## Abstract

Much data shows that biological metals other than  $\text{Fe}^{3+}$  can interfere with  $\text{Fe}^{3+}$  acquisition by siderophores in bacteria. Siderophores are small  $\text{Fe}^{3+}$  chelators produced by the microorganism to obtain access to  $\text{Fe}^{3+}$ . Here, we show that  $\text{Co}^{2+}$  is imported into *Pseudomonas aeruginosa* cells in a complex with the siderophore pyochelin (PCH) by the ferri-PCH outer membrane transporter FptA. Moreover, the presence of  $\text{Co}^{2+}$  in the bacterial environment strongly affects the production of PCH. Proteomic and transcriptomic approaches showed that a decrease of PCH production is associated with repression of the expression of the genes involved in PCH biosynthesis. We used various molecular biology approaches to show that this repression is not Fur- (Ferric uptake transcriptional regulator) dependent but due to competition of PCH-Co with PCH-Fe for PchR (transcriptional activator), thus inhibiting the formation of PchR-PCH-Fe and consequently the expression of the PCH genes. We observed a similar mechanism of repression of PCH production, but to a lesser extent, by  $\text{Ni}^{2+}$ , but not for  $\text{Zn}^{2+}$ ,  $\text{Cu}^{2+}$ , or  $\text{Mn}^{2+}$ . Here, we show, for the first time at a molecular level, how the presence of a contaminant metal can interfere with  $\text{Fe}^{3+}$  acquisition by the siderophores PCH and PVD.

## Introduction

In living organisms, interactions between biomolecules and biological metals (Na, Mg, K, Ca, Mn, Fe, Zn, Ni, Cu, Co, and Mo) are vital and play a role in macromolecule structure and cell metabolism. For example, one third of proteins require metals for their effective functioning. The interactions between macromolecules and metals are highly specific. Waldron and Robinson proposed that to ensure that each metalloprotein or metalloenzyme in bacteria binds the correct metal and functions properly, 'metals are not in competition for a limited pool of proteins, but rather the proteins compete for a limited pool of metals in the cells'.<sup>2,3</sup> Therefore, any disequilibrium of this limited intracellular pool of metals (the bacterial metallome) affects bacterial cell viability. However, bacteria are often subject to variations in metal concentrations in their environment, including during infections, in which they may be confronted with "nutriment immunity", whereby the host uses deprivation of, or poisoning with, metals as defense strategies against microbial invaders.<sup>4,5</sup> For example phagocytes use Cu and/or Zn intoxication to reduce the intracellular survival of pathogens.<sup>6</sup> How bacteria cope with such metal concentration disequilibria at the molecular level and the cross-talk to maintain homeostasis of different biological metals in bacterial cells are still poorly understood.

Bacterial iron homeostasis has attracted the most attention over the last decades. Iron is a key nutriment for bacterial growth, which is paradoxically poorly bioavailable because of its very low solubility under aerobic conditions and physiological pH. Thus, to gain access to  $\text{Fe}^{3+}$ , most bacteria produce siderophores.<sup>7</sup> These compounds have various chemical structures, a molecular weight usually between 200 and 2 000 Da, and are characterized by an extremely high affinity for  $\text{Fe}^{3+}$ , with, for example,  $K_a$  values of  $10^{43}$  for the siderophores enterobactin.<sup>8</sup> Siderophores provide bacteria with  $\text{Fe}^{3+}$  by scavenging this metal from the bacterial environment and transporting it into either the bacterial periplasm or cytoplasm.<sup>9,10</sup> This strategy works in any bacterial environment, such as in the rhizosphere<sup>11</sup>, but also plays a key role in the host during infections.<sup>12</sup> *P. aeruginosa*, an opportunistic pathogen and used as a model in the present study, produces two major siderophores, pyoverdine

(PVD) and pyochelin (PCH) (Figure 1).<sup>9</sup> The synthesis of these chelators is correlated with the concentration of iron, both in bacterial cells and the environment.<sup>13</sup> In media with moderately low concentrations of iron (approximately 300 nM), *P. aeruginosa* cells produce more PCH than PVD, whereas in more severely iron-restricted media (approximately 20 nM), PCH production remains highly active and, in addition, PVD production is strongly stimulated.<sup>13,14</sup>

$\text{Fe}^{3+}$  uptake into bacteria *via* siderophores always involves a siderophore-specific TonB-dependent transporter for its uptake across the outer membrane in Gram-negative bacteria.<sup>15</sup> Depending on the siderophore,  $\text{Fe}^{3+}$  is then either delivered into the bacterial periplasm or cytoplasm. Transport into the cytoplasm involves further transport of the ferri-siderophore complex across the inner membrane *via* proton motive force-dependent permeases or ABC transporters.<sup>16</sup> Iron release from siderophores in the bacterial periplasm or cytoplasm requires  $\text{Fe}^{3+}$  reduction (siderophores having a lower affinity for  $\text{Fe}^{3+}$  compared to  $\text{Fe}^{2+}$ ), often associated with chemical modification or hydrolysis of the siderophores.<sup>16</sup> Siderophore production is generally negatively regulated by the presence of  $\text{Fe}^{2+}$  *via* the Fur transcriptional regulator<sup>19</sup> and positively by iron restriction and the response of various regulatory systems, such as sigma and anti-sigma factors<sup>20</sup>, the AraC regulators, or two component systems.<sup>21</sup> Under iron starvation, PCH production is activated *via* the action of the AraC regulator PchR and PVD by anti-sigma (FpvR) and sigma factors (PvdS and FpvI).<sup>21-23</sup>

An increasing number of studies have also reported that siderophores are able to chelate efficiency metals other than  $\text{Fe}^{3+}$ .<sup>18</sup> Previously, using the spectral properties of PVD and PCH, we have shown that both PVD and PCH are able to chelate the biological metals  $\text{Co}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Ni}^{2+}$  and  $\text{Zn}^{2+}$  as well as metals like  $\text{Ag}^+$ ,  $\text{Pb}^{2+}$ ,  $\text{Al}^{3+}$ .<sup>24,25</sup> PVD chelates metals with a 1 : 1 stoichiometry and stability constants have been determined for some PVD-metal complexes: PVD-Fe ( $K_a = 10^{30.8} \text{ M}^{-1}$ ), PVD- $\text{Ni}^{2+}$  ( $K_a = 10^{10.9} \text{ M}^{-1}$ ), PVD- $\text{Cd}^{2+}$  ( $K_a = 10^{8.2} \text{ M}^{-1}$ ), PVD- $\text{Cu}^{2+}$  ( $K_a = 10^{20.1} \text{ M}^{-1}$ ).<sup>26,27</sup> PCH forms predominantly 1 : 2 ( $\text{M}^{2+}$  /PCH) complexes and the stability constant determined are: for  $\text{Fe}^{3+}$  ( $K_a = 10^{28.8} \text{ M}^{-2}$ ), for  $\text{Zn}^{2+}$  ( $K_a = 10^{26.0} \text{ M}^{-2}$ ) and for  $\text{Cu}^{2+}$  ( $K_a = 10^{25.0} \text{ M}^{-2}$ ).<sup>28</sup> Baysse *et al.* have shown that PCH can also bind the transition metal

1  
2  
3 vanadium generating a Fenton reaction in the cells.<sup>29</sup> Moreover several studies have shown that the  
4 presence of metals other than  $\text{Fe}^{3+}$  in the bacterial environment can modulate the bacterial production  
5 of siderophores, but nothing is known concerning the molecular mechanisms involved.<sup>30-32</sup> For  
6 example, PCH synthesis in *P. aeruginosa*, is repressed by  $10\ \mu\text{M}$   $\text{Fe}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Mo}^{+6}$ ,  $\text{Ni}^{2+}$ , and  $\text{Cu}^{2+}$ .<sup>33,34</sup> At  
7 last, an increasing number of studies have reported that siderophores, in addition to their important  
8 role in  $\text{Fe}^{3+}$  acquisition, also protect bacterial cells against excess toxic metals present in their  
9 environment and can consequently play a role in bacterial metal resistance.<sup>13,17,18</sup> Previous studies by  
10 our group have shown that both PVD and PCH protect *P. aeruginosa* from toxic metals or an excess of  
11 essential metals, to a similar extent, by preventing their intracellular accumulation, thus maintaining  
12 the homeostasis of the various biological metals present in bacterial cells.<sup>13,17</sup>

27  
28 To better understand the possible role of PVD and PCH in the homeostasis of biological metals other  
29 than iron, we explored the effect of the presence of various biological metals ( $\text{Co}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Mn}^{2+}$   
30 and  $\text{Zn}^{2+}$ ) in bacterial growth media on PVD and PCH production and investigated the possible  
31 molecular mechanisms involved in the phenotype(s) observed. Heavy metals were not included in our  
32 study, the possible role of the two siderophores in heavy metal resistance being not the focus of this  
33 work. We observed that  $\text{Co}^{2+}$  repressed PCH synthesis with the same efficiency as  $\text{Fe}^{3+}$ , and repression  
34 was also observed with  $\text{Ni}^{2+}$ , but with lower efficiency. There was no repression by  $\text{Zn}^{2+}$ ,  $\text{Mn}^{2+}$ , or  $\text{Cu}^{2+}$ .

The repression observed is Fur-independent and due to the ability of  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  to interfere with the  
transcriptional regulator PchR (activator of PCH production, Scheme 1).  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  inhibit PchR-PCH-  
Fe formation and consequently the concentration of this complex in bacterial cells decreases, resulting  
in a decrease of the transcription of the genes encoding the enzymes involved in PCH synthesis.

## Materials and methods

**Chemicals.** The metals used were in the following forms:  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$  (Strem Chemicals),  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$  (Strem Chemicals),  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$  (Strem Chemicals),  $\text{FeCl}_3$  (Alfa Aesar),  $\text{Mn}(\text{OAc})_2 \cdot 4\text{H}_2\text{O}$  (Strem Chemicals) and  $\text{ZnCl}_2$  (Strem Chemicals). All solutions were prepared at concentrations between 1 nM and 100  $\mu\text{M}$  in 0.5 N HCl or 0.5 N  $\text{HNO}_3$ . These stock solutions were then diluted with 50 mM Tris-HCl pH 8.0. The PCH used in these experiments was synthesized according to a previously published protocol.<sup>35</sup>

**Bacterial strains and growth media.** *P. aeruginosa* strains used throughout this study are shown in Table 1. For cultures of *P. aeruginosa* strains in iron-limited media, bacteria were first grown in LB broth overnight at 30°C. The bacteria were then washed in CAA medium (casamino acid medium, composition: 5 g.L<sup>-1</sup> low-iron CAA (Difco), 1.46 g.L<sup>-1</sup>  $\text{K}_2\text{HPO}_4 \cdot 3\text{H}_2\text{O}$ , 0.25 g.L<sup>-1</sup>  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ ), diluted two-fold and incubated for 24 h at 30°C.

**Siderophore quantification.** The production of PCH and PVD were evaluated as described previously.<sup>25</sup> PVD production was monitored by its characteristic absorbance of 400 nm at neutral pH.<sup>36</sup> PCH has a characteristic absorbance of 320 nm, but unlike PVD, this siderophore cannot be detected directly in the bacterial growth medium and needs first to be extracted from the cultures and concentrated before absorbance monitoring.<sup>13,36</sup>

**UV and fluorescence spectra of PCH-metal complexes.** PCH was solubilized in methanol and PCH-metal complexes were prepared in methanol by mixing 1 eq. of metal with 2 eq. of PCH. 50 mM TrisHCl pH 8.0 buffer was added to reach a concentration of PCH-metal complexes of 50  $\mu\text{M}$ . UV spectra were measured on a Nanodrop 2000 spectrophotometer and fluorescence spectra were measured on a TECAN M200 multiplate reader. All measures were carried out in 50 mM TrisHCl buffer. For emission spectra :  $\lambda_{\text{exc}} = 350 \text{ nm}$ ; for excitation spectra :  $\lambda_{\text{em}} = 422 \text{ nm}$ .

1  
2  
3 ***Bacterial growth and quantification of fluorescence intensity.*** Cells were cultured overnight in CAA  
4 medium, pelleted by centrifugation, resuspended in fresh CAA medium, and the resulting suspension  
5 diluted so as to obtain an optical density at 600 nm of 0.01 units. We dispensed 200  $\mu$ L of the  
6 suspension per well into a 96-well plate (Greiner, U-bottomed microplate) with or without the  
7 different metals tested. The plates were incubated at 30°C, with shaking, in a Tecan microplate reader  
8 (Infinite M200, Tecan) for measurements of OD<sub>600nm</sub> and mCherry (excitation/emission wavelengths:  
9 570 nm/610 nm) fluorescence at 30-min intervals, for 40 h. We calculated the mean of three replicates  
10 for each measurement.

21  
22

23 ***Proteomics analysis.*** Bacteria were grown in CAA medium as described above (for growth curve see  
24 Figure 1SM in Supplementary Materials). After the first overnight culture in CAA medium, the bacteria  
25 were diluted in 10 mL CAA to an OD<sub>600 nm</sub> of 0.1 and incubated with or without 10  $\mu$ M Fe<sup>3+</sup> or Co<sup>2+</sup> for  
26 8 h at 30°C. For the digestion and cleanup steps, the same strategy was used as previously described.<sup>37</sup>  
27 For the shotgun proteomics assays, 1  $\mu$ g of peptides of each sample were subjected to LC–MS (liquid  
28 chromatography-mass spectrometry) analysis using the same approach as previously described.<sup>37</sup>

35  
36  
37  
38

39 ***Transcriptomic analysis.*** Bacteria were grown in CAA medium exactly as described above for the  
40 proteomic analyses and harvested after 8 h of cultures at 30°C. The total RNA were extracted by hot  
41 phenol treatment. Briefly, an aliquot of  $8 \times 10^8$  cells from the cultures were added to two volumes of  
42 RNAprotect Bacteria Reagent (Qiagen). After centrifugation, the cell pellets were dissolved in 1 ml of  
43 lysis buffer (300 mM NaCl ; 1% SDS ; 8 mM EDTA), incubated at 90°C for 1 min before the addition of  
44 1 mL of phenol and a further incubation at 65°C for 10 min. The extracted RNAs (aqueous phase) were  
45 purified again with 1 volume of Phenol/Chloroform. To eliminate any DNA traces, the RNAs were  
46 submitted twice to DNaseI treatment. The RNAs were then submitted to ribosomal depletion using  
47 the RiboZero Bacteria kit (Illumina). The efficiency of depletion was validated on a Bioanalyzer  
48 nanochip (Agilent). Directional cDNA libraries for sequencing were constructed using the TruSeq  
49  
50

53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Stranded RNA LT Sample Prep kit (Illumina) from enriched non-rRNA samples, following the  
4 manufacturer's instructions. After validation of the libraries on a Bioanalyzer DNA1000 chip (Agilent)  
5 and QuBit (Invitrogen) quantification, sequencing was performed on a HiSeq 2500 (Illumina). Reads  
6 were 65 bp-long in single mode.  
7  
8  
9

10  
11  
12 Count data were analyzed using R version 3.3.1<sup>38</sup> and the Bioconductor package DESeq2 version  
13 1.12.4.<sup>39</sup> Normalization and the estimation of dispersion were performed with DESeq2, using the  
14 default parameters, and statistical tests for differential expression were performed, applying the  
15 independent filtering algorithm. A generalized linear model was used to test for the differential  
16 expression between the three biological conditions: PAO1 without metals, PAO1 in the presence of  
17  $\text{Co}^{2+}$  or  $\text{Fe}^{3+}$ . For each pairwise comparison, raw p-values were adjusted for multiple testing according  
18 to the Benjamini and Hochberg (BH) procedure<sup>40</sup> and genes with an adjusted p-value lower than 0.05  
19 were considered to be differentially expressed.  
20  
21  
22

23  
24  
25 Reads were cleaned of adapter sequences and low-quality sequences using an in-house program  
26 ([https://github.com/baj12/clean\\_ngs](https://github.com/baj12/clean_ngs)). Only sequences at least 25 nt in length were considered for  
27 further analysis. Bowtie version 0.12.7<sup>41</sup>, with default parameters, was used for alignment on the  
28 reference genome (*Pseudomonas aeruginosa* PAO1 from NCBI). Genes were counted using  
29 featureCounts version 1.4.6-p3<sup>42</sup> from Subreads package (parameters: -t gene -s 1).  
30  
31  
32

33  
34  
35 ***Metal quantification by ICP-AES.*** PCH-metal complexes were prepared by incubating PCH solubilized  
36 in methanol with  $\text{FeCl}_3$ ,  $\text{CoCl}_2$ ,  $\text{NiCl}_2$  or  $\text{ZnCl}_2$  at a molar ratio of 2:1 for 15 min. Tris-HCl (50 mM) pH 8.0  
37 buffer was added to bring the siderophore-metal complexes to a final concentration of 4 mM.  
38  *$\Delta pvdF\Delta pchA$*  and  *$\Delta pvdF\Delta pchA\Delta fptX$*  cells were grown overnight in CAA media as described above. Cells  
39 were then washed and resuspended in CAA medium at an  $\text{OD}_{600 \text{ nm}}$  of 1.5. PCH-Fe or PCH-Co were  
40 added to a final concentration of 4  $\mu\text{M}$  and the solutions incubated for 30 min at 30°C with shaking.  
41  
42  
43 The samples were then centrifuged and the bacterial pellets washed once with ultrapure water and  
44 dried at 50°C for 48 h. Cells were mineralized by incubation in 70% (v/v)  $\text{HNO}_3$  for 48 h at room  
45

2  
3 temperature. The volume was brought up to 10 mL with ultrapure water and the samples filtered  
4  
5 through a membrane with a 0.22  $\mu\text{m}$  syringe filter unit. The samples were then analyzed with an ICP-  
6  
7 AES apparatus (Varian 720 ES) at the following wavelengths (nm): Co (228.62), Fe (238.20), Ca (393.37),  
8  
9 Cd (214.44), Co (228.62), Cr (267.72), Cu (327.40), Fe 238.20), K 766.49), Mg (279.55), Mn (257,61),  
10  
11 Mo (202.03), Na (589.59), Ni (231.60), Pb 220.35), V (292.40), and Zn (213.86).

12  
13  
14 For the data in Figure 4, bacteria were grown in CAA medium in the presence of 5  $\mu\text{M}$   $\text{CoCl}_2$ . At the  
15  
16 end of the exponential phase, samples were centrifuged, and the bacterial pellets treated as described  
17  
18 above for the experiment with PCH-Co or PCH-Ni complexes.

19  
20  
21  
22  
23  **$^{55}\text{Fe}^{3+}$  uptake.**  $^{55}\text{FeCl}_3$  was obtained from Perkin Elmer Life and Analytical Sciences (Billerica, MA, USA),  
24  
25 in solution, at a concentration of 71.1 mM, with a specific activity of 10.18 Ci/g. Siderophore- $^{55}\text{Fe}$   
26  
27 complexes were prepared at  $^{55}\text{Fe}$  concentrations of 20  $\mu\text{M}$ , with a siderophore:  $^{55}\text{Fe}^{3+}$  (mol:mol) ratio  
28  
29 of 20:1.  $^{55}\text{Fe}^{3+}$  uptake assays were carried out as previously described,<sup>43</sup> except that, after growth,  
30  
31 bacteria were incubated with 0.2  $\mu\text{M}$  PCH- $^{55}\text{Fe}$  and with or without 0.2 and 2  $\mu\text{M}$  PCH-Co or PCH-Zn  
32  
33 complexes.

34  
35  
36  
37  
38  
39 **Electrophoresis mobility shift assays (EMSA).** EMSA experiments were performed as previously  
40  
41 described<sup>44</sup> using a DNA fragment gcgCGCCCGCCAATGATAATAAATCTCATTTCCCCAACAgcg containing  
42  
43 the -65 to -31 *pchD* promoter region containing a Fur box (underlined) with gcg on both side added for  
44  
45 stabilization. DNA radiolabelling was performed by incubating 20-30 nM DNA for 30 min at 37°C in the  
46  
47 presence of 1 unit T4 polynucleotide kinase (NEB) and 0.5  $\mu\text{L}$  gamma ATP at 1 mCi /mmol. Labelled  
48  
49 DNA was diluted 10 times in binding buffer (20 mM BisTrisPropane pH 8.5, 100 mM KCl, 3 mM  $\text{MgCl}_2$ ,  
50  
51 10  $\mu\text{M}$   $\text{CoCl}_2$ , 5% v/v glycerol, and 0.01% Triton X-100), desalted on G25 mini-spin columns and stored  
52  
53 at -20°C. EMSA were performed with 200-250 pM of freshly prepared radiolabelled DNA incubated 30  
54  
55 min at 25°C with various concentrations of Fur protein in binding buffer in the presence of 10  $\mu\text{M}$   $\text{Co}^{2+}$   
56  
57 or  $\text{Mn}^{2+}$ . Fur protein was purified as previously described.<sup>44</sup> After a 30-min incubation at room  
58  
59  
60

16 **Transcriptional reporters.** For the construction of transcriptional reporter plasmid pAYC5 (carrying  
17 both PchR and Fur boxes of *pchD* promoter), the promoters of the gene of interest were amplified  
18 from the chromosomal DNA of *P. aeruginosa* PAO1 by PCR with specific primers (Table SM2 in  
19 Supplemental Materials), allowing overlapping with a second PCR fragment encompassing the open  
20 reading frame of mCherry. A second PCR was performed using the two first PCR fragment as template  
21 to obtain the transcriptional reporter fragment. This fragment was trimmed by digestion with *EcoRI*  
22 and *HindIII* or *BamHI* and inserted between the sites for these enzymes in pSEVA631 vector to generate  
23 pAYC5 and bacteria were transformed with this vector. The mutation of the Fur box of the *pchD*  
24 promoters to generate pAYC5-FURmut vector has been obtained with the Q5-site directed  
25 mutagenesis kit from New England Biolabs, using specific primers (Table 2SM).

41 **Binding assays with MBP-PchR.** The *E. coli* DH5 $\alpha$ -pME7180 strain (Table 1), expressing the  
42 recombinant protein PchR tagged with MBP at the N-terminal domain,<sup>45</sup> was used to express MBP-  
43 PchR protein for the binding assays. The protein was purified (Figure SM3) as described previously<sup>45</sup>  
44 and the protocol from Lin *et al.*<sup>46</sup> was used to investigate the binding between MBP-PchR and the  
45 different PCH-metal complexes, metals, and apo-PCH. The PCH-metal complexes were generated by  
46 mixing 20 mM PCH with  $\text{FeCl}_3$ ,  $\text{CoCl}_2$ ,  $\text{NiCl}_2$ , or  $\text{ZnCl}_2$  in methanol at a molar ratio of 2:1 (PCH:metal) to  
47 obtain a final metal concentration of 500  $\mu$ M. The complexes were incubated for 15 min at RT and  
48 finally 50 mM Tris-HCl pH 8 was added to adjust the volume to the desired concentration. The  
49 complexes were prepared just before use for the binding experiments.

5 **Quantitative real-time PCR.** Specific gene expression was measured by RT-qPCR, as previously  
6 described.<sup>47</sup> Briefly, overnight cultures of strains grown in CAA medium were pelleted, re-suspended  
7 and diluted in fresh medium to obtain an OD<sub>600nm</sub> of 0.1 units. The cells were then incubated in the  
8 presence or absence of 5 μM Fe<sup>3+</sup> or Co<sup>2+</sup>, with vigorous shaking, at 30°C for 8 h. RNAs were purified  
9 as described previously.<sup>37</sup> We then reverse transcribed 1 μg of total RNA with a High-Capacity RNAtc-  
10 cDNA Kit, in accordance with the manufacturer's instructions (Applied Biosystems). The amounts of  
11 specific complementary DNAs were assessed in a StepOne Plus instrument (Applied Biosystems) with  
12 Power Sybr Green PCR Master Mix (Applied Biosystems) and the appropriate primers (Table SM2). The  
13 transcript levels for a given gene in a given strain were normalized with respect to those for *uvrD* and  
14 are expressed as a ratio (fold change) relative to the reference conditions.

## Results

***Co<sup>2+</sup> can repress PCH and PVD production.*** We first investigated the impact of the biological metals ( $\text{Co}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Mn}^{2+}$  and  $\text{Zn}^{2+}$ ) on the production of both siderophores PVD and PCH in iron restricted growth conditions. Bacteria were grown in casamino acids (CAA) medium in the presence of three metal concentrations (Figure 2). CAA contains approximately 20 nM Fe (LB Broth medium contains 4.3  $\mu\text{M}$ )<sup>13</sup> and is considered to be highly iron-restricted. As previously described by Cunrath *et al.*,<sup>13</sup> PAO1 cells produced twice as much PVD as PCH under such growth conditions and in the absence of any biological metal:  $116.5 \pm 30.7 \mu\text{M}/\text{OD}_{600 \text{ nm}}$  and  $51.7 \pm 3.1 \mu\text{M}/\text{OD}_{600 \text{ nm}}$  for PVD and PCH, respectively.

The presence of  $\text{Fe}^{3+}$  completely repressed PVD production at 1  $\mu\text{M}$  and PCH production only at 15  $\mu\text{M}$  (Figure 2).  $\text{Co}^{2+}$  was the only other metal able to repress the production of both siderophores, with 41.1%, 48.5%, and 61.4% repression of PVD production in the presence of 1.5, 15, and 150  $\mu\text{M}$   $\text{Co}^{2+}$ , respectively. Surprisingly, we observed similar dose-dependent repression for both  $\text{Fe}^{3+}$  and  $\text{Co}^{2+}$  for PCH production.  $\text{Ni}^{2+}$  had no effect on PVD production and only affected PCH biosynthesis at 150  $\mu\text{M}$ , repressing production by 42 %.  $\text{Mn}^{2+}$  and  $\text{Zn}^{2+}$  had no significant effect on either PVD or PCH production at the concentrations tested.

Overall, PVD production was repressed, as expected, by the presence of  $\text{Fe}^{3+}$ , but also to a lesser extent by  $\text{Co}^{2+}$ , whereas surprisingly PCH production was repressed with equivalent efficiency by  $\text{Fe}^{3+}$  and  $\text{Co}^{2+}$  and, to a lesser extent, by the presence of  $\text{Ni}^{2+}$ .

***Genes up- and downregulated in P. aeruginosa cells in the presence of Co<sup>2+</sup>.*** We further investigated the impact of the presence of  $\text{Co}^{2+}$  on *P. aeruginosa* by carrying out proteomic and transcriptomic analyses of bacteria grown in CAA medium with or without 10  $\mu\text{M}$   $\text{Fe}^{3+}$  or  $\text{Co}^{2+}$ . Changes in gene transcription and expression are given as the log<sub>2</sub> ratio between *P. aeruginosa* grown with or without  $\text{Co}^{2+}$  (Table 2). The transcription and expression of several proteins of the PCH pathway was repressed in the presence of  $\text{Fe}^{3+}$  and  $\text{Co}^{2+}$ , showing a similar repressive effect of both metals, consistent with

1  
2  
3 the observed decrease of PCH production (Figure 2). In contrast, the transcription and expression of  
4 all genes detected belonging to the PVD pathway were repressed in the presence of  $Fe^{3+}$ , as expected,  
5 but at a clearly lower level in the presence of  $Co^{2+}$ . These data were confirmed by RT-qPCR  
6 experiments using several genes: two genes of the PVD pathway (an enzyme involved in PVD  
7 biosynthesis *pvdJ* and the transcriptional regulator *pvdS*) and five genes of the PCH pathway (the  
8 transcriptional regulator *pchR*, the inner membrane permease *fptX*, the outer membrane transporter  
9 *fptA* and two enzymes involved in PCH biosynthesis *pchA* and *pchE*) and the housekeeping gene *uvrD*,  
10 which was used for normalization (Figure 3A). RT-qPCR demonstrated a large decrease in transcript  
11 levels for all genes of the PCH pathway in the presence of both  $Fe^{3+}$  and  $Co^{2+}$ , except for the gene  
12 encoding the transcriptional regulator *pchR*. Concerning the genes of the PVD pathway, a strong  
13 repression is observed for the two genes tested with  $Fe^{3+}$  and at a lower extend with  $Co^{2+}$ . For  $Ni^{2+}$   
14 and  $Zn^{2+}$  no significant transcriptional repression of the seven genes tested was observed (Figure 3A),  
15 but in some case a very small increase of transcription.

23  
24  
25  
26  
27  
28  
29  
30  
31  
32 In conclusion, the transcription and expression of the proteins of the PCH pathway (exception for  
33 PchR) are more strongly repressed in the presence of  $Co^{2+}$ , than the genes of the PVD pathway.

34  
35  
36  
37  
38  
39 ***Co<sup>2+</sup> differently affects the expression of the genes the PCH operons.*** The RT-qPCR experiment  
40 (Figure 3A) highlighted for all genes of the PCH pathway, except for the one corresponding to the  
41 transcriptional regulator *pchR*, a large decrease in transcript levels in the presence of  $Co^{2+}$  compared  
42 to growth conditions in the absence of metals, while the presence of  $Fe^{3+}$  repressed the transcription  
43 of all genes including *pchR*. This observation indicates that  $Co^{2+}$ , and not  $Fe^{3+}$ , affects differently the  
44 transcription of the genes of PCH operons. The genes of these four PCH genes belong to three  
45 different operons: *pchA* and *pchE* belong to the two operons coding for the enzymes involved in PCH  
46 biosynthesis *pchDCBA* and *pchEFGHI*, *fptX* to the PCH-Fe *fptABCX* operon, and *pchR* which is not in an  
47 operon with other genes (Scheme 1).  $Co^{2+}$  is apparently able to repress *fptABCX*, *pchDCBA* and  
48 *pchEFGHI* operons and not *pchR*.

1  
2  
3 To investigate further this observation, we followed the expression of the four proteins PchA, PchE,  
4 FptX and PchR of the PCH pathway during bacterial growth, in the presence of the biological metals,  
5 using four strains that express fluorescent fusion proteins between mCherry and PchA (*pchA-mCherry*  
6 strain, Table 1), PchE (*pchE-mcherry*), FptX (*fptX-mCherry*), and the transcriptional regulator PchR  
7 (*mCherry-pchR*).<sup>48</sup> These proteins were tagged with mCherry at the N- or C-terminal end, and the  
8 tagged proteins chromosomally integrated. The presence of the tag has been shown to affect neither  
9 the transcription of the proteins (by RT-qPCR) nor their biological activities (siderophore production  
10 or ferri-siderophore uptake).<sup>48</sup> During bacterial growth, in the absence of any metals, two different  
11 variation of mCHERRY fluorescence were observed depending on the strains. For *pchA-mCherry*,  
12 *pchE-mcherry* and *fptX-mCherry* strains a strong increase of fluorescence is observed corresponding  
13 to an increase of PchA-mCHERRY, PchE-mCHERRY and FptX-mCHERRY fusion protein expression  
14 (Figure 3B). On the opposite, for *mcherry-pchR* in the same growth conditions, mCHERRY  
15 fluorescence decreased slightly after 6 hours culture (Figure 3C). As expected, the presence of 5  $\mu\text{M}$   
16  $\text{Fe}^{3+}$  repressed strongly PchA-mCHERRY, PchE-mCHERRY, mCHERRY-FptX and mCHERRY-PchR fusion  
17 protein expression during bacterial growth. Consistent with the RT-qPCR data (Figure 3A),  $\text{Co}^{2+}$   
18 repressed the expression of PchA-mCHERRY, PchE-mCHERRY and mCHERRY-FptX but not of  
19 mCHERRY-PchR.  $\text{Ni}^{2+}$  and  $\text{Zn}^{2+}$  at the concentrations tested had no effect on the expression of the four  
20 fusion proteins. Actually their presence slightly induced the expression of PchA-mCHERRY, PchE-  
21 mCHERRY and mCHERRY-FptX, probably because of the metal-restriction growth conditions.  
22  
23 Based on the *P. aeruginosa* genome, *pchR* expression is regulated solely by Fur (presence only of a  
24 Fur-Box) and *pchDCBA*, *pchEFGHI*, and *fptABCX* operons by both Fur and PchR regulators (the  
25 presence of both Fur- and PchR-boxes upstream of these genes) (Scheme 1). Our data show that the  
26 presence of  $\text{Co}^{2+}$  inhibits only the transcription of genes that depend on a PchR box for their  
27 expression.

2  
3 ***Co<sup>2+</sup> can enter *P. aeruginosa* cells by the TonB-dependent transporter FptA.*** According to current  
4  
5 knowledge concerning the interaction of the transcriptional regulators Fur and PchR with Fe  
6  
7 (formation of Fur-Fe and PchR-PCH-Fe complexes), the interaction of  $\text{Co}^{2+}$  with one of these  
8  
9 regulators includes the importation of  $\text{Co}^{2+}$  into the bacteria and, in the case of PchR, the presence  
10  
11 of PCH-Co to form a PchR-PCH-Co complex.<sup>46</sup> When  $\text{Co}^{2+}$ ,  $\text{Ni}^{2+}$  and  $\text{Zn}^{2+}$  are incubated with PCH in  
12  
13 solution, the UV spectral modifications observed compared to the UV spectrum of apo PCH, indicates  
14  
15 that PCH is able to chelate these three metals (Figure 2SM). Moreover, previously we have  
16  
17 determined a  $K_a$  of PCH for  $\text{Zn}^{2+}$  of  $K_a = 10^{26.0} \text{ M}^{-2}$  ( $K_a = 10^{28.8} \text{ M}^{-2}$  for  $\text{Fe}^{3+}$ ).<sup>28</sup> Previous studies of our  
18  
19 group, in which we used ICP-AES (Inductively Coupled Plasma Atomic Emission Spectroscopy, which  
20  
21 allows the detection of metals traces), showed that  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  can both enter *P. aeruginosa* cells  
22  
23 *via* the FptA/PCH pathway when bacteria were grown in succinate-containing medium.<sup>24</sup> Here, we  
24  
25 used the same approach to verify that bacteria grown in CAA medium are also able to efficiently  
26  
27 import  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$ . CAA is 10 fold more iron-restricted than succinate medium: iron concentration  
28  
29 of 300 nM for succinate medium and 20 nM for CAA.<sup>13</sup> We used a PVD and PCH-deficient strain  
30  
31 ( $\Delta pvdF\Delta pchA$ , Table 1) to control the presence of siderophores and their concentrations in the assay.  
32  
33 The importance of the PCH pathway in metal uptake was evaluated by using the *fptA* (PCH-Fe outer  
34  
35 membrane transporter) mutant strain  $\Delta pvdF\Delta pchA\Delta fptA$  (Table 1).  
36  
37 As expected, *fptA* deletion markedly affected Fe accumulation in *P. aeruginosa* cells in the presence  
38  
39 of PCH (Figure 4A), as well as that of  $\text{Co}^{2+}$ , showing that  $\text{Co}^{2+}$  is imported into *P. aeruginosa* cells by  
40  
41 the FptA transporter (Figure 4A).  $\text{Co}^{2+}$  uptake certainly occurs in a complex with PCH, since this  
42  
43 transporter recognizes only PCH-metal complexes and not siderophore-free metals.<sup>49,50</sup> However, the  
44  
45 amount of  $\text{Co}^{2+}$  imported by the FptA/Pch system is lower than the amount of  $\text{Fe}^{3+}$  acquired. We  
46  
47 observed no significant FptA-dependent uptake for  $\text{Ni}^{2+}$  and  $\text{Zn}^{2+}$  at the metal concentrations tested  
48  
49 here, as previously reported.<sup>24</sup>  
50  
51 We also investigated the ability of PCH-Co complexes to compete with and inhibit PCH-<sup>55</sup>Fe import in  
52  
53 *P. aeruginosa* cells. The PVD and PCH-deficient strain ( $\Delta pvdF\Delta pchA$ ) was incubated with 0.2  $\mu\text{M}$  PCH-  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  $^{55}\text{Fe}$  with or without 0.2  $\mu\text{M}$  and 2  $\mu\text{M}$  (1 and 10-fold excess) PCH-metal complexes and the  
4 radioactivity incorporated into the bacteria (during a 30-min incubation) counted. Incubation of the  
5 bacteria in the presence of PCH- $^{55}\text{Fe}$  alone resulted in the uptake of approximately 90 pmol of  $^{55}\text{Fe}$   
6 per cell per 30 min (Figure 4B). We observed 60 % inhibition of this uptake in the presence of 2  $\mu\text{M}$   
7 PCH-Co. We also carried out a competition assay with PCH-Ni and PCH-Zn complexes, but observed  
8 no significant inhibition of  $^{55}\text{Fe}$  uptake *via* PCH.  
9

10 These data all suggest that, in the range of metal concentrations tested,  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  can enter  
11 bacteria both by diffusion ( $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  accumulation in the *fptA* mutant, Figure 3A) and also *via* the  
12 PCH/FptA uptake system for  $\text{Co}^{2+}$ . Consequently, PCH-Co complexes, as well as siderophore-free  $\text{Co}^{2+}$   
13 and  $\text{Ni}^{2+}$ , are present in *P. aeruginosa* cells.

27  
28 ***The presence of  $\text{Co}^{2+}$  in the bacterial environment does not affect the intracellular iron***  
29 ***concentration in *P. aeruginosa* cells.*** *P. aeruginosa* PAO1 cells were also grown in the presence of 5  
30  $\mu\text{M}$   $\text{Co}^{2+}$  or  $\text{Ni}^{2+}$  to assess how the intracellular concentrations of all biological metals were affected  
31 by the presence of an excess of these two metals (Figure 5). Surprisingly, although  $\text{Co}^{2+}$  can enter  
32 bacteria by diffusion or in competition with  $\text{Fe}^{3+}$  by the FptA/PCH pathway, the intracellular iron  
33 concentration was not affected. This suggests that bacteria can adapt to potential competition  
34 between  $\text{Fe}^{3+}$  and  $\text{Co}^{2+}$  for the FptA/PCH system during growth and that the intracellular iron content  
35 is maintained, even in the presence of 5  $\mu\text{M}$   $\text{Co}^{2+}$  contamination.  
36  
37

43  
44  
45  
46  
47

48 ***Excess  $\text{Co}^{2+}$  in the bacterial environment does not affect Fur regulation.*** We next elucidated the  
49 molecular mechanism involved in the Co-dependent repression of PCH pathway expression by  
50 investigating the ability of Fur-Co complexes to interact with the Fur boxes *in vitro*. *E. coli* Fur has been  
51 shown to bind DNA sequences containing Fur boxes by interacting with metals other than  $\text{Fe}^{2+}$ <sup>51</sup> and  
52 Fur of *P. aeruginosa* has been shown to be capable of binding to the Fur box in the presence of  $\text{Co}^{2+}$  in  
53 a nuclease protection assay<sup>44</sup> and in the presence of  $\text{Mn}^{2+}$  in an EMSA (electrophoretic mobility shift  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 assay) assay.<sup>52</sup> It is not possible to run EMSA in the presence of  $\text{Fe}^{2+}$  because of its oxidation.  
4  
5 Consequently, it is well accepted in the literature to use  $\text{Mn}^{2+}$  ions to mimic  $\text{Fe}^{2+}$  for the DNA binding  
6  
7 assay.<sup>52</sup> Here EMSA experiments were carried out in the presence of  $\text{Co}^{2+}$  and  $\text{Mn}^{2+}$ , with purified Fur  
8  
9 protein and the promoter region of *pchD*, containing the Fur-box present upstream of the *pchDCBE*  
10  
11 operon. An interaction between Fur-Co and the *pchD* promoter sequence was observed (Figure 6),  
12  
13 proving that Fur-Co is able to bind to this sequence. However, our proteomic, transcriptomic and RT-  
14  
15 qPCR data (Table 2 and Figure 3A), as well as the expression data using mCherry fusion proteins (Figure  
16  
17 3B-3C), clearly show that the presence of  $\text{Co}^{2+}$  in the bacterial environment does not repress all Fur-  
18  
19 dependent genes, as does the presence of  $\text{Fe}^{3+}$ . Therefore, we also used a plasmid (pAYC5) carrying  
20  
21 the mCherry sequence and the PCH promoter of *pchDCBA* operon (Table 1SM) to investigate the  
22  
23 behavior of Fur in the presence of  $\text{Co}^{2+}$  in *P. aeruginosa* cells. Since this promoter region also contains  
24  
25 a PchR box, we carried out this experiments in strain unable to express PchR ( $\Delta pchR$  strain). Bacteria  
26  
27 carrying this construct were grown in CAA medium with increasing concentration (0-100  $\mu\text{M}$ ) of  $\text{Co}^{2+}$   
28  
29 or  $\text{Fe}^{3+}$  and the mCherry fluorescent signal monitored at 610 nm (excitation at 570 nm). As expected,  
30  
31 the addition of  $\text{Fe}^{3+}$  to the bacterial growth medium caused the repression of mCherry expression  
32  
33 (Figure 7A): the Fur-Fe complex interacts with the bacterial Fur boxes, which represses the  
34  
35 transcription and expression of mCherry and any Fur-dependent genes. The addition of  $\text{Co}^{2+}$  to the  
36  
37 bacterial medium had no significant effect on mCherry expression (Figure 7B) for concentrations of  
38  
39  $\text{Co}^{2+}$  equivalent or lower than 10  $\mu\text{M}$  and a weak effect was observed at 100  $\mu\text{M}$ . We carried out the  
40  
41 same experiment with 10 and 100  $\mu\text{M}$   $\text{Ni}^{2+}$  or  $\text{Zn}^{2+}$  (Figure 7C and 7D) and no repression of mCherry  
42  
43 expression was observed.  
44  
45  
46  
47  
48  
49

50 Overall, our data show that, Fur-Co can bind to the PCH Fur-box but does not repress Fur-dependent  
51  
52 gene expression *in vivo* like  $\text{Fe}^{2+}$  whereas equivalent effects are observed for both metals for PCH  
53  
54 production (Figure 2).  
55  
56  
57  
58

59 ***The purified cytoplasmic regulator PchR can bind to PCH-Co and PCH-Ni in addition to PCH-Fe.*** PchR,  
60

1  
2  
3 the transcriptional activator of the genes of the PCH pathway, activates the transcription of all PCH  
4 genes, except *pchR*, by interacting with the PchR box (no PchR box upstream of *pchR* gene).<sup>21-23</sup> We  
5 carried out binding assays between purified PchR (MBP fused PchR<sup>46</sup> and purified protein shown in  
6 Figure SM3) and PCH-Co and PCH-Ni, based on a spectroscopy approach previously described, using  
7 the fluorescent properties of the tryptophans (Trp) of PchR published previously.<sup>46</sup> When MBP-PchR  
8 is excited at 280 nm, tryptophan present in the protein emits intrinsic fluorescence with maximal  
9 intensity at 330 nm (Figure 4SM). Upon the addition of ligands, such as PCH-Fe, the fluorescence is  
10 quenched. Thus, the protein's affinity for its ligand can be determined by plotting the relative  
11 fluorescence intensity,  $F_0/F$ , with  $F_0$  being the fluorescence emitted by MBP-PchR without ligand and  
12  $F$  the fluorescence emitted by MBP-PchR once a specific concentration of ligand has been added.  
13 Afterwards,  $K_d$  values are determined using the Stern-Volmer representation and linear regression.  
14 PCH-metal complexes were prepared by incubating 2 equivalent of PCH with one of metal (Figure  
15 2SM).

16 We determined an affinity of PCH-Fe ( $K_d = 5.82 \pm 2.84 \mu\text{M}$ ) for MBP-PchR that was slightly better as  
17 that described previously ( $K_d = 41 \pm 5 \mu\text{M}$ )<sup>46</sup>. PCH-Co was also able to bind to PchR with a  $K_d$  of  $13.9 \pm$   
18  $3.4 \mu\text{M}$ , as well as PCH-Ni and PCH-Zn ( $K_d$  values of  $42 \pm 4.3 \mu\text{M}$  and  $47.4 \pm 2.2 \mu\text{M}$ , respectively -for  
19 details see Figure 4SM). We were unable to investigate the ability of PchR-PCH-Co to bind the PchR  
20 box (EMSA assays with the purified MBP fused PchR protein), probably because of the presence of  
21 the tag, as well as problems with protein aggregation.

47  
48 **Role of PchR in the repression of the PCH pathway in the presence of  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$ .** We further  
49 explored the mechanism involved in the repression of PCH production observed in the presence of  
50  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  by constructing a plasmid (pAYC5-FURmut) carrying the mCherry sequence and the  
51 promoter of the *pchDCBA* operon containing only the PchR box and the Fur box having being mutated  
52 (Table 1SM and 2SM). The strains PAO1 and  $\Delta pchR$  (unable to express PchR) carrying this plasmid  
53 were grown in CAA medium supplemented with increasing concentrations of metals ( $\text{Fe}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Ni}^{2+}$   
54  
55  
56  
57  
58  
59  
60

1  
2  
3 or Zn<sup>2+</sup>). In the absence of metals, in the WT (PAO1) background (kinetics with black dots in Figure  
4 8A-8D), the fluorescence corresponding to mCherry expression highly increased in function of time,  
5  
6 but not in the  $\Delta pchR$  strain unable to express the transcriptional activator PchR (kinetics with grey  
7  
8 triangles in Figure 8A-8D), indicating that PchR is necessary to observe mCherry expression. For PAO1,  
9  
10 in the presence of increasing concentrations of Fe<sup>3+</sup>, this fluorescence corresponding to mCherry  
11  
12 expression decreased during bacterial growth (Figure 8A). This observation is due to Fur which gets  
13  
14 loaded with Fe<sup>2+</sup>, interacts with its promoter regions and consequently the expression of PchR and  
15  
16 the other proteins of the PCH pathway is repressed (Figure 3A and Table 2). Since less PchR is  
17  
18 expressed, *mcherry* transcription is no more activated and lower level of fluorescence are observed  
19  
20 compared to the condition in the absence of metal.  
21  
22  
23  
24

25 In the presence of increasing concentrations of Co<sup>2+</sup> or Ni<sup>2+</sup> (but not Zn<sup>2+</sup>; Figure 8B-8D), the  
26  
27 fluorescence corresponding to mCherry expression also decreased in PAO1 cultures, but less than in  
28  
29 the presence of Fe<sup>3+</sup>. Higher concentrations of Co<sup>2+</sup> (10  $\mu$ M) and Ni<sup>2+</sup> (100  $\mu$ M) are necessary to elicit  
30  
31 an effect equivalent to that observed with Fe<sup>3+</sup> (5  $\mu$ M). In that case, the decrease of fluorescence is  
32  
33 not due to an absence of PchR expression, since Co<sup>2+</sup> or Ni<sup>2+</sup> present in the *P. aeruginosa* environment  
34  
35 were both unable to repress the expression of Fur-regulated genes (Figure 7). Co<sup>2+</sup> (and probably  
36  
37 also Ni<sup>2+</sup>) are likely present in the bacterial cytoplasm, mostly in their PCH-complexed forms (50  $\mu$ M  
38  
39 is the concentration of PCH in the bacterial culture and 5  $\mu$ M metals are added to the growth media).  
40  
41 Increasing concentrations of PCH-Co or PCH-Ni complexes in the bacterial cytoplasm certainly leads  
42  
43 to an increase in the concentrations of PchR-PCH-Co or PchR-PCH-Ni complexes, at the expense of  
44  
45 PchR-PCH-Fe complexes, but only PchR-PCH-Fe complexes are probably able to activate transcription  
46  
47 of the genes for the proteins of the PCH pathway and *mcherry* from pAYC5-FURmut plasmid. In such  
48  
49 a scenario, the expression of PchR-regulated genes, as the genes of the PCH pathway, is less highly  
50  
51 activated and less PCH is produced (Figure 2). This also explains why the presence of Co<sup>2+</sup> or Ni<sup>2+</sup> does  
52  
53 not repress *pchR* expression, as the transcription of this gene is not regulated by the PchR promoter,  
54  
55 but only the Fur box (Scheme 1).<sup>45</sup>  
56  
57  
58  
59  
60

1  
2  
3 In conclusion, the presence of high levels of  $\text{Fe}^{3+}$ ,  $\text{Co}^{2+}$ , or  $\text{Ni}^{2+}$  (to a lesser extent) in the bacterial  
4 environment induces repression of the transcription of PCH genes (except *pchR*) by two different  
5 molecular mechanisms. In the presence of  $\text{Fe}^{3+}$  in the bacterial environment, the transcriptional  
6 repressor Fur, in a complex with  $\text{Fe}^{2+}$ , represses the expression of these genes. In the presence of  $\text{Co}^{2+}$   
7 or  $\text{Ni}^{2+}$ , Fur is not involved, but rather the transcriptional activator PchR, which is no more able to  
8 activate the production of PCH, probably due to a decrease in the intracellular concentration of PchR-  
9 PCH-Fe complexes.

## Discussion

The requirement for different biological metals in bacteria are very different and depend on their biological function. The relative intracellular concentrations of these metals in *P. aeruginosa* PAO1 cells are Na-K > Mg >> Ca >> Fe-Zn >> Mn-Mo-Cu-V-Cr-Ni >> Co<sup>13</sup>, with Fe and Zn being the two most abundant transition metals (concentrations between 10<sup>-3</sup> and 10<sup>-4</sup> M, depending on the growth medium). The intracellular concentrations of Cu, Mn, Mo, and Ni are generally between 10<sup>-5</sup> and 10<sup>-4</sup> M<sup>13</sup> and Co is used only in very small amounts by *P. aeruginosa* (a concentration too low to be detected by ICP-AES<sup>13</sup>). Very similar values have been described for wild type *E. coli*<sup>53</sup> and can probably be found in many Gram-negative bacteria in planktonic growth conditions.

Since, all biological metals become toxic at high concentrations and are highly deleterious to living organisms, the intracellular concentrations of these biological metals have to be finely regulated to stay constant. Siderophores play a key role in iron homeostasis.<sup>21</sup> Increasing number of publications also suggest that siderophores may play a role in the homeostasis of other biological metals.<sup>18</sup> Indeed, these compounds are able to chelate many metals other than Fe<sup>3+</sup>,<sup>18</sup> their production can be modulated by different metals<sup>30-34</sup> and they often play a role in bacterial metal resistance.<sup>17,18</sup> These observations lead to the question whether bacteria are able to activate their siderophore production in response to the presence of metals other than Fe<sup>3+</sup>. As in previous studies,<sup>24</sup> we showed that none of the metals tested was able to significantly activate PVD or PCH production above that induced by iron restriction (Figure 2). Moreover, there is currently no data available to support the existence of bacterial sensors that detect toxic metals in the bacterial environment and consequently activate siderophore production. All current data suggest that for example the protective role of siderophores against toxic metals is probably only a consequence of the presence of large amounts of siderophores produced in response to iron starvation. However, the formation of siderophore-metal complexes with metals other than Fe<sup>3+</sup> may increase the sense of iron starvation by bacteria, because siderophores are in complex with metals other than Fe<sup>3+</sup> and consequently less siderophore-Fe is imported into the bacteria.

1  
2  
3 In the present work,  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  were able to repress the production of PCH and for  $\text{Co}^{2+}$ , with the  
4 same efficiency as  $\text{Fe}^{3+}$ . PCH production is positively regulated by the transcriptional activator PchR  
5 and negatively by the transcriptional repressor Fur (Scheme 1). PchR activates the transcription of all  
6 PCH genes, except *pchR*, by interacting with the PchR box (no PchR box upstream of *pchR*, Scheme 1).  
7 Consequently, a decrease of PCH production must be due to either Fur-dependent repression or the  
8 inability of PchR to still activate PCH production. Our data show that Fur regulation is insensitive to the  
9 presence of excess  $\text{Co}^{2+}$  (or  $\text{Ni}^{2+}$ ), even if  $\text{Co}^{2+}$  bound to Fur proteins *in vitro* and formed complexes with  
10 Fur boxes. Our experimental data show that the repression of PCH production by  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  involves  
11 PchR. They also show that PCH-Co enters bacteria via the TonB-dependent outer membrane  
12 transporter FptA and can bind to PchR *in vitro*. Since a repression of PCH production is as well observed  
13 in the presence of  $\text{Ni}^{2+}$ , we cannot exclude that PCH-Ni is also able to enter *P. aeruginosa* cells but with  
14 uptake rates too low to be detected by our approach. Altogether, these data describe a mechanism in  
15 which PCH-Co, after entering *P. aeruginosa* cells by FptA, interacts with PchR to form PchR-PCH-Co  
16 complexes unable to activate the transcription of PchR-regulated genes. The formation of PchR-PCH-  
17 Co or PchR-PCH-Ni complexes in the bacterial cytoplasm certainly leads to a decrease in the  
18 intracellular concentration of PchR-PCH-Fe, leading to a decrease in the transcription of PCH pathway  
19 genes and, thus, the production of PCH.

32  
33  
34  
35  
36  
37  
38  
39  
40  
41 The repression of PCH production was more pronounced with  $\text{Co}^{2+}$  than  $\text{Ni}^{2+}$  and cannot be explained  
42 simply by the difference in affinities of PchR for the PCH-Co and PCH-Ni complexes. Previous studies,  
43 based on titration experiments, have shown that the binding affinity of PCH is higher for  $\text{Ni}^{2+}$  than  $\text{Co}^{2+}$   
44 (relative affinity of PCH for biological metals having been proposed  $\text{Fe(III)} > \text{Mo(VI)} = \text{Cu(II)} > \text{Ni(II)} >$   
45  $\text{Co(II)} > \text{Zn(II)} > \text{Mn(II)}$ ).<sup>33</sup> On the contrary, the PCH-Co complex more efficiently competes with PCH-Fe  
46 for the TonB-dependent transporter FptA (affinities of PCH-Co and PCH-Ni for FptA in the range of 15  
47 nM and 50 nM, respectively<sup>24</sup>) and is more efficiently transported into *P. aeruginosa* cells. The higher  
48 efficiency of  $\text{Co}^{2+}$  to repress PCH production is probably linked to its higher ability to enter *P.*  
49 *aeruginosa* cells as a PCH-Co complex relative to PCH-Ni.

1  
2  
3 ICP-AES measurements of intracellular metal concentrations of *P. aeruginosa* cells grown with or  
4 without  $\text{Co}^{2+}$  showed no effect of this metal on the intracellular iron concentration. This indicates that  
5 the inhibition of PCH production in the presence of  $\text{Co}^{2+}$  has little effect on bacterial iron homeostasis  
6 under our growth conditions. The ability of  $\text{Co}^{2+}$  to interfere with  $\text{Fe}^{3+}$  acquisition *via* the PCH/FptA  
7 pathway (55 % inhibition of PCH- $^{55}\text{Fe}$  uptake in *P. aeruginosa* PAO1 cells when incubated for 30 min in  
8 the presence of PCH-Co complexes) does not affect the access to iron of the pathogen. This organism  
9 uses several strategies to obtain access to iron; if one iron acquisition pathway is compromised, the  
10 bacteria simply uses another.<sup>12</sup>

11  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23 FptA plays a key role in the outer membrane for the uptake of the right metal by PCH. Previous studies  
24 from our group have shown that FptA at the bacterial surface can bind different PCH-metal complexes,  
25 with affinities ranging from 10 nM to 4.8  $\mu\text{M}$ , (the affinity of PCH-Fe being 10 nM).<sup>24</sup> However, only  
26  $\text{Fe}^{3+}$  and, to a lesser extent,  $\text{Co}^{2+}$  can accumulate significantly in *P. aeruginosa* cells via the PCH  
27 pathway, but with uptake rates clearly lower than those for  $\text{Fe}^{3+}$ . Moreover, previous studies have also  
28 shown that PCH complexes  $\text{Ga}^{3+}$  and the formed complex is transported into *P. aeruginosa* cells via  
29 FptA.<sup>24,54</sup>  $\text{Ni}^{2+}$  is probably also transported in complex with PCH with low uptake rates, since the  
30 presence of this metal in the bacterial environment represses PchR regulated genes. FptA, due to its  
31 uptake specificity, avoids and controls the uptake of most metals other than  $\text{Fe}^{3+}$  across the outer  
32 membrane and limits the uptake of  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$ .  $\text{Fe}^{3+}$ ,  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  are part of the iron triad and all  
33 three elements show similar properties such as the metallic radius (124, 125, 125 pm, respectively)  
34 and the electronic configuration.  $\text{Ga}^{3+}$  has a radius slightly larger (187 pm) than  $\text{Fe}^{3+}$  but very similar  
35 coordination properties. Consequently, PCH-Co, PCH-Ni and PCH-Ga have certainly very close  
36 conformations, which is not the case for PCH-Cu and PCH-Zn complexes (two metals with different  
37 coordination properties compared to  $\text{Fe}^{3+}$ ). The metallic radius and similar coordination properties  
38 could be responsible for the high specificity of FptA for PCH-metal complexes.

1  
2  
3 We are aware that the  $\mu\text{M}$  concentrations of  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  used in this study are not truly physiological  
4 in the natural environment thrived by *P. aeruginosa*, and exposure to such concentrations appears  
5 unlike during infections and exceptional also in natural environment. However, such concentrations  
6 are often used in the literature in studies investigating the role of siderophores in bacterial resistance  
7 to metals or in development of bioremediation processes using siderophore producing bacteria to  
8 decontaminated metal polluted media or wastes. In such contexts, it is important to understand how  
9 siderophore production and siderophore-dependent  $\text{Fe}^{3+}$  uptake pathways in bacteria interfere with  
10 an excess of metals other than  $\text{Fe}^{3+}$  and what are the molecular mechanisms involved.

## 23 Conclusion

24  
25  
26 We show for the first time, how an excess of biological metals, other than iron, can interfere with  
27 transcriptional regulators that control the transcription of genes of the PCH pathway. The presence  
28 of high levels of  $\text{Fe}^{3+}$ ,  $\text{Co}^{2+}$ , or  $\text{Ni}^{2+}$  (to a lesser extent) in the bacterial environment represses the  
29 transcription of PCH genes by two different molecular mechanisms. In the presence of increasing  $\text{Fe}^{3+}$   
30 concentrations, the transcriptional repressor Fur gets loaded with  $\text{Fe}^{2+}$  and represses the expression  
31 of all *pch* genes. In the presence of increasing  $\text{Co}^{2+}$  or  $\text{Ni}^{2+}$  concentrations, Fur is not involved, but the  
32 transcriptional activator PchR gets loaded with PCH-Co and PCH-Ni and consequently is no more able  
33 to activate the transcription of *pch* genes, due to a decrease in the intracellular concentration of  
34 PchR-PCH-Fe complexes.  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45

46 PchR appears to have broad metal-binding specificity, but since only a few metals ( $\text{Fe}^{3+}$ ,  $\text{Ga}^{3+}$ ,  $\text{Co}^{2+}$ , and  
47  $\text{Ni}^{2+}$ ) are able to enter bacteria by the FptA/PCH pathway, most which could be present as a  
48 contaminant in the bacterial environment do not affect PCH production. Indeed, FptA acts as a  
49 selective gate for the uptake of PCH-metal complexes and allows the uptake of only PCH-Fe and, to a  
50 lesser extent, PCH-Ga, PCH-Co, and PCH-Ni. The presence of these PCH-metal complexes in the  
51 bacterial cytoplasm interferes with the regulation of PCH production by interacting with PchR and  
52 inhibiting the positive autoregulatory loop that involves PchR (Scheme 2). The inability of PchR-PCH-

1  
2  
3 Co and PchR-PCH-Ni to activate the expression of PCH genes highly suggests that PCH is not involved  
4  
5 in the acquisition by *P. aeruginosa* of these two metals, but that their uptake via PCH is simply a non-  
6  
7 specific interference of these two metals with the PCH pathway. Moreover, the Achilles heel of the *P.*  
8  
9 *aeruginosa* PCH pathway, in terms of excess  $\text{Co}^{2+}$  in the bacterial environment, is the selectivity of FptA  
10  
11 for metal transport. However, the ability of PchR to interact with many different PCH-metal complexes  
12  
13 leads to a decrease in PCH production and consequently a decrease in PCH-Co and PCH-Ni import.

## Legends of figures

**Figure 1: Chemical structure of pyoverdine (PVD) and pyochelin (PCH).**

**Scheme 1. Organization of PCH pathway genes in the *P. aeruginosa* PAO1 genome.** *fptABCX*, *pchEFGHI*, *pchR*, and *pchDCBA* are all genes coding for proteins involved in Fe<sup>3+</sup> acquisition by PCH. Fur is a transcription regulator. Fur loaded with Fe<sup>2+</sup> represses the expression of all PCH genes via an interaction with the Fur box. PchR is a transcriptional activator of the AraC family. PchR in complex with PCH-Fe<sup>3+</sup> activates the transcription of all PCH genes, except *pchR*, by interacting with the PchR box (no PchR box upstream of *pchR*).<sup>21–23</sup>

**Figure 2. PVD (A) and PCH (B) production by *P. aeruginosa* PAO1 in the absence and presence of different biological metals.** Bacteria were grown 24 h in CAA medium with or without 1, 15, or 150 μM of biological metals (no metal (control): black; FeCl<sub>3</sub>: red; CoCl<sub>2</sub>: pink; NiCl<sub>2</sub>: blue; CuCl<sub>2</sub>: yellow; MnCl<sub>2</sub>: purple and ZnCl<sub>2</sub>: green). The concentration of PVD and PCH (μM/OD<sub>600 nm</sub>) was monitored after 24 h in culture and calculated as described in Materials and Methods.

**Figure 3. A. Analysis of fold-change in transcription for genes of the PVD and PCH pathways.** *pvdS* and *pvdJ* genes encode a sigma factor and an enzyme involved in PVD pathway. The other five genes belong to the PVD pathway: *pchR*, encodes the transcriptional regulator, *pchA* and *pchE* are NRPS involved in PCH biosynthesis and *fptA* and *fptX* the outer and inner membrane transporters of PCH-Fe, respectively. RT-qPCR was performed on *P. aeruginosa* PAO1 grown in CAA medium with or without 5 μM FeCl<sub>3</sub>, CoCl<sub>2</sub>, NiCl<sub>2</sub> or ZnCl<sub>2</sub>. The data were normalized relative to the reference gene *uvrD* and are representative of three independent experiments. Results are given as a ratio between the values obtained in the presence of metals over those obtained in the absence. All values fold-change values are given in Table 3SM in Supplemental Materials.

**B. PchA-mCherry, PchE-mCHERRY and FptX-mCHERRY expression in *P. aeruginosa* cells grown in CAA medium with or without 5  $\mu\text{M}$   $\text{FeCl}_3$ ,  $\text{CoCl}_2$ ,  $\text{NiCl}_2$  or  $\text{ZnCl}_2$ .** *pchA-mcherry*, *pchE-mcherry* and *fptX-mcherry* strains were grown in CAA medium. The metals were added at the beginning of culture and bacterial growth monitored at  $\text{OD}_{600 \text{ nm}}$  and the expression of the fluorescent fusion proteins measured by following the fluorescence at 610 nm (excitation at 570 nm). All kinetics are an average of 5 kinetics.

**C. mCHERRY-PchR expression in *P. aeruginosa* cells grown in CAA medium with or without  $\text{FeCl}_3$ ,  $\text{CoCl}_2$  or  $\text{NiCl}_2$ .** Since the emission of fluorescence in *mcherry-pchR* strain and the variation of fluorescence observed in the presence of  $\text{Fe}^{3+}$  are low, different metal concentrations were tested. The metals were added at the beginning of culture and bacterial growth monitored at  $\text{OD}_{600 \text{ nm}}$  and the expression of the fluorescent fusion proteins measured by following the fluorescence at 610 nm (excitation at 570 nm). All kinetics are an average of 5 kinetics

**Figure 4. A. Transport of PCH-Fe and PCH-Co in *P. aeruginosa* cells.**  $\Delta\text{pvdF}\Delta\text{pchA}$  (grey bars) and  $\Delta\text{pvdF}\Delta\text{pchA}\Delta\text{fptA}$  (white bars) strains at an  $\text{OD}_{600 \text{ nm}}$  of 1 in CAA medium were incubated with or without 4  $\mu\text{M}$  of preformed PCH-metal complexes. For both panels, bacteria were pelleted after a 30-min incubation, washed, and the amount of metal monitored by ICP-AES. **B. Kinetics of intracellular  $^{55}\text{Fe}$  accumulation in *P. aeruginosa* cells in the presence of PCH-metal complexes.**  $\Delta\text{pvdF}\Delta\text{pchA}$  cells at an  $\text{OD}_{600 \text{ nm}}$  of 1 were incubated with 0.2  $\mu\text{M}$  PCH- $^{55}\text{Fe}$  and without (black dots) or with 1 eq. (0.2  $\mu\text{M}$ ) or 10 eq. (2  $\mu\text{M}$ ) PCH-metal complexes (PCH-Co in green, PCH-Ni in blue, or PCH-Zn in orange). Aliquots were removed at various times and the radioactivity in the cells monitored.

**Figure 5. Total content of biological metals in *P. aeruginosa* PAO1 cells grown in CAA medium with or without 5  $\mu\text{M}$   $\text{CoCl}_2$ .** *P. aeruginosa* PAO1 cells were grown in CAA medium without (grey bars) or with 5  $\mu\text{M}$   $\text{CoCl}_2$  (black bars). The data are expressed as moles per volume as described previously.<sup>13</sup> The absence of columns for some metals corresponds to the detection limits for low-abundance

1  
2  
3 elements under these experimental conditions. For all experiments, bacteria were grown in CAA,  
4  
5 harvested at the end of the exponential phase, and prepared for ICP-AES measurements as described  
6  
7 in Materials and Methods.  
8

### Significance to Metalloomics statement

It is well known that bacteria produce siderophores to get access to iron. Several studies have also shown that the presence of metals other than iron in the bacterial environment can modulate the production of siderophores, but nothing is known concerning the molecular mechanisms involved. We present here how  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  affects the production of the siderophore pyochelin in *P. aeruginosa* and how these metals interfere specifically or not with different proteins of the pyochelin-dependent iron uptake pathway, including the corresponding transcriptional regulators. We show for the first time, how an excess of biological metals, other than iron, can interfere with transcriptional regulators that control the transcription of genes of a siderophore pathway.

## Abstract

Much data shows that biological metals other than  $\text{Fe}^{3+}$  can interfere with  $\text{Fe}^{3+}$  acquisition by siderophores in bacteria. Siderophores are small  $\text{Fe}^{3+}$  chelators produced by the microorganism to obtain access to  $\text{Fe}^{3+}$ . Here, we show that  $\text{Co}^{2+}$  is imported into *Pseudomonas aeruginosa* cells in a complex with the siderophore pyochelin (PCH) by the ferri-PCH outer membrane transporter FptA. Moreover, the presence of  $\text{Co}^{2+}$  in the bacterial environment strongly affects the production of PCH. Proteomic and transcriptomic approaches showed that a decrease of PCH production is associated with repression of the expression of the genes involved in PCH biosynthesis. We used various molecular biology approaches to show that this repression is not Fur- (Ferric uptake transcriptional regulator) dependent but due to competition of PCH-Co with PCH-Fe for PchR (transcriptional activator), thus inhibiting the formation of PchR-PCH-Fe and consequently the expression of the PCH genes. We observed a similar mechanism of repression of PCH production, but to a lesser extent, by  $\text{Ni}^{2+}$ , but not for  $\text{Zn}^{2+}$ ,  $\text{Cu}^{2+}$ , or  $\text{Mn}^{2+}$ . Here, we show, for the first time at a molecular level, how the presence of a contaminant metal can interfere with  $\text{Fe}^{3+}$  acquisition by the siderophores PCH and PVD.

## Introduction

In living organisms, interactions between biomolecules and biological metals (Na, Mg, K, Ca, Mn, Fe, Zn, Ni, Cu, Co, and Mo) are vital and play a role in macromolecule structure and cell metabolism. For example, one third of proteins require metals for their effective functioning. The interactions between macromolecules and metals are highly specific. Waldron and Robinson proposed that to ensure that each metalloprotein or metalloenzyme in bacteria binds the correct metal and functions properly, 'metals are not in competition for a limited pool of proteins, but rather the proteins compete for a limited pool of metals in the cells'.<sup>2,3</sup> Therefore, any disequilibrium of this limited intracellular pool of metals (the bacterial metallome) affects bacterial cell viability. However, bacteria are often subject to variations in metal concentrations in their environment, including during infections, in which they may be confronted with "nutriment immunity", whereby the host uses deprivation of, or poisoning with, metals as defense strategies against microbial invaders.<sup>4,5</sup> For example phagocytes use Cu and/or Zn intoxication to reduce the intracellular survival of pathogens.<sup>6</sup> How bacteria cope with such metal concentration disequilibria at the molecular level and the cross-talk to maintain homeostasis of different biological metals in bacterial cells are still poorly understood.

Bacterial iron homeostasis has attracted the most attention over the last decades. Iron is a key nutriment for bacterial growth, which is paradoxically poorly bioavailable because of its very low solubility under aerobic conditions and physiological pH. Thus, to gain access to Fe<sup>3+</sup>, most bacteria produce siderophores.<sup>7</sup> These compounds have various chemical structures, a molecular weight usually between 200 and 2 000 Da, and are characterized by an extremely high affinity for Fe<sup>3+</sup>, with, for example, K<sub>a</sub> values of 10<sup>43</sup> for the siderophores enterobactin.<sup>8</sup> Siderophores provide bacteria with Fe<sup>3+</sup> by scavenging this metal from the bacterial environment and transporting it into either the bacterial periplasm or cytoplasm.<sup>9,10</sup> This strategy works in any bacterial environment, such as in the rhizosphere<sup>11</sup>, but also plays a key role in the host during infections.<sup>12</sup> *P. aeruginosa*, an opportunistic pathogen and used as a model in the present study, produces two major siderophores, pyoverdine

1  
2  
3 (PVD) and pyochelin (PCH) (Figure 1).<sup>9</sup> The synthesis of these chelators is correlated with the  
4 concentration of iron, both in bacterial cells and the environment.<sup>13</sup> In media with moderately low  
5 concentrations of iron (approximately 300 nM), *P. aeruginosa* cells produce more PCH than PVD,  
6  
7 whereas in more severely iron-restricted media (approximately 20 nM), PCH production remains highly  
8  
9 active and, in addition, PVD production is strongly stimulated.<sup>13,14</sup>

10  
11  
12  
13  
14  $\text{Fe}^{3+}$  uptake into bacteria *via* siderophores always involves a siderophore-specific TonB-dependent  
15 transporter for its uptake across the outer membrane in Gram-negative bacteria.<sup>15</sup> Depending on the  
16  
17 siderophore,  $\text{Fe}^{3+}$  is then either delivered into the bacterial periplasm or cytoplasm. Transport into the  
18  
19 cytoplasm involves further transport of the ferri-siderophore complex across the inner membrane *via*  
20  
21 proton motive force-dependent permeases or ABC transporters.<sup>16</sup> Iron release from siderophores in  
22  
23 the bacterial periplasm or cytoplasm requires  $\text{Fe}^{3+}$  reduction (siderophores having a lower affinity for  
24  
25  $\text{Fe}^{3+}$  compared to  $\text{Fe}^{2+}$ ), often associated with chemical modification or hydrolysis of the  
26  
27 siderophores.<sup>16</sup>

28  
29  
30  
31  
32 Siderophore production is generally negatively regulated by the presence of  $\text{Fe}^{2+}$  *via* the Fur  
33  
34 transcriptional regulator<sup>19</sup> and positively by iron restriction and the response of various regulatory  
35  
36 systems, such as sigma and anti-sigma factors<sup>20</sup>, the AraC regulators, or two component systems.<sup>21</sup>  
37  
38 Under iron starvation, PCH production is activated via the action of the AraC regulator PchR and PVD  
39  
40 by anti-sigma (FpvR) and sigma factors (PvdS and FpvI).<sup>21-23</sup>

41  
42  
43  
44  
45 An increasing number of studies have also reported that siderophores are able to chelate efficiency  
46  
47 metals other than  $\text{Fe}^{3+}$ .<sup>18</sup> Previously, using the spectral properties of PVD and PCH, we have shown  
48  
49 that both PVD and PCH are able to chelate the biological metals  $\text{Co}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Ni}^{2+}$  and  $\text{Zn}^{2+}$  as well as  
50  
51 metals like  $\text{Ag}^+$ ,  $\text{Pb}^{2+}$ ,  $\text{Al}^{3+}$ .<sup>24,25</sup> PVD chelates metals with a 1 : 1 stoichiometry and stability constants  
52  
53 have been determined for some PVD-metal complexes: PVD-Fe ( $K_a = 10^{30.8} \text{ M}^{-1}$ ), PVD- $\text{Ni}^{2+}$  ( $K_a = 10^{10.9}$   
54  
55  $\text{M}^{-1}$ ), PVD- $\text{Cd}^{2+}$  ( $K_a = 10^{8.2} \text{ M}^{-1}$ ), PVD- $\text{Cu}^{2+}$  ( $K_a = 10^{20.1} \text{ M}^{-1}$ ).<sup>26,27</sup> PCH forms predominantly 1 : 2 ( $\text{M}^{2+}$   
56  
57 /PCH) complexes and the stability constant determined are: for  $\text{Fe}^{3+}$  ( $K_a = 10^{28.8} \text{ M}^{-2}$ ), for  $\text{Zn}^{2+}$  ( $K_a =$   
58  
59  
60

1  
2  
3  $10^{26.0} \text{ M}^{-2}$ ) and for  $\text{Cu}^{2+}$  ( $K_a = 10^{25.0} \text{ M}^{-2}$ ).<sup>28</sup> Baysse *et al.* have shown that PCH can also bind the transition  
4  
5 metal vanadium generating a Fenton reaction in the cells.<sup>29</sup> Moreover several studies have shown that  
6  
7 the presence of metals other than  $\text{Fe}^{3+}$  in the bacterial environment can modulate the bacterial  
8  
9 production of siderophores, but nothing is known concerning the molecular mechanisms involved.<sup>30–</sup>  
10  
11 <sup>32</sup> For example, PCH synthesis in *P. aeruginosa*, is repressed by  $10 \mu\text{M}$   $\text{Fe}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Mo}^{+6}$ ,  $\text{Ni}^{2+}$ , and  
12  
13  $\text{Cu}^{2+}$ .<sup>33,34</sup> At last, an increasing number of studies have reported that siderophores, in addition to their  
14  
15 important role in  $\text{Fe}^{3+}$  acquisition, also protect bacterial cells against excess toxic metals present in  
16  
17 their environment and can consequently play a role in bacterial metal resistance.<sup>13,17,18</sup> Previous  
18  
19 studies by our group have shown that both PVD and PCH protect *P. aeruginosa* from toxic metals or  
20  
21 an excess of essential metals, to a similar extent, by preventing their intracellular accumulation, thus  
22  
23 maintaining the homeostasis of the various biological metals present in bacterial cells.<sup>13,17</sup>  
24  
25  
26  
27  
28  
29

30  
31 To better understand the possible role of PVD and PCH in the homeostasis of biological metals other  
32  
33 than iron, we explored the effect of the presence of various biological metals ( $\text{Co}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Mn}^{2+}$   
34  
35 and  $\text{Zn}^{2+}$ ) in bacterial growth media on PVD and PCH production and investigated the possible  
36  
37 molecular mechanisms involved in the phenotype(s) observed. Heavy metals were not included in our  
38  
39 study, the possible role of the two siderophores in heavy metal resistance being not the focus of this  
40  
41 work. We observed that  $\text{Co}^{2+}$  repressed PCH synthesis with the same efficiency as  $\text{Fe}^{3+}$ , and repression  
42  
43 was also observed with  $\text{Ni}^{2+}$ , but with lower efficiency. There was no repression by  $\text{Zn}^{2+}$ ,  $\text{Mn}^{2+}$ , or  $\text{Cu}^{2+}$ .  
44  
45 The repression observed is Fur-independent and due to the ability of  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  to interfere with the  
46  
47 transcriptional regulator PchR (activator of PCH production, Scheme 1).  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  inhibit PchR-PCH-  
48  
49 Fe formation and consequently the concentration of this complex in bacterial cells decreases, resulting  
50  
51 in a decrease of the transcription of the genes encoding the enzymes involved in PCH synthesis.

## Materials and methods

**Chemicals.** The metals used were in the following forms:  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$  (Strem Chemicals),  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$  (Strem Chemicals),  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$  (Strem Chemicals),  $\text{FeCl}_3$  (Alfa Aesar),  $\text{Mn}(\text{OAc})_2 \cdot 4\text{H}_2\text{O}$  (Strem Chemicals) and  $\text{ZnCl}_2$  (Strem Chemicals). All solutions were prepared at concentrations between 1 nM and 100  $\mu\text{M}$  in 0.5 N HCl or 0.5 N  $\text{HNO}_3$ . These stock solutions were then diluted with 50 mM Tris-HCl pH 8.0. The PCH used in these experiments was synthesized according to a previously published protocol.<sup>35</sup>

**Bacterial strains and growth media.** *P. aeruginosa* strains used throughout this study are shown in Table 1. For cultures of *P. aeruginosa* strains in iron-limited media, bacteria were first grown in LB broth overnight at 30°C. The bacteria were then washed in CAA medium (casamino acid medium, composition: 5 g.L<sup>-1</sup> low-iron CAA (Difco), 1.46 g.L<sup>-1</sup>  $\text{K}_2\text{HPO}_4 \cdot 3\text{H}_2\text{O}$ , 0.25 g.L<sup>-1</sup>  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ ), diluted two-fold and incubated for 24 h at 30°C.

**Siderophore quantification.** The production of PCH and PVD were evaluated as described previously.<sup>25</sup> PVD production was monitored by its characteristic absorbance of 400 nm at neutral pH.<sup>36</sup> PCH has a characteristic absorbance of 320 nm, but unlike PVD, this siderophore cannot be detected directly in the bacterial growth medium and needs first to be extracted from the cultures and concentrated before absorbance monitoring.<sup>13,36</sup>

**UV and fluorescence spectra of PCH-metal complexes.** PCH was solubilized in methanol and PCH-metal complexes were prepared in methanol by mixing 1 eq. of metal with 2 eq. of PCH. 50 mM TrisHCl pH 8.0 buffer was added to reach a concentration of PCH-metal complexes of 50  $\mu\text{M}$ . UV spectra were measured on a Nanodrop 2000 spectrophotometer and fluorescence spectra were measured on a TECAN M200 multiplate reader. All measures were carried out in 50 mM TrisHCl buffer. For emission spectra :  $\lambda_{\text{exc}} = 350 \text{ nm}$ ; for excitation spectra :  $\lambda_{\text{em}} = 422 \text{ nm}$ .

1  
2  
3 **Bacterial growth and quantification of fluorescence intensity.** Cells were cultured overnight in CAA  
4 medium, pelleted by centrifugation, resuspended in fresh CAA medium, and the resulting suspension  
5 diluted so as to obtain an optical density at 600 nm of 0.01 units. We dispensed 200  $\mu$ L of the  
6 suspension per well into a 96-well plate (Greiner, U-bottomed microplate) with or without the  
7 different metals tested. The plates were incubated at 30°C, with shaking, in a Tecan microplate reader  
8 (Infinite M200, Tecan) for measurements of OD<sub>600nm</sub> and mCherry (excitation/emission wavelengths:  
9 570 nm/610 nm) fluorescence at 30-min intervals, for 40 h. We calculated the mean of three replicates  
10 for each measurement.

19  
20  
21  
22

23 **Proteomics analysis.** Bacteria were grown in CAA medium as described above (for growth curve see  
24 Figure 1SM in Supplementary Materials). After the first overnight culture in CAA medium, the bacteria  
25 were diluted in 10 mL CAA to an OD<sub>600 nm</sub> of 0.1 and incubated with or without 10  $\mu$ M Fe<sup>3+</sup> or Co<sup>2+</sup> for  
26 8 h at 30°C. For the digestion and cleanup steps, the same strategy was used as previously described.<sup>37</sup>  
27 For the shotgun proteomics assays, 1  $\mu$ g of peptides of each sample were subjected to LC-MS (liquid  
28 chromatography-mass spectrometry) analysis using the same approach as previously described.<sup>37</sup>  
29

34  
35  
36  
37  
38

39 **Transcriptomic analysis.** Bacteria were grown in CAA medium exactly as described above for the  
40 proteomic analyses and harvested after 8 h of cultures at 30°C. The total RNA were extracted by hot  
41 phenol treatment. Briefly, an aliquot of 8 x 10<sup>8</sup> cells from the cultures were added to two volumes of  
42 RNAprotect Bacteria Reagent (Qiagen). After centrifugation, the cell pellets were dissolved in 1 ml of  
43 lysis buffer (300 mM NaCl ; 1% SDS ; 8 mM EDTA), incubated at 90°C for 1 min before the addition of  
44 1 mL of phenol and a further incubation at 65°C for 10 min. The extracted RNAs (aqueous phase) were  
45 purified again with 1 volume of Phenol/Chloroform. To eliminate any DNA traces, the RNAs were  
46 submitted twice to DNaseI treatment. The RNAs were then submitted to ribosomal depletion using  
47 the RiboZero Bacteria kit (Illumina). The efficiency of depletion was validated on a Bioanalyzer  
48 nanochip (Agilent). Directional cDNA libraries for sequencing were constructed using the TruSeq  
49

11  
12 Count data were analyzed using R version 3.3.1<sup>38</sup> and the Bioconductor package DESeq2 version  
13 1.12.4.<sup>39</sup> Normalization and the estimation of dispersion were performed with DESeq2, using the  
14 default parameters, and statistical tests for differential expression were performed, applying the  
15 independent filtering algorithm. A generalized linear model was used to test for the differential  
16 expression between the three biological conditions: PAO1 without metals, PAO1 in the presence of  
17 Co<sup>2+</sup> or Fe<sup>3+</sup>. For each pairwise comparison, raw p-values were adjusted for multiple testing according  
18 to the Benjamini and Hochberg (BH) procedure<sup>40</sup> and genes with an adjusted p-value lower than 0.05  
19 were considered to be differentially expressed.

43 ***Metal quantification by ICP-AES.*** PCH-metal complexes were prepared by incubating PCH solubilized  
44 in methanol with FeCl<sub>3</sub>, CoCl<sub>2</sub>, NiCl<sub>2</sub> or ZnCl<sub>2</sub> at a molar ratio of 2:1 for 15 min. Tris-HCl (50 mM) pH 8.0  
45 buffer was added to bring the siderophore-metal complexes to a final concentration of 4 mM.  
46 *ΔpvdFΔpchA* and *ΔpvdFΔpchAΔfptX* cells were grown overnight in CAA media as described above. Cells  
47 were then washed and resuspended in CAA medium at an OD<sub>600 nm</sub> of 1.5. PCH-Fe or PCH-Co were  
48 added to a final concentration of 4 μM and the solutions incubated for 30 min at 30°C with shaking.  
49 The samples were then centrifuged and the bacterial pellets washed once with ultrapure water and  
50 dried at 50°C for 48 h. Cells were mineralized by incubation in 70% (v/v) HNO<sub>3</sub> for 48 h at room

3 temperature. The volume was brought up to 10 mL with ultrapure water and the samples filtered  
4  
5 through a membrane with a 0.22  $\mu\text{m}$  syringe filter unit. The samples were then analyzed with an ICP-  
6  
7 AES apparatus (Varian 720 ES) at the following wavelengths (nm): Co (228.62), Fe (238.20), Ca (393.37),  
8  
9 Cd (214.44), Co (228.62), Cr (267.72), Cu (327.40), Fe 238.20), K 766.49), Mg (279.55), Mn (257,61),  
10  
11 Mo (202.03), Na (589.59), Ni (231.60), Pb 220.35), V (292.40), and Zn (213.86).

12  
13  
14 For the data in Figure 4, bacteria were grown in CAA medium in the presence of 5  $\mu\text{M}$   $\text{CoCl}_2$ . At the  
15  
16 end of the exponential phase, samples were centrifuged, and the bacterial pellets treated as described  
17  
18 above for the experiment with PCH-Co or PCH-Ni complexes.

19  
20  
21  
22  
23  **$^{55}\text{Fe}^{3+}$  uptake.**  $^{55}\text{FeCl}_3$  was obtained from Perkin Elmer Life and Analytical Sciences (Billerica, MA, USA),  
24  
25 in solution, at a concentration of 71.1 mM, with a specific activity of 10.18 Ci/g. Siderophore- $^{55}\text{Fe}$   
26  
27 complexes were prepared at  $^{55}\text{Fe}$  concentrations of 20  $\mu\text{M}$ , with a siderophore:  $^{55}\text{Fe}^{3+}$  (mol:mol) ratio  
28  
29 of 20:1.  $^{55}\text{Fe}^{3+}$  uptake assays were carried out as previously described,<sup>43</sup> except that, after growth,  
30  
31 bacteria were incubated with 0.2  $\mu\text{M}$  PCH- $^{55}\text{Fe}$  and with or without 0.2 and 2  $\mu\text{M}$  PCH-Co or PCH-Zn  
32  
33 complexes.

34  
35  
36  
37  
38  
39 **Electrophoresis mobility shift assays (EMSA).** EMSA experiments were performed as previously  
40  
41 described<sup>44</sup> using a DNA fragment gcgCGCCCGCCAATGATAATAAATCTCATTTCCCCAACAgcg containing  
42  
43 the -65 to -31 *pchD* promoter region containing a Fur box (underlined) with gcg on both side added for  
44  
45 stabilization. DNA radiolabelling was performed by incubating 20-30 nM DNA for 30 min at 37°C in the  
46  
47 presence of 1 unit T4 polynucleotide kinase (NEB) and 0.5  $\mu\text{L}$  gamma ATP at 1 mCi /mmol. Labelled  
48  
49 DNA was diluted 10 times in binding buffer (20 mM BisTrisPropane pH 8.5, 100 mM KCl, 3 mM  $\text{MgCl}_2$ ,  
50  
51 10  $\mu\text{M}$   $\text{CoCl}_2$ , 5% v/v glycerol, and 0.01% Triton X-100), desalted on G25 mini-spin columns and stored  
52  
53 at -20°C. EMSA were performed with 200-250 pM of freshly prepared radiolabelled DNA incubated 30  
54  
55 min at 25°C with various concentrations of Fur protein in binding buffer in the presence of 10  $\mu\text{M}$   $\text{Co}^{2+}$   
56  
57 or  $\text{Mn}^{2+}$ . Fur protein was purified as previously described.<sup>44</sup> After a 30-min incubation at room  
58  
59  
60

1  
2  
3 temperature, 10  $\mu$ L of each sample were loaded on an 8 % polyacrylamide (29/1) gel in TA buffer (40  
4 mM Tris acetate pH 8.2) with 10 % glycerol, supplemented with 100  $\mu$ M of  $\text{CoCl}_2$ . The gel was pre-run  
5  
6  
7 30 min at 100 V in TA buffer supplemented with 100  $\mu$ M of  $\text{CoCl}_2$ . Mobility shifts were revealed by  
8  
9 exposing the gels (2 to 12 h at room temperature) on a storage phosphor screen (GE healthcare) and  
10  
11  
12 quantified with a cyclone phosphoimager (Perkin Elmer).  
13  
14

15  
16 **Transcriptional reporters.** For the construction of transcriptional reporter plasmid pAYC5 (carrying  
17 both PchR and Fur boxes of *pchD* promoter), the promoters of the gene of interest were amplified  
18  
19 from the chromosomal DNA of *P. aeruginosa* PAO1 by PCR with specific primers (Table SM2 in  
20  
21 Supplemental Materials), allowing overlapping with a second PCR fragment encompassing the open  
22  
23 reading frame of mCherry. A second PCR was performed using the two first PCR fragment as template  
24  
25 to obtain the transcriptional reporter fragment. This fragment was trimmed by digestion with *EcoRI*  
26  
27 and *HindIII* or *BamHI* and inserted between the sites for these enzymes in pSEVA631 vector to generate  
28  
29 pAYC5 and bacteria were transformed with this vector. The mutation of the Fur box of the *pchD*  
30  
31 promoters to generate pAYC5-FURmut vector has been obtained with the Q5-site directed  
32  
33 mutagenesis kit from New England Biolabs, using specific primers (Table 2SM).  
34  
35  
36  
37  
38  
39

40  
41 **Binding assays with MBP-PchR.** The *E. coli* DH5 $\alpha$ -pME7180 strain (Table 1), expressing the  
42  
43 recombinant protein PchR tagged with MBP at the N-terminal domain,<sup>45</sup> was used to express MBP-  
44  
45 PchR protein for the binding assays. The protein was purified (Figure SM3) as described previously<sup>45</sup>  
46  
47 and the protocol from Lin *et al.*<sup>46</sup> was used to investigate the binding between MBP-PchR and the  
48  
49 different PCH-metal complexes, metals, and apo-PCH. The PCH-metal complexes were generated by  
50  
51 mixing 20 mM PCH with  $\text{FeCl}_3$ ,  $\text{CoCl}_2$ ,  $\text{NiCl}_2$ , or  $\text{ZnCl}_2$  in methanol at a molar ratio of 2:1 (PCH:metal) to  
52  
53 obtain a final metal concentration of 500  $\mu$ M. The complexes were incubated for 15 min at RT and  
54  
55 finally 50 mM Tris-HCl pH 8 was added to adjust the volume to the desired concentration. The  
56  
57 complexes were prepared just before use for the binding experiments.  
58  
59  
60

1  
2  
3  
4  
5 **Quantitative real-time PCR.** Specific gene expression was measured by RT-qPCR, as previously  
6 described.<sup>47</sup> Briefly, overnight cultures of strains grown in CAA medium were pelleted, re-suspended  
7 and diluted in fresh medium to obtain an OD<sub>600nm</sub> of 0.1 units. The cells were then incubated in the  
8 presence or absence of 5 μM Fe<sup>3+</sup> or Co<sup>2+</sup>, with vigorous shaking, at 30°C for 8 h. RNAs were purified  
9 as described previously.<sup>37</sup> We then reverse transcribed 1 μg of total RNA with a High-Capacity RNAtc-  
10 cDNA Kit, in accordance with the manufacturer's instructions (Applied Biosystems). The amounts of  
11 specific complementary DNAs were assessed in a StepOne Plus instrument (Applied Biosystems) with  
12 Power Sybr Green PCR Master Mix (Applied Biosystems) and the appropriate primers (Table SM2). The  
13 transcript levels for a given gene in a given strain were normalized with respect to those for *uvrD* and  
14 are expressed as a ratio (fold change) relative to the reference conditions.

## Results

***Co<sup>2+</sup> can repress PCH and PVD production.*** We first investigated the impact of the biological metals (Co<sup>2+</sup>, Cu<sup>2+</sup>, Ni<sup>2+</sup>, Mn<sup>2+</sup> and Zn<sup>2+</sup>) on the production of both siderophores PVD and PCH in iron restricted growth conditions. Bacteria were grown in casamino acids (CAA) medium in the presence of three metal concentrations (Figure 2). CAA contains approximately 20 nM Fe (LB Broth medium contains 4.3 μM)<sup>13</sup> and is considered to be highly iron-restricted. As previously described by Cunrath *et al.*,<sup>13</sup> PAO1 cells produced twice as much PVD as PCH under such growth conditions and in the absence of any biological metal:  $116.5 \pm 30.7 \mu\text{M}/\text{OD}_{600 \text{ nm}}$  and  $51.7 \pm 3.1 \mu\text{M}/\text{OD}_{600 \text{ nm}}$  for PVD and PCH, respectively.

The presence of Fe<sup>3+</sup> completely repressed PVD production at 1 μM and PCH production only at 15 μM (Figure 2). Co<sup>2+</sup> was the only other metal able to repress the production of both siderophores, with 41.1%, 48.5%, and 61.4% repression of PVD production in the presence of 1.5, 15, and 150 μM Co<sup>2+</sup>, respectively. Surprisingly, we observed similar dose-dependent repression for both Fe<sup>3+</sup> and Co<sup>2+</sup> for PCH production. Ni<sup>2+</sup> had no effect on PVD production and only affected PCH biosynthesis at 150 μM, repressing production by 42 %. Mn<sup>2+</sup> and Zn<sup>2+</sup> had no significant effect on either PVD or PCH production at the concentrations tested.

Overall, PVD production was repressed, as expected, by the presence of Fe<sup>3+</sup>, but also to a lesser extent by Co<sup>2+</sup>, whereas surprisingly PCH production was repressed with equivalent efficiency by Fe<sup>3+</sup> and Co<sup>2+</sup> and, to a lesser extent, by the presence of Ni<sup>2+</sup>.

***Genes up- and downregulated in P. aeruginosa cells in the presence of Co<sup>2+</sup>.*** We further investigated the impact of the presence of Co<sup>2+</sup> on *P. aeruginosa* by carrying out proteomic and transcriptomic analyses of bacteria grown in CAA medium with or without 10 μM Fe<sup>3+</sup> or Co<sup>2+</sup>. Changes in gene transcription and expression are given as the log<sub>2</sub> ratio between *P. aeruginosa* grown with or without Co<sup>2+</sup> (Table 2). The transcription and expression of several proteins of the PCH pathway was repressed in the presence of Fe<sup>3+</sup> and Co<sup>2+</sup>, showing a similar repressive effect of both metals, consistent with

1  
2  
3 the observed decrease of PCH production (Figure 2). In contrast, the transcription and expression of  
4 all genes detected belonging to the PVD pathway were repressed in the presence of Fe<sup>3+</sup>, as expected,  
5 but at a clearly lower level in the presence of Co<sup>2+</sup>. These data were confirmed by RT-qPCR  
6 experiments using several genes: two genes of the PVD pathway (an enzyme involved in PVD  
7 biosynthesis *pvdJ* and the transcriptional regulator *pvdS*) and five genes of the PCH pathway (the  
8 transcriptional regulator *pchR*, the inner membrane permease *fptX*, the outer membrane transporter  
9 *fptA* and two enzymes involved in PCH biosynthesis *pchA* and *pchE*) and the housekeeping gene *uvrD*,  
10 which was used for normalization (Figure 3A). RT-qPCR demonstrated a large decrease in transcript  
11 levels for all genes of the PCH pathway in the presence of both Fe<sup>3+</sup> and Co<sup>2+</sup>, except for the gene  
12 encoding the transcriptional regulator *pchR*. Concerning the genes of the PVD pathway, a strong  
13 repression is observed for the two genes tested with Fe<sup>3+</sup> and at a lower extend with Co<sup>2+</sup>. For Ni<sup>2+</sup>  
14 and Zn<sup>2+</sup> no significant transcriptional repression of the seven genes tested was observed (Figure 3A),  
15 but in some case a very small increase of transcription.

16  
17  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32 In conclusion, the transcription and expression of the proteins of the PCH pathway (exception for  
33 PchR) are more strongly repressed in the presence of Co<sup>2+</sup>, than the genes of the PVD pathway.

34  
35  
36  
37  
38  
39 **Co<sup>2+</sup> differently affects the expression of the genes the PCH operons.** The RT-qPCR experiment  
40 (Figure 3A) highlighted for all genes of the PCH pathway, except for the one corresponding to the  
41 transcriptional regulator *pchR*, a large decrease in transcript levels in the presence of Co<sup>2+</sup> compared  
42 to growth conditions in the absence of metals, while the presence of Fe<sup>3+</sup> repressed the transcription  
43 of all genes including *pchR*. This observation indicates that Co<sup>2+</sup>, and not Fe<sup>3+</sup>, affects differently the  
44 transcription of the genes of PCH operons. The genes of these four PCH genes belong to three  
45 different operons: *pchA* and *pchE* belong to the two operons coding for the enzymes involved in PCH  
46 biosynthesis *pchDCBA* and *pchEFGHI*, *fptX* to the PCH-Fe *fptABCX* operon, and *pchR* which is not in an  
47 operon with other genes (Scheme 1). Co<sup>2+</sup> is apparently able to repress *fptABCX*, *pchDCBA* and  
48 *pchEFGHI* operons and not *pchR*.

1  
2  
3 To investigate further this observation, we followed the expression of the four proteins PchA, PchE,  
4  
5 FptX and PchR of the PCH pathway during bacterial growth, in the presence of the biological metals,  
6  
7 using four strains that express fluorescent fusion proteins between mCherry and PchA (*pchA-mCherry*  
8  
9 strain, Table 1), PchE (*pchE-mcherry*), FptX (*fptX-mCherry*), and the transcriptional regulator PchR  
10  
11 (*mCherry-pchR*).<sup>48</sup> These proteins were tagged with mCherry at the N- or C-terminal end, and the  
12  
13 tagged proteins chromosomally integrated. The presence of the tag has been shown to affect neither  
14  
15 the transcription of the proteins (by RT-qPCR) nor their biological activities (siderophore production  
16  
17 or ferri-siderophore uptake).<sup>48</sup> During bacterial growth, in the absence of any metals, two different  
18  
19 variation of mCHERRY fluorescence were observed depending on the strains. For *pchA-mCherry*,  
20  
21 *pchE-mcherry* and *fptX-mCherry* strains a strong increase of fluorescence is observed corresponding  
22  
23 to an increase of PchA-mCHERRY, PchE-mCHERRY and FptX-mCHERRY fusion protein expression  
24  
25 (Figure 3B). On the opposite, for *mcherry-pchR* in the same growth conditions, mCHERRY  
26  
27 fluorescence decreased slightly after 6 hours culture (Figure 3C). As expected, the presence of 5  $\mu\text{M}$   
28  
29  $\text{Fe}^{3+}$  repressed strongly PchA-mCHERRY, PchE-mCHERRY, mCHERRY-FptX and mCHERRY-PchR fusion  
30  
31 protein expression during bacterial growth. Consistent with the RT-qPCR data (Figure 3A),  $\text{Co}^{2+}$   
32  
33 repressed the expression of PchA-mCHERRY, PchE-mCHERRY and mCHERRY-FptX but not of  
34  
35 mCHERRY-PchR.  $\text{Ni}^{2+}$  and  $\text{Zn}^{2+}$  at the concentrations tested had no effect on the expression of the four  
36  
37 fusion proteins. Actually their presence slightly induced the expression of PchA-mCHERRY, PchE-  
38  
39 mCHERRY and mCHERRY-FptX, probably because of the metal-restriction growth conditions.  
40  
41  
42  
43  
44  
45 Based on the *P. aeruginosa* genome, *pchR* expression is regulated solely by Fur (presence only of a  
46  
47 Fur-Box) and *pchDCBA*, *pchEFGHI*, and *fptABCX* operons by both Fur and PchR regulators (the  
48  
49 presence of both Fur- and PchR-boxes upstream of these genes) (Scheme 1). Our data show that the  
50  
51 presence of  $\text{Co}^{2+}$  inhibits only the transcription of genes that depend on a PchR box for their  
52  
53 expression.

2  
3 ***Co<sup>2+</sup> can enter *P. aeruginosa* cells by the TonB-dependent transporter FptA.*** According to current  
4 knowledge concerning the interaction of the transcriptional regulators Fur and PchR with Fe  
5 (formation of Fur-Fe and PchR-PCH-Fe complexes), the interaction of Co<sup>2+</sup> with one of these  
6 regulators includes the importation of Co<sup>2+</sup> into the bacteria and, in the case of PchR, the presence  
7 of PCH-Co to form a PchR-PCH-Co complex.<sup>46</sup> When Co<sup>2+</sup>, Ni<sup>2+</sup> and Zn<sup>2+</sup> are incubated with PCH in  
8 solution, the UV spectral modifications observed compared to the UV spectrum of apo PCH, indicates  
9 that PCH is able to chelate these three metals (Figure 2SM). Moreover, previously we have  
10 determined a Ka of PCH for Zn<sup>2+</sup> of Ka = 10<sup>26.0</sup> M<sup>-2</sup> (Ka = 10<sup>28.8</sup> M<sup>-2</sup> for Fe<sup>3+</sup>).<sup>28</sup> Previous studies of our  
11 group, in which we used ICP-AES (Inductively Coupled Plasma Atomic Emission Spectroscopy, which  
12 allows the detection of metals traces), showed that Co<sup>2+</sup> and Ni<sup>2+</sup> can both enter *P. aeruginosa* cells  
13 *via* the FptA/PCH pathway when bacteria were grown in succinate-containing medium.<sup>24</sup> Here, we  
14 used the same approach to verify that bacteria grown in CAA medium are also able to efficiently  
15 import Co<sup>2+</sup> and Ni<sup>2+</sup>. CAA is 10 fold more iron-restricted than succinate medium: iron concentration  
16 of 300 nM for succinate medium and 20 nM for CAA.<sup>13</sup> We used a PVD and PCH-deficient strain  
17 ( $\Delta pvdF\Delta pchA$ , Table 1) to control the presence of siderophores and their concentrations in the assay.  
18 The importance of the PCH pathway in metal uptake was evaluated by using the *fptA* (PCH-Fe outer  
19 membrane transporter) mutant strain  $\Delta pvdF\Delta pchA\Delta fptA$  (Table 1).

32  
33  
34  
35  
36  
37  
38  
39  
40  
41 As expected, *fptA* deletion markedly affected Fe accumulation in *P. aeruginosa* cells in the presence  
42 of PCH (Figure 4A), as well as that of Co<sup>2+</sup>, showing that Co<sup>2+</sup> is imported into *P. aeruginosa* cells by  
43 the FptA transporter (Figure 4A). Co<sup>2+</sup> uptake certainly occurs in a complex with PCH, since this  
44 transporter recognizes only PCH-metal complexes and not siderophore-free metals.<sup>49,50</sup> However, the  
45 amount of Co<sup>2+</sup> imported by the FptA/Pch system is lower than the amount of Fe<sup>3+</sup> acquired. We  
46 observed no significant FptA-dependent uptake for Ni<sup>2+</sup> and Zn<sup>2+</sup> at the metal concentrations tested  
47 here, as previously reported.<sup>24</sup>

2  
3  $^{55}\text{Fe}$  with or without 0.2  $\mu\text{M}$  and 2  $\mu\text{M}$  (1 and 10-fold excess) PCH-metal complexes and the  
4  
5 radioactivity incorporated into the bacteria (during a 30-min incubation) counted. Incubation of the  
6  
7 bacteria in the presence of PCH- $^{55}\text{Fe}$  alone resulted in the uptake of approximately 90 pmol of  $^{55}\text{Fe}$   
8  
9 per cell per 30 min (Figure 4B). We observed 60 % inhibition of this uptake in the presence of 2  $\mu\text{M}$   
10  
11 PCH-Co. We also carried out a competition assay with PCH-Ni and PCH-Zn complexes, but observed  
12  
13 no significant inhibition of  $^{55}\text{Fe}$  uptake *via* PCH.  
14  
15

16 These data all suggest that, in the range of metal concentrations tested,  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  can enter  
17  
18 bacteria both by diffusion ( $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  accumulation in the *fptA* mutant, Figure 3A) and also *via* the  
19  
20 PCH/FptA uptake system for  $\text{Co}^{2+}$ . Consequently, PCH-Co complexes, as well as siderophore-free  $\text{Co}^{2+}$   
21  
22 and  $\text{Ni}^{2+}$ , are present in *P. aeruginosa* cells.  
23  
24  
25

26  
27 ***The presence of  $\text{Co}^{2+}$  in the bacterial environment does not affect the intracellular iron***  
28  
29 ***concentration in *P. aeruginosa* cells.*** *P. aeruginosa* PAO1 cells were also grown in the presence of 5  
30  
31  $\mu\text{M}$   $\text{Co}^{2+}$  or  $\text{Ni}^{2+}$  to assess how the intracellular concentrations of all biological metals were affected  
32  
33 by the presence of an excess of these two metals (Figure 5). Surprisingly, although  $\text{Co}^{2+}$  can enter  
34  
35 bacteria by diffusion or in competition with  $\text{Fe}^{3+}$  by the FptA/PCH pathway, the intracellular iron  
36  
37 concentration was not affected. This suggests that bacteria can adapt to potential competition  
38  
39 between  $\text{Fe}^{3+}$  and  $\text{Co}^{2+}$  for the FptA/PCH system during growth and that the intracellular iron content  
40  
41 is maintained, even in the presence of 5  $\mu\text{M}$   $\text{Co}^{2+}$  contamination.  
42  
43  
44  
45

46  
47 ***Excess  $\text{Co}^{2+}$  in the bacterial environment does not affect Fur regulation.*** We next elucidated the  
48  
49 molecular mechanism involved in the Co-dependent repression of PCH pathway expression by  
50  
51 investigating the ability of Fur-Co complexes to interact with the Fur boxes *in vitro*. *E. coli* Fur has been  
52  
53 shown to bind DNA sequences containing Fur boxes by interacting with metals other than  $\text{Fe}^{2+}$  <sup>51</sup> and  
54  
55 Fur of *P. aeruginosa* has been shown to be capable of binding to the Fur box in the presence of  $\text{Co}^{2+}$  in  
56  
57 a nuclease protection assay<sup>44</sup> and in the presence of  $\text{Mn}^{2+}$  in an EMSA (electrophoretic mobility shift  
58  
59  
60

1  
2  
3 assay) assay.<sup>52</sup> It is not possible to run EMSA in the presence of Fe<sup>2+</sup> because of its oxidation.  
4  
5 Consequently, it is well accepted in the literature to use Mn<sup>2+</sup> ions to mimic Fe<sup>2+</sup> for the DNA binding  
6  
7 assay.<sup>52</sup> Here EMSA experiments were carried out in the presence of Co<sup>2+</sup> and Mn<sup>2+</sup>, with purified Fur  
8  
9 protein and the promoter region of *pchD*, containing the Fur-box present upstream of the *pchDCBE*  
10  
11 operon. An interaction between Fur-Co and the *pchD* promoter sequence was observed (Figure 6),  
12  
13 proving that Fur-Co is able to bind to this sequence. However, our proteomic, transcriptomic and RT-  
14  
15 qPCR data (Table 2 and Figure 3A), as well as the expression data using mCherry fusion proteins (Figure  
16  
17 3B-3C), clearly show that the presence of Co<sup>2+</sup> in the bacterial environment does not repress all Fur-  
18  
19 dependent genes, as does the presence of Fe<sup>3+</sup>. Therefore, we also used a plasmid (pAYC5) carrying  
20  
21 the mCherry sequence and the PCH promoter of *pchDCBA* operon (Table 1SM) to investigate the  
22  
23 behavior of Fur in the presence of Co<sup>2+</sup> in *P. aeruginosa* cells. Since this promoter region also contains  
24  
25 a PchR box, we carried out this experiments in strain unable to express PchR ( $\Delta pchR$  strain). Bacteria  
26  
27 carrying this construct were grown in CAA medium with increasing concentration (0-100  $\mu$ M) of Co<sup>2+</sup>  
28  
29 or Fe<sup>3+</sup> and the mCherry fluorescent signal monitored at 610 nm (excitation at 570 nm). As expected,  
30  
31 the addition of Fe<sup>3+</sup> to the bacterial growth medium caused the repression of mCherry expression  
32  
33 (Figure 7A): the Fur-Fe complex interacts with the bacterial Fur boxes, which represses the  
34  
35 transcription and expression of mCherry and any Fur-dependent genes. The addition of Co<sup>2+</sup> to the  
36  
37 bacterial medium had no significant effect on mCherry expression (Figure 7B) for concentrations of  
38  
39 Co<sup>2+</sup> equivalent or lower than 10  $\mu$ M and a weak effect was observed at 100  $\mu$ M. We carried out the  
40  
41 same experiment with 10 and 100  $\mu$ M Ni<sup>2+</sup> or Zn<sup>2+</sup> (Figure 7C and 7D) and no repression of mCherry  
42  
43 expression was observed.

44  
45 Overall, our data show that, Fur-Co can bind to the PCH Fur-box but does not repress Fur-dependent  
46  
47 gene expression *in vivo* like Fe<sup>2+</sup> whereas equivalent effects are observed for both metals for PCH  
48  
49 production (Figure 2).

50  
51 ***The purified cytoplasmic regulator PchR can bind to PCH-Co and PCH-Ni in addition to PCH-Fe.*** PchR,

1  
2  
3 the transcriptional activator of the genes of the PCH pathway, activates the transcription of all PCH  
4 genes, except *pchR*, by interacting with the PchR box (no PchR box upstream of *pchR* gene).<sup>21-23</sup> We  
5 carried out binding assays between purified PchR (MBP fused PchR<sup>46</sup> and purified protein shown in  
6 Figure SM3) and PCH-Co and PCH-Ni, based on a spectroscopy approach previously described, using  
7 the fluorescent properties of the tryptophans (Trp) of PchR published previously.<sup>46</sup> When MBP-PchR  
8 is excited at 280 nm, tryptophan present in the protein emits intrinsic fluorescence with maximal  
9 intensity at 330 nm (Figure 4SM). Upon the addition of ligands, such as PCH-Fe, the fluorescence is  
10 quenched. Thus, the protein's affinity for its ligand can be determined by plotting the relative  
11 fluorescence intensity,  $F_0/F$ , with  $F_0$  being the fluorescence emitted by MBP-PchR without ligand and  
12  $F$  the fluorescence emitted by MBP-PchR once a specific concentration of ligand has been added.  
13 Afterwards,  $K_d$  values are determined using the Stern-Volmer representation and linear regression.  
14 PCH-metal complexes were prepared by incubating 2 equivalent of PCH with one of metal (Figure  
15 2SM).

16 We determined an affinity of PCH-Fe ( $K_d = 5.82 \pm 2.84 \mu\text{M}$ ) for MBP-PchR that was slightly better as  
17 that described previously ( $K_d = 41 \pm 5 \mu\text{M}$ )<sup>46</sup>. PCH-Co was also able to bind to PchR with a  $K_d$  of  $13.9 \pm$   
18  $3.4 \mu\text{M}$ , as well as PCH-Ni and PCH-Zn ( $K_d$  values of  $42 \pm 4.3 \mu\text{M}$  and  $47.4 \pm 2.2 \mu\text{M}$ , respectively -for  
19 details see Figure 4SM). We were unable to investigate the ability of PchR-PCH-Co to bind the PchR  
20 box (EMSA assays with the purified MBP fused PchR protein), probably because of the presence of  
21 the tag, as well as problems with protein aggregation.

47  
48 **Role of PchR in the repression of the PCH pathway in the presence of  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$ .** We further  
49 explored the mechanism involved in the repression of PCH production observed in the presence of  
50  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  by constructing a plasmid (pAYC5-FURmut) carrying the mCherry sequence and the  
51 promoter of the *pchDCBA* operon containing only the PchR box and the Fur box having being mutated  
52 (Table 1SM and 2SM). The strains PAO1 and  $\Delta pchR$  (unable to express PchR) carrying this plasmid  
53 were grown in CAA medium supplemented with increasing concentrations of metals ( $\text{Fe}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Ni}^{2+}$ )  
54  
55  
56  
57

59  
60

1  
2  
3 or Zn<sup>2+</sup>). In the absence of metals, in the WT (PAO1) background (kinetics with black dots in Figure  
4 8A-8D), the fluorescence corresponding to mCherry expression highly increased in function of time,  
5  
6 but not in the  $\Delta pchR$  strain unable to express the transcriptional activator PchR (kinetics with grey  
7  
8 triangles in Figure 8A-8D), indicating that PchR is necessary to observe mCherry expression. For PAO1,  
9  
10 in the presence of increasing concentrations of Fe<sup>3+</sup>, this fluorescence corresponding to mCherry  
11  
12 expression decreased during bacterial growth (Figure 8A). This observation is due to Fur which gets  
13  
14 loaded with Fe<sup>2+</sup>, interacts with its promoter regions and consequently the expression of PchR and  
15  
16 the other proteins of the PCH pathway is repressed (Figure 3A and Table 2). Since less PchR is  
17  
18 expressed, *mcherry* transcription is no more activated and lower level of fluorescence are observed  
19  
20 compared to the condition in the absence of metal.  
21  
22  
23  
24

25 In the presence of increasing concentrations of Co<sup>2+</sup> or Ni<sup>2+</sup> (but not Zn<sup>2+</sup>; Figure 8B-8D), the  
26  
27 fluorescence corresponding to mCherry expression also decreased in PAO1 cultures, but less than in  
28  
29 the presence of Fe<sup>3+</sup>. Higher concentrations of Co<sup>2+</sup> (10  $\mu$ M) and Ni<sup>2+</sup> (100  $\mu$ M) are necessary to elicit  
30  
31 an effect equivalent to that observed with Fe<sup>3+</sup> (5  $\mu$ M). In that case, the decrease of fluorescence is  
32  
33 not due to an absence of PchR expression, since Co<sup>2+</sup> or Ni<sup>2+</sup> present in the *P. aeruginosa* environment  
34  
35 were both unable to repress the expression of Fur-regulated genes (Figure 7). Co<sup>2+</sup> (and probably  
36  
37 also Ni<sup>2+</sup>) are likely present in the bacterial cytoplasm, mostly in their PCH-complexed forms (50  $\mu$ M  
38  
39 is the concentration of PCH in the bacterial culture and 5  $\mu$ M metals are added to the growth media).  
40  
41 Increasing concentrations of PCH-Co or PCH-Ni complexes in the bacterial cytoplasm certainly leads  
42  
43 to an increase in the concentrations of PchR-PCH-Co or PchR-PCH-Ni complexes, at the expense of  
44  
45 PchR-PCH-Fe complexes, but only PchR-PCH-Fe complexes are probably able to activate transcription  
46  
47 of the genes for the proteins of the PCH pathway and *mcherry* from pAYC5-FURmut plasmid. In such  
48  
49 a scenario, the expression of PchR-regulated genes, as the genes of the PCH pathway, is less highly  
50  
51 activated and less PCH is produced (Figure 2). This also explains why the presence of Co<sup>2+</sup> or Ni<sup>2+</sup> does  
52  
53 not repress *pchR* expression, as the transcription of this gene is not regulated by the PchR promoter,  
54  
55 but only the Fur box (Scheme 1).<sup>45</sup>  
56  
57  
58  
59  
60

1  
2  
3 In conclusion, the presence of high levels of  $\text{Fe}^{3+}$ ,  $\text{Co}^{2+}$ , or  $\text{Ni}^{2+}$  (to a lesser extent) in the bacterial  
4 environment induces repression of the transcription of PCH genes (except *pchR*) by two different  
5 molecular mechanisms. In the presence of  $\text{Fe}^{3+}$  in the bacterial environment, the transcriptional  
6 repressor Fur, in a complex with  $\text{Fe}^{2+}$ , represses the expression of these genes. In the presence of  $\text{Co}^{2+}$   
7 or  $\text{Ni}^{2+}$ , Fur is not involved, but rather the transcriptional activator PchR, which is no more able to  
8 activate the production of PCH, probably due to a decrease in the intracellular concentration of PchR-  
9 PCH-Fe complexes.

## Discussion

The requirement for different biological metals in bacteria are very different and depend on their biological function. The relative intracellular concentrations of these metals in *P. aeruginosa* PAO1 cells are Na-K > Mg >> Ca >> Fe-Zn >> Mn-Mo-Cu-V-Cr-Ni >> Co<sup>13</sup>, with Fe and Zn being the two most abundant transition metals (concentrations between 10<sup>-3</sup> and 10<sup>-4</sup> M, depending on the growth medium). The intracellular concentrations of Cu, Mn, Mo, and Ni are generally between 10<sup>-5</sup> and 10<sup>-4</sup> M<sup>13</sup> and Co is used only in very small amounts by *P. aeruginosa* (a concentration too low to be detected by ICP-AES<sup>13</sup>). Very similar values have been described for wild type *E. coli*<sup>53</sup> and can probably be found in many Gram-negative bacteria in planktonic growth conditions.

Since, all biological metals become toxic at high concentrations and are highly deleterious to living organisms, the intracellular concentrations of these biological metals have to be finely regulated to stay constant. Siderophores play a key role in iron homeostasis.<sup>21</sup> Increasing number of publications also suggest that siderophores may play a role in the homeostasis of other biological metals.<sup>18</sup> Indeed, these compounds are able to chelate many metals other than Fe<sup>3+</sup>,<sup>18</sup> their production can be modulated by different metals<sup>30-34</sup> and they often play a role in bacterial metal resistance.<sup>17,18</sup> These observations lead to the question whether bacteria are able to activate their siderophore production in response to the presence of metals other than Fe<sup>3+</sup>. As in previous studies,<sup>24</sup> we showed that none of the metals tested was able to significantly activate PVD or PCH production above that induced by iron restriction (Figure 2). Moreover, there is currently no data available to support the existence of bacterial sensors that detect toxic metals in the bacterial environment and consequently activate siderophore production. All current data suggest that for example the protective role of siderophores against toxic metals is probably only a consequence of the presence of large amounts of siderophores produced in response to iron starvation. However, the formation of siderophore-metal complexes with metals other than Fe<sup>3+</sup> may increase the sense of iron starvation by bacteria, because siderophores are in complex with metals other than Fe<sup>3+</sup> and consequently less siderophore-Fe is imported into the bacteria.

1  
2  
3 In the present work,  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  were able to repress the production of PCH and for  $\text{Co}^{2+}$ , with the  
4 same efficiency as  $\text{Fe}^{3+}$ . PCH production is positively regulated by the transcriptional activator PchR  
5 and negatively by the transcriptional repressor Fur (Scheme 1). PchR activates the transcription of all  
6 PCH genes, except *pchR*, by interacting with the PchR box (no PchR box upstream of *pchR*, Scheme 1).  
7 Consequently, a decrease of PCH production must be due to either Fur-dependent repression or the  
8 inability of PchR to still activate PCH production. Our data show that Fur regulation is insensitive to the  
9 presence of excess  $\text{Co}^{2+}$  (or  $\text{Ni}^{2+}$ ), even if  $\text{Co}^{2+}$  bound to Fur proteins *in vitro* and formed complexes with  
10 Fur boxes. Our experimental data show that the repression of PCH production by  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  involves  
11 PchR. They also show that PCH-Co enters bacteria via the TonB-dependent outer membrane  
12 transporter FptA and can bind to PchR *in vitro*. Since a repression of PCH production is as well observed  
13 in the presence of  $\text{Ni}^{2+}$ , we cannot exclude that PCH-Ni is also able to enter *P. aeruginosa* cells but with  
14 uptake rates too low to be detected by our approach. Altogether, these data describe a mechanism in  
15 which PCH-Co, after entering *P. aeruginosa* cells by FptA, interacts with PchR to form PchR-PCH-Co  
16 complexes unable to activate the transcription of PchR-regulated genes. The formation of PchR-PCH-  
17 Co or PchR-PCH-Ni complexes in the bacterial cytoplasm certainly leads to a decrease in the  
18 intracellular concentration of PchR-PCH-Fe, leading to a decrease in the transcription of PCH pathway  
19 genes and, thus, the production of PCH.

20  
21

30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41 The repression of PCH production was more pronounced with  $\text{Co}^{2+}$  than  $\text{Ni}^{2+}$  and cannot be explained  
42 simply by the difference in affinities of PchR for the PCH-Co and PCH-Ni complexes. Previous studies,  
43 based on titration experiments, have shown that the binding affinity of PCH is higher for  $\text{Ni}^{2+}$  than  $\text{Co}^{2+}$   
44 (relative affinity of PCH for biological metals having been proposed  $\text{Fe(III)} > \text{Mo(VI)} = \text{Cu(II)} > \text{Ni(II)} >$   
45  $\text{Co(II)} > \text{Zn(II)} > \text{Mn(II)}$ ).<sup>33</sup> On the contrary, the PCH-Co complex more efficiently competes with PCH-Fe  
46 for the TonB-dependent transporter FptA (affinities of PCH-Co and PCH-Ni for FptA in the range of 15  
47 nM and 50 nM, respectively<sup>24</sup>) and is more efficiently transported into *P. aeruginosa* cells. The higher  
48 efficiency of  $\text{Co}^{2+}$  to repress PCH production is probably linked to its higher ability to enter *P.*  
49 *aeruginosa* cells as a PCH-Co complex relative to PCH-Ni.

1  
2  
3 ICP-AES measurements of intracellular metal concentrations of *P. aeruginosa* cells grown with or  
4 without  $\text{Co}^{2+}$  showed no effect of this metal on the intracellular iron concentration. This indicates that  
5  
6  
7 the inhibition of PCH production in the presence of  $\text{Co}^{2+}$  has little effect on bacterial iron homeostasis  
8  
9  
10 under our growth conditions. The ability of  $\text{Co}^{2+}$  to interfere with  $\text{Fe}^{3+}$  acquisition *via* the PCH/FptA  
11  
12 pathway (55 % inhibition of PCH- $^{55}\text{Fe}$  uptake in *P. aeruginosa* PAO1 cells when incubated for 30 min in  
13  
14 the presence of PCH-Co complexes) does not affect the access to iron of the pathogen. This organism  
15  
16 uses several strategies to obtain access to iron; if one iron acquisition pathway is compromised, the  
17  
18 bacteria simply uses another.<sup>12</sup>  
19  
20  
21  
22

23 FptA plays a key role in the outer membrane for the uptake of the right metal by PCH. Previous studies  
24  
25 from our group have shown that FptA at the bacterial surface can bind different PCH-metal complexes,  
26  
27 with affinities ranging from 10 nM to 4.8  $\mu\text{M}$ , (the affinity of PCH-Fe being 10 nM).<sup>24</sup> However, only  
28  
29  $\text{Fe}^{3+}$  and, to a lesser extent,  $\text{Co}^{2+}$  can accumulate significantly in *P. aeruginosa* cells via the PCH  
30  
31 pathway, but with uptake rates clearly lower than those for  $\text{Fe}^{3+}$ . Moreover, previous studies have also  
32  
33 shown that PCH complexes  $\text{Ga}^{3+}$  and the formed complex is transported into *P. aeruginosa* cells via  
34  
35 FptA.<sup>24,54</sup>  $\text{Ni}^{2+}$  is probably also transported in complex with PCH with low uptake rates, since the  
36  
37 presence of this metal in the bacterial environment represses PchR regulated genes. FptA, due to its  
38  
39 uptake specificity, avoids and controls the uptake of most metals other than  $\text{Fe}^{3+}$  across the outer  
40  
41 membrane and limits the uptake of  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$ .  $\text{Fe}^{3+}$ ,  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  are part of the iron triad and all  
42  
43 three elements show similar properties such as the metallic radius (124, 125, 125 pm, respectively)  
44  
45 and the electronic configuration.  $\text{Ga}^{3+}$  has a radius slightly larger (187 pm) than  $\text{Fe}^{3+}$  but very similar  
46  
47 coordination properties. Consequently, PCH-Co, PCH-Ni and PCH-Ga have certainly very close  
48  
49 conformations, which is not the case for PCH-Cu and PCH-Zn complexes (two metals with different  
50  
51 coordination properties compared to  $\text{Fe}^{3+}$ ). The metallic radius and similar coordination properties  
52  
53 could be responsible for the high specificity of FptA for PCH-metal complexes.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 We are aware that the  $\mu\text{M}$  concentrations of  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  used in this study are not truly physiological  
4  
5 in the natural environment thrived by *P. aeruginosa*, and exposure to such concentrations appears  
6  
7 unlike during infections and exceptional also in natural environment. However, such concentrations  
8  
9 are often used in the literature in studies investigating the role of siderophores in bacterial resistance  
10  
11 to metals or in development of bioremediation processes using siderophore producing bacteria to  
12  
13 decontaminated metal polluted media or wastes. In such contexts, it is important to understand how  
14  
15 siderophore production and siderophore-dependent  $\text{Fe}^{3+}$  uptake pathways in bacteria interfere with  
16  
17 an excess of metals other than  $\text{Fe}^{3+}$  and what are the molecular mechanisms involved.

20  
21  
22

## 23 **Conclusion**

24  
25  
26 We show for the first time, how an excess of biological metals, other than iron, can interfere with  
27  
28 transcriptional regulators that control the transcription of genes of the PCH pathway. The presence  
29  
30 of high levels of  $\text{Fe}^{3+}$ ,  $\text{Co}^{2+}$ , or  $\text{Ni}^{2+}$  (to a lesser extent) in the bacterial environment represses the  
31  
32 transcription of PCH genes by two different molecular mechanisms. In the presence of increasing  $\text{Fe}^{3+}$   
33  
34 concentrations, the transcriptional repressor Fur gets loaded with  $\text{Fe}^{2+}$  and represses the expression  
35  
36 of all *pch* genes. In the presence of increasing  $\text{Co}^{2+}$  or  $\text{Ni}^{2+}$  concentrations, Fur is not involved, but the  
37  
38 transcriptional activator PchR gets loaded with PCH-Co and PCH-Ni and consequently is no more able  
39  
40 to activate the transcription of *pch* genes, due to a decrease in the intracellular concentration of  
41  
42 PchR-PCH-Fe complexes.  
43  
44  
45

46 PchR appears to have broad metal-binding specificity, but since only a few metals ( $\text{Fe}^{3+}$ ,  $\text{Ga}^{3+}$ ,  $\text{Co}^{2+}$ , and  
47  
48  $\text{Ni}^{2+}$ ) are able to enter bacteria by the FptA/PCH pathway, most which could be present as a  
49  
50 contaminant in the bacterial environment do not affect PCH production. Indeed, FptA acts as a  
51  
52 selective gate for the uptake of PCH-metal complexes and allows the uptake of only PCH-Fe and, to a  
53  
54 lesser extent, PCH-Ga, PCH-Co, and PCH-Ni. The presence of these PCH-metal complexes in the  
55  
56 bacterial cytoplasm interferes with the regulation of PCH production by interacting with PchR and  
57  
58 inhibiting the positive autoregulatory loop that involves PchR (Scheme 2). The inability of PchR-PCH-  
59  
60

1  
2  
3 Co and PchR-PCH-Ni to activate the expression of PCH genes highly suggests that PCH is not involved  
4  
5 in the acquisition by *P. aeruginosa* of these two metals, but that their uptake via PCH is simply a non-  
6  
7 specific interference of these two metals with the PCH pathway. Moreover, the Achilles heel of the *P.*  
8  
9 *aeruginosa* PCH pathway, in terms of excess  $\text{Co}^{2+}$  in the bacterial environment, is the selectivity of FptA  
10  
11 for metal transport. However, the ability of PchR to interact with many different PCH-metal complexes  
12  
13 leads to a decrease in PCH production and consequently a decrease in PCH-Co and PCH-Ni import.

## 52 **Author contributions**

53  
54  
55 ACL evaluated the siderophore production in the presence of metals, performed the iron uptake  
56  
57 assays, the experiment with the fluorescent strains (Figure 2) and binding assays with MBP-PchR. OC  
58  
59 performed the metal uptake assays and metal quantifications. AF realized the molecular biology  
60

1  
2  
3 (plasmid and strain constructions) and the fluorescent experiments in Figure 7 with GG, RL, HV, OS,  
4  
5 JYC performed the transcriptional experiments and analyses. PMS and DB performed the proteomic  
6  
7 experiments and analysis. JP and IM-S performed the electrophoresis mobility shift assays. BP and  
8  
9 GLAM synthesized the PCH used in the experiments. QP realized the spectral characterization of PCH-  
10  
11 metal complexes. PF realized the RT-qPCR experiment and participated in the design of all experiments  
12  
13 and the analysis of all data. IJS directed the project, analyzed data and wrote the paper. All authors  
14  
15 discussed the results and contributed to the writing of the manuscript.

3 **Table 2. Expression values from transcriptomic and proteomic analysis of genes of the PVD and PCH**  
4 **pathways in *P. aeruginosa* PAO1 cells grown in CAA medium with or without 10  $\mu$ M Fe<sup>3+</sup> or Co<sup>2+</sup>. ‘-**

7 ‘ indicates a non-significant difference in expression:  $-1 < \log_2 \text{ fold change} < 1$ .

## Legends of figures

### Figure 1: Chemical structure of pyoverdine (PVD) and pyochelin (PCH).

**Scheme 1. Organization of PCH pathway genes in the *P. aeruginosa* PAO1 genome.** *fptABCX*, *pchEFGHI*, *pchR*, and *pchDCBA* are all genes coding for proteins involved in Fe<sup>3+</sup> acquisition by PCH. Fur is a transcription regulator. Fur loaded with Fe<sup>2+</sup> represses the expression of all PCH genes via an interaction with the Fur box. PchR is a transcriptional activator of the AraC family. PchR in complex with PCH-Fe<sup>3+</sup> activates the transcription of all PCH genes, except *pchR*, by interacting with the PchR box (no PchR box upstream of *pchR*).<sup>21–23</sup>

**Figure 2. PVD (A) and PCH (B) production by *P. aeruginosa* PAO1 in the absence and presence of different biological metals.** Bacteria were grown 24 h in CAA medium with or without 1, 15, or 150 μM of biological metals (no metal (control): black; FeCl<sub>3</sub>: red; CoCl<sub>2</sub>: pink; NiCl<sub>2</sub>: blue; CuCl<sub>2</sub>: yellow; MnCl<sub>2</sub>: purple and ZnCl<sub>2</sub>: green). The concentration of PVD and PCH (μM/OD<sub>600 nm</sub>) was monitored after 24 h in culture and calculated as described in Materials and Methods.

**Figure 3. A. Analysis of fold-change in transcription for genes of the PVD and PCH pathways.** *pvdS* and *pvdJ* genes encode a sigma factor and an enzyme involved in PVD pathway. The other five genes belong to the PVD pathway: *pchR*, encodes the transcriptional regulator, *pchA* and *pchE* are NRPS involved in PCH biosynthesis and *fptA* and *fptX* the outer and inner membrane transporters of PCH-Fe, respectively. RT-qPCR was performed on *P. aeruginosa* PAO1 grown in CAA medium with or without 5 μM FeCl<sub>3</sub>, CoCl<sub>2</sub>, NiCl<sub>2</sub> or ZnCl<sub>2</sub>. The data were normalized relative to the reference gene *uvrD* and are representative of three independent experiments. Results are given as a ratio between the values obtained in the presence of metals over those obtained in the absence. All values fold-change values are given in Table 3SM in Supplemental Materials.

**B. PchA-mCherry, PchE-mCHERRY and FptX-mCHERRY expression in *P. aeruginosa* cells grown in CAA medium with or without 5  $\mu\text{M}$   $\text{FeCl}_3$ ,  $\text{CoCl}_2$ ,  $\text{NiCl}_2$  or  $\text{ZnCl}_2$ .** *pchA-mcherry*, *pchE-mcherry* and *fptX-mcherry* strains were grown in CAA medium. The metals were added at the beginning of culture and bacterial growth monitored at  $\text{OD}_{600 \text{ nm}}$  and the expression of the fluorescent fusion proteins measured by following the fluorescence at 610 nm (excitation at 570 nm). All kinetics are an average of 5 kinetics.

**C. mCHERRY-PchR expression in *P. aeruginosa* cells grown in CAA medium with or without  $\text{FeCl}_3$ ,  $\text{CoCl}_2$  or  $\text{NiCl}_2$ .** Since the emission of fluorescence in *mcherry-pchR* strain and the variation of fluorescence observed in the presence of  $\text{Fe}^{3+}$  are low, different metal concentrations were tested. The metals were added at the beginning of culture and bacterial growth monitored at  $\text{OD}_{600 \text{ nm}}$  and the expression of the fluorescent fusion proteins measured by following the fluorescence at 610 nm (excitation at 570 nm). All kinetics are an average of 5 kinetics

**Figure 4. A. Transport of PCH-Fe and PCH-Co in *P. aeruginosa* cells.**  $\Delta pvdF\Delta pchA$  (grey bars) and  $\Delta pvdF\Delta pchA\Delta fptA$  (white bars) strains at an  $\text{OD}_{600 \text{ nm}}$  of 1 in CAA medium were incubated with or without 4  $\mu\text{M}$  of preformed PCH-metal complexes. For both panels, bacteria were pelleted after a 30-min incubation, washed, and the amount of metal monitored by ICP-AES. **B. Kinetics of intracellular  $^{55}\text{Fe}$  accumulation in *P. aeruginosa* cells in the presence of PCH-metal complexes.**  $\Delta pvdF\Delta pchA$  cells at an  $\text{OD}_{600 \text{ nm}}$  of 1 were incubated with 0.2  $\mu\text{M}$   $\text{PCH-}^{55}\text{Fe}$  and without (black dots) or with 1 eq. (0.2  $\mu\text{M}$ ) or 10 eq. (2  $\mu\text{M}$ ) PCH-metal complexes (PCH-Co in green, PCH-Ni in blue, or PCH-Zn in orange). Aliquots were removed at various times and the radioactivity in the cells monitored.

**Figure 5. Total content of biological metals in *P. aeruginosa* PAO1 cells grown in CAA medium with or without 5  $\mu\text{M}$   $\text{CoCl}_2$ .** *P. aeruginosa* PAO1 cells were grown in CAA medium without (grey bars) or with 5  $\mu\text{M}$   $\text{CoCl}_2$  (black bars). The data are expressed as moles per volume as described previously.<sup>13</sup> The absence of columns for some metals corresponds to the detection limits for low-abundance

1  
2  
3 elements under these experimental conditions. For all experiments, bacteria were grown in CAA,  
4  
5 harvested at the end of the exponential phase, and prepared for ICP-AES measurements as described  
6  
7 in Materials and Methods.

42 **Figure 8. Expression of mCherry from pAYC5-FURmut plasmid in the absence or presence of  $\text{FeCl}_3$ ,**  
43  
44  **$\text{CoCl}_2$ ,  $\text{NiCl}_2$  or  $\text{ZnCl}_2$  under PchR regulation.** PAO1 (all kinetics with the symbol ● in panels A, B, C and  
45  
46 D) and  $\Delta pchR$  (kinetics in grey with the symbol ▲ in panels A, B, C and D) cells were transformed with  
47  
48 pAYC5-FURmut plasmid carrying the *pchD* promoter sequence with the PchR box and a Fur mutated  
49  
50 box. These cells were grown in CAA medium in the presence of increasing concentrations of  $\text{FeCl}_3$ ,  
51  
52  $\text{CoCl}_2$ ,  $\text{NiCl}_2$  or  $\text{ZnCl}_2$ . Bacterial growth was followed at  $\text{OD}_{600 \text{ nm}}$  and mCherry expression by monitoring  
53  
54 the emission of fluorescence at 610 nm (excitation at 570 nm). All kinetics are an average of 5 kinetics.  
55  
56 No significant variation of mCherry expression was observed in  $\Delta pchR$  mutant in the presence of  
57  
58 metals as shown in Supplemental Materials, Figure 4SM.  
59  
60

1  
2  
3  
4  
5 **Scheme 2. The PCH pathway and its interaction with Fe<sup>3+</sup> and Co<sup>2+</sup>.** PCH can chelate both Fe<sup>3+</sup> and  
6  
7 Co<sup>2+</sup>. FptA at the bacterial cell surface can interact with both PCH-metal complexes, but with the  
8  
9 highest affinity for PCH-Fe, and both complexes are transported efficiently into *P. aeruginosa* cells. The  
10  
11 biological function of Fur is not affected by the presence of contaminant Co<sup>2+</sup> in the bacterial growth  
12  
13 medium. PchR can bind PCH-Fe and PCH-Co as well as PCH-Ni, and PCH-Zn, but only PchR-PCH-Fe  
14  
15 activates the transcription of PCH genes. The presence of contaminant Co<sup>2+</sup> in the bacteria growth  
16  
17 media leads to the formation of PchR-PCH-Co complexes. This will decrease the intracellular  
18  
19 concentration of PchR-PCH-Fe, leading to a decrease in the expression of PCH genes and PCH  
20  
21 production.

Kinetics of intracellular  $^{55}\text{Fe}$  accumulation in *P. aeruginosa* cells in the presence of PCH-metal complexes.  $\Delta pvdF\Delta pchA$  cells at an OD<sub>600 nm</sub> of 1 were incubated with 0.2  $\mu\text{M}$  PCH- $^{55}\text{Fe}$  and without (black dots) or with 1 eq. (0.2  $\mu\text{M}$ ) or 10 eq. (2  $\mu\text{M}$ ) PCH-metal complexes (PCH-Co in green, PCH-Ni in blue, or PCH-Zn in orange). Aliquots were removed at various times and the radioactivity in the cells monitored.

80x55mm (300 x 300 DPI)

Figure 5. Total content of biological metals in *P. aeruginosa* PAO1 cells grown in CAA medium with or without 5  $\mu\text{M}$   $\text{CoCl}_2$ . *P. aeruginosa* PAO1 cells were grown in CAA medium without (grey bars) or with 5  $\mu\text{M}$   $\text{CoCl}_2$  (black bars). The data are expressed as moles per volume (Log representation) as described previously.<sup>13</sup> The absence of columns for some metals corresponds to the detection limits for low-abundance elements under these experimental conditions. For all experiments, bacteria were grown in CAA, harvested at the end of the exponential phase, and prepared for ICP-AES measurements as described in Materials and Methods.

Figure 6. Electrophoretic mobility shifts of specific 41bp DNA fragments (g -65 to -31 pchD gene promoter containing a Fur box) incubated with Fur protein in the presence of 10 μM  $\text{Co}^{2+}$  or  $\text{Mn}^{2+}$ . See the experimental part for details. It is not possible to run EMSA in presence of ferrous iron because of its oxidation, consequently, it is well accepted in the literature to use manganese ions to mimic ferrous iron for the DNA binding assay.<sup>52</sup>

80x36mm (300 x 300 DPI)

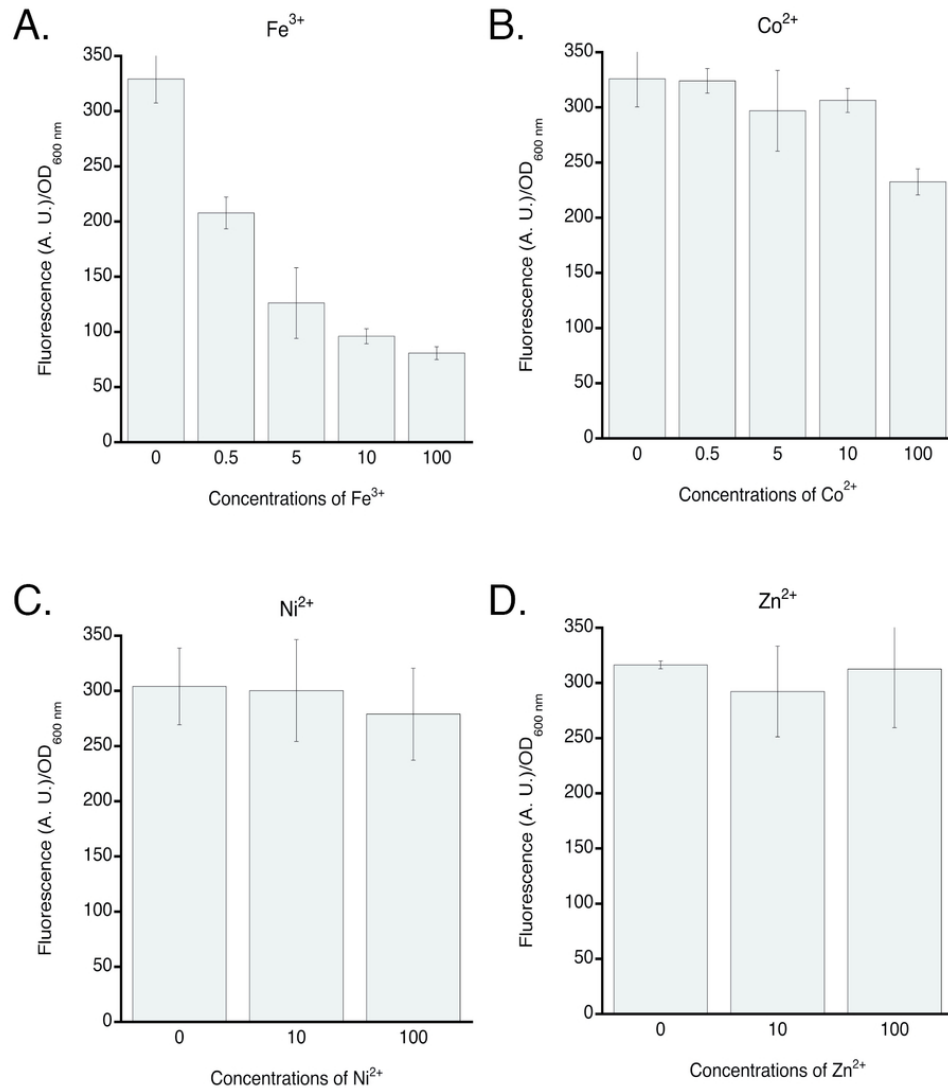

Figure 7. Expression of mCherry from pAYC5 plasmid in the absence or presence of  $FeCl_3$ ,  $CoCl_2$ ,  $NiCl_2$ , or  $ZnCl_2$  under Fur regulation.  $\Delta pchR$  cells were transformed with pAYC5 plasmid carrying the *pchD* promoter sequence with the Fur and PchR boxes. These cells were grown in the presence of increasing concentrations of  $FeCl_3$ ,  $CoCl_2$ ,  $NiCl_2$  or  $ZnCl_2$  (see legend on figure). Bacterial growth was followed at OD<sub>600 nm</sub> and mCherry expression by monitoring the emission of fluorescence at 610 nm (excitation at 570 nm).

79x87mm (300 x 300 DPI)

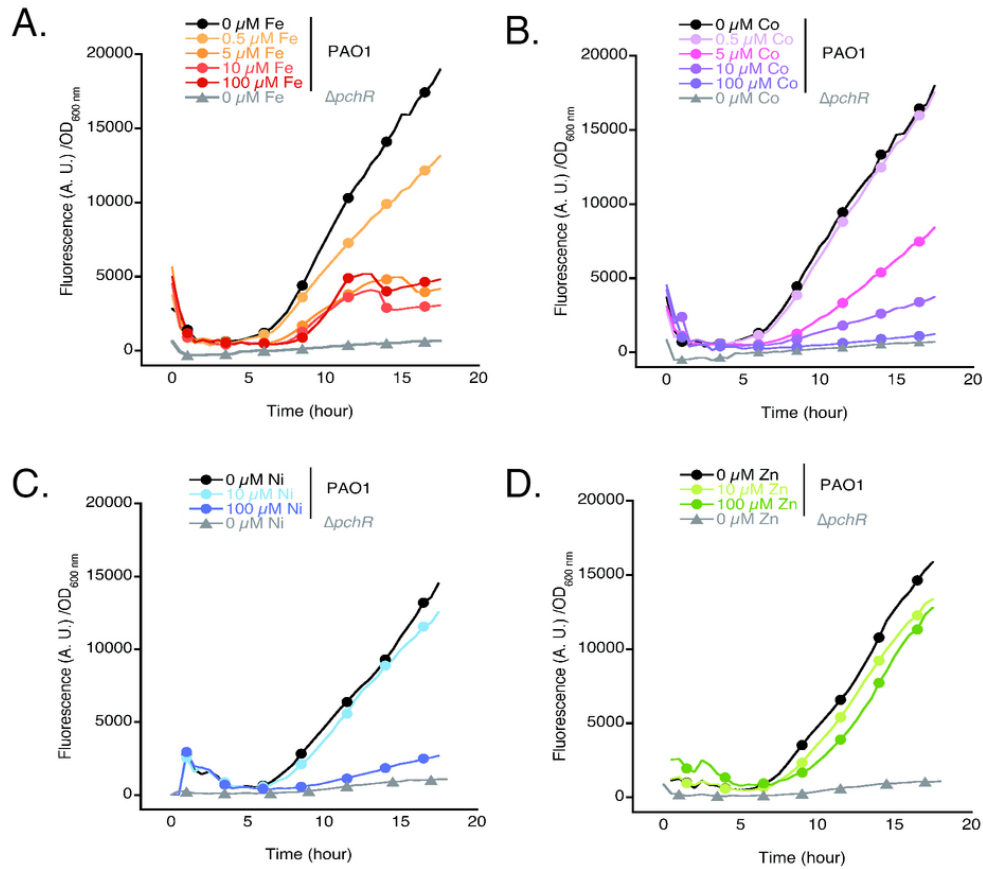

Figure 8. Expression of mCherry from pAYC5-FURmut plasmid in the absence or presence of  $\text{FeCl}_3$ ,  $\text{CoCl}_2$ ,  $\text{NiCl}_2$  or  $\text{ZnCl}_2$  under PchR regulation. PAO1 (all kinetics with the symbol ● in panels A, B, C and D) and  $\Delta pchR$  (kinetics in grey with the symbol  $\Delta$  in panels A, B, C and D) cells were transformed with pAYC5-FURmut plasmid carrying the *pchD* promoter sequence with the PchR box and a Fur mutated box. These cells were grown in CAA medium in the presence of increasing concentrations of  $\text{FeCl}_3$ ,  $\text{CoCl}_2$ ,  $\text{NiCl}_2$  or  $\text{ZnCl}_2$ . Bacterial growth was followed at  $\text{OD}_{600 \text{ nm}}$  and mCherry expression by monitoring the emission of fluorescence at 610 nm (excitation at 570 nm). All kinetics are an average of 5 kinetics. No significant variation of mCherry expression was observed in  $\Delta pchR$  mutant in the presence of metals as shown in Supplemental Materials, Figure 4SM.

79x69mm (300 x 300 DPI)

45 Scheme 2. The PCH pathway and its interaction with  $\text{Fe}^{3+}$  and  $\text{Co}^{2+}$ . PCH can chelate both  $\text{Fe}^{3+}$  and  $\text{Co}^{2+}$ .

46 FptA at the bacterial cell surface can interact with both PCH-metal complexes, but with the highest affinity  
47 for PCH-Fe, and both complexes are transported efficiently into *P. aeruginosa* cells. The biological function of

48 Fur is not affected by the presence of contaminant  $\text{Co}^{2+}$  in the bacterial growth medium. PchR can bind  
49 PCH-Fe and PCH-Co as well as PCH-Ni, and PCH-Zn, but only PchR-PCH-Fe activates the transcription of PCH  
50 genes. The presence of contaminant  $\text{Co}^{2+}$  in the bacteria growth media leads to the formation of PchR-PCH-  
51 Co complexes. This will decrease the intracellular concentration of PchR-PCH-Fe, leading to a decrease in the  
52 expression of PCH genes and PCH production.

**Table 3SM: Experimental data of RT-qPCR experiment presented in Figure 3A.**

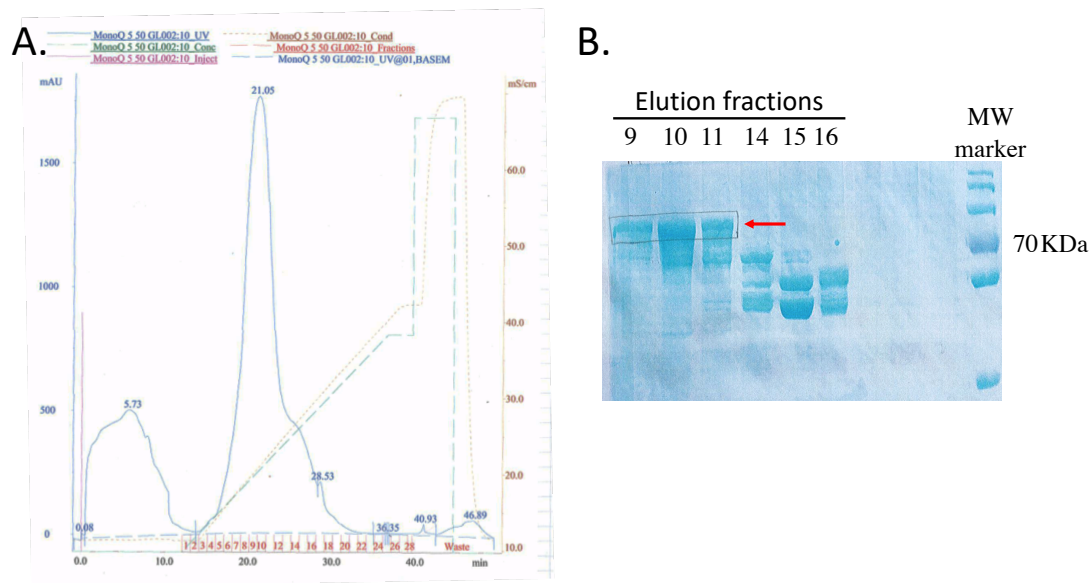

**Figure 1SM:** Growth curve of PAO1 grown in CAA medium in the absence and presence of  $10 \mu\text{M Fe}^{3+}$  or  $\text{Co}^{2+}$ . Growth conditions used for proteomic and transcriptomic analyses.

**Figure 2SM:** **A.** UV spectra of apo PCH and PCH-metal complexes recorded in 50 mM TrisHCl pH 8.0. **B-F.** Superposition of the normalized emission (red) and excitation (green) spectra recorded in 50 mM TrisHCl pH 8.0 for apo PCH and the different PCH-metal complexes. Emission spectra :  $\lambda_{\text{exc}} = 350 \text{ nm}$ ; excitation spectra :  $\lambda_{\text{em}} = 422 \text{ nm}$ .

The complexes have been prepared as described in Materials and Methods by mixing 1 equivalent of metal with 2 equivalents of PCH. UV and fluorescence spectra of apo PCH were carried out at  $100 \mu\text{M}$  for apo PCH and at  $50 \mu\text{M}$  for the PCH-metal complexes. The fluorescence emission scale is not the same in panels B-F: PCH-Zn is much more fluorescent than apo PCH and the other PCH-metal complexes; for PCH-Fe and PCH-Ni the fluorescence is slightly quenched. Apo PCH and PCH-Ni have both a maximum of fluorescence at 438 nm, PCH-Fe at 443 nm, PCH-Co at 440 and PCH-Zn at 452 nm.

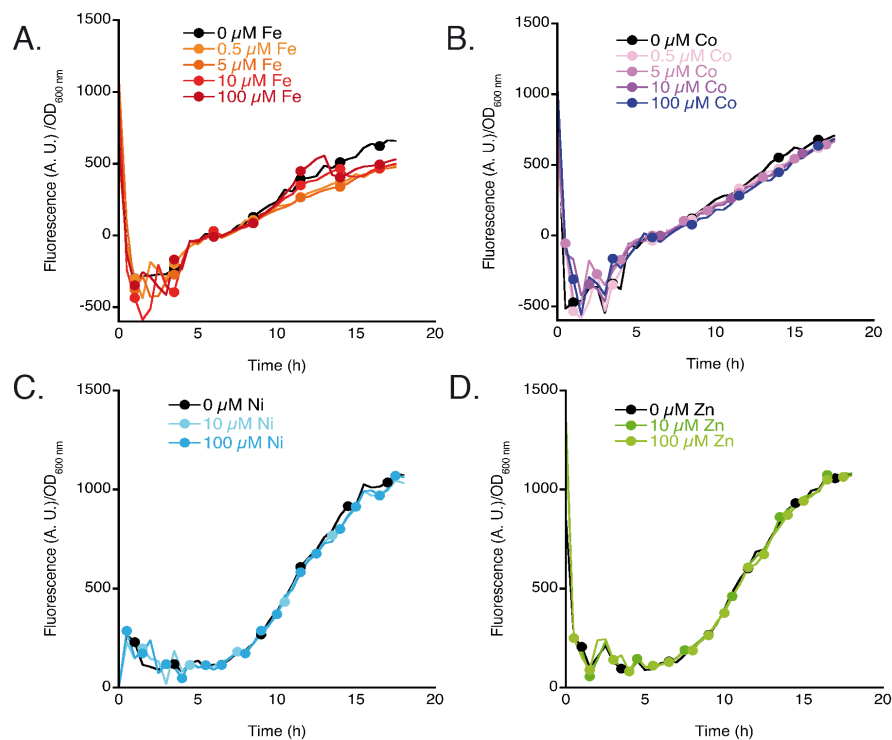

**Figure 3SM: MBP-PchR purification.** For detailed protocol see in Materials and Methods. **A.** Ionic exchange chromatogram of MBP-PchR (Mono Q™ 5/50 GL). MBP-PchR was eluted with a NaCl<sub>2</sub> gradient. **B.** SDS-PAGE analysis of the elution peak at 21 min. MBP-PchR has a molecular weight of 75 kDa and was detected in fractions 9-11.

**Figure 4SM: A. Fluorescence emission spectra of MBP-PchR in the presence of different PCH-Fe or PCH-Co concentrations.** MBP-PchR has a maximal fluorescence emission at 343 nm (black line, excitation at 280 nm). Its fluorescence was quenched with addition of increasing concentrations of PCH-Fe or PCH-Co. PCH-Fe and PCH-Co have a maximal fluorescence emission at 440 nm.

**B. Stern-Volmer plot for siderophore binding affinity determination of MBP-PchR.** Relative fluorescence intensity ( $F_0/F$ ) of MBP-PchR at 343 nm in the presence of PCH-Fe, PCH-Co, PCH-Ni and PCH-Zn were plotted against PCH-metal concentrations. Data were fit with a linear regression.

**Figure 5SM: Expression of mCherry from pAYC5-FURmut plasmid in the absence or presence of Fe<sup>3+</sup>, Co<sup>2+</sup>, Ni<sup>2+</sup> or Zn<sup>2+</sup> under Fur regulation in the  $\Delta pchR$  mutant.**  $\Delta pchR$  cells were transformed with pAYC5-FURmut plasmid carrying the *pchD* promoter sequence with the PchR box and a Fur mutated box. These cells were grown in CAA medium as PAO1 cells in Figure 7 in the presence of increasing concentrations of Fe<sup>3+</sup>, Co<sup>2+</sup>, Ni<sup>2+</sup> or Zn<sup>2+</sup>. Bacterial growth was followed at OD<sub>600 nm</sub> and mCherry expression by monitoring the emission of fluorescence at 610 nm (excitation at 570 nm). All kinetics are an average of 5 kinetics.
