m_s using pseudoscalar mesons masses tuned on gluon field configurations with 2+1+1 dynamical flavors of HISQ quarks with *u/d* masses down to the physical value.
- ¹⁰ AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using $N_f = 2 + 1$ dynamical flavors of domain wall fermions.
- ¹¹ BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f=2$ dynamical twisted-mass Wilson fermions.
- ¹² BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.
- ¹³ DAVIES 10 and MCNEILE 10 determine $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $N_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass m_s is obtained from this using the value of m_c from ALLISON 08 or MCNEILE 10.
- ¹⁴ ALLTON 08 use a lattice computation of the π, K , and Ω masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- ¹⁵ BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
- ¹⁶ DOMINGUEZ 08a make determination from QCD finite energy sum rules for the pseudoscalar two-point function computed to order a^4 .
- ¹⁷ ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of $O(a)$ improved Wilson quarks, and one-loop perturbative renormalization.
- ¹⁸ NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.

Quark Particle Listings

Light Quarks (u, d, s)

- ¹⁹BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- ²⁰CHETYRKIN 06 use QCD sum rules in the pseudoscalar channel to order α_s^4 .
- ²¹GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization, to obtain $\overline{m}_s(2 \text{ GeV}) = 111 \pm 6 \pm 4 \pm 6 \text{ MeV}$, where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
- ²²GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization.
- ²³JAMIN 06 determine $\overline{m}_s(2 \text{ GeV})$ from the spectral function for the scalar $K\pi$ form factor.
- ²⁴MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate u and d quarks. Perturbative corrections were included at NNLO order.
- ²⁵NARISON 06 uses sum rules for $e^+e^- \rightarrow$ hadrons to order α_s^3 .
- ²⁶NARISON 06 obtains the quoted range from positivity of the spectral functions.
- ²⁷BAIKOV 05 determines $\overline{m}_s(M_\tau) = 100^{+5}_{-3} + 17^{+17}_{-19}$ from sum rules using the strange spectral function in τ decay. The computations were done to order α_s^3 , with an estimate of the α_s^4 terms. We have converted the result to $\mu = 2 \text{ GeV}$.
- ²⁸GAMIZ 05 determines $\overline{m}_s(2 \text{ GeV})$ from sum rules using the strange spectral function in τ decay. The computations were done to order α_s^2 , with an estimate of the α_s^3 terms.
- ²⁹GORBUNOV 05 use hadronic tau decays to N3LO, including power corrections.
- ³⁰NARISON 05 determines $\overline{m}_s(2 \text{ GeV})$ from sum rules using the strange spectral function in τ decay. The computations were done to order α_s^3 .
- ³¹AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
- ³²AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory. Determines $m_s = 113.8 \pm 2.3^{+5.8}_{-2.9}$ using K mass as input and $m_s = 142.3 \pm 5.8^{+22}_{-0}$ using ϕ mass as input. We have performed a weighted average of these values.
- ³³AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the $\mathcal{O}(a)$ improved Wilson action.
- ³⁴BEČIREVIĆ 03 perform quenched lattice computation using the vector and axial Ward identities. Uses $\mathcal{O}(a)$ improved Wilson action and nonperturbative renormalization. They also quote $\overline{m}/m_s = 24.3 \pm 0.2 \pm 0.6$.
- ³⁵CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.
- ³⁶GAMIZ 03 determines m_s from SU(3) breaking in the τ hadronic width. The value of V_{us} is chosen to satisfy CKM unitarity.
- ³⁷GAMIZ 03 determines m_s from SU(3) breaking in the τ hadronic width. The value of V_{us} is taken from the PDG.

- ¹BAZAVOV 14A is a lattice computation using 4 dynamical flavors of HISQ fermions.
- ²CARRASCO 14 is a lattice QCD computation of light quark masses using 2 + 1 + 1 dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The u and d quark masses are obtained separately by using the K meson mass splittings and lattice results for the electromagnetic contributions.
- ³ARTHUR 13 is a lattice computation using 2+1 dynamical domain wall fermions.
- ⁴DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- ⁵AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using $N_f = 2 + 1$ dynamical flavors of domain wall fermions.
- ⁶BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f=2$ dynamical twisted-mass Wilson fermions.
- ⁷ALLTON 08 use a lattice computation of the π , K , and Ω masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- ⁸BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
- ⁹OLLER 07A use unitarized chiral perturbation theory to order p^4 .
- ¹⁰Three flavor dynamical lattice calculation of pseudoscalar meson masses.

WEIGHTED AVERAGE
27.33±0.15-0.12 (Error scaled by 1.6)

Q MASS RATIO

$$Q \equiv \sqrt{(m_s^2 - \overline{m}^2)/(m_d^2 - m_u^2)}; \quad \overline{m} \equiv (m_u + m_d)/2$$

- 1 NARISON 20 determines the quark mass using QCD Laplace sum rules from the B_c mass, combined with previous determinations of the QCD condensates and c and b masses.
- 2 ABRAMOWICZ 18 determine $\overline{m}_c(\overline{m}_c) = 1.290 \pm 0.046 \pm 0.062 \pm 0.003$ from the production of c quarks in $e p$ collisions at HERA using combined H1 and ZEUS data. The experimental/fitting errors, and those from modeling and parameterization have been combined in quadrature.
- 3 BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
- 4 LYTLE 18 combined with CHAKRABORTY 15 determine $\overline{m}_c(3 \text{ GeV}) = 0.9874(48) \text{ GeV}$ from a lattice simulation with $n_f = 2+1+1$ flavors. They also determine the quoted value $\overline{m}_c(\overline{m}_c)$ for $n_f = 4$ dynamical flavors.
- 5 PESET 18 determine $\overline{m}_c(\overline{m}_c)$ and $\overline{m}_b(\overline{m}_b)$ using an N3LO calculation of the η_c, η_b and B_c masses.
- 6 CHETYRKIN 17 determine $\overline{m}_c(\mu = 3 \text{ GeV}) = 0.993 \pm 0.008 \text{ GeV}$ and $\overline{m}_c(\overline{m}_c)$ from a four-loop sum-rule computation of the cross-section for $e^+e^- \rightarrow$ hadrons in the charm threshold region.
- 7 ERLER 17 determine $\overline{m}_c(\overline{m}_c) = 1.272 \pm 0.008 \text{ GeV}$ from a three-loop QCD sum-rule computation of the vector current correlator. This result is for fixed $\alpha_s(M_Z) = 0.1182$. Including an α_s uncertainty of ± 0.0016 , the charm mass error increases from 8 to 9 MeV.
- 8 KIYO 16 determine $\overline{m}_c(\overline{m}_c)$ from the $J/\psi(1S)$ mass at order α_s^3 (N3LO).
- 9 DEHNADI 15 determine $\overline{m}_c(\overline{m}_c)$ using sum rules for $e^+e^- \rightarrow$ hadrons at order α_s^3 (N3LO), and fitting to both experimental data and lattice results.
- 10 CARRASCO 14 is a lattice QCD computation of light quark masses using $2+1+1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The u and d quark masses are obtained separately by using the K meson mass splittings and lattice results for the electromagnetic contributions.
- 11 ALEKHIN 13 determines m_c from charm production in deep inelastic scattering at HERA using approximate NNLO QCD.
- 12 SAMOYLOV 13 determines m_c from a study of charm dimuon production in neutrino-iron scattering using the NLO QCD result for the charm quark production cross section.
- 13 BODENSTEIN 11 determine $\overline{m}_c(3 \text{ GeV}) = 0.987 \pm 0.009 \text{ GeV}$ and $\overline{m}_c(\overline{m}_c) = 1.278 \pm 0.009 \text{ GeV}$ using QCD sum rules for the charm quark vector current correlator.
- 14 LASCHKA 11 determine the c mass from the charmonium spectrum. The theoretical computation uses the heavy $Q\overline{Q}$ potential to order $1/m_Q$ obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.
- 15 AUBERT 10A determine the b - and c -quark masses from a fit to the inclusive decay spectra in semileptonic B decays in the kinetic scheme (and convert it to the \overline{MS} scheme).
- 16 SIGNER 09 determines the c -quark mass using non-relativistic sum rules to analyze the $e^+e^- \rightarrow c\overline{c}$ cross-section near threshold. Also determine the PS mass $m_{PS}(\mu_P = 0.7 \text{ GeV}) = 1.50 \pm 0.04 \text{ GeV}$.
- 17 NARISON 18A determines simultaneously $\overline{m}_c(\overline{m}_c)$ and the 4-dimension gluon condensate using QCD exponential sum rules and their ratios evaluated at the optimal scale $\mu = 2.85 \text{ GeV}$ at N2LO-N3LO of perturbative QCD and including condensates up to dimension 6-8 in the (axial-)vector and (pseudo-)scalar charmonium channels.
- 18 NARISON 18B determines $\overline{m}_c(\overline{m}_c)$ using QCD vector moment sum rules and their ratios at N2LO-N3LO of perturbative QCD and including condensates up to dimension 8.
- 19 BERTONE 16 determine $\overline{m}_c(\overline{m}_c)$ from HERA deep inelastic scattering data using the FONLL scheme. Also determine $\overline{m}_c(\overline{m}_c) = 1.318 \pm 0.054 \pm 0.490 \pm 0.022$ using the fixed flavor number scheme.
- 20 CHAKRABORTY 15 is a lattice QCD computation using $2+1+1$ dynamical flavors. Moments of pseudoscalar current-current correlators are matched to α_s^3 -accurate QCD perturbation theory with the η_c meson mass tuned to experiment.
- 21 ABRAMOWICZ 13c determines m_c from charm production in deep inelastic $e p$ scattering, using the QCD prediction at NLO order. The uncertainties from model and parameterization assumptions, and the value of α_s , of ± 0.03 , ± 0.02 , and ± 0.02 respectively, have been combined in quadrature.
- 22 DEHNADI 13 determines m_c using QCD sum rules for the charmonium spectrum and charm continuum to order α_s^3 (N3LO). The statistical and systematic experimental errors of ± 0.006 and ± 0.009 have been combined in quadrature. The theoretical uncertainties ± 0.019 from truncation of the perturbation series, ± 0.010 from α_s , and ± 0.002 from the gluon condensate have been combined in quadrature.
- 23 NARISON 13 determines m_c using QCD spectral sum rules to order α_s^2 (NNLO) and including condensates up to dimension 6.
- 24 ALEKHIN 12 determines m_c from heavy quark production in deep inelastic scattering at HERA using approximate NNLO QCD.
- 25 NARISON 12A determines m_c using sum rules for the vector current correlator to order α_s^3 , including the effect of gluon condensates up to dimension eight.

C

$$J(J^P) = 0(\frac{1}{2}^+)$$

Charge = $\frac{2}{3} e$ Charm = +1

c-QUARK MASS

The c -quark mass corresponds to the "running" mass $m_c(\mu = m_c)$ in the \overline{MS} scheme. We have converted masses in other schemes to the \overline{MS} scheme using two-loop QCD perturbation theory with $\alpha_s(\mu = m_c) = 0.38 \pm 0.03$. The value $1.27 \pm 0.02 \text{ GeV}$ for the \overline{MS} mass corresponds to $1.67 \pm 0.07 \text{ GeV}$ for the pole mass (see the "Note on Quark Masses").
