Key words and phrases. Milliken’s tree theorem, Ramsey’s theorem, partition theory, computable combinatorics, reverse mathematics, structural Ramsey theory
Abstract. Milliken’s tree theorem is a deep result in combinatorics that generalizes a vast number of other results in the subject, most notably Ramsey’s theorem and its many variants and consequences. In this sense, Milliken’s tree theorem is paradigmatic of structural Ramsey theory, which seeks to identify the common combinatorial and logical features of partition results in general. Its investigation in this area has consequently been extensive.

Motivated by a question of Dobrinen, we initiate the study of Milliken’s tree theorem from the point of view of computability theory. The goal is to understand how close it is to being algorithmically solvable, and how computationally complex are the constructions needed to prove it. This kind of examination enjoys a long and rich history, and continues to be a highly active endeavor. Applied to combinatorial principles, particularly Ramsey’s theorem, it constitutes one of the most fruitful research programs in computability theory as a whole. The challenge to studying Milliken’s tree theorem using this framework is its unusually intricate proof, and more specifically, the proof of the Halpern-Läuchli theorem, which is a key ingredient.

Our advance here stems from a careful analysis of the Halpern-Läuchli theorem which shows that it can be carried out effectively (i.e., that it is computably true). We use this as the basis of a new inductive proof of Milliken’s tree theorem that permits us to gauge its effectiveness in turn. The key combinatorial tool we develop for the inductive step is a fast-growing computable function that can be used to obtain a finitary, or localized, version of Milliken’s tree theorem. This enables us to build solutions to the full Milliken’s tree theorem using effective forcing.

The principal outcome of this is a comprehensive classification of the computable content of Milliken’s tree theorem, stratified by the size of instance. In terms of upper bounds, we show that Milliken’s tree theorem always admits arithmetical solutions (relative to the instances). For lower bounds, we show that Milliken’s tree theorem for trees of height three or more can code the halting set, while Milliken’s tree theorem for trees of height two cannot. Thus, there is a computability-theoretically detectable distinction between these two cases, which is analogous to the situation for Ramsey’s theorem (for colorings of triples of integers versus pairs of integers), albeit proceeding by entirely different methods. As usual, all of these results translates into the parlance of reverse mathematics, yielding a complete understanding of the fragments of second-order arithmetic required to prove Milliken’s tree theorem on the one hand, and provable from it on the other.

We apply our analysis also to several well-known applications of Milliken’s tree theorem, namely Devlin’s theorem, a partition theorem for Rado graphs, and a generalized version of the so-called tree theorem of Chubb, Hirst, and McNicholl. These are all certain kinds of extensions of Ramsey’s theorem for different structures, namely the rational numbers, the Rado graph, and perfect binary trees, respectively. We obtain a number of new results about how these principles relate to Milliken’s tree theorem and to each other, in terms of both their computability-theoretic and combinatorial aspects. We identify again the familiar dichotomy between coding the halting problem or not based on the size of instance, but this is more subtle here owing to the more complicated underlying structures, particularly in the case of Devlin’s theorem. We also establish new structural Ramsey-theoretic properties of the Rado graph theorem and the generalized Chubb-Hirst-McNicholl tree theorem using Zucker’s notion of big Ramsey structure.

The authors express their gratitude and appreciation to the Institut Henri Poincaré in Paris for kindly hosting them in February of 2020, during which time this project was conceived, and much of it completed.

They also thank Natasha Dobrinen, Lu Liu, and Andy Zucker, for their valuable insights, suggestions, and clarifications during the preparation of this manuscript.
CHAPTER 1

Introduction

This monograph is part of the longstanding project of exploring connections between logic and combinatorics. Our focus is, more specifically, on studying the computable (or effective) content of combinatorial theorems. This has a long history, as we survey below. The interest stems from the realization that combinatorial notions tend to be computability-theoretically natural, and vice-versa. Traditionally, this has led to fine-grained analyses of different combinatorial constructions, often resulting in new, more computationally efficient proofs of various combinatorial results.

Over time, this work has made increasing use of powerful set-theoretic and combinatorial techniques, whose adaptation to the realm of computability theory has produced new insights into unsolved problems. Such will be the case for our investigation here of Milliken’s tree theorem (named for its author, and originally proved in [29]; cf. also [30]). This is a deep result whose significance in Ramsey theory and related areas has made it the objective of much attention in combinatorics and set theory. This makes all the more surprising its near complete absence from the computability-theoretic literature. To our knowledge, the only published mentions are by Carlson and Simpson [2, Section 3] and Chubb, Hirst, and McNicholl [8]. The authors of the former paper introduce the so-called dual Ramsey’s theorem, and give as a consequence a new proof of the Halpern-Laïhi theorem, an important result for understanding Milliken’s tree theorem that we investigate at length also here. The latter paper focuses on what is ultimately a kind of weak or degenerate form of Milliken’s tree theorem, which has garnered a great deal of interest in its own right. See Chapter 7, where we give a full account of the theorem of Chubb, Hirst, and McNicholl and how it relates to Milliken’s in the context of our work here. (We add that during the writing of this manuscript, we learned of a concurrent project of Chong, Li, Liu, and Yang in progress, whose focus is the Chubb, Hirst, and McNicholl theorem but which also obtains results about Milliken’s tree theorem proper. Specifically, the authors obtain by independent means our Corollary 4.7 below.)

The problem of determining the computable content of Milliken’s tree theorem was proposed by Dobrinen [10]. We give a complete analysis here, using the tools of computability theory and reverse mathematics. As we will show, Milliken’s tree theorem turns out to be surprisingly rich and intricate
in this respect, reflecting its centrality among other partition theorems, including Ramsey’s theorem and its many variants.

1.1. Milliken’s tree theorem and Ramsey theory

Ramsey theory is a vast area of combinatorics, broadly interested in results about when some sort of regularity is unavoidable when a large given structure is partitioned into a small number of pieces. (Here “large” is typically taken to mean a particular finite or infinite cardinality, and “small” is understood relative to this cardinality.) Canonical examples include, of course, the finite and infinite Ramsey’s theorems, both due to F. P. Ramsey [34], which we recall. Let \( \mathbb{N} \) denote the set of natural numbers, \( \{0, 1, 2, \ldots\} \), and given a set \( X \subseteq \mathbb{N} \) and integer \( n \geq 1 \), let \( [X]^n = \{ (x_0, \ldots, x_{n-1}) \in X^n : x_0 < \cdots < x_{n-1} \} \). We identify each \( k \in \mathbb{N} \) with the set of its predecessors, \( \{0, 1, \ldots, k-1\} \).

**Theorem 1.1** (Finite Ramsey’s theorem). For all \( n, k \geq 1 \) and \( m_1, \ldots, m_{k-1} \in \mathbb{N} \) there is a number \( M \in \mathbb{N} \) such that for every \( f : [M]^n \to k \) there is an \( i < k \) and a set \( H \subseteq M \) of size \( m_i \) such that \( f(\vec{x}) = i \) for all \( \vec{x} \in [H]^n \).

**Theorem 1.2** (Infinite Ramsey’s theorem). For all \( n, k \geq 1 \) and every \( f : [\mathbb{N}]^n \to k \) there is an \( i < k \) and an infinite set \( H \subseteq \mathbb{N} \) such that \( f(\vec{x}) = i \) for all \( \vec{x} \in [X]^n \).

The sets \( H \) above are called homogeneous sets for the coloring \( f \). There are also versions of Ramsey’s theorem for colorings of uncountable sets, but we will restrict our attention here to the countable setting.

In broad strokes, Ramsey’s theorem(s) can be seen as saying that in any configuration of integers, however complicated or random, some amount of order is necessary. Understanding this order, and how it arises, is naturally captivating, and its study has resulted in important advances across mathematics, from combinatorics to logic to number theory. These include, for example, the celebrated Szemerédi’s theorem (cf. [44, 45]), the various proofs of which over the years, and the myriad mathematical ideas used in them, led to it be called the “Rosetta stone” of mathematics by Tao [46]. We will explore a number of other examples in this monograph. For a general introduction to Ramsey theory, we refer the reader to the book of Graham, Rothschild, and Spencer [17]. For more background on the kind of combinatorics most relevant to us here, we refer to Todorcevic [47].

The main subject of the present monograph, Milliken’s tree theorem, is a strong generalization of the infinite Ramsey’s theorem. We state it here in a restricted form in order to be able to begin discussing it. The full statement requires more nuanced definitions that we delay until the next chapter. For now, we recall that \( 2^{<\omega} \) denotes the set of all finite binary strings, i.e., finite sequences of 0s and 1s. For \( \sigma \in 2^{<\omega} \), we write \( |\sigma| \) for the length of \( \sigma \), i.e., the number of bits occurring in \( \sigma \), and we let \( 2^n \) and \( 2^{<n} \) denote the sets of \( \sigma \in 2^{<\omega} \) with \( |\sigma| = n \) and \( |\sigma| < n \), respectively. For \( \sigma, \tau \in 2^{<\omega} \) we write
σ ≤ τ to mean that σ is an initial segment (not necessarily proper) of τ, and σ < τ to mean σ ≤ τ and σ ≠ τ. We also write σ ∧ τ for the longest common initial segment of σ and τ. The crucial notion in the statement of Milliken’s tree theorem is the following: $S \subseteq 2^{<\omega}$ is a strong subtree of $2^{<\omega}$ if $S$ is closed under ∧, and $(S, \leq)$ is isomorphic, as a structure, to either $(2^{<\omega}, \preceq)$ or $(2^{<n}, \preceq)$ for some $n$, via a map that preserves whether or not a pair of nodes has the same length. Thus, for instance, \{01, 0101, 0110\} is a strong subtree of $2^{<\omega}$, whereas \{01, 0100, 0101\} and \{01, 0101, 011\} are not, even though all three sets, under ≤, are isomorphic to $(2^{<n}, \preceq)$. (See Figure 1.1.)

![Figure 1.1. Three subsets, $S_0$, $S_1$, and $S_2$, of $2^{<\omega}$. Solid circles indicate strings in the set, hollow circles strings not in the set. Only $S_0$ is a strong subtree of $2^{<\omega}$.](image)

Given $T \subseteq 2^{<\omega}$, let $S_\omega(T)$ denote the set of strong subtrees of $2^{<\omega}$ that are contained in $T$ and isomorphic to $(2^{<\omega}, \preceq)$. For $n \geq 1$, let $S_n(T)$ denote the set of strong subtrees of $2^{<\omega}$ that are contained in $T$ and isomorphic to $(2^{<n}, \preceq)$.

**Theorem 1.3** (Milliken’s tree theorem for $2^{<\omega}$). For all $n, k \geq 1$ and all $f : S_n(2^{<\omega}) \to k$ there exists $i < k$ and a $T \in S_\omega(2^{<\omega})$ such that $f(S) = i$ for all $S \in S_n(T)$.

To begin, note that the infinite Ramsey’s theorem is a straightforward consequence of (even this version of) Milliken’s tree theorem. Indeed, given a coloring $f : [\mathbb{N}]^n \to k$, we define $g : S_n(2^{<\omega}) \to k$ as follows. For each $S \in S_n(2^{<\omega})$, let $\bar{x}_S = \{\sigma : \sigma \in S\}$, which is a set of size $n$ and so can be viewed as an element of $[\mathbb{N}]^n$. Let $g(S) = f(\bar{x}_S)$. Now if $T \in S_\omega(2^{<\omega})$ is as given by Milliken’s tree theorem for this $g$, then $H = \{\sigma : \sigma \in T\}$ is easily seen to be an infinite homogeneous set for $f$.

Indeed, it is well-known that Milliken’s tree theorem implies a great many partition theorems, including a number that are significantly more difficult to prove than Ramsey’s. We will look at several of these theorems in this manuscript, and show that their implications from Milliken’s tree theorem can be made constructive in the sense of computability theory and reverse mathematics, which we discuss below. Much of this will rely on carefully identifying and examining features common between strong subtrees of
2^{<\omega}$ and the combinatorial structures underlying these other principles, using a combination of ideas that have previously been successfully employed in structural Ramsey theory, along with techniques newly developed here.

We refer the reader to Todorcevic [47, Chapter 6] for an in-depth discussion of Milliken’s tree theorem, and a careful development of a proof. As with Ramsey’s theorem, the proof has an inductive form based on the exponent, $n$, of the colorings being considered. Thus, we prove it first for finite colorings of $S_1(2^{<\omega})$, and then assuming it holds for finite colorings of $S_n(2^{<\omega})$, we prove it for finite colorings of $S_{n+1}(2^{<\omega})$. The base case, $n = 1$, is actually not difficult to prove directly (though it is less trivial than the $n = 1$ case of Ramsey’s theorem, i.e., the infinitary pigeonhole principle). However, unlike in standard proofs of Ramsey’s theorem, where the inductive step uses just the $n = 1$ case to increase the exponent, in the case of Milliken’s tree theorem a stronger result is needed. This is the so-called Halpern-Lauchli theorem, due originally to Halpern and Lauchli [18], and independently Laver (unpublished) and Pincus [32] (see [33] for more on the history).

Given $d \geq 1$ and $T_0, \ldots, T_{d-1} \subseteq 2^{<\omega}$, let $S_\alpha(T_0, \ldots, T_{d-1})$ for $\alpha \in \mathbb{N}\cup\{\omega\}$ be the collection of all tuples $(S_0, \ldots, S_{d-1})$ such that for each $i < d$ we have $S_i \subseteq S_\alpha(T_i)$, and for all $i, j < d$ and all $\sigma \in S_i$ and $\tau \in S_j$, we have that $\sigma$ has the same number of initial segments in $S_i$ as $\tau$ does in $S_j$ if and only if $|\sigma| = |\tau|$.

**Theorem 1.4 (Halpern-Lauchli theorem for $2^{<\omega}$).** For all $d, k \geq 1$ and all $f : \bigcup_{n \in \mathbb{N}}(2^n)^d \to k$ there exists $i < k$ and $(T_0, \ldots, T_{d-1}) \in S_\omega(2^{<\omega}, \ldots, 2^{<\omega})$ such that $f(\bar{\sigma}) = i$ for all $\bar{\sigma} = (\sigma_0, \ldots, \sigma_{d-1}) \in T_0 \times \cdots \times T_{d-1}$ with $|\sigma_0| = \cdots = |\sigma_{d-1}|$.

Prima facie, this theorem appears as a kind of parallelized version of Milliken’s tree theorem for colorings of $S_1(2^{<\omega})$, and one may expect it to be not much more complicated to prove. In fact, this is misleading, and the Halpern-Lauchli theorem largely encompasses the entire combinatorial core of (the full) Milliken’s tree theorem. We will analyze the Halpern-Lauchli theorem in detail in this monograph, and use it in a careful way to give a more effective proof of Milliken’s tree theorem.

### 1.2. Computable combinatorics

The principal theme of modern computability theory is *relative* computability: a set $X \subseteq \mathbb{N}$ is computable from (or Turing reducible to) a set $Y$, written $X \leq_T Y$, if there is an algorithm to decide which numbers belong to $X$ using information about which numbers belong to $Y$. If $X \leq_T Y$ and $Y \leq_T X$ we write $X \equiv_T Y$. This notion, along with a precise formalization of the concept of an algorithm, was a seminal achievement of Turing in the 1930s. Sets can be classified in numerous ways, such as in terms of their structural properties or by their syntactic descriptions.
As a rule, all such properties can be relativized, leading to increasingly larger classes of sets. For example, the halting problem relative to $X$, denoted $X'$ and also called the (Turing) jump of $X$, refers to the set of $e \in \mathbb{N}$ such that the $e$th algorithm in some fixed listing, with access to information about $X$, halts on input $e$. For every $X$ we have that $X \leq_T X'$ but $X' \nleq_T X$, which yields in particular a canonical example of a non-computable set. The complexity of a set of natural numbers in computability theory (or by extension, of any object that can be naturally represented or encoded by such a set) is a measure of “how far” it is from being computable, according to various hierarchies of classes of sets obtained in this fashion. For general background in computability theory, we refer the reader to Soare [41] and to Downey and Hirschfeldt [11].

Computability theory lends itself to analyzing a vast collection of problems that are sometimes called instance-solution problems. This refers to theorems having the form

$$\forall A \ [P(A) \implies \exists B \ Q(A, B)],$$

where $P$ and $Q$ are some sort of properties of $A$, and of $A$ and $B$, respectively. One can regard such a theorem as the problem, “Given an $A$ such that $P(A)$ holds, find a $B$ such that $Q(A, B)$ holds”. In this context, we call such $A$ the instances of the problem (or theorem), and all such $B$ the solutions to $A$. This is a natural way of thinking about theorems of this shape. For example, the instances of Ramsey’s theorem are all finite colorings of $[\omega]^n$ for some $n$, and the solutions to any such coloring are its infinite homogeneous sets.

One way to gauge the complexity of an instance-solution problem is by studying the relationship between the complexity of instances and solutions, when these can be presented as subsets of $\mathbb{N}$, as will be the case in all the examples we consider in this manuscript. From this perspective, a problem that is computably true, i.e., one each of whose instances has at least one solution computable in that instance, is trivial from the algorithmic standpoint. By contrast, a problem that has an instance all of whose solutions compute the jump of that instance, is strictly harder, being, in a certain sense, at least as difficult as “solving the halting problem”. In general, the further apart the instances and solutions are in this sense, the more algorithmically complex it is. We can thus directly compare different problems in terms of their complexity, yielding a notion of algorithmic or computability-theoretic strength. For a thorough introduction to this kind of analysis, which is generally called computable mathematics, see the book of Hirschfeldt [19].

A complementary approach is provided by the foundational program of reverse mathematics, developed by Friedman and Simpson in the late 1970s. The setting here is second-order arithmetic, a formal system strong enough to express countable analogues of most results of classical mathematics. Its axioms include the usual ordered semi-ring axioms for the natural numbers, together with comprehension axioms asserting that the set of all numbers $x$
satisfying a given formula (property) exists. By restricting to only certain kinds of formulas we get various subsystems of second-order arithmetic, the most basic of which is called RCA$_0$ and roughly corresponds to computable mathematics. The traditional approach in the subject has been to compare a given theorem with several benchmark subsystems (WKL$_0$, ACA$_0$, ATR$_0$) extending RCA$_0$, corresponding to increasing levels of non-constructibility. Isolating the weakest such system that the theorem can be proved in, and the strongest that can in turn be proved from it over the base system RCA$_0$, yields a measure of its proof-theoretic strength. There is a fruitful and well-understood interplay between reverse mathematics and computability theory, with ideas and results from one often leading to results in the other (see Shore [37]). This has been made even more pronounced in recent years by the introduction of various Weihrauch-style reducibilities to the subject, which have come to be viewed largely as an extension and refinement of the traditional program of reverse mathematics. Computable reducibility, in particular, which is a non-uniform analogue of Weihrauch reducibility originally introduced in [12], will figure in a number of our results here.

The standard reference on reverse mathematics is Simpson [40]. Weihrauch reducibility was introduced by Weihrauch [49] in the 1990s, and has since been widely deployed in computable analysis and other fields; for a recent survey, see Brattka, Gherardi, and Pauly [1].

Of course, instance-solution problems are ubiquitous across mathematics, but problems from combinatorics have figured especially prominently in the above frameworks for many decades. The classification and differentiation of combinatorial theorems according to their computability-theoretic and proof-theoretic strength is nowadays called computable combinatorics. Perhaps the earliest result here is the following one from the late 1960s, stating that Ramsey’s theorem for pairs is not computably true.

**Theorem 1.5** (Specker [42]). There is a computable $f : \omega^2 \to 2$ with no computable infinite homogeneous set.

(In the parlance of reverse mathematics, this shows that Ramsey’s theorem for colorings of pairs is not provable in the base theory, RCA$_0$.) This result was greatly extended in the seminal 1972 paper of Jockusch [22], which set off an industry of research on Ramsey’s theorem in computability theory that is still highly active today.

The computability-theoretic perspective offers insights that are not readily discernible in combinatorics alone. In the case of Ramsey’s theorem, a well-known example is provided by the following pair of results.

**Theorem 1.6** (Jockusch [22], Theorem 5.7). For each $n \geq 3$, there is a computable $f : \omega^n \to 2$ each of whose infinite homogeneous sets computes $\emptyset^{(n-2)}$ (and in particular $\emptyset'$).

**Theorem 1.7** (Seetapun; see [36]). Every computable $f : \omega^2 \to 2$ has an infinite homogeneous set that does not compute $\emptyset'$.
Thus, there is a direct computational distinction between Ramsey’s theorem for colorings of pairs and Ramsey’s theorem for colorings triples and larger tuples. (Formalizing these results in RCA\(_0\) yields that Ramsey’s theorem for colorings of triples implies the system ACA\(_0\) over RCA\(_0\), whereas Ramsey’s theorem for colorings of pairs does not.)

Such threshold phenomena, where an increase in a parameter changes a theorem from not being able to encode specific non-computable information to being able to do so, are observed quite widely. For example, as was shown by Dzhafarov and Patey [14], this is the case for the aforementioned theorem introduced by Chubb, Hirst, and McNicholl [8]. And more recently, Chong et al. [5] obtained similar results for a theorem of Erdős and Rado about colorings of pairs of rationals. We will likewise establish threshold phenomena for Milliken’s tree theorem and the various consequences of it we consider.

Another computability-theoretic feature that will feature prominently in our work is cone avoidance. In the subject, a cone refers to a set of subsets of \(\omega\) closed upward under \(\leq_T\). As a case in point, the set of all sets \(X\) that compute \(\emptyset'\) is a cone, and Seetapun’s theorem (Theorem 1.7 above) can be seen as saying that every computable instance of Ramsey’s theorem for colorings of pairs has a solution that lies outside (or avoids) this cone. The emphasis here is on the restriction to computable instances, however; indeed, it is easy to see that there is a (necessarily non-computable) \(f : [\omega]^2 \to 2\), each of whose infinite homogeneous sets does compute \(\emptyset'\). By contrast, some instance-solution problems enjoy a stronger property called strong cone avoidance, whereby every instance (computable or not) has at least one solution that avoids the cone of sets that compute \(\emptyset'\). This is the case, for example, for the infinitary pigeonhole principle, as shown by Dzhafarov and Jockusch [13, Lemma 3.2]. We shall investigate both cone avoidance and strong cone avoidance for versions of Milliken’s tree theorem, and in particular, for the Halpern-Laüchli theorem. It is worth noting, too, that while every computably true problem obviously possesses cone avoidance, not every such problem satisfies strong cone avoidance. (For example, consider the identity problem, whose instances are all \(X \subseteq \omega\), and the only solution of \(X\) is \(X\) itself.)

1.3. Plan of the manuscript

The manuscript is organized as follows. In Chapter 2, we give further background and definitions to allow us to state the full versions of Milliken’s tree theorem and the Halpern-Laüchli theorem. In Chapter 3, we proceed to the computability-theoretic analysis of the Halpern-Lauchli theorem, as a bootstrap to understanding the computational content of Milliken’s tree theorem. In particular, we prove that the Halpern-Lauchli theorem is computably true (Theorem 3.4) and admits strong cone avoidance (Theorem 3.21). Then, in Chapter 4, we analyse a product version of Milliken’s
tree theorem. We prove that the statement is equivalent to $\text{ACA}_0$ for strong
subtrees of height at least 3 (Corollary 4.7), and that its restriction to col-
orings of strong subtrees of height 2 admits cone avoidance (Theorem 4.15).
Lastly, we prove that a weakening to the product version of Milliken’s tree
theorem for height 3, for which the solutions have now at most 2 colors
instead of 1, admits cone avoidance (Theorem 4.28). In ??, we study three
applications of Milliken’s tree theorem for pairs, namely: Devlin’s theorem
concerning colorings of tuples of rationals; a theorem about colorings of
finite subgraphs of the Rado graph; and a generalization of the combinator-
rial theorem of Chubb, Hirst, and McNicholl discussed above. Finally, in
Chapter 8, we state some questions that our investigation leaves open.
CHAPTER 2

Definitions

The aim of this chapter is to review key concepts to make the rest of this monograph more easily accessible to computability theorists, set theorists, and combinatorialists. Our terminology and notation will for the most part be standard, following, e.g., [11] and [47]. Where there is less uniformity in the literature, we highlight our particular usage in this chapter and, as the need arises, in the sequel. In Section 2.1 we set out our notation for finite strings, operations on them, and spaces of subsets of \( \mathbb{N} \), which are largely common across these fields. Sections 2.2 and 2.3 provide an overview of some technical notions from computability theory and reverse mathematics. In Sections 2.4 and 2.5, we review combinatorial definitions relevant to stating Milliken’s tree theorem and some of its corollaries, which we then present in Section 2.6. Finally, in Section 2.7, we review some terminology from structural Ramsey theory that helps give a common framing for these principles.

We begin with some basics. We use \( \sqcup \) to denote disjoint union. For every set \( X \), we denote by \( \mathcal{P}(X) \) the power set of \( X \). And given a function \( f \) on \( X \), we let \( f \upharpoonright Y \) denote the restriction of \( f \) to \( Y \subseteq X \).

Throughout, we use \( (\cdots) \) to denote (ordered) tuples of objects, and given a function \( f \) defined on a tuple \( (a_0, \ldots, a_n) \) we write \( f(a_0, \ldots, a_n) \) in place of \( f((a_0, \ldots, a_n)) \). In the computability-theoretic setting, we do not make a notational distinction for coded tuples (of numbers, subsets of \( \mathbb{N} \), or combinations thereof). Thus, we also let \( (\cdots) \) denote a fixed computable bijection from finite ordered tuples of natural numbers to \( \mathbb{N} \), e.g., as in [41, p. xxxii]. For \( X_0, \ldots, X_{n-1} \subseteq \mathbb{N} \) we will sometimes use \( (X_0, \ldots, X_{n-1}) \) as an alternative notation for the join, \( X_0 \oplus \cdots \oplus X_{n-1} = \{(x, i) : x \in X_i, i < n\} \subseteq \mathbb{N} \). In the case that some \( X_i \) is a singleton, say containing \( x \), we will write simply \( (X_0, \ldots, x, \ldots, X_{n-1}) \) in place of \( (X_0, \ldots, \{x\}, \ldots, X_{n-1}) \).

Given a countable collection of sets \( \{X_0, X_1, \ldots\} \) indexed by the natural numbers, we write \( \bigcup_n X_n \) for \( \bigcup_{n \in \mathbb{N}} X_n \).

2.1. Strings and subsets of \( \mathbb{N} \)

The following definition is included for completeness.

**Definition 2.1.**

1. \( \omega^{<\omega} \) denotes the set of all finite strings of natural numbers, i.e., functions \( \sigma : n \to \omega \) for some \( n \in \mathbb{N} \).
2. DEFINITIONS

(2) $2^{<\omega}$ denotes the subset of $\omega^{<\omega}$ of binary ($\{0, 1\}$-valued) strings.

(3) The length of $\sigma \in \omega^{<\omega}$ is the cardinality of its domain, and is denoted by $|\sigma|$.

(4) The unique string of length 0 is denoted by $\varepsilon$.

(5) For $n \in \mathbb{N}$, $\omega^n$ and $\omega^{<n}$ denote the sets of $\sigma \in \omega^{<\omega}$ with $|\sigma| = n$ and $|\sigma| < n$, respectively.

(6) For $n \in \mathbb{N}$, $2^n$ and $2^{<n}$ denote the sets of $\sigma \in 2^{<\omega}$ with $|\sigma| = n$ and $|\sigma| < n$, respectively.

As is customary, we will alternate between the function and sequence point of view for elements of $\omega^{<\omega}$. For $\sigma \in \omega^{<\omega}$ and $i < |\sigma|$ we will thus speak of $\sigma(i)$ and the $(i + 1)$st element of $\sigma$ (or $(i + 1)$st bit, if $\sigma \in 2^{<\omega}$) interchangeably, or as convenient. We will sometimes specify $\sigma$ explicitly as $(\sigma(0)\sigma(1) \cdots \sigma(|\sigma| - 1))$.

**Definition 2.2.** Fix $\sigma, \tau \in \omega^{<\omega}$.

1. $\sigma$ is an initial segment of $\tau$, and $\tau$ is an extension of $\sigma$, written $\sigma \preceq \tau$, if $\sigma = \tau | n$ for some $n \leq |\tau|$.

2. $\sigma$ is a proper initial segment of $\tau$, and $\tau$ is a proper extension of $\sigma$, written $\sigma \prec \tau$, if $\sigma = \tau | n$ for some $n < |\tau|$, i.e., if $\sigma \preceq \tau$ and $\sigma \neq \tau$.

3. $\sigma$ and $\tau$ are incompatible, written $\sigma \perp \tau$, if $\sigma \nprec \tau$ and $\tau \nprec \sigma$.

4. The meet of $\sigma$ and $\tau$, denoted by $\sigma \land \tau$, is the longest common initial segment of $\sigma$ and $\tau$, i.e., $\sigma \land \tau = \sigma | n$ for the longest $n$ such that $\sigma | n = \tau | n$.

5. The concatenation of $\sigma$ by $\tau$ is the string $\sigma \tau : |\sigma| + |\tau| \rightarrow \omega$ with $(\sigma \tau)(i) = \sigma(i)$ for all $i < |\sigma|$ and $(\sigma \tau)(i) = \tau(i - |\sigma|)$ for all $|\sigma| \leq i < |\sigma| + |\tau|$.

So, for the sake of completeness, notice that if $\sigma \land \tau = \sigma$ then $\sigma \preceq \tau$. Observe too that $\varepsilon$ is an initial segment of every $\sigma$, and $\varepsilon \sigma = \sigma \varepsilon = \sigma$. Finally, if $\sigma, \tau \in 2^{<\omega}$ then so is $\sigma \tau$.

**Definition 2.3.**

1. $\omega^{\omega}$ denotes the set of all functions $X : \mathbb{N} \rightarrow \mathbb{N}$, and $2^{\omega}$ the set of all $\{0, 1\}$-valued such functions.

2. $\sigma \in \omega^{<\omega}$ is an initial segment of $X \in \omega^{\omega}$, and $X$ is an extension of $\sigma$, written $\sigma \prec X$, if $\sigma(i) = X(i)$ for all $i < |\sigma|$.

When convenient, we identify sets with their characteristic functions, which gives us the usual equivalence between elements of $2^{\omega}$ and elements of $P(\mathbb{N})$. For this reason, we use $X | \ell$ for $\ell \in \mathbb{N}$, which denotes the restriction of the characteristic function of $X$ to $\ell$, also as shorthand for $\{x \in X : x < \ell\}$.

The sets $\omega^{\omega}$ and $2^{\omega}$ each have natural topologies defined on them, respectively generated by basic open sets of the form

$$[\sigma] = \{X \in \omega^{\omega} : \sigma \prec X\}.$$
for $\sigma \in 2^{<\omega}$, and

$$[\sigma] = \{X \in 2^\omega : \sigma \prec X\}.$$  

for $\sigma \in 2^{<\omega}$. This turns $\omega^\omega$ into a Baire space and $2^\omega$ into a Cantor space. For our purposes here, the main relevant topological consideration will be that $2^\omega$ is compact.

## 2.2. Computability and reverse mathematics

Everywhere, we adopt the Church-Turing thesis, and therefore forego any specifics of our model of computation. We take as fixed some listing $\Phi_0, \Phi_1, \ldots$ of all partial computable functions such that from each $e$ we can computably determine the program of $\Phi_e$, and conversely, from each program we can computably find an $e$ such that $\Phi_e$ executes this program. Nominally, we think of $e$ as being a code for the sequence of steps in the program under a Gödel coding (see, e.g., [41], Definitions 1.5.1 and 1.7.2).

Recall that a set $W \subseteq \mathbb{N}$ is *computably enumerable (c.e.)* if it is the domain of some partial computable function, i.e., the set of inputs on which a given Turing program halts in finite time. We denote the domain of $\Phi_e$ by $W_e$.

**Definition 2.4.** A *Turing functional* is a c.e. set $\Gamma$ of pairs $(\sigma, \tau) \in 2^{<\omega} \times 2^{<\omega}$ (coded as numbers) such that if $(\sigma, \tau)$ and $(\sigma', \tau')$ belong to $\Gamma$ and $\sigma \leq \tau$ then $\tau \leq \tau'$. In this case, for every set $X \subseteq \mathbb{N}$, we also define the following.

1. $\Gamma^X = \bigcup \{ \tau \in 2^{<\omega} : (\exists \sigma \prec X)[(\sigma, \tau) \in \Gamma] \}$.
2. We write $\Gamma^X(x) = y$ or $\Gamma^X(x) \downarrow = y$ if $\tau(x) = y$ for some (and hence all) $(\sigma, \tau) \in X$ with $\sigma \prec X$ and $|\tau| > x$; we write $\Gamma^X(x) \downarrow$ if $\Gamma^X(x) = y$ for some $y$, and otherwise we write $\Gamma^X(x) \uparrow$.
3. $\Gamma^X$ is *total* if $\Gamma^X(x) \downarrow$ for all $x \in \mathbb{N}$.

Note that if $\Gamma^X$ is total then it is, in fact, equal to an element of $2^\omega$. In particular, if $\Gamma^X$ is total for all $X \in 2^\omega$ then $\Gamma$ is a continuous map $2^\omega \to 2^\omega$. If $\Gamma = W_e$, then for all $X$ we also denote $\Gamma^X$ by $\Phi^X_e$ when convenient.

For simplicity, we abuse notation and write $\Phi_e$ instead of $\Phi^0_e$. (Formally, this is only incorrect up to a fixed computable permutation of $\mathbb{N}$. Indeed, given any computable set $X$ there is a computable bijection $f : \mathbb{N} \to \mathbb{N}$ such that $\Phi^X_e = \Phi^X_{f(e)}$ for all $e \in \mathbb{N}$.) This highlights the fact that the main role of Turing functionals is to facilitate relativization of computability-theoretic notions to arbitrary subsets of $\mathbb{N}$. For example, a set $Y \subseteq \mathbb{N}$ is computable *relative to $X$* (or *from $X$*, or is *$X$-computable*), if $Y = \Gamma^X$ for some Turing functional $\Gamma$, in which case we write $Y \leq_T X$; $Y$ is computably enumerable *relative to $X$* (or *$X$-c.e.* if $Y$ is the domain of $\Gamma^X$ for some Turing functional $\Gamma$; etc. Recall, too, that for each set $X$, the *jump* of $X$ is the $X$-c.e. set $X' = \{ e \in \mathbb{N} : \Phi^X_e(e) \downarrow \}$.

An important object in investigations like ours is the following.
Definition 2.5. A class $\mathcal{C} \subseteq 2^\omega$ is a $\Pi^0_1$ class if there is a c.e. set $W$, viewed as a subset of $2^{<\omega}$, such that $\mathcal{C} = 2^\omega \setminus \bigcup_{\sigma \in W} [\sigma] = \{ Y \in 2^\omega : (\forall \sigma \in W) (\sigma \not\in Y) \}$. 

If we take $W$ in the definition to be $X$-c.e. rather than c.e., we get the relativized concept of a $\Pi^0_{1, X}$ class. Such classes are ubiquitous, often showing up as the collection of sets satisfying some natural computability-theoretic or combinatorial property. A prototypical example, given an infinite set $X$ and a Turing functional $\Gamma$, is the class $\mathcal{C}_{X, \Gamma}$ of all pairs of sets $(Y_0, Y_1)$ such that $Y_0 \cup Y_1 = X$ and for each $i < 2$, each $x \in \mathbb{N}$, and every finite subset $F$ of $Y_i$, $\Gamma^F(x) \uparrow$. It is easy to verify that $\mathcal{C}_{X, \Gamma}$ is a $\Pi^0_{1, X}$ class.

Note that a $\Pi^0_1$ class is, in particular, a closed subset of $2^\omega$. (The additional property, worth emphasizing, is that a $\Pi^0_1$ class is one whose complement is effectively generated.) Every closed subset of $2^\omega$ is also compact, which yields the following simple but significant result.

Lemma 2.6 (Compactness for $\Pi^0_1$ classes). If $W$ is c.e. and $\mathcal{C} = 2^\omega \setminus \bigcup_{\sigma \in W} [\sigma] = \emptyset$, then there is an $\ell \in \mathbb{N}$ such that $\sigma \in 2^{<\omega}$ has an initial segment in $W$ of length at most $\ell$.

For instance, if the class $\mathcal{C}_{X, \Gamma}$ mentioned above is empty, then compactness yields an $\ell$ such that for every partition of $X$ into two sets, $Y_0$ and $Y_1$, there is an $i < 2$ and a finite subset $F$ of $Y_i \upharpoonright \ell$ with $\Gamma^F(x) \downarrow$ for some $x$. Our use of compactness will often take this form.

Equally important for us will be the case when a $\Pi^0_1$ class we are dealing with is non-empty. To study the members of such classes, we typically employ basis theorems of various kinds, a basis in this context being a collection of subsets of $\mathbb{N}$ that intersects every non-empty $\Pi^0_1$ class. The most celebrated example of this is the low basis theorem of Jockusch and Soare [24, Theorem 2.1], which shows that the collection of low sets $Y$ with $\overline{Y} \leq_T 0'$ forms a basis. In this monograph, we will most often use the following cone avoidance basis theorem.

Theorem 2.7 (Jockusch and Soare [23], Corollary 2.11). Let $C \subseteq \mathbb{N}$ be non-computable. Every non-empty $\Pi^0_1$ class contains a member $Y$ such that $C \not\leq_T Y$.

Observe that to relativize the cone avoidance basis theorem to a set $X$, we need $C$ above to be not only non-computable, but non-$X$-computable. Without this additional condition the result would be false, as can be easily seen, for example, by noticing that the singleton $\{X\}$ is a $\Pi^0_{1, X}$ class. This distinction—computing a given non-computable set on the one hand, and computing it together with a given other set on the other—turns out to be an important one, and we will return to it in the next chapter.

2.3. Second-order arithmetic and computable reducibility

As mentioned, our main focus in this manuscript is a computability-theoretic one. As such, our contributions to reverse mathematics here are
largely ancillary, and except where noted otherwise, will follow by straightforward formalization of our computability results. The framework of reverse mathematics nonetheless provides a convenient way to succinctly state many relationships between the various theorems we will be considering, and also motivates many questions we look at. Indeed, many of these questions would not arise otherwise. We thus begin with a brief overview of this framework.

Let $L_2$ denote the (two-sorted, first-order) language of second-order arithmetic. We use lowercase letters $x, y, \ldots$ to range over first-order variables, and uppercase letters $X, Y, \ldots$ to range over second-order variables. All formulas discussed may include both first- and second-order variables and parameters.

**Definition 2.8.** The following axiomatic systems are defined in the language of second-order arithmetic.

1. $PA^-$ consists of the algebraic axioms of Peano arithmetic (i.e., all axioms except for induction).
2. $RCA_0$ consists of the axioms of $PA^-$, together with $\Delta_1^0$ *comprehension* (i.e., the scheme
   $$(\forall x)[\phi(x) \iff \psi(x)] \rightarrow (\exists X)(\forall x)[x \in X \iff \phi(x)],$$
   where $\phi$ is a $\Sigma_1^0$ formula and $\psi$ is $\Pi_1^0$) and $\Sigma_1^0$ *induction* (i.e., the scheme
   $$(\phi(0) \land (\forall x)[\phi(x) \rightarrow \phi(x + 1)]) \rightarrow (\forall x)[\phi(x)]$$
   where $\phi$ is a $\Sigma_1^0$ formula).
3. $ACA_0$ consists of the axioms of $RCA_0$, together with *arithmetic comprehension* (i.e., the scheme
   $$(\exists X)(\forall x)[x \in X \iff \phi(x)]$$
   where $\phi$ is a $\Sigma_n^0$ formula for some $n \in \mathbb{N}$).

$RCA_0$ corresponds more or less to formalized computable mathematics, since by Post’s theorem, being computable from a set is the same as being $\Delta_1^0$ definable from it. Thus, morally, all effectively true theorems ought to be provable in $RCA_0$. The one complicating factor in this is the restriction in $RCA_0$ to $\Sigma_1^0$ induction, as even effective arguments sometimes require induction beyond this level, and so may fail in a non-standard model of $RCA_0$. While this can lead to interesting questions concerning the first-order content of mathematical principles, the majority of our results in this monograph can be readily formalized in $RCA_0$. Therefore, we will follow the common practice of presenting all our arguments semantically (i.e., we will not give formal proofs in second-order arithmetic), and obtain provability results in $RCA_0$ implicitly.

The preceding definition lists two of the so-called “big five” subsystems of second-order arithmetic, as these will be the only ones of interest to us. In the classical program of reverse mathematics, $RCA_0$ serves as the base theory, over which implications between (formal versions of) various
mathematical theorems are considered, giving a measure of their relative proof-theoretic and computability-theoretic strength. Implications to and from ACA\(_0\) over RCA\(_0\), in particular, constitute an important benchmark in this measurement, as we discuss further below.

We now discuss the models of RCA\(_0\) and ACA\(_0\).

**Definition 2.9.** A model of second-order arithmetic is a pair \((N, S)\), where \(N\) is (the domain of) a model of first-order arithmetic and \(S \subseteq \mathcal{P}(N)\). If \(N = \mathbb{N}\), then this is an \(\omega\)-model.

Thus, an \(\omega\)-model is specified entirely by the collection \(S\) of subsets of \(\mathbb{N}\) that it includes. The following is immediate.

**Lemma 2.10.** Let \((\mathbb{N}, S)\) be an \(\omega\)-model.

1. \((\mathbb{N}, S) \models \text{RCA}_0\) if and only if \(S\) is closed under \(\oplus\) and under \(\leq_T\) (i.e., if \(S\) is a Turing ideal).
2. \((\mathbb{N}, S) \models \text{ACA}_0\) if and only if \(S\) is closed under \(\oplus\), \(\leq_T\), and the map \(X \mapsto X'\) (i.e., if \(S\) is a jump ideal).

All the theorems we consider, from Milliken’s tree theorem onward, can be expressed by \(\Pi^1_1\) formulas in the language of second-order arithmetic, and more specifically, in the form given by Equation (1.1) above. As discussed in the introduction, we think of these as problems, in the following sense.

**Definition 2.11.** An instance-solution problem (or just problem)—textbf—is a relation \(P \subseteq 2^\omega \times 2^\omega\). For every \((X, Y) \in P\), \(X\) is a instance of \(P\) (or \(P\-instance\)) and \(Y\) is a solution to \(X\) for the problem \(P\) (or \(P\-solution to \(X)\).

It should be noted that every \(\Pi^1_1\) problem can be written in the syntactic form of Equation (1.1) in many different ways. In practice, however, there is a canonical such form one works with, and whenever we refer to a \(\Pi^1_1\) statement in this monograph we will have this form in mind.

Not all instance-solution problems naturally come from \(\Pi^1_2\) principles (see, e.g., [16, 25]), but this will be the case in all of the examples we consider. We will move freely between the two perspectives, as convenient. The main practical connection comes from the following definition and basic observation.

**Definition 2.12.** Let \(P\) and \(Q\) be problems. \(P\) is computably reducible to \(P\), written \(Q \leq_c P\), if every \(Q\)-instance \(X\) computes a \(P\)-instance \(\hat{X}\) such that if \(\hat{Y}\) is any \(P\)-solution to \(\hat{X}\) then \(X \oplus \hat{Y}\) computes a \(Q\)-solution \(Y\) to \(X\).

**Lemma 2.13.** Let \(P\) and \(Q\) be \(\Pi^1_2\) statements. If \(Q \leq_c P\) as problems, then every \(\omega\)-model of \(\text{RCA}_0 \land P\) is a model of \(Q\).

Computable reducibility is a convenient tool for making certain natural constructions in reverse mathematics more explicit. For example, the most common way of showing that a \(\Pi^1_2\) statement \(P\) implies ACA\(_0\) over RCA\(_0\) is
to show that for every set $A \subseteq \mathbb{N}$, there is an $A$-computable $Q$-instance $X$, all of whose solutions $Y$ satisfy $A' \leq_T A \oplus Y$. If we let $Q$ be the problem whose instances are all $X \in 2^\omega$, such that the only solution to each $X$ is $X'$, then the preceding precisely says that $Q \leq_c P$.

We conclude this section with a note on non-implications.

**Definition 2.14.** Let $P$ be a problem.

1. $P$ admits cone avoidance if for all sets $A, C \subseteq \mathbb{N}$ with $C \not\leq_T A$, every $A$-computable $P$-instance $X$ has a solution $Y$ so that $C \not\leq_T A \oplus Y$.
2. $P$ admits strong cone avoidance if for all sets $A, C \subseteq \mathbb{N}$ with $C \not\leq_T A$, every $P$-instance $X$ has a solution $Y$ so that $C \not\leq_T A \oplus Y$.

The distinction to note well is that the instance $X$ in item 2 can be arbitrary, and in particular, need not be $A$-computable. As pointed out in the introduction, all computably true principles satisfy cone avoidance, but not necessarily strong cone avoidance. Indeed, strong cone avoidance is a fairly special property which makes it possible to freely use a principle in a construction without increasing its overall complexity, as we will do, e.g., with the Halpern-Läuchli theorem in the next chapters.

Ordinary cone avoidance suffices for the following important result, which we will make repeated use of. We include a proof for completeness.

**Lemma 2.15.** If $P$ is a $\Pi_3^1$ statement that, as a problem, admits cone avoidance, then there is a $\omega$-model of $\text{RCA}_0 \land P$ in which $\text{ACA}_0$ does not hold. In particular, $P$ does not imply $\text{ACA}_0$ over $\text{RCA}_0$.

**Proof.** Let $C = \emptyset'$. We inductively define $A_0, A_1, \ldots \subseteq \mathbb{N}$ as follows. Let $A_0 = \emptyset$, and suppose we have defined $A_s$ for some $s \in \mathbb{N}$ and that $C \not\leq_T A_s$. If $s \neq (e, t)$ for some $e \in \mathbb{N}$ and some $t < s$, or if $\Phi_{e^t}^A$ is not a $P$-instance, then let $A_{s+1} = A_s$. Otherwise, by cone avoidance of $P$ choose a solution $Y$ to $X = \Phi_{e^t}^A$ so that $C \not\leq_T A_s \oplus Y$, and let $A_{s+1} = A_s \oplus Y$.

Let $S = \{Z : (\exists s)[Z \leq_T A_s]\}$, which is a Turing ideal since $A_t \leq_T A_s$ for all $t \leq s$. By construction, if $X$ is any instance of $P$ in $S$ then $S$ contains a solution to $X$. (Indeed, if $X = \Phi_{A_s}^A$, say, let $s = (e, t)$; then a solution to $X$ is computable from $A_{s+1}$.) It follows that $(\mathbb{N}, S)$ is a model of $\text{RCA}_0 \land P$. But $\emptyset' \not\leq_T A_s$ for all $s \in \mathbb{N}$, hence $\emptyset' \notin S$. This means $S$ is not a jump ideal and so $(\mathbb{N}, S)$ is not a model of $\text{ACA}_0$. \qed

### 2.4. Trees and strong subtrees

Trees have different meanings in different areas of mathematics, and what is noteworthy for us here, is that we will not be following the common definition used in computability theory.

**Definition 2.16.** A tree is a non-empty subset $T$ of $\omega^{<\omega}$ satisfying the following properties:

1. there exists $\rho \in T$, called a root of $T$, such that $\rho \leq \sigma$ for all $\sigma \in T$;
2. if $\sigma, \tau \in T$ then $\sigma \wedge \tau \in T$;
(3) for every $\sigma \in T$ there are at most finitely many $\tau \in T$ such that $\sigma \prec \tau$ and such that there is no $\tau' \in T$ with $\sigma \prec \tau' \prec \tau$.

Thus, in brief, our trees are rooted, meet-closed, finitely-branching subsets of $\omega^{<\omega}$. By contrast, the trees commonly used in computability theory are not required to be closed under meets, but are required to be closed downwards under the initial segment, $\leq$, which we do not insist on here. In particular, our trees need not have $\epsilon$ as their root.

Moving forward, we will use trees exclusively in the sense of Definition 2.16, except in Chapter 7 where we deliberately look at the relationship of the two.

As usual, we will refer to the elements of a tree as its nodes.

**Definition 2.17.** Let $T$ be a tree.

1. The *level* of $\sigma \in T$ is $|\{\tau \in T : \tau \prec \sigma\}|$. We say $\sigma$ is at this level in $T$.
2. For $n \in \mathbb{N}$, $T(n)$ denotes the set of all $\sigma \in T$ at level $n$ in $T$.
3. The *height* of $T$ is the least ordinal $\alpha$ larger than the level of every $\sigma \in T$.
4. If $\sigma, \tau \in T$ with $\sigma \prec \tau$ and there is no $\tau' \in T$ with $\sigma \prec \tau' \prec \tau$, then $\tau$ is a *direct extension* of $\sigma$ in $T$.
5. For $k \in \omega$, a node $\sigma \in T$ is $k$-branching/nodes in $T$ if it has exactly $k$ many direct extensions in $T$.
6. A node $\sigma \in T$ is a *leaf* of $T$ if it is 0-branching in $T$. The set of leaves of $T$ is denoted by $\text{leaves}(T)$.
7. $T$ is $k$-branching if every $\sigma \in T$ is $k$-branching in $T$ or a leaf.

Note that all direct extensions of a given node in a tree $T$ must be pairwise incomparable. The height of a tree is always at most $\omega$, and as trees are non-empty, the height is always defined and at least 1. Since all trees are finitely-branching by definition, a tree is of height $\omega$ if and only if it is infinite.

**Remark 2.18.** It is worth stressing that if two nodes of $T$ are at the same level, they need *not* have the same length. This is because length is not a structural property of a tree as a graph, but rather of its presentation (i.e., the labeling of its nodes). The same is true of being closed under meets. Thus, in general, any result we state or prove for trees will apply also, after appropriate relabeling, to any subset $S$ of $\omega^{<\omega}$ such that $(S, \leq)$ is isomorphic to $(T, \leq)$ for some tree $T$. For any such set $S$ we can freely employ the terms in the preceding definition, since these are independent of presentation.

**Definition 2.19.** Given $b : \omega \to \omega$, a tree $T$ is $b$-bounded, or bounded by $b$, if for every $\sigma \in T$ we have $\sigma(i) < b(i)$ for all $i < |\sigma|$. $T$ is computably bounded if $T$ is $b$-bounded for some computable $b$.

A $k$-branching tree is thus one which is bounded by precisely the functions whose ranges lie in the interval $[k, \infty)$. Clearly, every finitely branching tree is computably bounded relative to its Turing jump.
2.5. Forests and products of trees

Notice, however, that because our trees are not closed downwards under \(\leq\), computably bounded trees here do not necessarily enjoy the usual effectiveness properties familiar from computability theory (see, e.g., [41], Chapter 3). For example, the set of infinite paths through a computable, computably bounded tree need not be a \(\Pi^0_1\) class.

A subset \(S\) of a tree \(T\) may not itself be a tree, and even if it is, it may not preserve all the structure of \(T\). For example, two nodes at the same level in \(S\) may be at different levels in \(T\), or a node may have fewer direct extensions in \(S\) than it did in \(T\). This motivates the following definition.

**Definition 2.20.** A tree \(S\) of height \(\alpha\) is a **strong subtree** of a tree \(T\) if it satisfies the following two properties:

1. there exists a function \(f : \alpha \to \omega\), called a *level function*, such that for all \(n < \alpha\), if \(\sigma \in S(n)\) then \(\sigma \in T(f(n))\);
2. for all \(k\), a node in \(S\) which is not at level \(\alpha - 1\) in \(S\) is \(k\)-branching in \(S\) if and only if it is \(k\)-branching in \(T\).

Given a tree \(T\) and \(1 \leq \alpha \leq \omega\), we let \(S_\alpha(T)\) be the collection of all strong subtrees of \(T\) of height \(\alpha\).

A strong subtree \(S\) of a tree \(T\) is itself a tree, and so is closed under meets. The branching in \(S\) is thus completely determined by the direct extensions in \(T\) of the (non-trivial) meets of nodes in \(S\). The level function \(f\) ensures that if \(\sigma \in S \cap T(f(n))\) is not a leaf of \(S\), then for every \(\tau \in T(f(n) + 1)\) extending \(\sigma\), there exists a unique \(\rho \in S \cap T(f(n) + 1)\) extending \(\tau\). (See Figure 2.1.)

If the height of \(T\) is \(\alpha < \omega\) then \(S_\beta(T) = \emptyset\) for all \(\beta > \alpha\), and it is also easy to see that the only element of \(S_\alpha(T)\) in this case is \(T\) itself. Being a strong subtree of a tree is a transitive relation, so in particular, if \(S \in S_\alpha(T)\) and \(U \in S_\beta(S)\) for some \(\beta \leq \alpha\) then \(U \in S_\beta(T)\).

### 2.5. Forests and products of trees

As mentioned above, in order to study the proof of Milliken’s tree theorem we will need to examine the Halpern–Läuchli theorem, whose statements requires us to consider multiple trees in parallel.

**Definition 2.21.** A **forest** is a non-empty subset \(X\) of \(\omega^{<\omega}\) such that if a pair of nodes \(\sigma, \tau \in X\) has a common initial segment in \(X\) then also \(\sigma \land \tau \in X\).

Since every pair of nodes in a tree has at least one common initial segment (the root), it is clear that every tree is a forest. Indeed, the following is easy to see: \(X \subseteq \omega^{<\omega}\) is a forest if and only if it is a union of disjoint trees. For this reason, we refer to the elements of a forest as nodes, and lift all other terminology from trees to forests. For definiteness, we make this explicit in the following definition.

**Definition 2.22.** Let \(X\) be a forest.
Figure 2.1. A strong subtree $S$ of a tree $T$, with level function $f$. The circles represent nodes in $T$; the solid circles in $S$, the hollow circles are in $T \setminus S$. The levels of $S$ are included in the levels of $T$; solid gray horizontal lines represent levels in $S$, dashed gray horizontal lines levels in $T \setminus S$. A node connected to another below it by a straight black line denotes a direct extension in $T$. Wavy lines indicate omitted (skipped over) portions of $T$. Note that all branchings are preserved: a nodes in $S$ has the same number of direct extensions in $S$ as in $T$.

1. A root of $X$ is any $\rho \in T$ having no proper initial segment in $X$. The set of all roots of $X$ is denoted by roots($X$).
2. The level of $\sigma \in X$ is $|\{\tau \in X : \tau < \sigma\}|$. We say $\sigma$ is at this level in $X$.
3. For $n \in \mathbb{N}$, $X(n)$ denotes the set of all $\sigma \in X$ at level $n$ in $X$.
4. The height of $X$ is the least ordinal $\alpha$ larger than the level of every $\sigma \in X$.
5. If $\sigma, \tau \in X$ with $\sigma < \tau$ and there is no $\tau' \in X$ with $\sigma < \tau' < \tau$, then $\tau$ is a direct extension of $\sigma$ in $X$.
6. For $k \in \omega$, a node $\sigma \in X$ is $k$-branching in $X$ if it has exactly $k$ many direct extensions in $X$.
7. A node $\sigma \in X$ is a leaf of $X$ if it is 0-branching. The set of leaves of $X$ is denoted leaves($X$).

Thus, a forest $X$ is a tree if and only if roots($X$) is a singleton. The height of $X$ is the maximum of the heights of the disjoint trees that comprise it.

Given a forest $X$ and a node $\sigma \in X$, we let $X \upharpoonright \sigma = \{\tau \in X : \tau \geq \sigma\}$. In particular, whenever $\sigma \in X$ we have that $X \upharpoonright \sigma$ is a tree with root $\sigma$.

**Definition 2.23.** A forest $Y$ of height $\alpha \leq \omega$ is a strong subforest of a forest $X$ if it satisfies the following two properties:

1. there exists a function $f : \alpha \to \omega$, called a level function, such that for all $n \leq \alpha$, if $\sigma \in X(n)$ then $\sigma \in X(f(n))$;
2.6. Statements of Theorems

(2) for all \( k \), a node in \( Y \) which is not at level \( \alpha \) in \( Y \) is \( k \)-branching in

\( Y \) if and only if it is \( k \)-branching in \( X \).

Given a forest \( X \) and an \( \alpha \leq \omega \), we let \( S_\alpha(X) \) be the collection of all strong
subforests of \( X \) of height \( \alpha \). We also add the following slightly more general
definition.

**Definition 2.24.** For each \( d \geq 1 \), if \( T_0, \ldots, T_{d-1} \) are trees then \( S_\alpha(T_0, \ldots, T_{d-1}) \)
for \( \alpha \leq \omega \) is the collection of all tuples \((S_0, \ldots, S_{d-1})\) such that for each \( i < d \)
we have \( S_i \in S_\alpha(T_i) \), witnessed by one and the same level function. In addition, \( S_{<\alpha}(T_0, \ldots, T_{d-1}) \) denotes \( \bigcup_{n<\alpha} S_n(T_0, \ldots, T_{d-1}) \).

Thus, if \( X = \bigcup_{i<d} T_i \), where \( T_0, \ldots, T_{d-1} \) are disjoint trees, then \( S_\alpha(X) = S_\alpha(T_0, \ldots, T_{d-1}) \). However, the preceding definition applies to arbitrary trees \( T_0, \ldots, T_{d-1}, \) disjoint or not.

We include one final definition, which is standard in other investigations
of Milliken’s tree theorem and will be important to us going forward.

**Definition 2.25.** Fix \( m \geq 1 \).

(1) For a forest \( X \) and node \( \sigma \in X \), a subset \( P \) of \( X \) is \( m-\sigma \)-dense if

every \( \tau \in X(m) \) that extends \( \sigma \) has an extension in \( P \).

(2) For forests \( X_0, \ldots, X_{d-1} \) and tuple \( \pi = (\sigma_0, \ldots, \sigma_{d-1}) \in \bigcup_n X_0(n) \times

\cdots \times X_{d-1}(n) \), a subset \( P \) of \( X_0 \times \cdots \times X_{d-1} \) is an \( m-\pi \)-dense matrix
if \( P = P_0 \times \cdots \times P_{d-1} \) where \( P_i \) is an \( m-\sigma_i \)-dense subset of \( X_i \), for

each \( i < d \).

We will of course only be interested in the case where \( m \) is larger than the
level of \( \sigma \) in \( X \), respectively, of the (common) level in \( X_i \) of each of the entries \( \sigma_i \) of \( \pi \). In the latter case, we will call this common level the **level of \( \pi \)** in \( X \).

The main point in item 2 above is that if \( P \) is an \( m-\pi \)-dense matrix
then for every \( \tau_i \in X_i(m) \) that extends \( \sigma_i \) we can find a \( \rho_i \) such that

\( (\rho_0, \ldots, \rho_{d-1}) \in P \), and the latter is true for every choice of possible \( \rho_i \).

Note that the \( \rho_i \) do not have to be at the same level in their respective
forests. Also, notice that the \( X_i \) need not be disjoint, and so their union
need not be itself a forest.

2.6. Statements of Theorems

In this section, we can finally define Milliken’s tree theorem and its
combinatorial variants that we will investigate in Chapters 3 and 4, as well
as the various application of Milliken’s tree theorem that we will discuss in
Chapters 5 to 7.

**Theorem 2.26 (Milliken’s tree theorem).** Let \( T \) be an infinite tree with
no leaves. For all \( n, k \geq 1 \) and all \( f : S_n(T) \to k \) there is an \( S \in S_\omega(T) \)
such that \( f \) is constant on \( S_n(S) \).
By analogy with Ramsey’s theorem, we will break this statement up into sub-statements, in this case according to the height of the subtrees being colored. Thus, we define the following:

**Statement 2.27.** For all \( n \geq 1 \), \( \text{MTT}^n \) is the restriction of Milliken’s tree theorem to colorings to strong subtrees of height \( n \).

We will sometimes also refer to \( \text{MTT}^n \) as *Milliken’s tree theorem for height* \( n \) in the sequel. From the computability-theoretic point of view, we will regard an instance of \( \text{MTT}^n \) as being a tuple \((T, b, f, k)\), where \( T \) is an infinite \( b \)-bounded tree with no leaves, and \( f \) is a map \( S_n(T) \rightarrow k \). In effect, this means all computable instances of \( \text{MTT}^n \) are computably bounded.

As discussed in the introduction, the next theorem is the analogue of the pigeonhole principle in the proof of Milliken’s tree theorem.

**Theorem 2.28 (Halpern-Lauchli theorem).** Let \( T_0, \ldots, T_{d-1} \) be infinite trees with no leaves. For all \( k \geq 1 \) and all \( f : \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \rightarrow k \) there exists \((S_0, \ldots, S_{d-1}) \in S_d(T_0, \ldots, T_{d-1})\) such that \( f \) is constant on \( \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n) \).

Again, one would naturally expect \( \text{MTT}^1 \) to play this role, so the need for the Halpern-Lauchli theorem is not a priori obvious. In fact, the original paper [29] that introduced what we now call Milliken’s tree theorem actually proved a version for products that looks much more like the “general case” of the Halpern-Lauchli theorem. In many ways, this is really the more natural result, and Milliken’s tree theorem is merely a restriction that suffices for most applications.

**Theorem 2.29 (Product version of Milliken’s tree theorem).** Let \( T_0, \ldots, T_{d-1} \) be infinite trees with no leaves. For all \( n, k \geq 1 \) and all \( f : S_n(T_0, \ldots, T_{d-1}) \rightarrow k \) there exists \((S_0, \ldots, S_{d-1}) \in S_d(T_0, \ldots, T_{d-1})\) such that \( f \) is constant on \( S_n(S_0, \ldots, S_{d-1}) \).

**Statement 2.30.** For all \( n \geq 1 \), \( \text{PMTT}^n \) is the restriction of the product version of Milliken’s tree theorem for height \( n \).

The Halpern-Lauchli theorem is exactly \( \text{PMTT}^1 \), since for all \( T_0, \ldots, T_{d-1} \) we have

\[ S_1(T_0, \ldots, T_{d-1}) = \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n). \]

In our analysis, we will regard an instance of \( \text{PMTT}^n \) as a tuple

\[ (d, T_0, \ldots, T_{d-1}, b, f, k), \]

where the \( T_i \) are infinite \( b \)-bounded trees with no leaves, and \( f \) is a map \( S_n(T_0, \ldots, T_{d-1}) \rightarrow k \).

We now state some further applications of Milliken’s tree theorem, which concern various structures besides trees. Each of these structures will be countable and, unless otherwise stated, infinite, and will have a countable, relational underlying language. For a finite substructure \( \mathcal{A} \) of a structure
2.6. Statements of theorems

Let \( \mathcal{B} \), \( \mathcal{A} \), and \( \mathcal{R} \) denote the set of isomorphic copies of \( \mathcal{A} \) contained in \( \mathcal{B} \). Recall also that if \( X \) is a set and \( n \) is a positive integer then \( [X]^n \) denotes the set of \( n \)-element subsets of \( X \). In particular, if \( B \) is the domain of \( \mathcal{B} \), then each element of \( [B]^n \) may be regarded as a substructure of \( \mathcal{B} \) by restriction since the language of \( \mathcal{B} \) is relational. (In general, however, \( [B]^n \) need not equal \( \mathcal{B} \) for any one \( \mathcal{A} \).) When convenient, we may also write \( [B]^n \) for \( [B]^n \).

The first application of Milliken’s tree theorem we consider is Deulin’s theorem, also called Deulin’s second theorem, e.g., in [47, Chapter 6].

**Theorem 2.31 (Deulin’s theorem).** For every \( n \geq 1 \) there exists \( \ell \geq 1 \) such that for every \( k \geq 1 \) and every \( f : [Q]^n \to k \) there is a dense suborder \( S \) of \( Q \) with no endpoints satisfying \( |f([S]^n)| \leq \ell \).

The key here is that the bound \( \ell \) does not depend on \( k \) or the particular coloring, but only on \( n \). As an instance-solution problem, we will study Deulin’s theorem in the following form:

**Statement 2.32.** For all \( n, k, \ell \geq 1 \), \( DT^n_{k,\ell} \) is the assertion that for every \( f : [Q]^n \to k \) there is a dense suborder \( S \) of \( Q \) with no endpoints satisfying \( |f([S]^n)| \leq \ell \).

Note that \( DT^n_{k,\ell} \) is merely a formal statement, not a necessarily a true theorem for all possible \( n, k, \) and \( \ell \). For example, it is easy to see that \( DT^1_{k,1} \) is true for all \( k \). However, \( DT^2_{2,1} \) is false. To see this, let \( (q_n)_{n \in \mathbb{N}} \) be an enumeration of the rationals, and define \( f : [Q]^2 \to 2 \) by letting \( f(q_n, q_m) = 0 \) if \( q_n < q_m \iff n < m \), and \( f(q_n, q_m) = 1 \) otherwise. Then it is readily seen that every subset \( S \subseteq Q \) of order-type \( Q \) (or even \( Z \)) must contain pairs of both colors under \( f \). For \( n = 2 \), this situation turns out to be as bad as it can be, as \( DT^2_{k,2} \) is true for all \( k \). This fact was originally observed by Galvin (unpublished). For general \( n \), the corresponding \( \ell \) values were obtained by Deulin [9, Chapter 4].

The second application we consider concerns graph colorings. We use \( \mathcal{G} \) as generic notation for a graph, and unless otherwise specified, assume the set of vertices of \( \mathcal{G} \) is \( G \), and the set of edges, \( E \). For \( x, y \in G \), we write \( xEy \) if \( (x, y) \in E \) and \( \neg xEy \) if \( (x, y) \notin E \). The graph \( \mathcal{G} \) is a Rado graph (or random graph) if for every two disjoint finite sets of vertices \( F_0, F_1 \subseteq G \) there exists \( x \in G \) such that \( xEy \) for all \( y \in F_0 \) and \( \neg xEy \) for all \( y \in F_1 \). Such a graph is, in particular, universal, containing every finite graph as an induced subgraph. All Rado graphs are isomorphic by the standard back and forth construction, so we usually speak just of the Rado graph, and assume we have fixed a canonical computable representative of it, denoted by \( \mathcal{R} \). The principle of interest to us is following, which we will call the Rado graph theorem here for definiteness.

**Theorem 2.33 (Rado graph theorem).** For every finite graph \( \mathcal{G} \) there exists \( \ell \geq 1 \) such that for every \( k \geq 1 \) and every \( f : \left( \mathcal{G}^{\ell} \right) \to k \) there is an isomorphic subgraph \( \mathcal{R}' \) of \( \mathcal{R} \) satisfying \( |f''(\mathcal{R}')| \leq \ell \).
Again, the bound \( \ell \) does not depend on \( k \), but only, in this case, on the particular subgraph \( G \). The precise bounds here were obtained by Sauer [35] and Laflamme, Sauer, and Vuksonovic [26]. The result shares much in common with Devlin’s theorem, as we will see further below. Both results are well-known consequences of Milliken’s theorem. (See, e.g., Todorcevic [47], Theorems 6.23 and 6.25 for direct proofs.) We give a more effective proof of the Rado graph theorem from Milliken’s tree theorem in Section 6.3.

We will investigate the Rado graph theorem in the following two forms.

**Statement 2.34.** For all finite graphs \( G \) and all \( k, \ell \geq 1 \), \( \text{RG}^G_{k, \ell} \) is the assertion that for every coloring \( f : (\mathcal{R}^n) \to k \), there is an isomorphic subgraph \( \mathcal{R}' \) of \( \mathcal{R} \) satisfying \( |f''(\mathcal{R}')| \leq \ell \).

**Statement 2.35.** For all \( n, k, \ell \geq 1 \), \( \text{RG}^n_{k, \ell} \) is the assertion that for every coloring \( f : [\mathcal{R}]^n \to k \), there is an isomorphic subgraph \( \mathcal{R}' \) of \( \mathcal{R} \) satisfying \( |f''(\mathcal{R}')| \leq \ell \).

Since there are, up to isomorphism, only finitely many graphs \( G \) of a given finite size, we immediately get the implication

\[
(\forall G)(\exists \ell)(\forall k)[\text{RG}^G_{k, \ell}] \rightarrow (\forall n)(\exists \ell)(\forall k)[\text{RG}^n_{k, \ell}].
\]

The final application we look at, unlike the previous two, is not a familiar one in set theory. However, it has been studied extensively in computable combinatorics and reverse mathematics (see, e.g., [6, 7, 5, 14, 31] for some very recent papers). This is the tree theorem of Chubb, Hirst, and McNicholl [8], which we will refer to as the Chubb-Hirst-McNicholl (CHM) tree theorem in this monograph, to avoid confusion with Milliken’s tree theorem. The CHM tree theorem concerns a weaker structure of tree than in Definition 2.16, where we do not insist on being closed under meets. A tree is thus any subset of \( 2^{<\omega} \) with a root. The theorem asserts the existence, for every finite coloring of the \( n \)-tuples of comparable nodes of \( 2^{<\omega} \), of an infinite monochromatic perfect subtree in this weaker sense. The restriction to comparable nodes comes from wanting to extend Ramsey’s theorem to these “weak” trees. And indeed, as in Devlin’s theorem, it is easy to devise a coloring of arbitrary tuples of nodes here where no monochromatic solution exists (e.g., consider coloring all comparable pairs of strings 0, and all incomparable pairs of strings 1). As it turns out, this restriction loses a great deal of combinatorial structure, which becomes apparent if we look not for monochromatic solutions, but merely for bounds on the numbers of colors used in a solution. It is this generalization of the CHM tree theorem that we investigate.

**Theorem 2.36** (Generalized CHM tree theorem). For every \( n \geq 1 \) there exists \( \ell \geq 1 \) such that for every \( k \geq 1 \) and every \( f : [2^{<\omega}]^n \to k \) there is an \( S \subseteq 2^{<\omega} \) such that \((S, \leq)\) is isomorphic to \((2^{<\omega}, \preceq)\) and \(|f([S]^n)| \leq \ell\).
Statement 2.37. For all $n, k, \ell \geq 1$, CHMTT$^n_{k,\ell}$ is the assertion that for every $f : [2^{\leq \omega}]^n \to k$ there is an $S \subseteq 2^{\leq \omega}$ such that $(S, \leq)$ is isomorphic to $(2^{\leq \omega}, \leq)$ and $|f([S]^n)| \leq \ell$.

As with the previous two principles, the CHM tree theorem is a consequence of Milliken’s tree theorem. We include a proof in Theorem 7.9 below.

2.7. Big Ramsey degrees and structures

Though we will study each of Devlin’s theorem, the Rado graph theorem, and the CHM tree theorem separately and in its own right, we mention a common framework within which all three can be presented, and which better highlights some of the main similarities between the three. Some of the terminology here will also be convenient in our discussions later on.

All three principles can be stated more succinctly using the concept of big Ramsey degrees, which we now review. Recall that if $\mathcal{B}$ is an infinite structure and $\mathcal{A}$ is a finite substructure of $\mathcal{B}$, then for positive numbers $\ell \leq k$ the notation

$$\mathcal{B} \to (\mathcal{B})_{k,\ell}^\mathcal{A}$$

means that for every coloring $f : (\mathcal{B})_{k,\ell}^\mathcal{A} \to k$ there exists an isomorphic substructure $\mathcal{B}'$ of $\mathcal{B}$ such that $|f''(\mathcal{B})_{k,\ell}^\mathcal{A}| \leq \ell$. The following terminology is standard in structural Ramsey theory.

Definition 2.38. Let $\mathcal{B}$ be a structure.

- For a finite substructure $\mathcal{A}$ of $\mathcal{B}$, the big Ramsey degree of $\mathcal{A}$ in $\mathcal{B}$ is the least number $\ell \in \omega$, if it exists, such that $\mathcal{B} \to (\mathcal{B})_{k,\ell}^\mathcal{A}$ for all $k \in \omega$, in which case we say that the big Ramsey degree of $\mathcal{A}$ is finite.
- We say that a structure $\mathcal{B}$ has finite big Ramsey degrees if, for every finite substructure $\mathcal{A}$ of $\mathcal{B}$ has finite big Ramsey degree.

In the parlance of this definition, then, the Rado graph theorem is simply the assertion that the Rado graph has finite big Ramsey degrees. Similarly, Devlin’s theorem is the assertion that $(\mathbb{Q}, <)$ has finite big Ramsey degrees, since up to isomorphism $(\mathbb{Q}, <)$ has exactly one finite substructure $\mathcal{A}$ of each size $n \geq 1$, and so $(\mathbb{Q}, <) = (\mathbb{Q})^n$. For the generalized CHM tree theorem the situation is slightly different. While $(2^{\leq \omega}, \leq)$ can have more than one non-isomorphic substructure of a given finite size, it still has only finitely many. Thus, the generalized CHM tree theorem is equivalent to the statement that $(2^{\leq \omega}, \leq)$ has finite big Ramsey degrees.

The bounds $\ell$ in each of Devlin’s theorem, the Rado graph theorem, and the generalized CHM tree theorem are not determined purely by properties of the underlying structures. For example, even though $\mathbb{Q}$ has only one substructure of size 2 up to isomorphism, we saw that we could differentiate two types of substructure of size 2 by enriching the structure by an enumeration of the domain. Enrichments of this kind play an important role in these
computations, since they can be taken into account in designing colorings with a certain number of unavoidable colors.

A precise formalization of the concept of “enrichment” is given by Zucker [50].

**Definition 2.39** (Zucker [50], Definition 1.3). Let $\mathcal{B}$ be a structure in a language $\mathcal{L}$. A big Ramsey structure for $\mathcal{B}$ is a structure $\hat{\mathcal{B}}$ in a language $\hat{\mathcal{L}}$ satisfying the following properties:

1. $\mathcal{L} \subseteq \hat{\mathcal{L}}$;
2. the restriction of $\hat{\mathcal{B}}$ to $\mathcal{L}$ is $\mathcal{B}$;
3. for every finite substructure $\mathcal{A}$ of $\mathcal{B}$ there is a number $t_{\hat{\mathcal{B}}}(\mathcal{A})$ such that, up to isomorphism, there are exactly $t_{\hat{\mathcal{B}}}(\mathcal{A})$ many different substructures $\hat{\mathcal{A}}$ of $\hat{\mathcal{B}}$ whose restriction to $\mathcal{L}$ is a copy of $\mathcal{A}$;
4. every finite substructure $\mathcal{A}$ of $\mathcal{B}$ has big Ramsey degree equal to $t_{\hat{\mathcal{B}}}(\mathcal{A})$;
5. for every finite substructure $\mathcal{A}$ of $\mathcal{B}$ and choice $\hat{\mathcal{A}}_0, \ldots, \hat{\mathcal{A}}_{t_{\hat{\mathcal{B}}}(\mathcal{A})-1}$ of substructures of $\hat{\mathcal{B}}$ as in property 3, the coloring $f : (\hat{\mathcal{A}}_i) \to t_{\hat{\mathcal{B}}}(\mathcal{A})$ mapping each copy of $\mathcal{A}'$ of $\mathcal{A}$ in $\mathcal{B}$ to the unique $i < t_{\hat{\mathcal{B}}}(\mathcal{A})$ such that $\mathcal{A}'$, viewed as a substructure of $\hat{\mathcal{B}}$ by restriction, is isomorphic to $\hat{\mathcal{A}}_i$ witnesses that the big Ramsey degree of $\mathcal{A}$ in $\mathcal{B}$ is at least $t_{\hat{\mathcal{B}}}(\mathcal{A})$.

The idea here is that for every finite substructure $\mathcal{A}$ of $\mathcal{B}$, the substructures $\hat{\mathcal{A}}_0, \ldots, \hat{\mathcal{A}}_{t_{\hat{\mathcal{B}}}(\mathcal{A})}$ of $\hat{\mathcal{B}}$ satisfying property 3 represent all recognizable or describable types of the copies of $\mathcal{A}$ in $\mathcal{B}$, and the additional structure of $\hat{\mathcal{B}}$ facilitates these descriptions. In the literature, these instances are called more specifically embedding types or Devlin types based on the specific structure $\mathcal{B}$.

Zucker [50, Theorem 7.1] provides some sufficient (and somewhat technical) conditions for a structure to admit a big Ramsey structure. For our purposes here, it is enough to know that each of $(\mathbb{Q}, \leq)$, the Rado graph, and $(2^{<\omega}, \preceq)$ does. We will study the big Ramsey structure of the Rado graph in detail (see also [50], Section 6.3), and we will carefully develop the appropriate notion of type in the sense of the big Ramsey structure for the generalized CHM tree theorem. For an account of a big Ramsey structure for $(\mathbb{Q}, \leq)$, see [50, Section 6.2].
CHAPTER 3

The Halpern-Laüchli theorem

We begin our analysis of Milliken’s tree theorem by studying the computable content of the Halpern-Laüchli theorem (Theorem 2.28). The two main theorems of this chapter are Theorem 3.4, that the Halpern-Laüchli theorem is computably true, and Theorem 3.21, that it admits strong cone avoidance. The first result will be used in the proof that the product version of Milliken’s tree theorem admits arithmetical solutions. The second result will be used to prove that the product version of Milliken’s tree theorem for colorings of strong subtrees of height 2 admits cone avoidance, in the same way that strong cone avoidance of the pigeonhole principle can be used to prove cone avoidance of Ramsey’s theorem for pairs (see, e.g., Hirschfeldt [19], Section 6.7).

3.1. An effective proof of the Halpern-Laüchli theorem

Our effectivization of the the Halpern-Laüchli theorem is based on the proof of that theorem given in Todorcevic [47], where it appears as Theorem 3.2. We include that proof here largely in full, emphasizing the effective analysis when it shows up, with the exception of one technical lemma that we present first. For trees $T_0, \ldots, T_{d-1}$ and a tuple $\pi \in T_0(n) \times \cdots \times T_{d-1}(n)$ for some $n \in \mathbb{N}$, we call $n$ the level of $\pi$.

**Lemma 3.1** (Halpern and Laüchli [18], Theorem 1). Let $T_0, \ldots, T_{d-1}$ be infinite tree with no leaves. For all $k \geq 1$ and all $g : T_0 \times \cdots \times T_{d-1} \to k$ there is $a \in \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n)$, an $m$ larger than the level of $\pi$, and an $m$-dense matrix $P$ for $T_0, \ldots, T_{d-1}$ on which $g$ is constant.

Nota bene that the coloring $g$ above is defined on the full product $T_0 \times \cdots \times T_{d-1}$, rather than the level product $\bigcup_n T_0(n) \times \cdots \times T_{d-1}(n)$. However, we can obtain a level version, as follows.

**Lemma 3.2.** Let $T_0, \ldots, T_{d-1}$ be infinite trees with no leaves. For all $k \geq 1$ and all $f : \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \to k$ there is a $\pi \in \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n)$, an $m$ larger than the level of $\pi$, and an $m$-dense matrix $P \subseteq \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n)$ on which $f$ is constant.

**Proof (from [47], proof of Theorem 3.2).** Fix $T_0, \ldots, T_{d-1}$. By compactness, for every $k \geq 1$ there is an $n_k \geq 1$ such that for every coloring $g : T_0 \times \cdots \times T_{d-1} \to k$ we can find a $\pi$, an $m$, and an $m$-dense matrix $P = P_0 \times \cdots \times P_{d-1}$ as in Lemma 3.1 with $P_i \subseteq \bigcup_{n < n_k} T_i(n)$ for all $i < d$. 

27
Consider now \( f : \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \to k \). We define \( g : T_0 \times \cdots \times T_{d-1} \to k \) as follows. First, for each \( \sigma \in \bigcup_{n<n_k} T_i(n) \) fix an extension \( \hat{\sigma} \in T_i(n_k) \). Now for all \( (\sigma_0, \ldots, \sigma_{d-1}) \in T_0 \times \cdots \times T_{d-1}, \) set
\[
g(\sigma_0, \ldots, \sigma_{d-1}) = \begin{cases} f(\hat{\sigma}_0, \ldots, \hat{\sigma}_{d-1}) & \text{if } \sigma_i \in \bigcup_{n<n_k} T_i(n) \text{ for all } i < d, \\ 0 & \text{otherwise.} \end{cases}
\]

By choice of \( n_k \) there is a \( \pi \in \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \), an \( m \) larger than the level of \( \pi \), and an \( m-\pi \)-dense matrix \( Q = Q_0 \times \cdots \times Q_{d-1} \) such that \( \mathcal{Q} \subseteq \bigcup_{n<n_k} T_i(n) \) for all \( i < d \) and \( g \) is constant on \( Q \). For each \( i < d \), let \( P_i = \{ \hat{\rho} : \rho \in Q \} \), so that now \( P_i \subseteq T_i(n_k) \). By definition of \( g \), we have that \( f \) is constant on \( P = P_0 \times \cdots \times P_{d-1} \). Thus, \( \pi, m, \) and \( P \) are as desired. \( \square \)

One final critical lemma for us is the following, which is a consequence of the previous one. We include the proof for completeness.

**Lemma 3.3.** Let \( T_0, \ldots, T_{d-1} \) be infinite trees with no leaves. For all \( k \geq 1 \) and all \( f : \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \to k \) there is a tuple \( \pi \in \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \) such that for every \( m \) larger than the level of \( \pi \) there is an \( m-\pi \)-dense matrix \( P \subseteq \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \) on which \( f \) is constant.

**Proof (from [47], proof of Theorem 3.2).** Suppose otherwise. Then for every \( (\sigma_0, \ldots, \sigma_{d-1}) \in \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \) there is an \( m \geq 1 \) such that \( f \) is not constant on any \( m-\pi \)-dense matrix \( P \subseteq \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \).

Let \( m_\pi \) be the least such \( m \). Then choose \( m_0 < m_1 < \cdots \) so that \( m_0 = 0 \) and for all \( s \geq 0 \), \( m_\pi < m_{s+1} \) for all tuples \( \pi \in \bigcup_{n \leq m_s} T_0(n) \times \cdots \times T_{d-1}(n) \).

For each \( i < d \), define \( S_i = \bigcup S_i(m_s) \), and note that the structure \( (S_0, \leq) \) is isomorphic to a tree, so \( S_0 \times \cdots \times S_{d-1} \) can be regarded as a product of trees.

Using Remark 2.18, apply Lemma 3.2 to the restriction of \( f \) to \( S_0 \times \cdots \times S_{d-1} \) to get a tuple \( \pi \in \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n) \), an \( m \) larger than the level of \( \pi \) in this product, and an \( m-\pi \)-dense matrix \( P \subseteq \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n) \) on which \( f \) is constant. But by construction, the level of \( \pi \) must be equal to \( m_s \) for some \( s \), and \( m \) must be equal to \( m_t \) for some \( t > s \). So \( f \) cannot, in fact, be constant on \( P \), which is a contradiction. \( \square \)

We now come to proving our first main theorem of this chapter.

**Theorem 3.4.** The Halpern-Laüchli theorem is computably true (i.e., every instance computes a solution for itself).

**Proof.** Fix an instance of the Halpern-Laüchli theorem, which is to say, infinite trees \( T_0, \ldots, T_{d-1} \) with no leaves (and which, recall, we take to be presented with an explicit bound) and a coloring \( f : \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \to k \) for some \( k \geq 1 \). We exhibit an \( (f \oplus T_0 \oplus \cdots \oplus T_{d-1}) \)-computable solution, i.e., \( (S_0, \ldots, S_{d-1}) \in \mathcal{S}_c(T_0, \ldots, T_{d-1}) \) such that \( f \) is constant on \( \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n) \).

Fix, non-effectively, a \( \pi = (\sigma_0, \ldots, \sigma_{d-1}) \in \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \) as in Lemma 3.3, and say \( m_0 \) is the level of \( \pi \). By the pigeonhole principle, we can also fix a \( j < k \) such that for every \( m > m_0 \) there is an \( m-\pi \)-dense
matrix $P \subseteq \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n)$ such that $f(\tau_0, \ldots, \tau_{d-1}) = j$ for all $(\tau_0, \ldots, \tau_{d-1}) \in P$. Call such a $P$ good above $m$.

Notice that given $m > m_0$ and a set $P \subseteq \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n)$, it is computable in $f$ and the $T_i$ whether or not $P$ is good above $n$. Hence, we can $(f \oplus T_0 \oplus \cdots \oplus T_{d-1})$-computably define sequences of numbers $m_1 < m_2 < \cdots$ and sets $P_1, P_2, \ldots$ such that $m_0 < m_1$ and each $P_s$ is good above $m_s$. Now, for each $i < d$, define $S_i \subseteq T_i$ inductively as follows: add $\sigma_i$ to $S_i$, and having added $\tau \supseteq \sigma_i$ choose the least $s$ such that $P_s$ contains an extension of each direct extension of $\tau$ in $T_i$, and add these extensions to $S_i$. Then $(S_0, \ldots, S_{d-1}) \in S_\omega(T_0, \ldots, T_{d-1})$, and $f(\tau_0, \ldots, \tau_{d-1}) = j$ for all $(\tau_0, \ldots, \tau_{d-1}) \in \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n)$. Clearly, $(S_0, \ldots, S_{d-1})$ is computable from the $T_i$ and the sequences of $m_s$ and $P_s$, hence from $f$ and the $T_i$, as desired. \hfill \square

In the next section, we will design a good notion of forcing for building infinite strong subtrees, and use this to give more effective proofs of Millikin’s tree theorem and its product version. We will need a forest version of the Halpern-Laüchli theorem.

**Theorem 3.5 (Halpern-Laüchli theorem for forests).** Let $T_0, \ldots, T_{d-1}$ be infinite trees with no leaves, and $X_0, \ldots, X_{d-1} \subseteq \omega^{\omega}$ be forests such that for each $i < d$, $X_i$ is a strong subforest of $T_i$ of height $\omega$, with common level function. For all $k \geq 1$ and all $f : \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \to k$ there exist strong subtrees $Y_0, \ldots, Y_{d-1}$ of $X_0, \ldots, X_{d-1}$, respectively, with common level function, such that:

1. for each $i < d$, every root of $X_i$ is extended by some root of $Y_i$;
2. for each $(\sigma_0, \ldots, \sigma_{d-1}) \in \text{roots}(X_0) \times \cdots \times \text{roots}(X_{d-1})$, $f$ is constant on $\bigcup_n (Y_0 \upharpoonright \sigma_0(n)) \times \cdots \times (Y_{d-1} \upharpoonright \sigma_{d-1}(n))$.

In other words, the lemma asserts that no part of any of the forests $X_i$ above any given root is wholly omitted in passing to the subforest $Y_i$, and the color under $f$ of a tuple in $\bigcup_n Y_0(n) \times \cdots \times Y_{d-1}(n)$ depends only on which roots of $X_0, \ldots, X_{d-1}$ the elements of the tuple extend.

As with the ordinary Halpern-Laüchli theorem, our interest will be more in an effective version, which we now prove using Theorem 3.4 above.

**Theorem 3.6.** Theorem 3.5 is computably true.

**Proof.** Fix a collection of trees $T_0, \ldots, T_{d-1}$ and strong subtrees $X_0, \ldots, X_{d-1}$ with a common level function, and a finite coloring $f : \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \to k$. For every $i < d$ and $\sigma \in \text{roots}(X_i)$, the set $T_i^\sigma = X_i \upharpoonright \sigma$ is a tree. The result will come from an application of Theorem 3.4 to the collection of $T_i^\sigma$ for $i < d$ and $\sigma \in \text{roots}(X_i)$. Define a coloring

$$h : \bigcup_n \prod_{i<d, \sigma \in \text{roots}(X_i)} T_i^\sigma(n) \to k^{\text{roots}(T_0) \times \cdots \times \text{roots}(T_{d-1})}$$
such that to a tuple \( \pi = (\tau^\sigma_i \in T^\sigma_i : i \leq d, \sigma \in \text{roots}(X_i)) \), \( h \) associates the tuple of all values that \( f \) can take on the elements of \( \pi \). That is, 
\[
h(\pi) = (f(\tau^\sigma_0, \ldots, \tau^\sigma_{d-1}) : (\sigma_0, \ldots, \sigma_{d-1}) \in \text{roots}(X_0) \times \cdots \times \text{roots}(X_{d-1})).
\]
Note that \( h \) is computable from \( f \) and the \( T^\sigma_i \), hence from \( f \), the \( T_i \), and the \( X_i \).

Apply Theorem 3.4 to define a sequence of strong subtrees \( S^\sigma_i \) of \( T^\sigma_i \), for \( i < d \) and \( \sigma \in \text{roots}(X_i) \), with a common level function, and computable from \( h \) and the \( T^\sigma_i \). For \( i < d \), define \( Y_i = \bigcup_{\sigma \in \text{roots}(X_i)} S^\sigma_i \), so that \( S^\sigma_i = Y_i \upharpoonright \sigma \). It is clear that each \( Y_i \) is a strong subforest of \( X_i \), and that every root of \( X_i \) has an extension in \( Y_i \). Moreover, if \( (\tau_0, \ldots, \tau_{d-1}) \) and \( (\tau'_0, \ldots, \tau'_{d-1}) \) both belong to \( \bigcup_n S^\sigma_0(n) \times \cdots \times S^\sigma_{d-1}(n) \), then we must have \( f(\tau_0, \ldots, \tau_{d-1}) = f(\tau'_0, \ldots, \tau'_{d-1}) \) since \( h \) is monochromatic on \( \bigcup_n \prod L < d, \sigma \in \text{roots}(X_i) S^\sigma_i(n) \).

3.2. Product tree forcing

We now design the main notion of forcing for building strong subtrees. Variants of this notion of forcing will be used throughout the manuscript. Fix a collection of finitely branching trees with no leaves \( T_0, \ldots, T_{d-1} \).

**Definition 3.7.** A **product tree condition** is a tuple \((F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})\) as follows:

1. \((F_0, \ldots, F_{d-1}) \in \mathcal{S}_n(T_0, \ldots, T_{d-1})\), for some \( n \in \mathbb{N} \);
2. \(X_0, \ldots, X_{d-1}\) are infinite strong subforests of \( T_0, \ldots, T_{d-1} \), respectively, with a common level function;
3. for every \( j < d \) and every leaf \( \sigma \) of \( F_j \), say at level \( k \) in \( T_j \), \( \text{roots}(X_j) \) is \((k+1)\)-\( \sigma \)-dense in \( T_j \).

Thus, the last condition asserts that every node \( \tau \in T_j(k+1) \) extending \( \sigma \) has an extension in \( \text{roots}(X_j) \).

For instance, let \( d = 1 \) and \( T_0 = 2^{<\omega} \), with \( F_0 = \{01, 01001, 01100 \} \) and \( X_0 \) any strong subforest of \( 2^{<\omega} \) such that \( \text{roots}(X_0) = \{0100100110, 0100110101, 01100000110, 01100111001 \} \). Then \((F_0, X_0)\) is a product tree condition. The leaves of \( F_0 \) are 01001 and 01100 and are at level 5 in \( 2^{<\omega} \). The roots 0100100110 and 0100110101 of \( X_0 \) witness \((5 + 1)\)-\( \sigma \)-density of \( \text{roots}(X_0) \) for \( \sigma = 01001 \), since the extensions of \( \sigma \) at level 6 in \( 2^{<\omega} \) are 010010 and 010011.

**Definition 3.8.** A product tree condition \( d = (\hat{F}_0, \ldots, \hat{F}_{d-1}, \hat{X}_0, \ldots, \hat{X}_{d-1}) \) extends \( c = (F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1}) \), written \( d \leq c \), if for every \( j < d \), \( F_j \subseteq \hat{F}_j \), \( \hat{X}_j \subseteq X_j \) and \( \hat{F}_j \setminus F_j \subseteq X_j \).

**Remark 3.9.** Given a product tree condition \( c = (F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1}) \), it is not necessarily the case that \( F_0 \cup X_0, \ldots, F_{d-1} \cup X_{d-1} \) are strong subtrees of \( T_0, \ldots, T_{d-1} \), respectively, as witnessed by the same level function. Indeed, the forests may have extra roots unrelated to the finite trees. However,
by removing some roots of the forests, one can always obtain an extension 
\( d = (F_0, \ldots, F_{d-1}, Y_0, \ldots, Y_{d-1}) \) for which it is the case. We can therefore 
assume this when convenient. However, in the proof of strong cone avoidance 
of the Halpern-Lauchli theorem (Theorem 3.21), we will use the degree 
of freedom of being able to have extra roots for the construction of multiple 
product tree conditions all sharing the same forests.

We now define a forcing relation for product tree conditions. We follow 
a standard approach to forcing in arithmetic, using strong forcing; see, e.g., 
Shore [38, Chapter 3] for a complete introduction. We use \( \forces \) ("forces") 
for the forcing relation irrespective of the underlying forcing notion, as no 
confusion will arise in our treatment. As is usual, we write \( \not\forces \) ("\( \not\) does not force \( \cdots \)"") an abbreviation \( \lnot \forces (\cdots \cdots \cdots) \) . Throughout, we work 
in the language of second-order arithmetic. We follow the usual convention 
that for a \( \Delta_0^{0,Z} \) formula \( \varphi(G) \) with a free set parameter \( G \), if \( \varphi(F) \) holds 
for a finite set \( F \), then so does \( \varphi(F \cup E) \) for every finite set \( E \) such that 
\( \min E \setminus F > \max F \). We also assume our pairing function is such that if 
\( \sigma, \tau \in \omega^{<\omega} \text{ and } |\tau| > |\sigma| \) then the code for \( \tau \) is larger than the code for \( \sigma \). So 
for example, if \( F \) is viewed as a subset of Baire and the length of \( \tau \in \omega^{<\omega} \) is 
larger than the length of every string in \( F \), then the code of \( \tau \) is larger than 
max \( F \). In particular, if every string in \( E \setminus F \) is longer than every string in 
\( F \) and \( \varphi(F) \) holds then so does \( \varphi(F \cup E) \).

**Definition 3.10.** Let \( c = (F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1}) \) be a product tree 
condition, \( Z \subseteq \mathbb{N} \) a set, and \( \varphi(G_0, \ldots, G_{d-1}, x) \) a \( \Delta_0^{0,Z} \) formula with a free 
set parameters \( G_0, \ldots, G_{d-1} \) and a free integer parameter \( x \).

1. \( c \forces (\exists x) \varphi(G_0, \ldots, G_{d-1}, x) \) if \( \varphi(F_0, \ldots, F_{d-1}, x) \) holds for some \( x \in \mathbb{N} \).
2. \( c \forces (\forall x) \varphi(G_0, \ldots, G_{d-1}, x) \) if \( \varphi(F_0 \cup E_0, \ldots, F_{d-1} \cup E_{d-1}, x) \) holds 
   for all \( x \in \mathbb{N} \) and all finite subsets \( E_0, \ldots, E_{d-1} \) of \( X_0, \ldots, X_{d-1} \), 
   respectively, such that \( F_0 \cup E_0, \ldots, F_{d-1} \cup E_{d-1} \) are finite strong 
   subtrees of \( T_0, \ldots, T_{d-1} \), respectively, with a common level function.

Of course, Item 2 should abstractly be defined as there being no \( d \) extending \( c \) 
such that \( d \forces (\exists x) \varphi(G_0, \ldots, G_{d-1}, x) \), but this is easily seen to be equivalent 
to the given formulation. We give it explicitly in the definition since we will 
make frequent use of it.

Every filter \( \mathcal{U} \) on the set of product tree conditions induces a \( d \)-tuple of 
(finite or infinite) strong subtrees \( G^d_0, \ldots, G^d_{d-1} \) of \( T_0, \ldots, T_{d-1} \), respectively, 
with common level function. Moreover, if \( c \forces (\exists x) \varphi(G_0, \ldots, G_{d-1}, x) \) or \( c \forces 
(\forall x) \varphi(G_0, \ldots, G_{d-1}, x) \) for some condition \( c \in \mathcal{U} \) and \( \Delta_0^{0,Z} \) formula \( \varphi \), then 
\( (\exists x) \varphi(G^d_0, \ldots, G^d_{d-1}, x) \) holds or \( (\forall x) \varphi(G^d_0, \ldots, G^d_{d-1}, x) \) holds, respectively.

Given a Turing functional \( \Gamma \), sets \( C, Z \subseteq \mathbb{N} \), and a condition \( c \), we 
write \( c \forces \Gamma_{G_0, \ldots, G_{d-1} \in Z} \varphi \neq C \) if there is an \( x \in \mathbb{N} \) such that either \( c \forces \Gamma_{G_0, \ldots, G_{d-1} \in Z} \varphi \uparrow \) or \( c \forces \Gamma_{G_0, \ldots, G_{d-1} \in Z} \varphi \downarrow \neq C \). (Note that \( C(x) \) is 
a definite value, so \( C \) is not a parameter in the latter formula.) The following
lemma states that given a filter $U$ on the set of product tree conditions, if for every Turing functional $\Gamma$ there is a condition $c \in U$ such that $c \not\models \Gamma G_0 \circ \cdots \circ G_{d-1} \circ Z \neq C$, then $G_0, \ldots, G_{d-1}$ are all infinite.

**Lemma 3.11.** For every $n \in \mathbb{N}$, and all sets $C, Z \subseteq \mathbb{N}$, there is a Turing functional $\Gamma$ such that if $c = (F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})$ is any product tree condition satisfying

$$c \not\models \Gamma G_0 \circ \cdots \circ G_{d-1} \circ Z \neq C$$

then $F_0, \ldots, F_{d-1}$ all have height at least $n$.

**Proof.** Let $\Gamma$ be the Turing functional such that for all sets $F_0, \ldots, F_{d-1}$ coding strong subtrees, if the height of each $F_j$ is not at least $n$ then $\Gamma F_0 \circ \cdots \circ F_{d-1} \circ Z(x) \uparrow$ for all $x \in \mathbb{N}$ and $Z \subseteq \mathbb{N}$, and otherwise $c \not\models \Gamma G_0 \circ \cdots \circ G_{d-1} \circ Z(x) \downarrow = 0$ for all $x$ and $Z$.

Now suppose $c \not\models \Gamma G_0 \circ \cdots \circ G_{d-1} \circ Z \neq C$. If $c \not\models \Gamma G_0 \circ \cdots \circ G_{d-1} \circ Z(x) \downarrow \neq C(x)$ for some $x \in \mathbb{N}$, then by Definition 3.10(1), $\Gamma F_0 \circ \cdots \circ F_{d-1} \circ Z(x) \downarrow \neq C(x)$, so by choice of $\Gamma$, $F_0, \ldots, F_{d-1}$ must all have height at least $n$.

If $c \not\models \Gamma G_0 \circ \cdots \circ G_{d-1} \circ Z(x) \uparrow$ for some $x \in \mathbb{N}$, then by Definition 3.10(2), we must have that $\Gamma (F_0 \cup E_0) \circ \cdots \circ (F_{d-1} \cup E_{d-1}) \circ Z(x) \uparrow$ for all finite subsets $E_0, \ldots, E_{d-1}$ of $X_0, \ldots, X_{d-1}$, respectively, such that $F_0 \cup E_0, \ldots, F_{d-1} \cup E_{d-1}$ are finite strong subtrees of $T_0, \ldots, T_{d-1}$ with a common level function. But since $X_0, \ldots, X_{d-1}$ are infinite, we can find some such $E_0, \ldots, E_{d-1}$ with $F_0 \cup E_0, \ldots, F_{d-1} \cup E_{d-1}$ all of height at least $n$, contradicting the definition of $\Gamma$. 

**Remark 3.12.** The definition of product tree condition is made with respect to our particular choice of trees $T_0, \ldots, T_{d-1}$. We will always work with a single such choice at any given time, and so do not decorate our conditions by these trees explicitly. In particular, when a product tree condition is mentioned it should be understood as being with respect to whichever trees $T_0, \ldots, T_{d-1}$ are currently under discussion.

### 3.3. Strong cone avoidance of MTT$^1$

Before proving strong cone avoidance of the product version of Milliken’s tree theorem, we prove a similar result for its non-product version. The proof is simpler and is actually sufficient to prove cone avoidance of the non-product version of Milliken’s tree theorem for height 2. The techniques involved are a variation of the notion of $k$-hierarchy of Chong et al [7, Section 4]. The theorem proven in this section will not be used in the remainder of the monograph, but can be seen as an instructive warm-up to the proof of Theorem 3.21.

**Theorem 3.13.** MTT$^1$ admits strong cone avoidance.

In what follows, fix two sets $C, Z \subseteq \mathbb{N}$ such that $C \nleq_T Z$. Also fix an infinite $Z$-computable $Z$-computably bounded tree $T$ with no leaves and
an arbitrary 2-partition $A_0 \sqcup A_1 = T$ representing an instance of $\text{MTT}^1_2$. Our task is to exhibit an $\text{MTT}^1$-solution to whose join with $Z$ still does not compute $C$.

Given a finite strong subtree $F$ of $T$, a cover of $F$ is a set $E \subseteq T$ such that for every leaf $\sigma$ of $F$, every immediate extension of $\sigma$ in $T$ has an extension in $E$.

**Definition 3.14.**

1. A tree condition is a pair $(F, X)$ such that $F$ is a finite strong subtree of $T$, $X$ is an infinite strong subforest of $T$, and roots($X$) is a cover of $F$.
2. A tree condition $(\hat{F}, \hat{X})$ extends $(F, X)$, written $(\hat{F}, \hat{X}) \leq (F, X)$, if $F \subseteq \hat{F}$, $\hat{X} \subseteq X$ and $\hat{F} \setminus F \subseteq X$.
3. $(F, X)$ is cone avoiding if $C \nleq_T X \oplus Z$.

Note that a tree condition is nothing but a product tree condition (Definition 3.7) relative to the 1-tuple $T$.

A tree condition inherits the forcing relation from the one for product tree conditions (Definition 3.10).

**Definition 3.15.** Let $(F, X)$ be a tree condition and $\varphi(G, x)$ a $\Delta^0_{0,z}$ formula with a free set parameter $G$ and a free integer parameter $x$.

1. $(F, X) \models (\exists x)\varphi(G, x)$ if $\varphi(F, x)$ holds for some $x \in \mathbb{N}$.
2. $(F, X) \models (\forall x)\varphi(G, x)$ if $\varphi(F \cup E, x)$ holds for all $x \in \mathbb{N}$ and all finite $E \subseteq X$ such that $F \cup E$ is a finite strong subtree of $T$.

Every filter $\mathcal{U}$ on the set of tree conditions induces a (finite or infinite) strong subtree $G_{\mathcal{U}}$ of $T$. Moreover, if $(F, X) \models (\exists x)\varphi(G, x)$ or $(F, X) \models (\forall x)\varphi(G, x)$ for some tree condition $(F, X) \in \mathcal{U}$ and $\Delta^0_{0,z}$ formula $\varphi$, then $(\exists x)\varphi(G_{\mathcal{U}}, x)$ or $(\forall x)\varphi(G_{\mathcal{U}}, x)$ holds, respectively.

Given a Turing functional $\Gamma$, we write $(F, X) \models \Gamma^{G\oplus Z} \neq C$ if there is an $x \in \mathbb{N}$ such that either $(F, X) \models \Gamma^{G\oplus Z}(x) \uparrow$ or $(F, X) \models \Gamma^{G\oplus Z}(x) \downarrow \neq C(x)$.

We have the following analogue of Lemma 3.11, which is proved in the same way.

**Lemma 3.16.** For every $n \in \mathbb{N}$, there is a Turing functional $\Gamma$ such that for every tree condition $(F, X)$, if $(F, X) \models \Gamma^{G\oplus Z} \neq C$ then $F$ has height at least $n$.

**Definition 3.17.** A compound tree condition is a tuple $(F, F, X)$ such that $(F, X)$ is a tree condition with $F \subseteq A_0$, and $F$ is a finite collection of finite sets as follows:

1. for every $E \in F$, $(E, X)$ is a tree condition with $E \subseteq A_1$;
2. $\bigcup_{E \in F} \text{roots}(E)$ is a cover of $F$.

A compound tree condition $(F, F, X)$ is cone avoiding if $C \nleq_T X \oplus Z$. 
Equivalently, \((F,F,X)\) is cone avoiding if \((F,X)\) is cone avoiding as a tree condition, and so is \((E,X)\) for every \(E \in F\). Note that we do not require the finite strong subtrees in \(F\) to be witnessed by the same level function.

**Lemma 3.18.**

1. For every tree condition \((F,X)\) with \(F \subseteq A_0\), and every level \(\ell \in \mathbb{N}\) such that \(X(\ell) \cap A_1\) is a cover of \(F\), \((F,F,Y)\) is a compound tree condition, where \(F = \{\{\rho\} : \rho \in X(\ell) \cap A_1\}\) and \(Y = X \cup \bigcup_{s \leq \ell} X(s)\).

2. For every compound tree condition \((F,F,X)\), every \(E \in F\), and every extension \((\hat{E},\hat{X}) \leq (E,X)\) with \(\hat{E} \setminus E \subseteq A_1\) and such that every root of \(X\) is extended by a root of \(\hat{X}\), \((F,F,X)\) is a compound tree condition, where \(\hat{F} = \{\hat{E}\} \cup (F \setminus \{E\})\).

**Proof.** Immediate from the definitions. \(\Box\)

**Lemma 3.19.** Suppose there is no infinite strong perfect subtree \(S \subseteq T\) such that \(S \subseteq A_0\) and \(C \not\leq_T S \oplus Z\). Then for every cone avoiding tree condition \((F,X)\), there is a level \(\ell \in \mathbb{N}\) such that \(X(\ell) \cap A_1\) is a cover of \(F\).

**Proof.** Suppose first there is some level \(\ell\) such that every root \(\rho\) of \(X\) has an extension \(\sigma \in X(\ell) \cap A_1\). Since \(\text{roots}(X)\) is a cover of \(F\), then so is \(X(\ell) \cap A_1\).

So now suppose that for every level \(\ell\), there is some root \(\rho\) of \(X\) all of whose extensions \(\sigma \in X(\ell)\) belong to \(A_0\). We claim there is an infinite strong subtree \(S \subseteq T\) such that \(S \subseteq A_0\) and \(C \not\leq_T S \oplus Z\), contrary to the hypothesis of the lemma. Let \(f : \mathbb{N} \to \text{roots}(X)\) be the function which to \(\ell\) associates such a root \(\rho\). By strong cone avoidance of \(RT\) \((\mathbb{N}, X)\) (Lemma 3.2), there is an infinite set of levels \(H\) which is \(f\)-homogeneous for some root \(\rho\) of \(X\) and such that \(C \not\leq_T H \oplus X \oplus Z\). In particular, for every level \(\ell \in H\) and every node \(\sigma\) at level \(\ell\) in \(X\) extending \(\rho\) we have \(\sigma \in A_0\). But now we can \(H \oplus X\)-computably build an infinite strong subtree \(S \subseteq T\) among these \(\sigma\). Then \(S \subseteq A_0\), and since \(S \not\leq_T H \oplus X\) we also have \(C \not\leq_T S \oplus Z\). \(\Box\)

**Lemma 3.20.** For every cone avoiding compound tree condition \((F,F,X)\) and every tuple of Turing functionals \((\Gamma_F, \Gamma_E : E \in F)\), one of the following holds:

1. There is a cone avoiding extension \((\hat{F},\hat{X}) \leq (F,X)\) such that \((\hat{F},\hat{X}) \vdash \Gamma_F^{G \oplus Z} \neq C\) and \(\hat{F} \setminus F \subseteq A_0\);

2. There is a cone avoiding extension \((\hat{E},\hat{X}) \leq (E,X)\) for some \(E \in F\) such that \((\hat{E},\hat{X}) \vdash \Gamma_E^{G \oplus Z} \neq C\) and \(\hat{E} \setminus E \subseteq A_1\) and every root of \(X\) is extended by a root of \(\hat{X}\).

**Proof.** Let \(W\) be the set of pairs \((x,v) \in \mathbb{N} \times \{0,1\}\) such that for every 2-partition \(B_0 \sqcup B_1 = X\) one of the following holds:

(a) there is a finite set \(H \subseteq X \cap B_0\) such that \(F \cup H\) is a finite strong subtree of \(T\) and \(\Gamma_F^{(F \cup H) \oplus Z}(x) \downarrow = v\);
3.3. Strong Cone Avoidance of $\text{MTT}^1$

(b) there is some $E \in \mathcal{F}$ and a finite set $H_E \subseteq X \cap B_1$ such that $E \cup H_E$ is a finite strong subtree of $T$ and $\Gamma^{(E \cup H_E) \oplus Z}(x) \downarrow v$.

By compactness, the set $W$ is $X \oplus Z$-c.e. There are three cases:

**Case 1:** $(x, 1 - C(x)) \in W$ for some $x \in \mathbb{N}$. Let $B_0 = X \cap A_0$ and $B_1 = X \cap A_1$. If (a) holds with witness $H$, then let $\ell$ be the level of the leaves of $F \cup H$ in $X$, and $\hat{X} = X \setminus \bigcup_{s \leq \ell} X(s)$. Now $(F \cup H, \hat{X})$ is a tree condition satisfying item 1 of the lemma. If (b) holds for some $E \in \mathcal{F}$ with witness $H_E$, then let $\ell$ be the level of the leaves of $E \cup H_E$ in $X$, and $\hat{X} = X \setminus \bigcup_{s \leq \ell} X(s)$. Now $(E \cup H_E, \hat{X})$ is a tree condition satisfying item 2 of the lemma.

**Case 2:** $(x, C(x)) \notin W$ for some $x \in \mathbb{N}$. Let $\mathcal{C}$ be the $\Pi_{1}^{0,X \oplus Z}$ class of all sets $B_0 \oplus B_1$ such that $B_0 \cup B_1 = X$ and neither (a) nor (b) holds for the pair $(x, C(x))$. By assumption, $\mathcal{C} \neq \emptyset$. By the cone avoidance basis theorem ([23], Corollary 2.11), there is a $B_0 \oplus B_1 \in \mathcal{C}$ such that $C \nleq_{T} B_0 \oplus B_1 \oplus X \oplus Z$. For $\sigma \in X$, write $B(\sigma)$ for the unique $i < 2$ such that $\sigma \in B_i$. Let $I = \text{roots}(X)$. By Theorem 3.4 applied to the finite $I$-tuple of infinite trees $(X \upharpoonright \rho : \rho \in I)$ and the coloring $g$ defined on $\bigcup_n \prod_{\rho \in I} (X \upharpoonright \rho)(n) / g(\sigma_{\rho} : \rho \in I) = (B(\sigma_{\rho}) : \rho \in I)$, there is a $B_0 \oplus B_1 \oplus X$-computable finite tuple of infinite strong subtrees $(Y_{\rho} : \rho \in I)$ of $(X \upharpoonright \rho : \rho \in I)$ with common level function, together with a tuple of colors $(i_{\rho} \in \{0, 1\} : \rho \in I)$ such that $Y_{\rho} \subseteq B_{i_{\rho}}$ for every $\rho \in I$. For every $E \in \mathcal{F}$, let $I_E$ be the set of nodes in $I$ extending the root of $E$. By assumption, $I_E$ is a cover of $E$.

If $I_E \subseteq \{\rho \in I : i_{\rho} = 1\}$ for some $E \in \mathcal{F}$, then $(E, \bigcup_{\rho \in I} Y_{\rho})$ is a cone avoiding extension of $(E, X)$ such that every root of $X$ is extended by a root of $\bigcup_{\rho \in I} Y_{\rho}$, and forcing $\Gamma^{G \oplus Z}_{E}(x) \uparrow$ or $\Gamma^{G \oplus Z}_{E}(x) \downarrow \neq C(x)$.

If $I_E \cap \{\rho \in I : i_{\rho} = 0\} \neq \emptyset$ for every $E \in \mathcal{F}$, then in particular, every root of every $E \in \mathcal{F}$ has an extension in $\{\rho \in I : i_{\rho} = 0\}$. Since the set of roots of the trees in $E$ form a cover of $F$, then $\{\rho \in I : i_{\rho} = 0\}$ is a cover of $F$. Thus, $(F, \bigcup_{\rho \in \mathbb{N}} Y_{\rho})$ is a cone avoiding extension of $(F, X)$ forcing $\Gamma^{G \oplus Z}_{F}(x) \uparrow$ or $\Gamma^{G \oplus Z}_{F}(x) \downarrow \neq C(x)$.

**Case 3:** otherwise. Then for $x, y \in \mathbb{N}$ we have $(x, y) \in W$ if and only if $y = C(x)$. But as $W$ is $X \oplus Z$-c.e., this implies that $C \leq_{T} X \oplus Z$, which is a contradiction.

We are now ready to prove strong cone avoidance of Milliken’s tree theorem for height 1.

**Proof of Theorem 3.13.** Suppose first there is a filter $\mathcal{U}$ of cone avoiding tree conditions such that $F \subseteq A_0$ for every $(F, X) \in \mathcal{U}$, and such that for every Turing functional $\Gamma$ there is a tree condition $(F, X) \in \mathcal{U}$ with $(F, X) \Vdash \Gamma^{G \oplus Z} \neq C$. Then by definition of a tree condition, $G_{\mathcal{U}}$ is a strong subtree of $T$. Moreover, by assumption, $G_{\mathcal{U}} \subseteq A_0$ and $C \nleq_{T} G_{\mathcal{U}} \oplus Z$. 

Last, by Lemma 3.16, \( G_{\mathcal{U}} \) is infinite, thus \( G_{\mathcal{U}} \) satisfies the statement of the theorem.

Suppose now there is no such filter. Then there is a cone avoiding tree condition \( (F, X) \) such that \( F \subseteq A_0 \) and a Turing functional \( \Gamma_F \) such that for every cone avoiding extension \( (\hat{F}, \hat{X}) \) with \( \hat{F} \setminus F \subseteq A_0 \) we have \((\hat{F}, \hat{X}) \not\equiv \Gamma_F^{G \oplus Z} \neq C\).

Assume there is no infinite strong subtree \( S \subseteq T \) such that \( S \subseteq A_0 \) and \( C \not\subseteq T S \oplus Z \); otherwise we are done. By Lemma 3.19, there is a level \( \ell \in \mathbb{N} \) such that \( X(\ell) \cap A_1 \) is a cover of \( F \). Let \( I = X(\ell) \cap A_1 \).

We claim there exists an infinite sequence of cone avoiding compound tree conditions

\[
(F, \mathcal{F}_0, X_0), (F, \mathcal{F}_1, X_1), \ldots
\]
such that for every \( s \in \mathbb{N} \), letting \( s = (\Gamma_\rho : \rho \in I) \), the following holds:

1. \( \mathcal{F}_s = \{E_{s, \rho} : \rho \in I\} \);
2. \( X_s \subseteq X \);
3. \( \mathcal{F}_{s+1} \setminus \{E_{s+1, \rho}\} = \mathcal{F}_s \setminus \{E_{s, \rho}\} \) for some \( \rho \in I \) such that \( (E_{s+1, \rho}, X_{s+1}) \leq (E_{s, \rho}, X_s) \) and \( (E_{s+1, \rho}, X_{s+1}) \not\equiv \Gamma_\rho^{G \oplus Z} \neq C \).

By Lemma 3.18(1), letting \( \mathcal{F}_0 = \{\{\rho\} : \rho \in I\} \) and \( X_0 = X \setminus \bigcup_{t \leq \ell} X(t) \), the tuple \((F, \mathcal{F}_0, X_0)\) is a cone avoiding compound tree condition. Given a compound tree condition \((F, \mathcal{F}_s, X_s)\) and letting \( s = (\Gamma_\rho : \rho \in I) \), by Lemma 3.20, either there is a cone avoiding extension \( (\hat{F}, \hat{X}) \leq (F, X) \) such that \( (\hat{F}, \hat{X}) \not\equiv \Gamma_F^{G \oplus Z} \neq C \) and \( \hat{F} \setminus F \subseteq A_0 \), or there some \( \rho \in I \) and a cone avoiding extension \( (E_{s+1, \rho}, X_{s+1}) \leq (E_{s, \rho}, X_s) \) such that \( (E_{s+1, \rho}, X_{s+1}) \not\equiv \Gamma_\rho^{G \oplus Z} \neq C \) and \( E_{s+1, \rho} \setminus E_{s, \rho} \subseteq A_1 \) and every root of \( X_s \) extends in a root of \( X_{s+1} \). The former case cannot happen, so the latter case holds, and we can define \((F, \mathcal{F}_{s+1}, X_{s+1})\) accordingly by Lemma 3.18(2). This proves our claim.

By a pairing argument, there is a \( \rho \in I \) such that for every Turing functional \( \Gamma \) there is an \( s \in \mathbb{N} \) such that \( (E_{s, \rho}, X_s) \not\equiv \Gamma_\rho^{G \oplus Z} \neq C \). By construction, the conditions \( (E_{s, \rho}, X_s) \) for this fixed \( \rho \) are compatible for all \( s \). Thus, we can fix a filter \( \mathcal{U} \) containing all of them. Again, by definition of a tree condition, \( G_{\mathcal{U}} \) is a strong subtree of \( T \). By assumption, \( G_{\mathcal{U}} \subseteq A_1 \) and \( C \not\subseteq T G_{\mathcal{U}} \oplus Z \). Last, by Lemma 3.16, \( G_{\mathcal{U}} \) is infinite, thus \( G_{\mathcal{U}} \) satisfies the statement of the theorem. This completes the proof of Theorem 3.13.

### 3.4. Strong cone avoidance of the Halpern-Laüchli theorem

We now prove that the Halpern-Laüchli theorem admits strong cone avoidance. This will be used in multiple parts of the rest of the manuscript, to prove that the product version of Milliken’s tree theorem for height 2 admits cone avoidance (Theorem 3.21) and hence does not imply \( \text{ACA}_0 \) over \( \text{RCA}_0 \), and also to prove the same for the product version of Milliken’s tree theorem for height 3, but where at most 2 colors are allowed in the solution (Theorem 4.28).
3.4. Strong Cone Avoidance of the Halpern-Läuchli Theorem

Theorem 3.21. The Halpern-Läuchli theorem admits strong cone avoidance.

The meta-analysis of a theorem sometimes requires the use of the classical version of the theorem itself. In order to prove Theorem 3.21, we need the following version of the Halpern-Läuchli theorem:

Theorem 3.22. Let $T_0, \ldots, T_{d-1}$ be infinite trees with no leaves. For all $k \geq 1$, there is an $N \in \mathbb{N}$ such that for every $f : T_0(N) \times \cdots \times T_{d-1}(N) \to k$ there is an $\ell < N$, a $\pi \in T_0(\ell) \times \cdots \times T_{d-1}(\ell)$, and an $(\ell + 1)$-$\pi$-dense matrix $P \subseteq T_0(N) \times \cdots \times T_{d-1}(N)$ on which $f$ is constant.

Proof. Fix $k$. The Halpern-Läuchli theorem (Theorem 2.28) implies that for every $k$-coloring of $\bigcup_n T_0(n) \times \cdots \times T_{d-1}(n)$ there exists an $N \in \mathbb{N}$ and a tuple of strong subtrees $(S_0, \ldots, S_{d-1}) \in S_2(T_0, \ldots, T_{d-1})$ with level function bounded by $N$ such that $f$ is constant on $\bigcup_{n \leq N} S_0(n) \times \cdots \times S_{d-1}(n)$. By compactness of the space of $k$-colorings of $\bigcup_n T_0(n) \times \cdots \times T_{d-1}(n)$, we can choose a single such $N$ that works for all $k$-colorings: that is, for every $k$-coloring, the trees $S_0, \ldots, S_{d-1}$ can be taken as strong subtrees of $\bigcup_{n<N} T_0(n), \ldots, \bigcup_{n<N} T_{d-1}(n)$, respectively. The claim is that this $N$ also witnesses the theorem.

Let $f : T_0(N) \times \cdots \times T_{d-1}(N) \to k$ be a coloring. For any $i < d$, $n \in \mathbb{N}$ and $\sigma \in T_i(n)$, let $e(\sigma)$ be any element of $T_i(N)$ compatible with $\sigma$: either an extension, or a prefix. Define the coloring $g : \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \to k$ by $g(\sigma_0, \ldots, \sigma_{d-1}) = f(e(\sigma_0), \ldots, e(\sigma_{d-1}))$ for all $(\sigma_0, \ldots, \sigma_{d-1})$. By choice of $N$, we can find $(S_0, \ldots, S_{d-1}) \in S_2(T_0, \ldots, T_{d-1})$ with level function bounded by $N$ so that $g$ is constant on $S_0(1) \times \cdots \times S_{d-1}(1)$. Thus, $f$ is constant on $P = e(S_0(1)) \times \cdots \times e(S_{d-1}(1))$. Moreover, if we let $\ell$ be the (common) first level of the $S_i$ in $T_i$, and let $\pi$ be the unique element of $S_0(0) \times \cdots \times S_{d-1}(0)$, then $P$ is an $(\ell + 1)$-$\pi$-dense matrix. \hfill $\Box$

In what follows, fix two sets $C$ and $Z$ such that $C \not\subseteq_T Z$. Also fix a tuple of infinite $Z$-computable $Z$-computably bounded trees with no leaves $T_0, \ldots, T_{d-1}$ and an arbitrary $k$-partition $A_0 \sqcup \cdots \sqcup A_{k-1} = \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n)$ representing an instance of the Halpern-Läuchli theorem (for $k$-colorings).

For this section, we will need to strengthen the extension relation for product tree conditions (relative to these $T_i$).

Definition 3.23. Let $T_0, \ldots, T_{d-1}$ be infinite trees with no leaves. A product tree condition $d = (\bar{F}_0, \ldots, \bar{F}_{d-1}, \bar{X}_0, \ldots, \bar{X}_{d-1})$ (relative to these $T_i$) extends $c = (F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})$, written $d \leq c$, if for every $j < d$, $F_j \subseteq \bar{F}_j$, $X_j \subseteq \bar{X}_j$ and $\bar{F}_j \setminus F_j \subseteq X_j$, and moreover, every root of $X_j$ is extended by a root of $\bar{X}_j$.

Definition 3.24. A product tree condition $(F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})$ is cone avoiding if $C \not\subseteq_T X_0 \oplus \cdots \oplus X_{d-1} \oplus Z$. It is level-homogeneous if for every $n$, there is some color $i < k$ such that $F_0(n) \times \cdots \times F_{d-1}(n) \subseteq A_i$. 
In particular, if $d$ extends $c$ in the sense of Definition 3.23, then $d$ extends $c$ in the sense of Definition 3.8.

Any product tree condition of the form
$$\langle \{\rho_0\}, \ldots, \{\rho_{d-1}\}, X_0, \ldots, X_{d-1} \rangle$$
is level-homogeneous. Let $\mathbb{P}$ be the set of cone avoiding level-homogeneous product tree conditions, ordered by the stronger relation of Definition 3.23. The following lemma is the core of the argument. The proof of Lemma 3.25 shows that the witnessed condition $c$ can actually be chosen so that its stems are singletons.

**Lemma 3.25.** There is a condition $c \in \mathbb{P}$ such that for every Turing functional $\Gamma$, the set of conditions $c' \in \mathbb{P}$ satisfying $c' \Vdash \Gamma^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C$ is $\mathbb{P}$-dense below $c$.

**Proof.** Assume for the sake of contradiction that for every condition $c \in \mathbb{P}$, there is a Turing functional $\Gamma$ and a $\mathbb{P}$-extension, every further $\mathbb{P}$-extension $c'$ of which satisfies $c' \not\Vdash \Gamma^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C$.

We build non-effectively a $d$-tuple of subsets $S_0, \ldots, S_{d-1}$ of $T_0, \ldots, T_{d-1}$, respectively. Formally, these sets will not be trees, as specified in Definition 2.16, since they will not be closed under $\wedge$. However, the prefix relation induces a tree structure, and seen as such, the $S_j$ will be finitely branching trees with no leaves. (In fact, the $S_j$ will have a common level function.) We may thus use Remark 2.18 to think of the $S_j$ as trees, and in particular, we may apply Theorem 3.22 to them.

Along with $S_0, \ldots, S_{d-1}$, we define the following functions:

1. $\text{sets} : \mathbb{N} \to \mathcal{P}(\omega^{\lt \omega}) \times \cdots \times \mathcal{P}(\omega^{\lt \omega})$ which to a level $\ell \in \mathbb{N}$ associates a $d$-tuple $X_0, \ldots, X_{d-1}$ of infinite strong subforests of $T_0, \ldots, T_{d-1}$, respectively, with a common level function, such that $C \not\in_T X_0 \oplus \cdots \oplus X_{d-1} \oplus Z$ and for every $j < d$, $S_j(\ell + 1) = \text{roots}(X_j)$;

2. $\text{stems} : \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n) \to \mathcal{S}_{\lt \omega}(T_0, \ldots, T_{d-1})$, which to a $\pi \in S_0(\ell) \times \cdots \times S_{d-1}(\ell)$ associates a tuple $(F_0, \ldots, F_{d-1})$ whose roots pointwise extend $\pi$, and such that $(F_0, \ldots, F_{d-1}, \text{sets}(\ell))$ is a $\mathbb{P}$-condition;

3. $\text{req} : \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n) \to \mathbb{N}$, which to a $\pi \in S_0(\ell) \times \cdots \times S_{d-1}(\ell)$ associates the index $e \in \mathbb{N}$ of a Turing functional $\Phi_e$ such that for every $\mathbb{P}$-extension $c'$ of the condition $(\text{stems}(\pi), \text{sets}(\ell))$, $c' \not\Vdash \Gamma_e^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C$.

Moreover, we ensure that for every level $\ell \in \mathbb{N}$, $\text{sets}(\ell+1)$ is a tuple of strong subforests of sets(\ell) with common level function.

**Construction.** We define $S_0, \ldots, S_{d-1}$ and the functions sets, stems and req level by level. For convenience of notation, let $\text{sets}(-1) = (T_0, \ldots, T_{d-1})$. At level $\ell \geq 0$, assume $\text{sets}(\ell - 1)$ is already defined. Say $(Y_0, \ldots, Y_{d-1}) = \text{sets}(\ell - 1)$. For every $j < d$, let $S_j(\ell) = \text{roots}(Y_j)$. Now let $\pi_0, \ldots, \pi_{d-1}$ be a finite listing of all the elements in $S_0(\ell) \times \cdots \times S_{d-1}(\ell)$. We define $\text{stems}(\pi_s)$...
and \( \text{req}(\pi_s) \) successively for each \( s < r \), together with a decreasing sequence of \( d \)-tuples of cone avoiding strong subforests \( (X_0^0, \ldots, X_{d-1}^0, \ldots, X_0^r, \ldots, X_{d-1}^r) \).

Then \( \text{sets}(\ell) = (X_0^r, \ldots, X_{d-1}^r) \). Initially, let \( (X_0^0, \ldots, X_{d-1}^0) \) be the tuple \( (Y_0 \setminus Y_0(0), \ldots, Y_{d-1} \setminus Y_{d-1}(0)) \). At stage \( s < r \), assume \( (X_0^s, \ldots, X_{d-1}^s) \) is defined. Say \( \pi_s = (\rho_0, \ldots, \rho_{d-1}) \). In particular, \( (\{\rho_0\}, \ldots, \{\rho_{d-1}\}, X_0^s, \ldots, X_{d-1}^s) \) is a \( \mathbb{P} \)-condition. By assumption, this has a \( \mathbb{P} \)-extension \( (F_0, \ldots, F_{d-1}, X_0^{s+1}, \ldots, X_{d-1}^{s+1}) \) for which there is a Turing functional \( \Phi_e \) such that every further \( \mathbb{P} \)-extension \( c' \) satisfies \( c' \not \models \Gamma^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C \). So we have \( (X_0^{s+1}, \ldots, X_{d-1}^{s+1}) \), and we set \( \text{stems}(\pi_s) = (F_0, \ldots, F_{d-1}) \) and \( \text{req}(\pi_s) = e \). Now if \( s < r - 1 \), proceed to \( s + 1 \). This finishes the construction. (See Figure 3.1.)

**Verification.**

**Claim 3.26.** For every \( \ell_0 < \ell_1 \) and every \( \pi \in S_0(\ell_0) \times \cdots \times S_{d-1}(\ell_0) \), the tuple \( (\text{stems}(\pi), \text{sets}(\ell_1)) \) is a \( \mathbb{P} \)-extension of \( (\text{stems}(\pi), \text{sets}(\ell_0)) \).

**Proof.** Say \( \text{sets}(\ell_0) = (X_0, \ldots, X_{d-1}) \) and \( \text{sets}(\ell_1) = (Y_0, \ldots, Y_{d-1}) \). By an immediate induction, \( \text{sets}(\ell_1) \) is a tuple of strong subforests of \( \text{sets}(\ell_0) \) with common level function. By construction, for all \( j < d \) we have \( S_j(\ell_0 + 1) = \text{roots}(X_j) \) and \( S_j(\ell_1 + 1) = \text{roots}(Y_j) \), and since we are dealing with extension in \( \mathbb{P} \) here, this implies that every root of \( X_j \) is extended by a root of \( Y_j \). It follows that \( d = (\text{stems}(\pi), \text{sets}(\ell_1)) \) is a \( \mathbb{P} \)-extension of \( (\text{stems}(\pi), \text{sets}(\ell_0)) \). \( \square \)
From the preceding fact, it follows that the $S_j$ are as claimed. The rest of Properties 1–3 above are evident from the construction.

By Theorem 3.22, there is a level $N \in \mathbb{N}$ such that for every coloring $h : S_0(N) \times \cdots \times S_{d-1}(N) \to k$, there is some $\ell < N$, some $\pi \in S_0(\ell) \times \cdots \times S_{d-1}(\ell)$ and some $(\ell + 1)$-\pi-dense matrix $M \subseteq S_0(N) \times \cdots \times S_{d-1}(N)$ on which $h$ is constant. Fix such an $N$. Let $(X_0, \ldots, X_{d-1}) = \text{sets}(N-1)$. In particular, for every $j < d$, $S_j(N) = \text{roots}(X_j)$.

Let $W$ be the set of pairs $(x, v) \in \mathbb{N} \times \{0, 1\}$ such that for every $k$-partition $B_0 \sqcup \cdots \sqcup B_{k-1} = \bigcup_n X_0(n) \times \cdots \times X_{k-1}(n)$, there is some $\ell < N$, some $\pi \in S_0(\ell) \times \cdots \times S_{d-1}(\ell)$, and for every $j < d$, a finite set $H_j \subseteq X_j$ such that if $(F_0, \ldots, F_{d-1}) = \text{stems}(\pi)$ then the following hold:

(a) $(F_0 \cup H_0, \ldots, F_{d-1} \cup H_{d-1}) \in S_{\omega}(T_0, \ldots, T_{d-1})$;
(b) $\bigcup_n H_0(n) \times \cdots \times H_{d-1}(n) \subseteq B_i$ for some $i < k$;
(c) $\Phi_e^{(F_0 \cup H_0) \oplus \cdots \oplus (F_{d-1} \cup H_{d-1}) \oplus Z}(x) \downarrow= v$, where $e = \text{req}(\pi)$.

Note that although the trees $S_0, \ldots, S_{d-1}$ and the functions sets, stems and req are built non-effectively, only their restrictions to the height $N$ are used. Therefore, since every finite object is computable, they do not add to the complexity of the set $W$. By compactness, the set $W$ is $X_0 \oplus \cdots \oplus X_{d-1} \oplus Z$-c.e. We break into three cases.

**Case 1:** $(x, 1 - C(x)) \in W$ for some $x \in \mathbb{N}$. For $i < k$, let $B_i = A_i \cap \bigcup_n X_0(n) \times \cdots \times X_{d-1}(n)$. Let $\ell < N$, $\pi = (F_0, \ldots, F_{d-1})$ and $H_0, \ldots, H_{d-1}$ witness that $(x, 1 - C(x)) \in W$ for the partition $B_0, \ldots, B_{k-1}$. Let $\ell_1$ be the common level of the leaves of $F_j \cup H_j$ in $X_j$, and $X_j = X_j \setminus \bigcup_{\ell_0 \leq \ell_1} X_j(\ell_0)$. Then $c' = (F_0 \cup H_0, \ldots, F_{d-1} \cup H_{d-1}, X_0, \ldots, X_{d-1})$ is a $\mathbb{P}$-extension of the condition $(F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})$ which, by Claim 3.26, is a $\mathbb{P}$-extension of $(\text{stems}(\pi), \text{sets}(\ell))$ since $\ell_1 \geq \ell$. Moreover

$$c' \models \Phi_e^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C$$

where $e = \text{req}(\pi)$. This contradicts Property 3 above, according to which $(\text{stems}(\pi), \text{sets}(\ell))$ has no such $\mathbb{P}$-extension.

**Case 2:** $(x, C(x)) \notin W$ for some $x \in \mathbb{N}$. Let $C$ be the $\Pi_1^{0, X_0 \oplus \cdots \oplus X_{d-1} \oplus Z}$ class of all sets $B_0 \oplus \cdots \oplus B_{k-1}$ such that $B_0 \sqcup \cdots \sqcup B_{k-1} = \bigcup_n X_0(n) \times \cdots \times X_{d-1}(n)$ and such that for every $\ell < N$, every $\pi \in S_0(\ell) \times \cdots \times S_{d-1}(\ell)$ and every $H_0 \subseteq X_0, \ldots, H_{d-1} \subseteq X_{d-1}$, one of (a), (b) or (c) in the definition of $W$ fails for the pair $(x, C(x))$. By assumption, $C \neq \emptyset$.

By the cone avoidance basis theorem, there is some $B_0 \oplus \cdots \oplus B_{k-1} \in C$ such that $C \notin T B_0 \oplus \cdots \oplus B_{k-1} \oplus X_0 \oplus \cdots \oplus X_{d-1} \oplus Z$. For $\pi \in \bigcup_n X_0(n) \times \cdots \times X_{d-1}(n)$, write $B(\pi)$ for the unique $i < k$ such that $\pi \in B_i$. Recall that for every $j < d$, $S_j(N) = \text{roots}(X_j)$. We define a finite coloring $g$ on $\bigcup_n X_0(n) \times \cdots \times X_{d-1}(n)$ by

$$g(\sigma_0, \ldots, \sigma_{d-1}) = B(\sigma_0, \ldots, \sigma_{d-1}).$$
By Theorem 3.6 applied to $g$, there is a $B_0 \oplus \cdots \oplus B_{k-1} \oplus X_0 \oplus \cdots \oplus X_{d-1}$-computable tuple of infinite strong subtrees $(Y_j, \rho : j < d, \rho \in S_j(N))$ of $(X_j \upharpoonright j < d, \rho \in S_j(N))$ with common level function, together with a coloring $h : S_0(N) \times \cdots \times S_{d-1}(N) \to k - 1$, such that

$$
\bigcup_n Y_{0, \rho_0}(n) \times \cdots \times Y_{d-1, \rho_{d-1}}(n) \subseteq B_h(\pi),
$$

for every $\pi = (\rho_0, \ldots, \rho_{d-1}) \in S_0(N) \times \cdots \times S_{d-1}(N)$.

By choice of $N$, there is some $\ell < N$, some $\pi = (\nu_0, \ldots, \nu_{d-1}) \in S_0(\ell) \times \cdots \times S_{d-1}(\ell)$ and some $(\ell + 1)$-dense matrix $M \subseteq S_0(N) \times \cdots \times S_{d-1}(N)$ on which $h$ is constant. Say $M = M_0 \times \cdots \times M_{d-1}$ and let $i < k$ be the color of $h$ on this matrix. For every $j < d$, let $P_j$ be the set of nodes in $S_j(N)$ which are not extensions of $v_j$. For every $j < k$, let $\hat{Y}_j = \bigcup_{\rho \in M_j} P_j Y_{j, \rho}$.

**Claim 3.27.** $(\text{stems}(\pi), \hat{Y}_0, \ldots, \hat{Y}_{d-1})$ is a $\mathbb{P}$-extension of $(\text{stems}(\pi), \text{sets}(\rho))$.

**Proof.** Let $(\hat{X}_0, \ldots, \hat{X}_{d-1}) = \text{sets}(\ell)$. Since $\ell < N$ and since $\text{sets}(N - 1) = (X_0, \ldots, X_{d-1})$, it follows by Claim 3.26 that the $X_j$ are strong subtrees of the $\hat{X}_j$ with common level function. Hence, so are the $Y_j$. Furthermore, by Property 1, for every $j < k$ we have that roots($\hat{X}_j$) = $S_j(\ell + 1)$. So every root of $\hat{X}_j$ is extended by a root of $\hat{Y}_j$.

It follows by Property 3 that $(\text{stems}(\pi), \hat{Y}_0, \ldots, \hat{Y}_{d-1}) \not\models \Phi_e^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C$ where $e = \text{req}(\pi)$. Now, since the forcing relation depends only on part of the reservoirs extending the roots of the stems, the following fact holds. However, we have the following contradictory fact:

**Claim 3.28.** $(\text{stems}(\pi), \hat{Y}_0, \ldots, \hat{Y}_{d-1}) \models \Phi_e^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C$, where $e = \text{req}(\pi)$.

**Proof.** For every $j < d$, let $H_j \subseteq \hat{Y}_j$ be such that $F_0 \cup H_0, \ldots, F_{d-1} \cup H_{d-1}$ are finite strong subtrees of $T_0, \ldots, T_{d-1}$, respectively, with common level function. Since the roots of the $F_j$ pointwise extend $\pi$, so do the nodes of each of the $H_j$. In particular, for every $j < d$, $H_j \subseteq \bigcup_{\rho \in M_j} Y_{j, \rho}$. It follows that $\bigcup_n H_0(n) \times \cdots \times H_{d-1}(n) \subseteq B_i$. But $B_0 \oplus \cdots \oplus B_{k-1} \in C$, so $\Phi_e^{F_0 \cup H_0 \oplus \cdots \oplus (F_{d-1} \cup H_{d-1}) \oplus Z}(x)$ either diverges or is different from $C(x)$. Since the $H_j$ were arbitrary, the claim is proved.

The contradiction completes Case 2.

**Case 3:** otherwise. Then $(x, y) \in W$ if and only if $y = C(x)$, which, since $W$ is $X_0 \oplus \cdots \oplus X_{d-1} \oplus Z$-c.e., implies $C \leq_T X_0 \oplus \cdots \oplus X_{d-1} \oplus Z$, a contradiction.

We are now ready to prove strong cone avoidance of the Halpern-Laüchli theorem.
3. THE HALPERN-LAUCHLI THEOREM

Proof of Theorem 3.21. Fix two sets $C$ and $Z$ such that $C \not\leq_T Z$. Also fix a tuple of infinite $Z$-computable $Z$-computably bounded trees with no leaves $T_0, \ldots, T_{d-1} \subseteq \omega^<\omega$ and an arbitrary $k$-partition $A_0 \sqcup \cdots \sqcup A_{k-1} = \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n)$. Let $\mathbb{P}$ be the set of cone avoiding level-homogeneous product tree conditions (relative to these given).

By Lemma 3.25, there is some $c \in \mathbb{P}$ below which, for every Turing functional $\Gamma$, the set

$$D_\Gamma = \{ c' \in \mathbb{P} : c' \models \Gamma^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C \}$$

is $\mathbb{P}$-dense. Let $\mathcal{U}$ be a $\mathbb{P}$-filter which intersects every set $D_\Gamma$. Then by definition of a product tree condition, $G_0^\mathcal{U}, \ldots, G_{d-1}^\mathcal{U}$ are strong subtrees of $T_0, \ldots, T_{d-1}$. Moreover, since all conditions in $\mathbb{P}$ are level-homogeneous, so are $G_0^\mathcal{U}, \ldots, G_{d-1}^\mathcal{U}$. Since $\mathcal{U}$ intersects every set $D_\Gamma$, then $C \not\leq_T G_0^\mathcal{U} \oplus \cdots \oplus G_{d-1}^\mathcal{U} \oplus Z$. Last, by Lemma 3.11, $G_0^\mathcal{U}, \ldots, G_{d-1}^\mathcal{U}$ are all infinite.

Let $f : \mathbb{N} \to k$ be the function which on level $\ell$ associates the color $i < k$ such that $G_0^\mathcal{U}(\ell) \times \cdots \times G_{d-1}^\mathcal{U}(\ell) \subseteq A_i$. By strong cone avoidance of $RT_k^1$, there is an infinite set of levels $H \subseteq \mathbb{N}$ on which $f$ is constant and $C \not\leq_T H \oplus G_0^\mathcal{U} \oplus \cdots \oplus G_{d-1}^\mathcal{U} \oplus Z$. Say $f$ takes the color $i < k$ on $H$. In particular, for every $\ell \in H$, $G_0^\mathcal{U}(\ell) \times \cdots \times G_{d-1}^\mathcal{U}(\ell) \subseteq A_i$, so we can $H \oplus G_0^\mathcal{U} \oplus \cdots \oplus G_{d-1}^\mathcal{U}$-computably thin out to infinite strong subtrees $S_0, \ldots, S_{d-1}$ of $G_0^\mathcal{U}, \ldots, G_{d-1}^\mathcal{U}$ with common level function, and such that $\bigcup_n S_0(n) \times \cdots \times S_{d-1}(n) \subseteq A_i$. In particular, $C \not\leq_T S_0 \oplus \cdots \oplus S_{d-1} \oplus Z$. This completes the proof of Theorem 3.21. $\square$
CHAPTER 4

Milliken’s tree theorem

We now turn to the computability-theoretic analysis of the product and non-product versions Milliken’s tree theorem, the base cases of which we already studied through the Halpern-Lauchli theorem in the previous chapter. As the product version obviously implies the non-product, we formulate our upper bounds in terms of the former and our lower bounds in terms of the latter. More specifically, we obtain the following. In Section 4.1, we provide an inductive proof of the product version of Milliken’s tree theorem in ACA₀, using the notion of prehomogeneous tree. Using standard methods, it is easy to obtain a reversal for (even the non-product version of) Milliken’s tree theorem for height at least 3. For height 1, we already saw in the previous chapter that the product version of Milliken’s tree theorem for height 1 is computably true, and hence does not imply ACA₀. This leaves the situation for trees of height 2, which we address in Section 4.2. Since Milliken’s tree theorem for height two implies Ramsey’s theorem for pairs, it is not computably true, but we show that the product version admits cone avoidance, and so is strictly weaker than ACA₀. Finally, in Section 4.4, we study a weakening of Milliken’s tree theorem that allows more than one color in the solutions. We prove that the product version of Milliken’s tree theorem for height 3, but where up to two colors are allowed in the solution, admits cone avoidance, and hence does not imply ACA₀. We will make use of this result in our discussion of Devlin’s theorem in Chapter 5.

4.1. A proof of PMT^n in ACA₀

Given a tree $F$ of height $\alpha \leq \omega$ and an a number $n < \alpha$, we write $F \upharpoonright n$ for the subtree of $F$ of height $n$.

Definition 4.1. Fix $n \in \mathbb{N}$, a collection of trees with no leaves $T_0, \ldots, T_{d-1}$ and a coloring $f : S_{n+1}(T_0, \ldots, T_{d-1}) \to k$.

1. A tuple $(S_0, \ldots, S_{d-1}) \in S_{\omega}(T_0, \ldots, T_{d-1})$ is prehomogeneous for $f$ if the color of every $(E_0, \ldots, E_{d-1}) \in S_{n+1}(S_0, \ldots, S_{d-1})$ depends only on $(E_0 \upharpoonright n, \ldots, E_{d-1} \upharpoonright n)$.

2. A product tree condition $(F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})$ is prehomogeneous for $f$ if the color of every

$(E_0, \ldots, E_{d-1}) \in S_{n+1}(F_0 \cup X_0, \ldots, F_{d-1} \cup X_{d-1})$

depends only on $(E_0 \upharpoonright n, \ldots, E_{d-1} \upharpoonright n)$ whenever $E_j \upharpoonright n \subseteq F_j$ for every $j < d$. 

43
In particular, note that the product tree condition \((\emptyset, \ldots, \emptyset, T_0, \ldots, T_{d-1})\) is prehomogeneous for a given \(f\) as above.

We add several other useful definitions.

**Definition 4.2.** Fix a collection of infinite trees with no leaves \(T_0, \ldots, T_{d-1}\). A product tree condition \(c = (F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})\) is computable if \(X_0, \ldots, X_{d-1}\) are all computable and computably bounded. An index of \(c\) is a finite tuple \((F_0, \ldots, F_{d-1}, e_0, \ldots, e_{d-1})\) such that \(\Phi_{e_j} = X_j\) for every \(j < d\).

**Definition 4.3.** If \(n \geq 1\) and \(T\) is a finite tree, then

\[
S_n^l(T) = \{ S \in S_n(T) : \text{leaves}(S) \subseteq \text{leaves}(T) \}. 
\]

More generally, if \(T_0, \ldots, T_{d-1}\) are finite trees, then

\[
S_n^l(T_0, \ldots, T_{d-1}) = \{ (S_0, \ldots, S_{d-1}) \in S_n(T_0, \ldots, T_{d-1}) : \forall i < d \}[S_i \in S_n^l(T_i)] \}. 
\]

The main combinatorial result of this section is the following density lemma.

**Lemma 4.4.** Fix \(n \in \mathbb{N}\), a collection of computable, computably bounded trees with no leaves \(T_0, \ldots, T_{d-1}\), and a computable coloring \(f : S_{n+1}(T_0, \ldots, T_{d-1}) \rightarrow k\). For every computable product tree condition \(c = (F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})\) which is prehomogeneous (for \(f\)), there is a computable prehomogeneous product tree condition \(\hat{c} = (\hat{F}_0, \ldots, \hat{F}_{d-1}, \hat{X}_0, \ldots, \hat{X}_{d-1})\) extending \(c\) such that \(F_j \subseteq \hat{F}_j\) for every \(j < d\). Moreover, an index of \(d\) can be found uniformly \(\emptyset''\)-computably from an index of \(c\).

**Proof.** By definition of a product tree condition (Definition 3.7), for every \(j < d\) and every leaf \(\sigma\) of \(F_j\), roots\((X_j)\) is \((t + 1)\)-\(\sigma\)-dense with respect to \(T_j\), where \(t\) is the level of the leaves of \(F_j\) within \(T_j\). For every \(j < k\), let \(\hat{F}_j\) be \(F_j\) augmented by the roots of \(X_j\) extending the leaves of \(F_j\). By Remark 3.9, we can assume that \((\hat{F}_0, \ldots, \hat{F}_{d-1}) \in S_{<\omega}(T_0, \ldots, T_{d-1})\). Let

\[
(E^0_0, \ldots, E^0_{d-1}), \ldots, (E^{p-1}_0, \ldots, E^{p-1}_{d-1}) 
\]

be the (finite) enumeration of all the tuples in \(S_n^l(\hat{F}_0, \ldots, \hat{F}_{d-1})\), meaning tuples of strong subtrees \((E_0, \ldots, E_{d-1})\) such that the leaves of \(E_j\) are among the leaves of \(\hat{F}_j\), i.e., belong to \(X_j(0)\).

We inductively define a finite sequence of \(d\)-tuples of computable forests

\[
(Y^0_0, \ldots, Y^0_{d-1}), \ldots, (Y^p_0, \ldots, Y^p_{d-1}) 
\]

such that for every \(s < p\):

1. \(Y^{s+1}_0, \ldots, Y^{s+1}_{d-1}\) are infinite strong subtrees of \(Y^s_0, \ldots, Y^s_{d-1}\), respectively, with common level function;
2. \((\hat{F}_0 \cup Y^0_0, \ldots, \hat{F}_{d-1} \cup Y^{s+1}_{d-1}) \in S_{\omega}(T_0, \ldots, T_{d-1})\);
3. there is some color \(i < k\) such that for every level \(\ell \in \mathbb{N}\), every \(j < d\), and every \(H_j \subseteq Y^{s+1}_j(\ell)\) for which \((E^s_0 \cup H_0, \ldots, E^s_{d-1} \cup H_{d-1}) \in S_{n+1}(T_0, \ldots, T_{d-1}), f(E^s_0 \cup H_0, \ldots, E^s_{d-1} \cup H_{d-1}) = i\).
Let $Y_0^{0}, \ldots, Y_{d-1}^{0}$ be $X_0, \ldots, X_{d-1}$, respectively, trimmed by their first levels. Assume $Y_0^{s}, \ldots, Y_{d-1}^{s}$ is defined for $s < p$. Let $m$ be the common level of the leaves of $\tilde{F}_0, \ldots, \tilde{F}_{d-1}$ in $T_0, \ldots, T_{d-1}$, respectively. For every $j < d$, let $R_j = \text{roots}(Y_j^{s})$, and for every $\rho \in R_j$, let $Y_j^{s, \rho} = Y_j^{s} \upharpoonright \rho$. We can see $Y_0^{s}, \ldots, Y_{d-1}^{s}$ as a tuple $(Y_j^{s, \rho} : j < d, \rho \in R_j)$ of trees.

Define a coloring $g$ of

\[
\bigcup_m \left( \prod_{\rho \in R_0} Y_{0, \rho}(m) \right) \times \cdots \times \left( \prod_{\rho \in R_{d-1}} Y_{d-1, \rho}(m) \right)
\]

as follows. For every $j < d$, let $U_j = \{ \rho \in R_j : (\exists \mu \in \text{leaves}(E_j^{s})) [\rho \geq \mu] \}$, and note that $(E_0^{s} \cup U_0, \ldots, E_{d-1}^{s} \cup U_{d-1}) \in \mathcal{S}_{n+1}(T_0, \ldots, T_{d-1})$. Now, given $\pi = \{ \sigma_{j, \rho} \in Y_{j, \rho} : j < d, \rho \in R_j \}$ in the domain of $g$, let

\[
G_j = E_j^{s} \cup \{ \sigma_{j, \rho} : \rho \in U_j \}.
\]

for each $j$. So $(G_0, \ldots, G_{d-1}) \in \mathcal{S}_{n+1}(T_0, \ldots, T_{d-1})$. Set $g(\pi) = f(G_0, \ldots, G_{d-1})$.

Since the Halpern-Lauchli theorem is computably true, there is a computable tuple $(Z_{j, \rho} : j < d, \rho \in R_j)$ of strong subtrees of $(Y_{j, \rho} : j < d, \rho \in R_j)$, respectively, with common level function, together with a color $i < k$ such that for every $\ell \in \mathbb{N}$, every $j < k$, if $H_j \subseteq \prod_{\rho \in R_j} Z_{j, \rho}(\ell)$ is such that $E_j^{s} \cup H_j \in \mathcal{S}_{n+1}(T_0, \ldots, T_{d-1})$ then $f(E_0^{s} \cup H_0, \ldots, E_{d-1}^{s} \cup H_{d-1}) = i$. For every $j < k$, let $Y_j^{s+1} = \bigcup_{\rho \in R_j} Z_{j, \rho}(\ell)$. This completes the construction of the sequence.

Let $\hat{c} = (\tilde{F}_0, \ldots, \tilde{F}_{d-1}, Y_0^{p}, \ldots, Y_{d-1}^{p})$. By items 1 and 2, $\hat{c}$ is a computable product tree condition extending $c$. Moreover, by item 3 and the fact that $c$ is prehomogeneous for $f$, so is $\hat{c}$.

One can $\emptyset^\prime$-computably search for a finite tuple $(E_0, \ldots, E_{d-1}, e_0, \ldots, e_{d-1})$ such that for every $j < d$, $\Phi_{e_j}$ is total, and $(E_0, \ldots, E_{d-1}, \Phi_{e_0}, \ldots, \Phi_{e_{d-1}})$ is a product tree condition extending $c$ and prehomogeneous for $f$. Indeed, being a strong subforest of $T_j$ is $\Pi^0_2$ since $T_j$ is computable and computably bounded. Thus, being a product tree condition is $\emptyset^\prime$-decidable. Moreover, being prehomogeneous is $\Pi^0_1$ since $f$ is computable, and being an extension of a product tree condition is also $\Pi^0_2$. Since we prove the existence of such an extension, an exhaustive search will always terminate, and the procedure is $\emptyset^\prime$-computable, uniformly in an index of $c$. This completes the proof of Lemma 4.4. \qed

**Lemma 4.5.** Fix $n \in \mathbb{N}$, a collection of computable, computably bounded trees with no leaves $T_0, \ldots, T_{d-1}$, and a computable coloring $f : \mathcal{S}_{n+1}(T_0, \ldots, T_{d-1}) \to k$. There is a $\Delta^0_n$ sequence $S_0, \ldots, S_{d-1}$ of strong subtrees of $T_0, \ldots, T_{d-1}$, respectively, with common level function, such that the tuple $(S_0, \ldots, S_{d-1})$ is prehomogeneous for $f$.\qed
4. MILLIKEN’S TREE THEOREM

PROOF. By iterating Lemma 4.4, build a $\Delta_3^0$ descending sequence of computable prehomogeneous product tree conditions $c_0 \geq c_1 \geq \ldots$ where

$$c_s = (F_0^s, \ldots, F_d^s, X_0^s, \ldots, X_d^s)$$

and such that $F_j^s \subseteq P_j^{s+1}$ for every $j < d$ and $s \in \mathbb{N}$. For every $j < d$, let $S_j = \bigcup_s F_j^s$. Since the $F_j^s$ are strictly increasing in $s$, it follows by definition of a product tree condition that $S_0, \ldots, S_{d-1}$ are strong subtrees of $T_0, \ldots, T_{d-1}$, respectively, with common level function. Moreover, $S_0, \ldots, S_{d-1}$ are $\Delta_3^0$, and by definition of a prehomogeneous condition, $(S_0, \ldots, S_{d-1})$ is prehomogeneous for $f$.

THEOREM 4.6. For every $n \geq 1$ and every set $X$, every $X$-computable instance of the product version of Milliken’s tree theorem for height $n$ admits a $\Delta_{2n-1}^0$ solution.

PROOF. By induction on $n$. For $n = 1$, the product version of Milliken’s tree theorem for height 1 is the Halpern-Lauchli theorem, which is computably true by Theorem 3.4.

Suppose the property holds for $n$, and fix a set $X$, and an $X$-computable sequence of $X$-computably bounded trees with no leaves $T_0, \ldots, T_{d-1} \subseteq \omega^{<\omega}$. Let $f : S_{n+1}(T_0, \ldots, T_{d-1}) \rightarrow k$ be an $X$-computable coloring. By Lemma 4.5, relativized to $X$, there is a $\Delta_3^{0,X}$ tuple $(S_0, \ldots, S_{d-1}) \in S_\omega(T_0, \ldots, T_{d-1})$ prehomogeneous for $f$. Let $g : S_n(S_0, \ldots, S_{d-1}) \rightarrow k$ be defined by $g(E_0, \ldots, E_{d-1}) = f(E_0 \cup H_0, \ldots, E_{d-1} \cup H_{d-1})$ for any $H_0 \subseteq S_0(n), \ldots, H_{d-1} \subseteq S_{d-1}(n)$ such that $(E_0 \cup H_0, \ldots, E_{d-1} \cup H_{d-1}) \in S_{n+1}(S_0, \ldots, S_{d-1})$. Such a coloring is well defined by prehomogeneity. The coloring $g$ can be seen as a $\Delta_{2n}^{0,X''}$ instance of the product version of Milliken’s tree theorem for height $n$. By induction hypothesis, there is a $\Delta_{2n-1}^{0,X''}$ (hence $\Delta_{2(n+1)-1}^{0,X}$) solution to $g$, which is by prehomogeneity also a solution to $f$. This completes the proof of Theorem 4.6.

COROLLARY 4.7. For every $n \geq 1$, the product version of Milliken’s tree theorem for height $n$ is provable in ACA$_0$, and the product version of Milliken’s tree theorem itself is provable in ACA’$_0$.

PROOF. The proof of Theorem 4.6 is formalizable in ACA$_0$. The induction on $n$ can then be carried out in ACA’$_0$.

THEOREM 4.8. Milliken’s tree theorem for height $n$ implies RT$^n$.

PROOF. Let $f : [\mathbb{N}]^n \rightarrow k$ be an instance of RT$^n$. Let $T = 1^{<\omega} = \{e, 00, 000, \ldots\}$ be the unary finitely branching tree with no leaves. Define $g : S_n(T) \rightarrow k$ by $g(\sigma_0, \ldots, \sigma_{n-1}) = f(|\sigma_0|, \ldots, |\sigma_{d-1}|)$. Now if $S$ is a strong subtree of $T$ such that $S_n(S)$ is monochromatic for $g$ then $H = \{|\sigma| : \sigma \in S\}$ is homogeneous for $f$.

COROLLARY 4.9. For every $n \geq 3$, PMTT$^n$ and MTT$^n$ are equivalent to ACA$_0$ over RCA$_0$. Moreover the product version of Milliken’s tree theorem and Milliken’s tree theorem are equivalent to ACA’$_0$.
4.2. CONE AVOIDANCE OF PMTT²

Proof. For every $n \geq 3$, by Corollary 4.7, ACA₀ implies PMTTⁿ, which generalizes MTTⁿ. By Theorem 4.8, MTTⁿ implies RTⁿ, and by formalization of a result of Jockusch [22, Theorem 5.7] (as formalized e.g. in [40], Lemma III.7.5), RTⁿ implies ACA₀. Moreover, by Corollary 4.7, ACA₀ implies $(\forall n)\text{PMTT}^n$ which generalizes $(\forall n)\text{MTT}^n$. By Theorem 4.8, $(\forall n)\text{MTT}^n$ implies $(\forall n)\text{RT}^n$, which is itself known to imply ACA₀ (see Hirschfeldt [19], Theorem 6.27, for a proof). □

4.2. Cone avoidance of PMTT²

This section is devoted to the proof of cone avoidance of the product version of Milliken’s tree theorem for height 2. As in the proof of cone avoidance for Ramsey’s theorem for pairs (see Cholak, Jockusch and Slaman [3], Sections 3 and 4) the proof of Theorem 4.15 will be decomposed into two steps, using the notion of stability.

Definition 4.10. Fix $n \geq 1$ and a collection of trees with no leaves $T₀, \ldots, T_{d-1}$. A coloring $f : S_{n+1}(T₀, \ldots, T_{d-1}) \to k$ is stable if for every $(F₀, \ldots, F_{d-1}) \in S_n(T₀, \ldots, T_{d-1})$, there is a threshold $t \in \mathbb{N}$ and a color $i < k$ such that for every level $t \geq t$ and all $E₀ \subseteq T₀(\ell), \ldots, E_{d-1} \subseteq T_{d-1}(\ell)$ for which $(F₀ \cup E₀, \ldots, F_{d-1} \cup E_{d-1}) \in S_{n+1}(T₀, \ldots, T_{d-1})$, $f(F₀ \cup E₀, \ldots, F_{d-1} \cup E_{d-1}) = i$.

We refer to the $i < k$ above as the limit color of the tuple $(F₀, \ldots, F_{d-1})$. Any stable coloring $f : S_{n+1}(T₀, \ldots, T_{d-1}) \to k$ induces a coloring

$$g : S_n(T₀, \ldots, T_{d-1}) \to k$$

which to $(F₀, \ldots, F_{d-1}) \in S_n(T₀, \ldots, T_{d-1})$ associates its limit color $i < k$. We shall call $g$ the limit coloring of $f$. Note that $g$ is $\Delta^0₂$ in $f$ and the sequence $T₀, \ldots, T_{d-1}$. The notion of stability is therefore as bridge between computable instances of PMTTⁿ⁺¹ and arbitrary instances of PMTTⁿ. This gives rise to a two step proof of cone avoidance of PMTT².

The first step consists of proving that for every instance of the product version of Milliken’s tree theorem for height 2 there exist cone avoiding strong subtrees on which the coloring is stable. We will actually prove a more general theorem for products of trees, and subtrees of arbitrary height.

The second step consists of applying strong cone avoidance of the product version of Milliken’s tree theorem for height 1, which is just a particular case of the Halpern-Lauchli theorem, and then computably thinning out the result to obtain a solution to the original instance of the product version of Milliken’s tree theorem of height 2.

We begin with the first step.

Theorem 4.11. Fix sets $C, Z \subseteq \mathbb{N}$ with $C \not\leq^T Z$, an $n \geq 1$, a $Z$-computable collection of $Z$-computably bounded trees with no leaves $T₀, \ldots, T_{d-1}$, and a coloring $f : S_{n+1}(T₀, \ldots, T_{d-1}) \to k$. There exists $(S₀, \ldots, S_{d-1}) \in S_n(T₀, \ldots, T_{d-1})$ such that $f$ is stable on $S_{n+1}(S₀, \ldots, S_{d-1})$ and such that $C \not\leq^T S₀ \oplus \cdots \oplus S_{d-1} \oplus Z$. 
The proof of Theorem 4.11 will employ a refinement of the forcing with product tree conditions. We will require some definitions and preliminary lemmas.

**Definition 4.12.** Fix sets $C, Z \subseteq \mathbb{N}$ with $C \not\subseteq_{T} Z$, an $n \geq 1$, a $Z$-computable collection of $Z$-computably bounded trees with no leaves $T_0, \ldots, T_{d-1}$, and a coloring $f : S_{n+1}(T_0, \ldots, T_{d-1}) \rightarrow k$. Let $c = (F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})$ be a product tree condition (with respect to the $T_i$).

1. $c$ is **cone avoiding** if $C \not\subseteq_{T} X_0 \oplus \cdots \oplus X_{d-1} \oplus Z$.
2. $c$ is **stable** for $f$ if for every tuple $(E_0, \ldots, E_{d-1}) \in S_n(F_0, \ldots, F_{d-1})$, there is a color $i < k$ such that for every level $\ell \in \mathbb{N}$ and every $H_0 \subseteq X_0(\ell), \ldots, H_{d-1} \subseteq X_{d-1}(\ell)$ for which $(E_0 \cup H_0, \ldots, E_{d-1} \cup H_{d-1}) \in S_{n+1}(T_0, \ldots, T_{d-1})$, $f(E_0 \cup H_0, \ldots, E_{d-1} \cup H_{d-1}) = i$.

Making progress in satisfying the cone avoidance requirements will demand the use of a computable function dominating the levels of a tuple of strong subtrees with certain nice combinatorial properties.

For now, we will take for granted the following technical result, which is a finite version of Milliken’s tree theorem where all subtrees are assumed to keep the leaves and the level function is bounded. For a given tree $T$, recall the notation $S^l_n(T)$ from Definition 4.3 which denotes the collection of strong subtrees of $T$ of height $n$ whose leaves are among those of $T$.

**Theorem 4.13.** Fix a level $\ell \in \mathbb{N}$, a height $n \geq 1$, a number of colors $k \in \mathbb{N}$, an arity $d \geq 1$, and a function $b : \omega \rightarrow \omega$. There exists a function $N \mapsto H(N, \ell, n+1, k, d, b)$, uniformly $b$-computable in $\ell, n, k, d$, and $d$, as follows. If $U_0, \ldots, U_{d-1}$ is a sequence of finite $b$-bounded trees of height $h = H(N, \ell, n+1, k, d, b)$ for some fixed $N \in \mathbb{N}$, and

$$\chi : S^l_{n+1}(U_0, \ldots, U_{d-1}) \rightarrow k$$

is any coloring where $\chi(F_0, \ldots, F_{d-1})$ depends only on $(F_0 \restriction n, \ldots, F_{d-1} \restriction n)$ whenever $F_i \restriction n \subseteq U_i \restriction \ell$ for every $i$, then there exists $(V_0, \ldots, V_{d-1}) \in S^l_{\ell+1+N}(U_0, \ldots, U_{d-1})$ such that:

1. $V_i \restriction \ell = U_i \restriction \ell$ for each $i < d$;
2. for any $i < d$, the level function of $V_i$ as a subset of $U_i$ is bounded by the function defined by $x \mapsto H(x, \ell, n+1, k, d, b)$ if $x \leq \ell$, and $x \mapsto x$ if $x > \ell$;
3. the color of $(F_0, \ldots, F_{d-1}) \in S^l_{n+1}(V_0, \ldots, V_{d-1})$ depends only on $(F_0 \restriction n, \ldots, F_{d-1} \restriction n) \in S_n(V_0, \ldots, V_{d-1})$.

To help understand the statement of Theorem 4.13, suppose $S_0, \ldots, S_{d-1}$ are infinite, computable, and computably bounded trees with no leaves. Also fix a coloring $g : S_{n+1}(S_0, \ldots, S_{d-1}) \rightarrow k$. Consider a product tree condition $(E_0, \ldots, E_{d-1}, X_0, \ldots, X_{d-1})$ for these $S_i$ which is stable for $g$. Say the $E_i$ are of height $\ell$. One would like to extend the stems with $N$ new levels in one step, so that the resulting stems are of height $\ell + N$, while keeping the resulting product tree condition stable for $g$. Theorem 4.13 provides a sufficient bound
\[ h = H(N, \ell, n+1, k, d, b) \]

depending on the number \( N \) of new levels we would like to add, on the height \( \ell \) of the stems, the parameters \( n+1 \) and \( k \) of the coloring \( g \), on the number \( d \) of trees in the product tree condition, and on the computable bound \( b \) over the trees \( E_0 \cup X_0, \ldots, E_{d-1} \cup X_{d-1} \), so that one can always find such an extension of the stems where the new elements are taken among the first \( h \) first levels of \( E_0 \cup X_0, \ldots, E_{d-1} \cup X_{d-1} \).

In the statement of Theorem 4.13, the finite trees \( U_0, \ldots, U_{d-1} \) correspond to the trees \( E_0 \cup X_0, \ldots, E_{d-1} \cup X_{d-1} \) up to level \( h \), respectively. Let \( Y_0, \ldots, Y_{d-1} \) be the forests obtained from the trees \( E_0 \cup X_0, \ldots, E_{d-1} \cup X_{d-1} \) by removing their first \( h - 1 \) many levels. For each \( j < d \), the tree \( U_j \) therefore has three parts. First, we have the first \( \ell \) levels, which correspond to the stem \( E_j \). Second, we have the levels up to the one before the leaves, which will serve to extend the stem \( E_j \). Very few of these levels will be kept, but \( h \) is chosen large enough so that we can always extend with \( N \) new levels. Last, the leaves of \( U_j \) correspond to the roots of the forest \( Y_j \).

Fixing strong subtrees \( (F_0, \ldots, F_{d-1}) \in \mathcal{S}_{n+1} \) of height \( n+1 \) should actually be understood as fixing strong subtrees \( (F_0 \upharpoonright n, \ldots, F_{d-1} \upharpoonright n) \) of height \( n \) from the trees \( U_0, \ldots, U_{d-1} \) trimmed from their leaves, and then picking a set of roots from \( Y_0, \ldots, Y_{d-1} \) (or equivalently picking a set of leaves from \( U_0, \ldots, U_{d-1} \)). This induces a product coloring of the nodes in \( Y_0, Y_1, \ldots, Y_d \) pointwise extending the product of the roots chosen, by considering which color the function \( g \) assigns to the strong subtrees \( (F_0 \upharpoonright n, \ldots, F_{d-1} \upharpoonright n) \) augmented by these nodes. Multiple applications of the Halpern-Lauchli theorem yield subforests \( Z_0, \ldots, Z_{d-1} \) of \( Y_0, \ldots, Y_{d-1} \) with the same set of roots such that the induced coloring has a limit color on products of nodes from the \( Z_i \). This limit color therefore depends only on the choice of element from \( \mathcal{S}_{n+1}(U_0, \ldots, U_{d-1}) \). This is how we define the limit function \( \chi : \mathcal{S}_{n+1}(U_0, \ldots, U_{d-1}) \).

The proof of Theorem 4.13 requires some rather heavy combinatorial development, and so we postpone it to the next section. Instead, we first show how to use the theorem to obtain Theorem 4.11.

**Lemma 4.14.** Fix sets \( C, Z \subset \mathbb{N} \) with \( C \notin** T Z \), an \( n \geq 1 \), a \( Z \)-computable collection of \( Z \)-computably bounded trees with no leaves \( T_0, \ldots, T_{d-1} \), and a coloring \( f : \mathcal{S}_n(T_0, \ldots, T_{d-1}) \rightarrow k \). Let \( \mathcal{P} \) be the partial order of all stable cone avoiding product tree conditions (with respect to the given). For every \( \mathcal{P} \)-condition \( c \) and every Turing functional \( \Gamma \), there is a \( \mathcal{P} \)-condition \( c' \) extending \( c \) such that \( c' \parallel \Gamma^G \).
that for every $j < d$, every root of $X_j$ is extended by a root of $Y_j$, there is some $d$-tuple $H_0 \subseteq Y_0, \ldots, H_{d-1} \subseteq Y_{d-1}$ with $(F_0 \cup H_0, \ldots, F_{d-1} \cup H_{d-1}) \in S_{<\omega}(T_0, \ldots, T_{d-1})$ and

$$\Gamma(F_0 \cup H_0) \oplus \cdots \oplus (F_{d-1} \cup H_{d-1}) \oplus Z(x) \downarrow v.$$  

By compactness, the set $W$ is $X_0 \oplus \cdots \oplus X_{d-1} \oplus Z$-$c.e$. We have three cases.

**Case 1:** $(x, 1 - C(x)) \in W$ for some $x \in \mathbb{N}$. By compactness, there is some height $N_0 \in \mathbb{N}$ such that the property holds for every $d$-tuple of strong subtrees of $X_0, \ldots, X_{d-1}$, respectively, of height $N_0$ with common level function dominated by $N \mapsto H(N, \ell, n + 1, k, d, b)$. Let $U_0, \ldots, U_{d-1}$ be the finite trees obtained by restricting $F_0 \cup X_0, \ldots, F_{d-1} \cup X_{d-1}$, respectively, to their first $H(N_0, \ell, n + 1, k, d, b)$ many levels. In particular, $U_0, \ldots, U_{d-1}$ are $b$-bounded trees of height $H(N_0, \ell, n + 1, k, d, b)$.

Fixing a tuple $(E_0, \ldots, E_{d-1}) \in S_{n+1}^d(U_0, \ldots, U_{d-1})$, the coloring $f$ induces a function

$$g : \bigcup_{m} \prod_{j < d, \rho \in \text{leaves}(E_j)} (X_j \upharpoonright \rho)(m) \rightarrow k$$

define for all tuples $\pi = (\sigma^\rho_j \in (X_j \upharpoonright \rho)(m) : j < d, \rho \in \text{leaves}(E_j))$ by

$$g(\pi) = f\{(E_j \upharpoonright n) \cup \{\sigma^\rho_j \rho \in \text{leaves}(E_j): j < d\}\}.$$  

Thus, by iteratively applying strong cone avoidance of the Halpern-Laüchli theorem (Theorem 3.21), there exists a $d$-tuple of strong subtrees $Y_0, \ldots, Y_{d-1}$ of $X_0, \ldots, X_{d-1}$, respectively, with common level function, such that:

(a) for every $j < d$, every leaf of $U_j$ is extended by exactly one root of $Y_j$;

(b) for every $(E_0, \ldots, E_{d-1}) \in S_{n+1}^d(U_0, \ldots, U_{d-1})$, there is a color $i < k$ such that for every $(\sigma^\rho_j : j < d, \rho \in \text{leaves}(E_j)) \in \bigcup_{m} \prod_{\rho \in \text{leaves}(E_j)} (X_j \upharpoonright \rho)(m)$, $f\{(E_j \upharpoonright n) \cup \{\sigma^\rho_j \rho \in \text{leaves}(E_j): j < d\}\} = i$;

(c) $C \not\leq_T Y_0 \oplus \cdots \oplus Y_{d-1} \oplus Z$.

Item (b) induces a coloring $\chi : S_{n+1}^d(U_0, \ldots, U_{d-1}) \rightarrow k$ which to $(E_0, \ldots, E_{d-1})$ associates the unique color $i < k$ as specified there. By Theorem 4.13, there are finite strong subtrees $V_0, \ldots, V_{d-1}$ of $U_0, \ldots, U_{d-1}$, respectively, of height $N_0 + \ell$ with common level function, such that for every $j < d$, $V_j \upharpoonright \ell = F_j$, the level function of $V_j$ is bounded by $N \mapsto H(N, \ell, n + 1, k, d, b)$ if $N > \ell$, and the color of $(E_0, \ldots, E_{d-1}) \in S_{n+1}^d(V_0, \ldots, V_{d-1})$ with respect to $\chi$ depends only on $(E_0 \upharpoonright n, \ldots, E_{d-1} \upharpoonright n)$. By choice of $N_0$, there are some $H_0 \subseteq V_0, \ldots, H_{d-1} \subseteq V_{d-1}$ such that $F_0 \cup H_0, \ldots, F_{d-1} \cup H_{d-1}$ are finite strong subtrees of $T_0, \ldots, T_{d-1}$, respectively, with common level function, and such that

$$\Gamma(F_0 \cup H_0) \oplus \cdots \oplus (F_{d-1} \cup H_{d-1}) \oplus Z(x) \downarrow v.$$
4.2. Cone Avoidance of PMTT$^2$

The tuple $c' = (F_0 \cup H_0, \ldots, F_{d-1} \cup H_{d-1}, Y_0, \ldots, Y_{d-1})$ is therefore a cone avoiding stable product tree condition extending $c$ that satisfies

$$c' \models \Gamma^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C.$$  

**Case 2**: $(x, C(x)) \notin W$ for some $x \in \mathbb{N}$. Let $\mathcal{C}$ be the class of all strong subforests $Y_0, \ldots, Y_{d-1}$ of $X_0, \ldots, X_{d-1}$, respectively, with common level function dominated by $N \mapsto H(N, \ell, n + 1, k, d, b)$ such that for every $j < d$, every root of $X_j$ is extended in a root of $Y_j$, and for every $d$-tuple $H_0 \subseteq Y_0, \ldots, H_{d-1} \subseteq Y_{d-1}$ for which $F_0 \cup H_0, \ldots, F_{d-1} \cup H_{d-1}$ are finite strong subtrees of $T_0, \ldots, T_{d-1}$, respectively, again with common level function, we have

$$\Gamma^{(F_0 \cup H_0) \oplus \cdots \oplus (F_{d-1} \cup H_{d-1}) \oplus Z}(x) \uparrow \quad \text{or} \quad \Gamma^{(F_0 \cup H_0) \oplus \cdots \oplus (F_{d-1} \cup H_{d-1}) \oplus Z}(x) \downarrow \neq n.$$

Since the trees $T_0, \ldots, T_{d-1}$ are $Z$-computably bounded and the level function of $Y_0, \ldots, Y_{d-1}$ is dominated by the $Z$-computable function $H$, it follows that $\mathcal{C}$ is a $\Pi^0_\infty$ class relative to $X_0 \oplus \cdots \oplus X_{d-1} \oplus Z$. Moreover, by assumption, $\mathcal{C}$ is non-empty.

By the cone avoidance basis theorem, there is some $(Y_0, \ldots, Y_{d-1}) \in \mathcal{C}$ such that $C \not \leq_T Y_0 \oplus \cdots \oplus Y_{d-1} \oplus Z$. The tuple $c' = (F_0, \ldots, F_{d-1}, Y_0, \ldots, Y_{d-1})$ is then a $\mathbb{P}$-condition extending $c$ such that

$$c' \not \models \Gamma^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C.$$  

**Case 3**: otherwise. Then we have that $(x, y) \in W$ if and only if $C(x) = y$, so $C \leq_T X_0 \oplus \cdots \oplus X_{d-1} \oplus Z$. 

**Proof of Theorem 4.11.** Fix two sets $C$ and $Z$ such that $C \not \leq_T Z$. Also fix a $Z$-computable collection of $Z$-computably bounded trees with no leaves $T_0, \ldots, T_{d-1} \subseteq \omega^{<\omega}$. Let $n \geq 1$ and $f : S_n(1)(T_0, \ldots, T_{d-1}) \to k$ be a coloring. Let $\mathbb{P}$ be the partial order of all cone avoiding product tree conditions which are stable for $f$, and let $\mathcal{U}$ be a sufficiently generic $\mathbb{P}$-filter. Let $G_0^d, \ldots, G_{d-1}^d$ be the strong subtrees of $T_0, \ldots, T_{d-1}$ induced by $\mathcal{U}$. By Lemma 4.14, for every Turing functional $\Gamma$, there is some $\mathbb{P}$-condition $c \in \mathcal{U}$ such that $c \models \Gamma^{G_0^d \oplus \cdots \oplus G_{d-1}^d \oplus Z} \neq C$. Hence, $C \not \leq_T G_0^d \oplus \cdots \oplus G_{d-1}^d \oplus Z$. Moreover, by Lemma 3.11, $G_0^d, \ldots, G_{d-1}^d$ are all infinite. And finally, since $\mathcal{U}$ contains only stable conditions, $f$ is stable on $S_n(G_0, \ldots, G_{d-1})$. This completes the proof of Theorem 4.11.

We are ready to prove cone avoidance of PMTT$^2$.

**Theorem 4.15.** The product version of Milliken’s tree theorem for height 2 admits cone avoidance.

**Proof.** Fix two sets $C$ and $Z$ such that $C \not \leq_T Z$. Also fix a $Z$-computable collection of $Z$-computably bounded trees with no leaves $T_0, \ldots, T_{d-1} \subseteq \omega^{<\omega}$ and a $Z$-computable coloring $f : S_2(T_0, \ldots, T_{d-1}) \to k$.

By Theorem 4.11, there are strong subtrees $S_0, \ldots, S_{d-1}$ of $T_0, \ldots, T_{d-1}$, respectively, with common level function, such that $f$ is stable on $S_2(S_0, \ldots, S_{d-1})$. 

and such that $C \not\leq_T S_0 \oplus \cdots \oplus S_{d-1} \oplus Z$. By stability, the coloring $f$ induces a $k$-partition $A_0 \sqcup \cdots \sqcup A_{k-1} = \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n)$ by letting $A_i$ be the set of tuples $(\sigma_0, \ldots, \sigma_{d-1}) \in \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n)$ such that for all but finitely many levels $\ell \in \mathbb{N}$, whenever $(\{\sigma_0\} \cup H_0, \ldots, \{\sigma_{d-1}\} \cup H_{d-1}) \in S_0(S_0, \ldots, S_{d-1})$ then $f(\{\sigma_0\} \cup H_0, \ldots, \{\sigma_{d-1}\} \cup H_{d-1}) = i$.

By Theorem 3.21, there is some color $i < k$ and some strong subtrees $U_0, \ldots, U_{d-1}$ of $S_0, \ldots, S_{d-1}$, respectively, with common level function, such that $\bigcup_n U_0(n) \times \cdots \times U_{d-1}(n) \subseteq A_i$ and $C \not\leq_T U_0 \oplus \cdots \oplus U_{d-1} \oplus Z$. By $U_0 \oplus \cdots \oplus U_{d-1} \oplus Z$-computably thinning out the set of levels, we can obtain a tuple of strong subtrees $V_0, \ldots, V_{d-1}$ of $U_0, \ldots, U_{d-1}$, respectively, with common level function, such that $S_2(V_0, \ldots, V_{d-1})$ is monochromatic for color $j$ with respect to $f$. In particular, by transitivity of the strong subtree relation, $V_0, \ldots, V_{d-1}$ are strong subtrees of $T_0, \ldots, T_{d-1}$ with common level function, and $C \not\leq_T V_0 \oplus \cdots \oplus V_{d-1} \oplus Z$. This completes the proof.

**Corollary 4.16.** $\text{RCA}_0 \land \text{PMTT}^2 \not\vdash \text{ACA}_0$.

**Proof.** Immediate by Theorem 4.15 and Lemma 2.15. 

### 4.3. Proof of Theorem 4.13

We now prove the main technical result used in the preceding section. We shall restate it in full below for convenience. First, we have the following lemma.

**Lemma 4.17** (Finitary Halpern-Laüchli theorem for leaves). Fix a number of colors $k \in \mathbb{N}$, an arity $d \geq 1$, and a function $b : \omega \to \omega$. There exists a function $N \mapsto h_{\text{HL}}(N, k, d, b)$, uniformly $b$-computable in $k$ and $d$ as follows. If $U_0, \ldots, U_{d-1}$ is a sequence of finite $b$-bounded trees of height $h = h_{\text{HL}}(N, k, d, b)$ for some fixed $N \geq 1$, and

$$g : U_0(h - 1) \times \cdots \times U_{d-1}(h - 1) \to k$$

is any coloring of the $d$-tuples of leaves from this sequence, then there exists $(V_0, \ldots, V_{d-1}) \in S_N'(U_0, \ldots, U_{d-1})$, such that $g$ is constant on the product of the leaves

$$V_0(N - 1) \times \cdots \times V_{d-1}(N - 1).$$

**Proof.** Let $C$ be the space of all functions

$$f : \bigcup_n T_0(n) \times \cdots \times T_{d-1}(n) \to k$$

where $T_0, \ldots, T_{d-1}$ are $b$-bounded trees. By compactness of $C$, the Halpern-Laüchli theorem (Theorem 2.28) yields the existence of a function $h_{\text{HL}}(\cdot, k, d, b) : \mathbb{N} \to \mathbb{N}$ such that for any $N$, any collections of $b$-bounded trees $T_0, \ldots, T_{d-1}$ of height $h_{\text{HL}}(N, k, d, b)$, and any $f : \bigcup_{n < h_{\text{HL}}(N, k, d, b)} T_0(n) \times \cdots \times T_{d-1}(n) \to k$, there exists $(S_0, \ldots, S_{d-1}) \in S_N(T_0, \ldots, T_{d-1})$ such that $f$ is constant on $\bigcup_{n < N} S_0(n) \times \cdots \times S_{d-1}(n)$. 

Now, consider the given trees $U_0, \ldots, U_{d-1}$ of height $h = h_{\text{HL}}(N, k, d, b)$, and the given coloring $g$. Define

$$f : \bigcup_{n<h} U_0(n) \times \cdots \times U_{d-1}(n) \to k$$

by $f(\sigma_0, \ldots, \sigma_{d-1}) = g(l_{\sigma_0}, \ldots, l_{\sigma_{d-1}})$, where $l_{\sigma}$ for each $\sigma \in U_i$ denotes a choice of leaf extending $\sigma$.

By the property of $h_{\text{HL}}$, let $S_0, \ldots, S_{d-1}$ be strong subtrees of $T_0, \ldots, T_{d-1}$ of height $N$ and with a common level function such that $f$ is constant on $\bigcup_{n<N} S_0(n) \times \cdots \times S_{d-1}(n)$. For $i < d$, set

$$V_i = \bigcup_{n<N-1} S_i(n) \cup \{l_\sigma : \sigma \in S_i(N-1)\}$$

Thus, $(V_0, \ldots, V_{d-1}) \in \mathcal{S}_N^l(U_0, \ldots, U_{d-1})$, and as $f$ is constant on $S_0(N-1) \times \cdots \times S_{d-1}(N-1)$ it follows that $g$ is constant on $V_0(N-1) \times \cdots \times V_{d-1}(N-1)$. (Note that by definition of the $V_i$ and the $l_{\sigma}$, $V_0(N-1) \times \cdots \times V_{d-1}(N-1)$ is a subset of $T_0(h-1) \times \cdots \times T_{d-1}(h-1)$, the domain of $g$.)

We are now ready to prove Theorem 4.13 stated earlier. Recall that it is a finitary version of Milliken’s tree theorem for $\mathcal{S}_{n+1}^l(\cdot)$, meaning that we color strong subtrees of a certain height that also preserve the leaves. We recall the full statement.

**Theorem 4.13.** Fix a level $\ell \in \mathbb{N}$, a height $n \geq 1$, a number of colors $k \in \mathbb{N}$, an arity $d \geq 1$, and a function $b : \omega \to \omega$. There exists a function $N \mapsto H(N, \ell, n+1, k, d, b)$, uniformly $b$-computable in $\ell$, $n$, $k$, and $d$, as follows. If $U_0, \ldots, U_{d-1}$ is a sequence of finite $b$-bounded trees of height $h = H(N, \ell, n+1, k, d, b)$ for some fixed $N \in \mathbb{N}$, and

$$\chi : \mathcal{S}_{n+1}^l(U_0, \ldots, U_{d-1}) \to k$$

is any coloring where $\chi(F_0, \ldots, F_{d-1})$ depends only on $(F_0 \upharpoonright n, \ldots, F_{d-1} \upharpoonright n)$ whenever $F_i \upharpoonright n \subseteq U_i \upharpoonright \ell$ for every $i$, then there exists $(V_0, \ldots, V_{d-1}) \in \mathcal{S}_{n+1}^l(U_0, \ldots, U_{d-1})$ such that:

1. $V_i \upharpoonright \ell = U_i \upharpoonright \ell$ for each $i < d$;
2. for any $i < d$, the level function of $V_i$ as a subset of $U_i$ is bounded by the function defined by $x \mapsto H(x, \ell, n+1, k, d, b)$ if $x > \ell$, and $x \mapsto x$ if $x \leq \ell$;
3. the color of $(F_0, \ldots, F_{d-1}) \in \mathcal{S}_{n+1}^l(U_0, \ldots, U_{d-1})$ depends only on $(F_0 \upharpoonright n, \ldots, F_{d-1} \upharpoonright n) \in \mathcal{S}_n(U_0, \ldots, U_{d-1})$.

We begin by giving the definition of the function $H$.

**Definition 4.18.** Fix a level $\ell \in \mathbb{N}$, a height $n \geq 1$, a number of colors $k \in \mathbb{N}$, an arity $d \geq 1$, and a function $b : \omega \to \omega$. Define a function $N \mapsto H(N, \ell, n, k, d, b)$ inductively as follows:

1. $H(0, \ell, n, k, d, b) = 0$;
(2) if \( \hat{H}(N - 1, \ell, n, k, d, b) = H_{N-1} \) is defined, then
\[
\hat{H}(N, \ell, n, k, b) = \hat{H}(N - 1, \ell, n, k, d, b) + h_{HL}(2, K, D, B),
\]
where
- \( K \) is the cardinality of the set of all \( k \)-valued functions defined on
\[
\mathcal{P}(U_0 \upharpoonright H_N) \times \cdots \times \mathcal{P}(U_{d-1} \upharpoonright H_N) \times \mathcal{P}(U_0(H_N)) \times \cdots \times \mathcal{P}(U_{d-1}(H_N))
\]
for some \( b \)-bounded trees \( T_0, \ldots, T_{d-1} \);
- \( D = d \times \prod_{i < \ell} b(i) \prod_{i < H_{N-1}} b(\ell + i) \);
- \( B \) is the function \( n \mapsto b(n + H_{N-1}) \).

Define \( H \) by
\[
H(N, \ell, n, k, d, b) = \ell + \hat{H}(N, \ell, n, k, d, b).
\]

Note that \( D \) corresponds to a bound on the number of leaves of \( d \) many \( b \)-bounded trees of height \( \ell + H_{N-1} \), and that \( B \) is a bounding function for subtrees of a \( b \)-bounded tree that contains all the levels starting from \( H_{N-1} \). Figure 4.1 helps shed light on some of the parameters given to \( h_{HL} \) in the definition of \( H \).

**Proof of Theorem 4.13.** We proceed by induction on \( N \), starting with \( N = 0 \). The base case holds by taking any \((V_0, \ldots, V_{d-1}) \in S^l_{\ell+1}(U_0, \ldots, U_{d-1})\) with \( V_i \upharpoonright \ell = U_i \upharpoonright \ell \) for all \( i < d \). These trees satisfy Items 1 and 2 by construction. Moreover, by assumption on \( \chi \), they also satisfy Item 3.

Now, suppose the result is true for some \( N \geq 0 \). To simplify notation, define \( H_N = H(N, \ell, n + 1, k, d, b) \) and \( H_{N+1} = H(N + 1, \ell, n + 1, k, d, b) \). The construction of the solution \( V_0, \ldots, V_{d-1} \) is divided into three steps, summarized as follows.

1. We apply Lemma 4.17 to the collection of trees \( U_i^\sigma = U_i \upharpoonright \sigma \) for \( \sigma \in U_i(H_N) \) and a certain coloring with a large number of colors. This will yield strong subtrees \( V_i^\sigma \) of \( U_i^\sigma \) of height 2 with a common level function. In turn, these will induce a coloring of \( S^l_{n+1}(U_0 \upharpoonright H_N, \ldots, U_{d-1} \upharpoonright H_N) \).

2. We apply the inductive hypothesis to \( U_0 \upharpoonright H_N, \ldots, U_{d-1} \upharpoonright H_N \) and the induced coloring, obtaining strong subtrees \( \dot{V}_0, \ldots, \dot{V}_{d-1} \).

3. For each \( i < d \), we replace the leaves of \( \dot{V}_i \) by \( V_i^\sigma \) to get \( V_i \).

We now give the details of each step of the construction.

**Construction.**

**Step 1.** We define a coloring
\[
g : \prod_{i < d} \prod_{\sigma \in U_i(H_N)} \text{leaves}(U_i^\sigma) \to K,
\]
where \( K \) is the finite set of all functions
\[
\zeta : \mathcal{P}(U_0 \upharpoonright H_N) \times \cdots \times \mathcal{P}(U_{d-1} \upharpoonright H_N) \times \mathcal{P}(U_0(H_N)) \times \cdots \times \mathcal{P}(U_{d-1}(H_N)) \to k.
\]
Let $\pi$ be an element of the domain of $g$, meaning a tuple $((\tau_i^\sigma)_{\sigma \in U_i(H_N)})_{i < d}$ consisting of one leaf $\tau_i^\sigma$ from each tree $U_i^\sigma$. Then $g(\pi)$ is the function $\zeta$ defined as follows. Given $F_i \subseteq U_i \mid H_N$ and $G_i \subseteq U_i(H_N)$ for each $i < d$,

$$
\zeta(F_0, \ldots, F_{d-1}, G_0, \ldots, G_{d-1}) = \chi((F_i \cup \{\tau_i^\sigma : \sigma \in G_i\})_{i < d})
$$

if $(F_i \cup \{\tau_i^\sigma : \sigma \in G_i\})_{i < d} \in \mathcal{S}_{n+1}(U_0, \ldots, U_{d-1})$, and

$$
\zeta(F_0, \ldots, F_{d-1}, G_0, \ldots, G_{d-1}) = 0
$$

otherwise. So in particular, $g(\pi)$ records the values of $\chi$ on all strong subtrees of height $n + 1$ that have leaves in $\pi$ and all other nodes below level $H_N$ in $U_0, \ldots, U_{d-1}$.

By Lemma 4.17 applied to the collection of $U_i^\sigma$ with the coloring $g$, using the fact that the height, $H_{N+1} - H_N$, of the trees is sufficiently large by definition of $H$, we obtain strong subtrees $V_i^\sigma$ of $U_i^\sigma$ of height 2 and with common level function such that $g$ is constant on the product of the leaves of the $V_i^\sigma$. Call the value assumed by $g$ on this product $\zeta_0 \in K$.

**Step 2.** The function $\zeta_0$ naturally induces a coloring

$$
\chi_N : \mathcal{S}_{n+1}(U_0 \mid H_N + 1, \ldots, U_{d-1} \mid H_N + 1) \rightarrow k
$$

as follows. Given $(F_0, \ldots, F_{d-1})$ in the domain of $\chi_N$, let

$$
\chi_N(F_0, \ldots, F_{d-1}) = \zeta_0(F_0 \mid n, \ldots, F_{d-1} \mid n, \text{leaves}(F_0), \ldots, \text{leaves}(F_{d-1})).
$$

Note that by choice of the $V_i^\sigma$, if $((\tau_i^\sigma)_{\sigma \in U_i(H_N)})_{i < d}$ is any tuple consisting of one leaf $\tau_i^\sigma$ from each tree $V_i^\sigma$, then $(F_i \mid n \cup \{\tau_i^\sigma : \sigma \in \text{leaves}(F_i)\})_{i < d} \in \mathcal{S}_{n+1}(U_0, \ldots, U_{d-1})$, so by definition we also have

$$
\chi_N(F_0, \ldots, F_{d-1}) = \chi((F_i \mid n \cup \{\tau_i^\sigma : \sigma \in \text{leaves}(F_i)\})_{i < d}).
$$

By assumption on $\chi$, it follows that if $F_i \mid \ell \subseteq (U_i \mid H_N + 1) \mid \ell = U_i \mid \ell$ for all $i < d$, then $\chi_N(F_0, \ldots, F_{d-1})$ depends only on $(F_0 \mid n, \ldots, F_{d-1} \mid n)$. We may thus apply the induction hypothesis to $\chi_N$ and the trees $U_0 \mid H_N + 1, \ldots, U_{d-1} \mid H_N + 1$ to obtain a tuple of strong subtrees $(V_0, \ldots, V_{d-1}) \in \mathcal{S}_{\ell+1}(U_0 \mid H_N + 1, \ldots, U_{d-1} \mid H_N + 1)$.

**Step 3.** Finally, we glue the trees $V_i$ to the trees $V_i^\sigma$ to finish the construction of the solution. More precisely, we let

$$
V_i = \hat{V}_i \setminus \text{leaves}(\hat{V}_i) \cup \bigcup_{\sigma \in \text{leaves}(\hat{V}_i)} V_i^\sigma.
$$

Note that the height of $V_i$ is $\ell + N + 2$, as desired. This completes the construction.

**Verification.** We now prove that the collection of $V_i$ is a solution. Item 1 is satisfied since it is satisfied by $\hat{V}_i$. This is because $V_i$ extends $\hat{V}_i \setminus \text{leaves}(\hat{V}_i)$, and the height of $\hat{V}_i$ is at least $\ell + 1$, so we have $V_i \mid \ell = (\hat{V}_i \setminus \text{leaves}(\hat{V}_i)) \mid \ell = \hat{V}_i \mid \ell = U_i \mid \ell$.

Item 2 is satisfied by construction.
4. MILLIKEN’S TREE THEOREM

It remains to verify Item 3. Suppose \((F_0, \ldots, F_{d-1}) \in \mathcal{S}_{n+1}^d(V_0, \ldots, V_{d-1})\). We consider two cases.

**Case 1:** \(F_i(n - 1) \subseteq V_i(\ell + N)\) for each \(i < d\). Since \(F_i \in \mathcal{S}_{n+1}^d(V_i)\) for each \(i < d\) and there is only one level in \(V_i\) above \(\ell + N\), the elements of \(F_i(n) = \text{leaves}(F_i)\) are uniquely determined by those of \(F_i(n - 1)\). Namely, \(F_i(n) = \{ \sigma \in V_i(\ell + n + 1) : (\exists \tau \in F_i(n - 1)) [\tau < \sigma]\}\). Thus, \(F_i\) is completely determined by \(F_i \restriction n\), and so also \(\chi(F_0, \ldots, F_{d-1})\) depends only on \((F_0 \restriction n, \ldots, F_{d-1} \restriction n)\).

**Case 2:** \(F_i(n - 1) \subseteq V_i \restriction \ell + N\) for each \(i < d\). In this case, we have \(F_i \restriction n \subseteq \hat{V}_i \setminus \text{leaves}(\hat{V}_i) \subseteq U_i \restriction H_N\). So, if we define \(\tilde{F}_i = F_i \restriction n \cup \{\sigma \in U_i(H_N) : (\exists \tau \in \text{leaves}(F_i)) [\sigma < \tau]\}\) then \((\tilde{F}_0, \ldots, \tilde{F}_{d-1}) \in \mathcal{S}_{n+1}^d(\hat{V}_0, \ldots, \hat{V}_{d-1})\). By choice of the \(\hat{V}_i\), we know that \(\chi_N(\tilde{F}_0, \ldots, \tilde{F}_{d-1})\) depends only on \((\tilde{F}_0 \restriction n, \ldots, \tilde{F}_{d-1} \restriction n) = (F_0 \restriction n, \ldots, F_{d-1} \restriction n)\).

Separately, by definition of \(\chi_N\) and choice of the \(V_i^\sigma\), we have that if \(((\tau_i^\sigma)_{\sigma \in U_i(H_N)})_{i < d}\) is any tuple consisting of one leaf \(\tau_i^\sigma\) from each tree \(V_i^\sigma\), then

\[
\chi_N(\tilde{F}_0, \ldots, \tilde{F}_{d-1}) = \chi((\tilde{F}_i \restriction n \cup \{\tau_i^\sigma : \sigma \in \text{leaves}(\tilde{F}_i)\})_{i < d}) = \chi((F_i \restriction n \cup \{\tau_i^\sigma : \sigma \in \text{leaves}(F_i)\})_{i < d}).
\]

Since the leaves of \(F_0, \ldots, F_{d-1}\) form precisely such a tuple \(((\tau_i^\sigma)_{\sigma \in U_i(H_N)})_{i < d}\) and \(F_i \restriction n \cup \text{leaves}(F_i) = F_i\) for each \(i < d\), we conclude

\[
\chi_N(\tilde{F}_0, \ldots, \tilde{F}_{d-1}) = \chi(F_0, \ldots, F_{d-1}).
\]

Combining the previous two paragraphs, we find that \(\chi(F_0, \ldots, F_{d-1})\) depends only on \((F_0 \restriction n, \ldots, F_{d-1} \restriction n)\), as was to be shown. \(\Box\)

### 4.4. Milliken’s tree theorem with more colors

As we have seen in the preceding sections, there is a computably detectable difference between Milliken’s tree theorem for heights 2 and 3 that parallels that for Ramsey’s theorem for pairs and triples. More specifically, Milliken’s tree theorem for height 2 admits cone avoidance while the version for height 3 does not. In the case of Ramsey’s theorem, more can be said. Wang [48, Theorem 3.2] proved the surprising result that if we weaken Ramsey’s theorem for \(n\)-tuples to permit a larger number \(\ell\) of colors in the solution (instead of just one, which is to say, requiring the solutions to be homogeneous sets), and if \(\ell\) is sufficiently large relative to \(n\), then the resulting statement admits strong cone avoidance. More recently, Cholak and Patey [4, Corollary 4.17] gave explicit bounds on the relationship between \(\ell\) and \(n\), proving that cone avoidance holds so long as \(\ell\) is at least as large as the \(n\)th Catalan number.
Figure 4.1. The construction of a tree in Theorem 4.13 when $d = 1$. Given a tree $T$ of height $H_N$, cutting at level $H_N$ yields a collection of finite perfect trees whose roots are nodes at level $H_N$. A finite coloring of $S^l_{n+1}(T)$ yields a coloring of product of leaves from the collection, by merging the colors of all possible closure into a tree of height $n + 1$. The level $H_{N+1}$ is chosen large enough above $H_N$ so that one can apply Lemma 4.17 to obtain strong subtrees of height 2, represented in bold. As explained in the proof, this yields a coloring of $S^l_n(T | H_N)$, and one can apply the induction hypothesis.

**Statement 4.19** (Ramsey’s theorem for $n$-tuples and $k$ colors). $\text{RT}_{k,r}^n$ is the statement: “For any coloring $f : [N]^n \to k$, there exists an infinite set $H \subseteq N$ such that $f$ uses at most $\ell$ colors on $[H]^n$.”

In this section, we prove a similar result for the product version of Milliken’s tree theorem for height 2. More precisely, we show that whenever the number of colors in the solutions is allowed to be at least 2, then the resulting statement for height 2 admits strong cone avoidance (Theorem 4.27), while the statement for height 3 admits cone avoidance (Theorem 4.28).

The notion of level-homogeneous coloring sets a bridge between Ramsey’s theorem and Milliken’s tree theorem. Let $T_0, \ldots, T_{d-1} \subseteq \omega^{<\omega}$ be finitely branching trees with no leaves. Recall that the level function witnessing a strong subtree is the function mapping the levels of the strong subtree to the levels in the original tree (see Definition 2.20).

**Definition 4.20.** A coloring $f : S_n(T_0, \ldots, T_{d-1}) \to k$ is **level-homogeneous** if the color of $(E_0, \ldots, E_{d-1}) \in S_n(T_0, \ldots, T_{d-1})$ depends only on its level
function. A product tree condition \((F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})\) is level-homogeneous for \(f\) if for every \((E_0, \ldots, E_{d-1}) \in S_n(F_0 \cup X_0, \ldots, F_{d-1} \cup X_{d-1})\) such that \(E_j \mid 1 \subseteq F_j\) for every \(j < d\), the color of \((E_0, \ldots, E_{d-1})\) depends only on its level function.

Note that the notion of level-homogeneous here extends that in Definition 3.24, which is the particular case when \(n = 1\) and \(f\) is the function mapping a tuple in \(S_1(T_0, \ldots, T_{d-1})\) to the unique \(i < k\) such that \(A_i\) contains this tuple.

Any level-homogeneous coloring \(f : S_n(T_0, \ldots, T_{d-1}) \to k\) induces a coloring \(g : [N]^n \to k\) which to some \(F \in [N]^n\) associates the color of any element of \(S_n(T_0, \ldots, T_{d-1})\) whose level function has range \(F\). This coloring \(g\) is well-defined by level-homogeneity of \(f\), and for every homogeneous set \(H \subseteq N\) for \(g\), the principal function \(p_H : N \to N\), which to \(x\) associates the \((x+1)st\) element of \(H\) in natural order, is the level function of a solution to \(f\).

**Theorem 4.21.** Fix two sets \(C\) and \(Z\) such that \(C \not\subseteq_T Z\). Also fix a \(Z\)-computable collection of \(Z\)-computably bounded trees with no leaves \(T_0, \ldots, T_{d-1}\). Let \(f : S_2(T_0, \ldots, T_{d-1}) \to k\) be a coloring. Then, there exist strong subtrees \((S_0, \ldots, S_{d-1}) \in S_{\omega}(T_0, \ldots, T_{d-1})\) over which \(f\) is level-homogeneous, and such that \(C \not\subseteq_T S_0 \oplus \cdots \oplus S_{d-1} \oplus Z\).

**Proof.** Fix \(C, Z, T_0, \ldots, T_{d-1}\) and \(f\). By Theorem 4.11, there are strong subtrees \((U_0, \ldots, U_{d-1}) \in S_{\omega}(T_0, \ldots, T_{d-1})\) on which \(f\) is stable, and such that \(C \not\subseteq_T U_0 \oplus \cdots \oplus U_{d-1} \oplus Z\).

We build strong subtrees \((G_0, \ldots, G_{d-1}) \in S_{\omega}(U_0, \ldots, U_{d-1})\) on which \(f\) is level-homogeneous, and such that \(C \not\subseteq_T G_0 \oplus \cdots \oplus G_{d-1} \oplus Z\). These sets will be constructed by forcing with product tree conditions. Recall that a product tree condition \(c = (F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1})\) is cone avoiding (with respect to the given set \(C\)) if \(C \not\subseteq_T X_0 \oplus \cdots \oplus X_{d-1} \oplus Z\) (see Definition 3.24). Let \(\mathbb{P}\) be the collection of all cone avoiding product tree conditions which are level-homogeneous for \(f\).

The proof of the following lemma is very similar to the proof of Lemma 3.25. In particular, we need again that condition extensions cannot remove roots of forests (see Definition 3.23).

**Lemma 4.22.** There is some condition \(c \in \mathbb{P}\) such that for every Turing functional \(\Gamma\), the set of conditions \(c' \in \mathbb{P}\) such that \(c' \models \Gamma_{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C\) is \(\mathbb{P}\)-dense below \(c\).

**Proof.** Assume for the sake of contradiction that for every condition \(c \in \mathbb{P}\), there is a Turing functional \(\Gamma\) and some extension, every further extension of which \(c'\) satisfies \(c' \not\models \Gamma_{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C\).

As in Lemma 3.25, we build (non-effectively) a \(d\)-tuple \(S_0, \ldots, S_{d-1}\) of infinite subsets of \(T_0, \ldots, T_{d-1}\), respectively, together with three functions:

1. \(\text{sets} : N \to \mathcal{P}(\omega^{<\omega}) \times \cdots \times \mathcal{P}(\omega^{<\omega})\) which to a level \(l \in N\) associates a \(d\)-tuple \(X_0, \ldots, X_{d-1}\) of infinite strong subforests of \(T_0, \ldots, T_{d-1}\),
4.4. MILLKEN’S TREE THEOREM WITH MORE COLORS

respectively, with common level function, such that \( C \not\leq_T X_0 \oplus \cdots \oplus X_{d-1} \oplus Z \) and such that for every \( j < d \), \( S_j(\ell + 1) = \text{roots}(X_j) \);
2. stems : \( \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n) \to S_{\omega}(T_0, \ldots, T_{d-1}) \), which to a \( \pi \in S_0(\ell) \times \cdots \times S_{d-1}(\ell) \) associates a tuple \( (F_0, \ldots, F_{d-1}) \) whose roots pointwise extend \( \pi \), and such that \( (F_0, \ldots, F_{d-1}, \text{sets}(\ell)) \) is a \( \mathbb{P} \)-condition;
3. req : \( \bigcup_n S_0(n) \times \cdots \times S_{d-1}(n) \to \mathbb{N} \), which to a \( \pi \in S_0(\ell) \times \cdots \times S_{d-1}(\ell) \) associates an index \( e \) of a Turing functional \( \Phi_e \) such that for every \( \mathbb{P} \)-extension \( c' \) of \( (\text{stems}(\pi), \text{sets}(\ell)) \), \( c' \not\models \Phi_e^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C \).

Moreover, we require that for every level \( \ell \in \mathbb{N} \), \( \text{sets}(\ell + 1) \) are strong subforests of \( \text{sets}(\ell) \) with common level function.

The construction is now exactly the same as in the proof Lemma 3.25. Moreover, the following fact still holds:

**Fact 4.23.** For every \( \ell_0 < \ell_1 \) and every \( \pi \in S_0(\ell_0) \times \cdots \times S_{d-1}(\ell_0) \), the tuple \( (\text{stems}(\pi), \text{sets}(\ell_1)) \) is a \( \mathbb{P} \)-extension of \( (\text{stems}(\pi), \text{sets}(\ell_0)) \).

By Theorem 3.22, there is a level \( N \in \mathbb{N} \) such that for every coloring \( h : S_0(N) \times \cdots \times S_{d-1}(N) \to k \), there is some \( \ell < N \), some \( \pi \in S_0(\ell) \times \cdots \times S_{d-1}(\ell) \) and some \( (\ell + 1) \)-\( \pi \)-dense matrix \( M \subseteq S_0(N) \times \cdots \times S_{d-1}(N) \) monochromatic for \( h \). Fix such an \( N \). Let \( (X_0, \ldots, X_{d-1}) = \text{sets}(N-1) \). In particular, for every \( j < d \), \( S_j(N) = \text{roots}(X_j) \).

Let \( W \) be the set of pairs \( (x, v) \in \mathbb{N} \times \{0, 1\} \) such that for every \( k \)-coloring \( g : S_2(X_0, \ldots, X_{d-1}) \to k \), there is some \( \ell < N \), some \( \pi \in S_0(\ell) \times \cdots \times S_{d-1}(\ell) \), and for every \( j < d \), there is a finite set \( H_j \subseteq X_j \) such that, letting \( (F_0, \ldots, F_{d-1}) = \text{stems}(\pi) \), the following holds

(a) \( (F_0 \cup H_0, \ldots, F_{d-1} \cup H_{d-1}) \in S_{\omega}(U_0, \ldots, U_d) \);
(b) \( g \) restricted to \( S_2(H_0, \ldots, H_{d-1}) \) is monochromatic for some \( i < k \);
(c) \( \Phi_e^{(F_0 \cup H_0) \oplus \cdots \oplus (F_{d-1} \cup H_{d-1}) \oplus Z} (x) \downarrow v \), where \( e = \text{req}(\pi) \).

By compactness, the set \( W \) is \( X_0 \oplus \cdots \oplus X_{d-1} \oplus Z \)-c.e. There are three cases:

**Case 1:** \( (x, 1 - C(x)) \in W \) for some \( x \in \mathbb{N} \). For \( i < k \), let \( g \) be the restriction of \( f \) to \( S_2(X_0, \ldots, X_{d-1}) \). Let \( \ell < N \), \( \pi = (F_0, \ldots, F_{d-1}) \) and \( H_0, \ldots, H_{d-1} \) witness that \( (x, 1 - C(x)) \in W \) for \( g \). Let \( \ell_1 \) be a level large enough to witness stability of \( f \) for every level of \( H_j \), and let \( \tilde{X}_j = X_j \setminus \bigcup_{0 \leq \ell_1} X_j(\ell_0) \). Then \( c' = (F_0 \cup H_0, \ldots, F_{d-1} \cup H_{d-1}, \tilde{X}_0, \ldots, \tilde{X}_{d-1}) \) is a \( \mathbb{P} \)-extension of \( (F_0, \ldots, F_{d-1}, X_0, \ldots, X_{d-1}) \) which, by Fact 4.23, is a \( \mathbb{P} \)-extension of \( (\text{stems}(\pi), \text{sets}(\ell)) \). Moreover

\[
c' \models \Phi_e^{G_0 \oplus \cdots \oplus G_{d-1} \oplus Z} \neq C
\]

where \( e = \text{req}(\pi) \). This contradicts item 3, according to which \( e \) has no such \( \mathbb{P} \)-extension.

**Case 2:** \( (x, C(x)) \notin W \) for some \( x \in \mathbb{N} \). Let \( C \) be the \( \Pi_1^0 \oplus \cdots \oplus X_{d-1} \oplus Z \) class of all colorings \( g : S_2(X_0, \ldots, X_{d-1}) \to k \) such that for every \( \ell < N \), every
\[ \pi \in S_0(\ell) \times \cdots \times S_{d-1}(\ell) \] and every \( H_0 \subseteq X_0, \ldots, H_{d-1} \subseteq X_{d-1} \), one of (a), (b) or (c) fails for the pair \((x, C(x))\). By assumption, \( C \neq \emptyset \).

By the cone avoidance basis theorem, there is some \( g \in C \) such that \( C \not\subseteq g \oplus X_0 \oplus \cdots \oplus X_{d-1} \oplus Z \). For every \( j < d \), recall that \( S_j(N) = \text{roots}(X_j) \).

We can see \( X_0, \ldots, X_{d-1} \) as a tuple \( (X_j \mid \rho : j < d, \rho \in S_j(N)) \) of trees. For every \( \theta = (\rho_0, \ldots, \rho_{d-1}) \in S_0(N) \times \cdots \times S_{d-1}(N) \), we let \( g_\theta \) be the restriction of \( g \) over

\[ S_2(X_0 \upharpoonright \rho_0, \ldots, X_{d-1} \upharpoonright \rho_{d-1}) \rightarrow k \]

By successive applications of cone avoidance of \text{PMTT}\(^2\) (Theorem 4.15) applied to \( g_\theta \) for each \( \theta \in S_0(N) \times \cdots \times S_{d-1}(N) \), there is a tuple of infinite strong subtrees \( (Y_{j,\rho} : j < d, \rho \in S_j(N)) \) of \( (X_j \mid \rho : j < d, \rho \in S_j(N)) \) with common level function, together with a coloring \( h : S_0(N) \times \cdots \times S_{d-1}(N) \rightarrow k \), such that for every \( \theta = (\nu_0, \ldots, \nu_{d-1}) \in S_0(N) \times \cdots \times S_{d-1}(N) \), \( g_\theta \) restricted to \( S_2(X_0 \upharpoonright \nu_0, \ldots, X_{d-1} \upharpoonright \nu_{d-1}) \) is monochromatic for color \( h(\theta) \).

By choice of \( N \), there is some \( \ell < N \), some \( \pi = (\nu_0, \ldots, \nu_{d-1}) \in S_0(\ell) \times \cdots \times S_{d-1}(\ell) \) and some \((\ell+1)\)-\(\pi\)-dense matrix \( M \subseteq S_0(N) \times \cdots \times S_{d-1}(N) \) monochromatic for \( h \). Say \( M = M_0 \times \cdots \times M_{d-1} \) and \( i < k \) is the color of monochromaticity. For every \( j < d \), let \( P_j \) be the set of nodes in \( S_j(N) \) which are not extensions of \( \nu_j \). For every \( j < k \), let \( \bar{Y}_j = \bigcup_{\rho \in M_j \cup P_j} Y_{j,\rho} \).

**Fact 4.24.** \( \mathcal{C} = (\text{stems}(\pi), \bar{Y}_0, \ldots, \bar{Y}_{d-1}) \) is a \( \mathbb{P} \)-extension of \( (\text{stems}(\pi), \text{sets}(\ell)) \).

**Proof.** Let \( (\bar{X}_0, \ldots, \bar{X}_{d-1}) = \text{sets}(\ell) \). By item 1, for every \( j < k \), \( \text{roots}(\bar{X}_j) = S_j(\ell + 1) \). In particular, every root of \( \bar{X}_j \) is extended by a root of \( \bar{Y}_j \).

In particular, by Fact 4.23 and item 3, \( \mathcal{C} \not\models \Phi^G_0 \oplus \cdots \oplus G_{d-1} \oplus Z \neq C \) where \( e = \text{req}(\pi) \). Moreover, since the forcing relation depends only on part of the reservoirs extending the roots of the stems, the following fact holds.

**Fact 4.25.** \( \mathcal{C} \models \Phi^G_0 \oplus \cdots \oplus G_{d-1} \oplus Z \neq C \), where \( e = \text{req}(\pi) \).

**Proof.** We claim that \( \mathcal{C} \models \Phi^G_0 \oplus \cdots \oplus G_{d-1} \oplus Z(x) \neq C(x) \), where as usual the inequality includes the possibility that the left side diverges. For every \( j < d \), let \( H_j \subseteq \bar{Y}_j \) be such that \( F_0 \cup H_0, \ldots, F_{d-1} \cup H_{d-1} \) are finite strong subtrees of \( \bar{T}_0, \ldots, \bar{T}_{d-1} \), respectively, with common level function. In particular, for every \( j < d \), \( H_j \subseteq \bigcup_{\rho \in M_j} Y_{j,\rho} \), so \( g \) restricted to \( S_2(H_0, \ldots, H_{d-1}) \) is monochromatic for color \( i \), hence since \( g \in C \), \( \Phi^G_0 \oplus \cdots \oplus G_{d-1} \oplus Z(x) \) either diverges, or is different from \( C(x) \). This means \( \mathcal{C} \models \Phi^G_0 \oplus \cdots \oplus G_{d-1} \oplus Z(x) \neq C(x) \), as needed.

Fact 4.25 contradicts Fact 4.24 and item 3 of the construction, according to which \( c \) has no such \( \mathbb{P} \)-extension. This completes Case 2.

**Case 3:** otherwise. Then \( W \) is an \( X_0 \oplus \cdots \oplus X_{d-1} \oplus Z \)-c.e. graph of the characteristic function of \( C \), hence \( C \subseteq X_0 \oplus \cdots \oplus X_{d-1} \oplus Z \). Contradiction. \( \square \)
We are now ready to complete the proof Theorem 4.21. By Lemma 4.22, there is some cone avoiding level-homogeneous product tree condition \( c \) below which, for every Turing functional \( \Gamma \), the set

\[
D_\Gamma = \{ c' \in \mathbb{P} : c' \models \Gamma^G_0 \oplus \cdots \oplus G_{d-1} \oplus Z \neq c \}
\]

is \( \mathbb{P} \)-dense. Let \( \mathcal{U} \) be a \( \mathbb{P} \)-filter which intersects every set \( D_\Gamma \). Then by definition of a product tree condition, \( G_0^d, \ldots, G_{d-1}^d \) are strong subtrees of \( T_0, \ldots, T_{d-1} \). Moreover, since all conditions in \( \mathbb{P} \) are level-homogeneous, so are \( G_0^d, \ldots, G_{d-1}^d \). Since \( \mathcal{U} \) intersects every set \( D_\Gamma \), we have \( C \nless_T G_0^d \oplus \cdots \oplus G_{d-1}^d \oplus Z \). Lastly, by Lemma 3.11, \( G_0^d, \ldots, G_{d-1}^d \) are all infinite. This completes the proof of Theorem 4.21.

**Statement 4.26.** For all \( n, k, \ell \geq 1 \), \( \text{PMTT}^n_{k, \ell} \) is the following statement.

Let \( T_0, \ldots, T_{d-1} \) be infinite trees with no leaves. For all \( f : S_n(T_0, \ldots, T_{d-1}) \rightarrow k \) there exists \( (S_0, \ldots, S_{d-1}) \in S_{\omega}(T_0, \ldots, T_{d-1}) \) such that \( f \) takes at most \( \ell \) values on \( S_n(S_0, \ldots, S_{d-1}) \).

**Theorem 4.27.** For every \( k \in \mathbb{N} \), \( \text{PMTT}^2_{k, 2} \) admits strong cone avoidance.

**Proof.** Fix two sets \( C \) and \( Z \) such that \( C \nless_T Z \). Also fix a \( Z \)-computable collection of \( Z \)-computably bounded trees with no leaves \( T_0, \ldots, T_{d-1} \subseteq \omega^\omega \). Let \( f : S_2(T_0, \ldots, T_{d-1}) \rightarrow k \) be a coloring. By Theorem 4.21, there exist strong subtrees \( (S_0, \ldots, S_{d-1}) \in S_{\omega}(T_0, \ldots, T_{d-1}) \) on which \( f \) is level-homogeneous, and such that \( C \nless_T S_0 \oplus \cdots \oplus S_{d-1} \oplus Z \).

Let \( g : [\mathbb{N}]^2 \rightarrow k \) which to some \( \{ x_0 < x_1 \} \in [\mathbb{N}]^2 \) associates the color of any element of \( S_2(S_0, \ldots, S_{d-1}) \) whose level function has for range \( \{ x_0, x_1 \} \). By strong cone avoidance of \( \text{RT}^2_{k, 2} \) (see Wang [48], Theorem 3.2, or Cholak and Patey [4], Corollary 4.17), there exists an infinite set \( H \subseteq \mathbb{N} \) such that \( g \) restricted to \( [H]^2 \) uses at most 2 colors. Using \( H \), one can compute strong subtrees \( (U_0, \ldots, U_{d-1}) \in S_{\omega}(S_0, \ldots, S_{d-1}) \) whose level function is the principal function of \( H \). By definition of \( g \), \( f \) uses at most 2 colors over \( S_2(U_0, \ldots, U_{d-1}) \). And by transitivity of the strong subtree relation, \( (U_0, \ldots, U_{d-1}) \in S_{\omega}(T_0, \ldots, T_{d-1}) \). This completes the proof of Theorem 4.27.

**Theorem 4.28.** \((\forall k)\text{PMTT}^3_{k, 2} \) admits cone avoidance.

**Proof.** Fix two sets \( C \) and \( Z \) such that \( C \nless_T Z \). Also fix a \( Z \)-computable collection of \( Z \)-computably bounded trees with no leaves \( T_0, \ldots, T_{d-1} \subseteq \omega^\omega \). Let \( f : S_3(T_0, \ldots, T_{d-1}) \rightarrow k \) be a \( Z \)-computable coloring.

By Theorem 4.11, there are strong subtrees \( (S_0, \ldots, S_{d-1}) \in S_{\omega}(T_0, \ldots, T_{d-1}) \) on which \( f \) is stable, and such that \( C \nless_T S_0 \oplus \cdots \oplus S_{d-1} \oplus Z \). Let \( g : S_2(S_0, \ldots, S_{d-1}) \) be the limit coloring induced by stability of \( f \). By strong cone avoidance of \( \text{PMTT}^2_{k, 2} \) (Theorem 4.27), there are strong subtrees \( (U_0, \ldots, U_{d-1}) \in S_{\omega}(S_0, \ldots, S_{d-1}) \) on which \( g \) uses at most 2 colors, and \( C \nless_T U_0 \oplus \cdots \oplus U_{d-1} \oplus Z \). By \( U_0 \oplus \cdots \oplus U_{d-1} \oplus Z \)-computably thinning
out the set of levels, we can obtain a tuple of strong subtrees \((V_0, \ldots, V_{d-1}) \in S_\omega(U_0, \ldots, U_{d-1})\), on which \(f\) uses at most 2 colors. In particular, by transitivity of the strong subtree relation, \((V_0, \ldots, V_{d-1}) \in S_\omega(T_0, \ldots, T_{d-1})\). Last, \(C \not\subseteq_T V_0 \oplus \cdots \oplus V_{d-1} \oplus Z\). This completes the proof of Theorem 4.28. \(\square\)

**Corollary 4.29.** \((\forall k)\)PMTT\(^3\)\(_{k,2}\) does not imply ACA\(_0\) over RCA\(_0\).

**Proof.** Immediate by Theorem 4.28 and Lemma 2.15. \(\square\)
CHAPTER 5

Devlin’s theorem

Devlin’s theorem states that the dense linear orders admits big Ramsey numbers, that is, for every \( n \) there exists an \( \ell \) such that for any finite coloring of the \( n \)-tuples of rationals, there exists a dense linear subordering of \( \mathbb{Q} \) on which the coloring takes only \( \ell \) colors. This corresponds to the statement \((\forall k)\)DT\(^n\)L\(_k\). Moreover, the function which associates to each \( n \) the minimal such \( \ell \) is known, being the sequence of the so-called “odd tangent numbers” \( t_{\text{DT}}(n) \), as defined in [47, p. 147]. (To list the first few, we have \( t_{\text{DT}}(1) = 1 \), \( t_{\text{DT}}(2) = 2 \), \( t_{\text{DT}}(3) = 16 \), and \( t_{\text{DT}}(4) = 272 \).

5.1. A big Ramsey structure for dense linear orders

As explained before, the big Ramsey degree of Devlin’s theorem for pairs is 2, while there is only one sub-order of size 2. We now describe an enrichment to the language of orders to obtain a big Ramsey structure, in the sense of Definition 2.39, of the dense linear orders with no endpoints.

We will see that we can represent any countable order as an anti-chain \( A \) in \( 2^{<\omega} \) with respect to the prefix relation, equipped with the lexicographic order \( <_{\text{lex}} \). Then, given two elements \( \sigma, \tau \in A \), some extra structure induced by the string representation can be exploited, such as the comparison between the length of \( \sigma \) and the length of \( \tau \), but as well with respect to length of their meet \( \sigma \wedge \tau \).

As we will see in Theorem 5.10 we can always ensure that the length of any string in \( A^\wedge = \{ \sigma \wedge \tau : \sigma, \tau \in A \} \) is unique. There are then 2 possible cases for a pair \( \sigma <_{\text{lex}} \tau \) in \( A \): either \( |\sigma| > \mathbb{N} |\tau| \), or \( |\sigma| < \mathbb{N} |\tau| \). The case of the equality has been ruled out since all lengths of the strings in \( A^\wedge \) will be unique. While there are examples where their lengths are not unique (see the figure below), the example where they are unique will prove to be very illustrative.

A finite subset of \( n \) elements in \( A \) can be represented as a particular kind of binary tree, known as a Joyce tree. A Joyce tree of size \( n \) is a labeled tree with \( 2n - 1 \) vertices, such that every non-leaf has exactly two immediate children. The labels are among \( \{1, \ldots, 2n - 1\} \) and so that every child has a label greater than its parent (see Street [43]). See Figure 5.1 for some examples of Joyce trees.

Recall that a function is symmetric if its value is the same no matter the order of its arguments. In what follows, we use the string representation of a countable order \((X, <)\) to enriching the order with a symmetric relation.
Figure 5.1. Eight Joyce trees among the sixteen Joyce trees with three leaves. The eight remaining Joyce trees are mirror reflections of these along a vertical axis through the root node.

binary function $[\cdot, \cdot] : X^2 \rightarrow \mathbb{N}$. We shall later refer to any value of the range of $[\cdot, \cdot]$ as a label. The label of an element $x \in X$ is $[x, x]$ and $[x, y]$ is the label given to $x \wedge y$. Again the illustrative example is when all lengths are unique, is to consider the lengths of these nodes as the labels.

However there are other examples. Consider the first tree in Figure 5.1 and name its leaves $x$, $y$ and $z$, from left to right. This tree induces a symmetric function $[\cdot, \cdot] : \{x, y, z\}^2 \rightarrow \{1, \ldots, 5\}$ as follows: $[x, x] = 4$, $[y, y] = 5$, $[z, z] = 3$, $[x, y] = 2$, $[x, z] = 1$, $[y, z] = 1$. The tree representation also induces an ordering of the labels $\{1, \ldots, 5\}$ by reading them from left to right. In this case, $4 < 2 < 5 < 1 < 3$. As we will later see in Lemma 5.4 ($\{x, y, z\}, <, [\cdot, \cdot]$) can be used to recover the original Joyce tree.

**Definition 5.1.** A Joyce order is an order $(X, <)$ equipped with a symmetric function $[\cdot, \cdot] : X^2 \rightarrow \mathbb{N}$ such that for every $x, y, z, t \in X$, not all equal, with $x \leq y$ and $z \leq t$:

1. $[x, y] <N [x, z] \iff (x < y \iff z < y)$;
2. $[x, y] <N [x, z] \iff [x, y] = [z, y]$;
3. $[x, y] = [z, t] \iff [x, y] <N \min([x, z], [y, t])$.

Note that the axioms of a Joyce order are universal, hence every subset of a Joyce order induces again a Joyce order.

Every Joyce tree gives rise to a Joyce order. Let $X$ be the set of leaves, $[x, y]$ be the label of the node $x \wedge y$, and $<_{\text{lex}}$ be the lexicographical order on $X$. Then, we claim that $(X, <_{\text{lex}}, [\cdot, \cdot])$ is a Joyce order: If $[x, y] <N [x, z]$, then as $x \wedge y$ and $x \wedge z$ are comparable and every child has a label greater than its parent, $x \wedge y < x \wedge z$. But then, $<_{\text{lex}} y \iff (x \wedge z) <_{\text{lex}} y \iff z <_{\text{lex}} y$, and $x \wedge y = (x \wedge z) \wedge y = z \wedge y$, so both (J1) and (J2) hold. Finally let $x, y, z, t \in X$ not all equal be such that $[x, y] = [z, t]$. By injectivity of the labelling, $x \wedge y = z \wedge t$. If $x = y$ then $x \wedge y = x$ is a leaf, so $z \wedge t$ is a
leaf, thus \( x = y = z = t \), a contradiction. Therefore, \( x \neq y \) and \( z \neq t \). Now, suppose \( y = z \). As a Joyce tree is binary branching, and \( x <_{\text{lex}} y = z <_{\text{lex}} t \), one cannot have \( x \land y = z \land t \), a contradiction. Finally suppose that \( x, y, z, t \) are all different. The fact that \( x <_{\text{lex}} y \) and \( z <_{\text{lex}} t \) implies \( (x \land y)0 \leq x \) and \( (x \land y)0 \leq z \), so \( x \land y < x \land z \). By the fact that the label of a child is greater than those of its parents, \( [x, y] <_{\text{N}} [x, z] \). Similarly, \( [x, y] <_{\text{N}} [y, t] \).

We can use the illustrative example when \( X \subseteq \omega^{<\omega} \), \( < \) is \( <_{\text{lex}} \), and all lengths in \( X^\land = \{ \sigma \land \tau : \sigma, \tau \in X \} \) are unique to get an intuition into these rules. Assume \( x \land z \) is longer than \( x \land y \). (J1) says that either \( y \) is to the left of both \( x \) and \( z \) (i.e., \( y < x \) and \( y < z \)) or \( y \) is to the right of both \( x \) and \( z \). (J2) says that \( x \land y = z \land y \) (after all \( x \land y \leq x \land z \)). The third axiom (J3) says that if both pairs \( x, y \) and \( z, t \) have a meet with the same label, \( x < y \), and \( z < t \), then \( x \land z \) must properly above \( x \land y \) and similarly for \( y \land t \). This implies the meets are binary branching in \( X^\land \). This also implies that different meets must have different labels.

**Lemma 5.2.** The following is true in any Joyce order \( (X, <, [\cdot, \cdot]) \):

1. for all \( x, y \in X \) with \( x \neq y \), \( [x, y] \triangleleft_{\text{N}} \min([x, x], [y, y]) \);
2. for all \( x, y \in X \) with \( x \neq z \), \( [x, x] \neq [z, z] \);
3. for all \( x, z, t \in X \) with \( z \neq t \), \( [x, x] \neq [z, t] \).

**Proof.** Item 1: by (J3) with \( x = z \) and \( y = t \). Item 2: by (J3) with \( x = y \) and \( z = t \), \( [x, x] = [z, z] \implies [x, x] \triangleleft_{\text{N}} \min([x, z], [x, z]) \). By Item 1, \( [x, x] \triangleleft_{\text{N}} \min([x, z], [x, z]) \) cannot hold, so \( [x, x] \neq [z, z] \). Item 3: by (J3) with \( x = y \), \( [x, x] = [z, t] \implies [x, x] \triangleleft_{\text{N}} \min([x, z], [x, t]) \). Since \( z \neq t \), then either \( x \neq z \) or \( x \neq t \). In either case, by Item 1, \( [x, z] \triangleleft_{\text{N}} [x, x] \) or \( [x, t] \triangleleft_{\text{N}} [x, x] \), so \( [x, x] \triangleleft_{\text{N}} \min([x, z], [x, t]) \) cannot hold, hence \( [x, x] \neq [z, t] \).

The first item says that the label of \( x \land y \) is less than the labels of \( x \) and \( y \). The second says that each leaf has a unique label. The third says that no meet can have the same label as a leaf. Items 4 and 5 of the following lemma show that the labels of the leaves and meets are always different.

**Lemma 5.3.** Let \( (X, <, [\cdot, \cdot]) \) be a (finite or infinite) Joyce order with minimal label \( \ell \in \omega \). Let \( x \leq y \in X \) be such that \( [x, y] = \ell \) and let \( X_x = \{ z \in X : [x, z] \triangleright_{\text{N}} \ell \} \) and \( X_y = \{ z \in X : [y, z] \triangleright_{\text{N}} \ell \} \). The following holds:

1. if \( x = y \) then \( |X| = 1 \) and \( X_x = X_y = \emptyset \);
2. if \( x < y \) then \( X = X_x \sqcup X_y \) with \( x \in X_x \) and \( y \in X_y \);
3. for all \( z \in X_x \) and all \( t \in X_y \), \( z < t \) and \([z, t] = \ell \);
4. the labels over \( X_x^2 \) and \( Y_y^2 \) are disjoint;
5. if \( |X| = n \) then there are \( 2n + 1 \) distinct labels over \( X^2 \).

**Proof.** Item 1: Let \( z \in X \). If \( z \neq x \) we would have by Item 1 of Lemma 5.2 \( [x, z] \triangleleft_{\text{N}} [x, x] \), a contradiction with the minimality of \( \ell \). Therefore, \( z = x \) and \( |X| = 1 \). As \( x \notin X_x \subseteq X \), \( X_x = X_y = \emptyset \).
5. DeVin's Theorem

Item 2: Let $z \in X_x$. By (J2), we must have $[y, z] = \ell$, and therefore $z \not\in X_y$, so $X_x \cap X_y = \emptyset$. Now, let $t \in X$ such that $[x, t] = \ell$. By (J3) applied with $x = z$, we have $[x, y] < [y, t]$, and so $t \in X_y$. By Item 1 of Lemma 5.2, $x \in X_x$ and $y \in X_y$.

Item 3: We have $[x, z] > \ell = [x, y]$, so by (J2), we must have $[y, z] = \ell$. But we also have $[t, y] > \ell = [y, z]$, so by another application of (J2), we must have $[z, t] = \ell$.

Item 4: Let $z_0, t_0 \in X_x$ and $z_1, t_1 \in X_y$. Suppose $[z_0, t_0] = [z_1, t_1]$. By application of (J3), we would have $[z_0, t_0] <_N [z_0, t_1]$, however by Item 3 $[z_0, t_1] = \ell$, and $[z_0, t_0] <_N \ell$ is a contradiction.

Item 5: By induction over $n \geq 1$. For $n = 1$, $X = \{x\}$, then the unique label is $[x, x]$. For $n > 1$, assume by induction hypothesis that any non-empty Joyce order of size $m < n$ has $2m - 1$ distinct labels. Let $\ell \in \omega$ be the minimal label of $X$ and let $x \leq y \in X$ be such that $[x, y] = \ell$. Define $X_x$ and $X_y$ as above. By Item 1, since $|X| > 1$, then $x < y$. By Item 2, $X_x \neq \emptyset$ and $X_y \neq \emptyset$ and $X = X_x \cup X_y$. By induction hypothesis, there are $2|X_x| - 1$ distinct labels over $X_x^2$ and $2|X_y| - 1$ distinct labels over $X_y^2$. By item 4, the labels are disjoint, so there are $2(|X_x| + |X_y|) - 2 = 2n - 2$ distinct labels over $X_x^2 \cup X_y^2$. Last, by Item 3, for every $z \in X_x$ and $t \in X_y$, $[z, t] = \ell$, so the only label over $X_x \times X_y$ is $\ell$. Therefore there are $2n - 1$ distinct labels over $X^2 = X_x^2 \cup X_y^2 \cup (X_x \times X_y)$.

**Lemma 5.4** (Representing a finite Joyce order as a Joyce tree). There is a computable function $J_X$ such that if $(X, <, [\cdot, \cdot])$ is a Joyce order of where $|X| = n$ then $J_X$ is Joyce tree of size $n$. We shall refer to $J_X$ as the Joyce tree coded by $X$.

**Proof.** Let $L$ be the set of labels over $X^2$ and $l$ be the minimal label. For every string $\sigma \in 2^{<\omega}$, we will define a binary tree $J_{X,\sigma} \subseteq 2^{<\omega}$ whose root is $\sigma$, with $2n - 1$ nodes, such that every non-leaf has two immediate children, and every node has a unique label in $L$. The construction goes inductively as follows:

If $\ell = [x, x]$ for some $x \in X$, then by Lemma 5.3, $X = \{x\}$ and $J_{X,\sigma} = \{\sigma\}$ where $\sigma$ has label $\ell$. If $\ell = [x, y]$ with $x < y$, then let $X_x$ and $X_y$ be defined as in Lemma 5.3. By Item 2 of Lemma 5.3, $X = X_x \cup X_y$. By Items 3 and 4 of Lemma 5.3, $L = L_x \cup L_y \cup \{\ell\}$, where $L_x$ and $L_y$ are the sets of labels over $X_x^2$ and $X_y^2$, respectively. By induction hypothesis one can define $J_{X_x,\sigma_0}$ and $J_{X_y,\sigma_1}$, which are $L_x$-labelled and $L_y$-labelled, respectively. Then $J_{X,\sigma} = \{\sigma\} \cup J_{X_x,\sigma_0} \cup J_{X_y,\sigma_1}$ where $\sigma$ is given label $\ell$.

Let $\nu : L \rightarrow \{1, \ldots, 2n - 1\}$ be the unique isomorphism between $(L, <_N)$ and $(\{1, \ldots, 2n - 1\}, <_N)$ seen as linear orders. Then renaming the labels of $J_{X,\ell}$ according to $\nu$, one obtains a Joyce tree $J_X$.

**Definition 5.5.** The Joyce structure of a Joyce order is a structure $(X, <, R)$ such that for all $x, y, z, t$, $R(x, y, z, t) \iff [x, y] < [z, t]$. A DLO Joyce structure is the Joyce structure of a dense linear Joyce order with no endpoints.
By abuse of language, we may say that two Joyce orders are isomorphic whenever their corresponding Joyce structures are isomorphic. The construction of a Joyce tree from a Joyce order does not depend on the labels but on the ordering of the labels. Moreover two different orders of the labels yields two different Joyce trees. Hence the following lemma holds.

**Lemma 5.6 (RCA₀).** Two finite Joyce structures are isomorphic if and only if they yield the same Joyce tree.

Just after the definition of a Joyce order, Definition 5.1, we showed every Joyce tree yielded a Joyce order which in turn yields a Joyce structure. Hence the number of Joyce tree of size $n$, Joyce orders of size $n$, and Joyce structure of size $n$ are all the same. Street [43] shows that this is the odd tangent number of $n$ (also see [47, p. 147]).

We now prove that every dense linear order with no endpoints can be enriched into a DLO Joyce structure. Actually, since these orders are computably categorical, that is, any two dense linear orders with no endpoints are isomorphic, and furthermore this isomorphism is computable in the orders, is suffices to prove the existence of a DLO Joyce order.

**Theorem 5.7 (RCA₀).** There exists a DLO Joyce order.

**Proof.** Let $X$ be the rational language $(000 \cup 100)^*01$, that is, the set of strings $\sigma \in 2^{<\omega}$ of length $3n + 2$ for some $n \in \omega$, such that $\sigma(3n) = 0$, $\sigma(3n + 1) = 1$, and for every $j < n$, $\sigma(3j + 1) = \sigma(3j + 2) = 0$. For example, $10000010001 \in X$. In particular, $X$ is an infinite antichain with respect to the prefix order. Let $<_{\text{lex}}$ be the lexicographic order restricted to $X$, that is, $\sigma <_{\text{lex}} \tau$ if $\sigma(\lceil \sigma \land \tau \rceil) <_N \tau(\lceil \sigma \land \tau \rceil)$. Then $(X, <_{\text{lex}})$ is a dense linear order with no endpoints. Indeed, letting $f$ be the natural one-to-one map from $X$ to $2^{<\omega}$, $f$ is an order isomorphism between $(X, <_{\text{lex}})$ and $(2^{<\omega}, <_Q)$ where $<_Q$ is order defined in Definition 5.27. Last, fix an injective function $v : 2^{<\omega} \to \omega$ such that for every $\sigma, \tau \in 2^{<\omega}$, if $|\sigma| < |\tau|$ then $v(\sigma) < v(\tau)$, and for every $\sigma, \tau \in X$, define $[\sigma, \tau] = v(\sigma \land \tau)$. Then $(X, <_{\text{lex}}, [\cdot, \cdot])$ is a dense linear Joyce order with no endpoints.

We prove that $(X, <_{\text{lex}}, [\cdot, \cdot])$ satisfies axioms (J1), (J2) and (J3). Let $x, y, z, t \in X$, not all equal, with $x \leq_{\text{lex}} y$ and $z \leq_{\text{lex}} t$.

Suppose $[x, y] < [x, z]$. By definition, $v(x \land y) < v(x \land z)$. By choice of the map $v$, $|x \land y| \leq |x \land z|$, so $x <_{\text{lex}} y$ if $z <_{\text{lex}} y$. This shows (J1).

Now suppose $[x, y] < [x, z]$. By definition, $v(x \land y) < v(x \land z)$. By choice of the map $v$, $|x \land y| \leq |x \land z|$, so $x \land y = z \land y$, hence $v(x \land y) = v(z \land y)$. This shows (J2).

Finally, suppose $[x, y] = [z, t]$. By definition, $v(x \land y) = v(z \land t)$. By injectivity of the map $v$, $x \land y = z \land t$, so $x \land y < x \land z$ and $x \land y < y \land t$, hence $v(x \land y) <_N \min(v(x \land z), v(y \land t))$. This shows (J3). \hfill $\square$

Depending on the choice of $v$ in the above construction, the DLO Joyce orders won’t be isomorphic. Consider the 3 leaves with the least labels. The leaf 01 always has the least label. The other 2 leaves with minimal labels are
always $x = 00001$ and $y = 10001$. Note that $x < y$. Now the structures yielded by $v_0$ and $v_1$ where $v_0(00001) < v_0(10001)$ (hence the label of $x$ is less than the label of $y$) and $v_1(00001) > v_1(10001)$ (hence the label of $x$ is greater than the label of $y$) are not isomorphic.

**Corollary 5.8** ($\text{RCA}_0$). Every dense linear order with no endpoints $(X, <)$ can be equipped with a function $[\cdot, \cdot] : X^2 \to \mathbb{N}$ to form a DLO Joyce order.

**Proof.** Let $(Y, <, [\cdot, \cdot])$ be the DLO Joyce order of Theorem 5.7. By computable categoricity of the dense linear orders with no endpoints, there exists an order isomorphism $f$ between $(X, <)$ and $(Y, <, [\cdot, \cdot])$. Define $[\cdot, \cdot] : X^2 \to \mathbb{N}$ by $[x, y] = [f(x), f(y)]_Y$. Then $(X, <, [\cdot, \cdot])$ is a DLO Joyce order. 

One can canonically represent any countable Joyce order as a set of strings which are pairwise incomparable under the prefix relation, equipped with the lexicographic order the natural $[\cdot, \cdot]$ operation, that is, $[\sigma, \tau] = |\sigma \wedge \tau|$.

**Definition 5.9.** A coded Joyce order is a Joyce order of the form $(X, <_{\text{lex}}$ , $|\cdot \wedge \cdot|)$, with $X \subseteq \mathbb{2}^{\omega}$, where $|\sigma \wedge \tau|$ is the length of the longest common prefix of $\sigma$ and $\tau$, such that for all $\sigma, \tau, \rho \in X$ with $|\rho| > |\sigma \wedge \tau|$ and $\sigma \wedge \tau \neq \rho$, then $\rho(|\sigma \wedge \tau|) = 0$.

In particular, letting $\sigma = \tau$, if $|\rho| > |\sigma|$, then $\rho(|\sigma|) = 0$. Since a coded Joyce order is fully specified by its set $X$, we shall simply refer to $X$ when talking about the coded Joyce order $(X, <_{\text{lex}}, |\cdot \wedge \cdot|)$. Note that any subset of a coded Joyce order is again a coded Joyce order, since the axioms are universal.

**Theorem 5.10** ($\text{RCA}_0$). Every countable Joyce order is isomorphic to a coded Joyce order.

**Proof.** Let $(X, <, [\cdot, \cdot])$ be a countable Joyce order. Let $L$ be the set of labels over $X^2$. For every $x \in X$, let $L_x$ be the set of labels $\ell \in L$ such that $\ell <_N [x, x]$ and such that there is some $y \in X$ such that $y < x$ and $[y, x] = \ell$. Let $\sigma_x \in 2^{<\omega}$ be the unique string of length $[x, x]$, such that for every $j < [x, x]$, $\sigma_x(j) = 1$ if and only if $j \in L_x$. Let $Y = \{\sigma_x : x \in X\}$.

**Claim 5.11.** $(Y, <_{\text{lex}}, |\cdot \wedge \cdot|)$ is isomorphic to $(X, <, [\cdot, \cdot])$.

**Proof.** We first prove that for all $x, y, z, t \in X$, $[x, y] < [z, t]$ $\implies$ $|\sigma_x \wedge \sigma_y| <_N |\sigma_z \wedge \sigma_t|$. We actually prove the stronger fact that for every $x, y \in X$, $[x, y] = [\sigma_x \wedge \sigma_y]$. If $x = y$, it is clear as by construction, $\sigma_x$ is of length $[x, x]$. If $x \neq y$, we first prove that $[x, y] \leq [\sigma_x \wedge \sigma_y]$: indeed, for all $\ell < [x, y]$, by (J2) we have $\ell \in L_x$ if and only if $\ell \in L_y$. It remains to show $[x, y] \geq [\sigma_x \wedge \sigma_y]$: if $x < y$ we have that $[x, y] \in L_y \setminus L_x$, and if $y < x$, $[x, y] \in L_x \setminus L_y$. So in any case, $\sigma_x([x, y]) \neq \sigma_y([x, y])$, so $|\sigma_x \wedge \sigma_y| \leq [x, y]$.

Let $x < y \in X$. Then, $[x, y] \not\in L_x$, as if $z$ is such that $[x, z] = [x, y]$, then by (J3) $[x, y] <_N [y, z]$ and by (J1) and the fact that $x < y$, we have
5.2. A Proof of Devlin’s Theorem

$x < z$. So $\sigma_x(\langle x \land y \rangle) = \sigma_x(\langle x, y \rangle) = 0$. However, $\langle x, y \rangle \in L_y$ as witnessed by $x$, so $\sigma_y(\langle x \land y \rangle) = \sigma_y(\langle x, y \rangle) = 1$. Therefore, $\sigma_x <_{\text{lex}} \sigma_y$. □

Claim 5.12. $(Y, <_{\text{lex}}, | \cdot \land |)$ is a coded Joyce order.

Proof. By the previous claim, $(Y, <_{\text{lex}}, | \cdot \land |)$ is a Joyce order isomorphic to $(X, <, [\cdot, \cdot])$. Fix $\sigma_x, \sigma_y, \sigma_z \in Y$ with $|\sigma_z| > |\sigma_x \land \sigma_y|$ and $\sigma_x \land \sigma_y \not\in \sigma_z$. Assume $x \leq y$ without loss of generality. Let $\ell = [x, y] = [\sigma_x \land \sigma_y]$. Suppose for the contradiction that $\ell \in L_z$. Then there is some $u \in X$ with $u < z$ such that $[u, z] = [\sigma_x \land \sigma_z] = \ell = [x, y] = [\sigma_x \land \sigma_y]$. Since $u < z$, then $\sigma_u <_{\text{lex}} \sigma_z$ and since $x \leq y$ and $u < z$, by (J3), $|\sigma_y \land \sigma_z| >_{\mathbb{N}} \ell$ and $|\sigma_u \land \sigma_x| >_{\mathbb{N}} \ell$. Let $\ell_0 = [\sigma_y \land \sigma_z]$. In particular, $\sigma_x \land \sigma_y = \sigma_x \land \sigma_y \downarrow \ell_0 = \sigma_x \land \sigma_z \downarrow \ell_0$, so $\sigma_x \land \sigma_y \not\in \sigma_z$, contradiction. So $\ell \not\in L_z$, hence $\sigma_z(\ell) = 0$. □

This completes the proof of Theorem 5.10.

Note that the proof in Theorem 5.10 yields a coded Joyce order whose set of lengths correspond exactly to the labels of the original Joyce order.

Remark 5.13. Since Joyce structures only consider the ordering between the labels and not their actual value, we can always pick a Joyce order isomorphic to the original one, whose set of labels is an initial segment of $\mathbb{N}$, and using Theorem 5.10, we can represent it as a coded Joyce order whose lengths coincide with the labels, hence form an initial segment of $\mathbb{N}$.

Todorcevic [47, Lemma 6.20] made an explicit construction of a computable coded DLO Joyce order, under a different terminology.

Corollary 5.14. There exists a computable coded DLO Joyce order.

Proof. Immediate by Theorem 5.10 and Theorem 5.7. □

5.2. A Proof of Devlin’s theorem

Note that the substructure of any Joyce structure is a Joyce structure, with the same witness function $| \cdot \land |$. Not all DLO Joyce structures are isomorphic, as already remarked in the paragraph below Theorem 5.7. However, they all contain all Joyce structures. In particular, two DLO Joyce structures might not be isomorphic, but there exists an embedding from the first to the second, as well as from the second to the first.

Theorem 5.15 (RCA$_0$). Let $X$ be a DLO Joyce structure, and $\mathbb{F}$ be a (finite or infinite) Joyce structure. Then, there exists an embedding from $\mathbb{F}$ to $X$.

Proof. Let $(X, <_{\text{lex}}, | \cdot \land |)$ be a computably coded DLO Joyce order with Joyce structure $\mathbb{X}$, which can always be found using Corollary 5.14. Let $(\mathbb{F}, <_{\text{lex}}, | \cdot \land |)$ be a Joyce order of $\mathbb{F}$. By Remark 5.13, we can suppose that the length of the elements of $F^\land$ form an initial segment of $\mathbb{N}$. The cardinality of $F^\land$, $S \in \omega \cup \{\omega\}$, is that for all $s < S$, there exists an unique element of $F^\land$ of length $s$, $\sigma_s$. We need to include the meets in our
construction, so instead of building a map from $F$ to $X$, we build a map from $F^\wedge$ to $X$. In the end, restricting the mapping to $F$ will yield the embedding.

By induction on $s < S$, we build $x_s, a_s$ and $b_s$ such that:

1. $x_s, a_s, b_s \in X$;
2. $a_s \ll \text{lex} x_s \ll \text{lex} b_s$;
3. $|a_s \land b_s| < \|x_s\| < \|a_{s+1} \land b_{s+1}\|$;
4. If $t < s$ and $\sigma_t < \sigma_s$, then: If $\sigma_s(t) = 0$, then $x_s, a_s, b_s$ are in the interval $(a_t, x_t)$. Similarly, if $\sigma_s(t) = 1$, then $x_s, a_s, b_s$ are in the interval $(x_t, b_t)$.

Suppose that $a_t, b_t$ and $x_t$ are defined for $t < s$. Let $t_0 < s$ be biggest such that there exists $\tau \in F$ such that $|\sigma_s \land \tau| = t_0$. Let $A$ be the interval $(a_{t_0}, x_{t_0})$ if $\sigma_s(t_0) = 0$, and $A$ be the interval $(x_{t_0}, b_{t_0})$ if $\sigma_s(t_0) = 1$. In either case $A$ is a dense linear Joyce order with no endpoints. Let $a_s, b_s \in A$ such that $|a_s \land b_s| > \|x_{s-1}\|$. They exist as $A$ is infinite and $|A| \geq n$ implies $|\{\sigma \land \tau : \sigma \neq \tau \in A\}| \geq \log_2(n)$. Define $x_s$ to be any element of $(a_s, b_s)$, which has to verify $|a_s \land b_s| < |x_s|$. Items 1, 2 and 3 are satisfied, as well as item 4 for $t_0$. By definition of $t_0$, if $\sigma_t < \sigma_s$, then either $t = t_0$ or $\sigma_t < \sigma_{t_0}$. In the former case, item 4 for $t$ is satisfied. In the latter case, as $a_{t_0}, \sigma_{t_0}$ and $b_{t_0}$ satisfy item 4, $x_{t_0}, a_{t_0}, b_{t_0}$ are in the interval specified by item 4. But then, so are $x_s, a_s, b_s$, so they satisfy item 4 for all $t$.

We now define the embedding $\phi$: if $y \in F$, then $\phi(y)$ is defined to be $x_{[y \land y]}$. It remains to show that $\phi$ is an embedding. An important fact is the following: If $x \ll \text{lex} y \in F$, and $t = |x \land y|$, then $|a_t \land b_t| \leq |x| \land \phi(x) \land \phi(y)| < |x_t|$. Indeed, by Item 4 $\phi(x) \in (a_t, x_t)$ and $\phi(y) \in (x_t, b_t)$. Combining the fact with Item 3, we get that $|x \land y| < |z \land t|$ implies $|\phi(x) \land \phi(y)| < |\phi(z) \land \phi(t)|$.

Now suppose that for $x, y, z, t \in F$ with $x \ll \text{lex} y$ and $z \ll \text{lex} t$, $|x \land y| = |z \land t| = s$. This implies that $s_0 = |x \land z| > \|s\}$ and $s_1 = |y \land t| > \|s\}$. But then by Item 3 and the fact of the previous paragraph, $|\phi(x) \land \phi(z)| > \|a_{s_0} \land b_{s_0}\} > |x_{s_0} > \|\phi(x) \land \phi(y)|$ and $|\phi(y) \land \phi(t)| > \|a_{s_0} \land b_{s_0}\} > |x_{s_0} > \|\phi(z) \land \phi(t)|$. Therefore, by (J2), $|\phi(x) \land \phi(y)| = |\phi(z) \land \phi(t)|$.

Finally, suppose $x \ll \text{lex} y \in F$. Let $s = |x \land y|$, by Item 4 we have $\phi(x) \in (a_s, x_s)$ and $\phi(y) \in (x_s, b_s)$ so $\phi(x) < \text{lex} \phi(y)$.

The age of a structure $M \in$ is the set of all its finitely generated substructures.

**Corollary 5.16.** The age of any DLO Joyce structure is the set of finite Joyce structures.

**Theorem 5.17 (RCA₀).** There exists a DLO Joyce order $(2^{<\omega}, \ll_T, [\cdot, \cdot]_T)$ such that for every coded Joyce order $X$, the Joyce structures of $(X, <_T$, $[\cdot, \cdot]_T$) and $(X, \ll, [\cdot, \cdot])$ are isomorphic.

**Proof.** Let $(U, \ll, [\cdot, \cdot])$ be the DLO Joyce order defined in Theorem 5.7, that is, $U = (00 \cup 01)^*01$ and $[\sigma, \tau]_U = v(\sigma \land \tau)$ for some
injective function \( v : 2^{<\omega} \to \omega \) such that for every \( \sigma, \tau \in 2^{<\omega} \), if \( |\sigma| < |\tau| \) then \( v(\sigma) < v(\tau) \).

Define the DLO Joyce order \( (2^{<\omega}, <_T, [\cdot, \cdot]_T) \) as follows: Given \( \sigma \in 2^{<\omega} \), let \( \hat{\sigma} \) be the binary string of length \( 3|\sigma| + 2 \) defined for every \( j < |\sigma| \) by \( \hat{\sigma}(3j) = \sigma(j) \), \( \hat{\sigma}(3j+1) = \hat{\sigma}(3j+2) = 0 \), and \( \hat{\sigma}(3|\sigma|) = 0 \) and \( \hat{\sigma}(3|\sigma|+1) = 1 \). For instance, if \( \sigma = 0110 \) then \( \hat{\sigma} = 00010010000001 \). Let \( \sigma <_T \tau \) if and only if \( \hat{\sigma} <_{\text{lex}} \hat{\tau} \) and \( [\sigma, \tau]_T = [\hat{\sigma}, \hat{\tau}]_U \).

Let \( X \) be a coded Joyce order. We shall now show that \( (X, <_T, [\cdot, \cdot]_T) \) and \( (X, <_{\text{lex}}, | \cdot \land \cdot |) \) are isomorphic via the identify function.

Fix \( \sigma, \tau \in X \). If \( \sigma <_{\text{lex}} \tau \), then \( \hat{\sigma} <_{\text{lex}} \hat{\tau} \), hence \( \sigma <_T \tau \). Conversely, if \( \sigma <_T \tau \), then \( \hat{\sigma} <_{\text{lex}} \hat{\tau} \), but since \( \sigma \) and \( \tau \) are incomparable with respect to the prefix relation, this implies that \( \sigma <_{\text{lex}} \tau \). Thus \( \sigma <_T \tau \) if and only if \( \sigma <_{\text{lex}} \tau \).

Fix \( \sigma, \tau, \rho, \mu \in X \). If \( |\sigma \land \tau| <_N |\rho \land \mu| \), then \( |\hat{\sigma} \land \hat{\tau}| <_N |\hat{\rho} \land \hat{\mu}| \), then \( v(\hat{\sigma} \land \hat{\tau}) <_N v(\hat{\rho} \land \hat{\mu}) \), hence \( [\sigma, \tau]_T <_N [\rho, \mu]_T \). Conversely, assume \( [\sigma, \tau]_T <_N [\rho, \mu]_T \). Unfolding the definition, \( v(\hat{\sigma} \land \hat{\tau}) <_N v(\hat{\rho} \land \hat{\mu}) \). If \( |\hat{\sigma} \land \hat{\tau}| \neq |\hat{\rho} \land \hat{\mu}| \), then by definition of \( v \), \( |\hat{\sigma} \land \hat{\tau}| <_N |\hat{\rho} \land \hat{\mu}| \), hence \( |\sigma \land \tau| <_N |\rho \land \mu| \). If \( |\hat{\sigma} \land \hat{\tau}| = |\hat{\rho} \land \hat{\mu}| \), then, since \( X \) is a coded Joyce order, \( \sigma \land \tau = \rho \land \mu \), so \( v(\hat{\sigma} \land \hat{\tau}) = v(\hat{\rho} \land \hat{\mu}) \), contradiction. \( \square \)

**Definition 5.18.** A Joyce order diagonalization for some Joyce order \( (U, <_U, [\cdot, \cdot]_U) \) is a function \( h : 2^{<\omega} \to U \), such that for every coded Joyce order \( X \),

\[
(h[X], <_U, [\cdot, \cdot]_U)
\]

is isomorphic to \( (X, <_{\text{lex}}, | \cdot \land \cdot |) \).

**Corollary 5.19** (RCA\(_0\)). Every DLO Joyce order \( (U, <_U, [\cdot, \cdot]_U) \) has a Joyce order diagonalization.

**Proof.** Let \( (2^{<\omega}, <_T, [\cdot, \cdot]_T) \) be the Joyce order of Theorem 5.17. By Theorem 5.15, there is an embedding \( h : 2^{<\omega} \to U \). By definition of an embedding, for every coded Joyce order \( X \subseteq 2^{<\omega} \), \( (h[X], <_U, [\cdot, \cdot]_U) \) is isomorphic to \( (X, <_T, [\cdot, \cdot]_T) \). By Theorem 5.17, \( (X, <_T, [\cdot, \cdot]_T) \) is isomorphic to \( (X, <_{\text{lex}}, | \cdot \land \cdot |) \). Thus \( h \) is a Joyce order diagonalization. \( \square \)

The following lemma bridges finite coded Joyce orders of size \( n \) and strong subtrees of \( 2^{<\omega} \) of height \( 2n - 1 \), by showing that any coded Joyce order of size \( n \) is a subset of a strong subtree of size \( 2n - 1 \), and, conversely, any strong subtree of height \( 2n - 1 \) is a superset of at most one coded Joyce order of size \( n \).

**Lemma 5.20.** Let \( F \) be a finite coded Joyce order of size \( n \) and \( T \in \mathcal{S}_\omega(2^{<\omega}) \). Then every \( E \in \mathcal{S}_{2n-1}(T) \) contains at most one coded Joyce order isomorphic to \( F \). Moreover, every coded Joyce order \( H \subseteq T \) isomorphic to \( F \) is included in some \( E \in \mathcal{S}_{2n-1}(T) \).
PROOF. Let $E \in \mathcal{S}_{2n-1}(T)$, $h$ its level function and $F_0, F_1 \subseteq E$ be two coded Joyce orders isomorphic to $F$. By Item 5 of Lemma 5.3, the set 
$\{ |\sigma \land \tau | : \sigma, \tau \in F_0 \}$ has cardinality $2n - 1$, and similarly for $F_1$.

Remark that $F_0$ and $F_1$ are uniquely identified as the set of leaves of respectively $F_0^\wedge$ and $F_1^\wedge$, and that the isomorphism between $F_i$ and $F$ can be extended to an isomorphism between $F_i^\wedge$ and $F^\wedge$, where the element of length $h(j)$ (or equivalently of level $j$) of $F_i^\wedge$ is mapped to the element of level $j$ of $F$. Let $\ell$ be the first level, if it exists, where $F_0^\wedge \mid h(\ell) \neq F_1^\wedge \mid h(\ell)$. Let $\sigma_i \in F_i^\wedge$ be the unique element of $F_i^\wedge(\ell)$, and $\sigma$ the unique element of $F(\ell)$. For every $j < \ell$, the values of $\sigma_0(h(j)) = \sigma_1(h(j))$ are determined: $0$ iff there is a $\tau$ where $\sigma <_{\text{lex}} \tau \in F^\wedge(j)$ and $1$ iff there is a $\tau$ where $\sigma >_{\text{lex}} \tau \in F^\wedge(j)$. As $E$ is a strong subtree, determining the values of $\sigma$ at levels $h(j)$ for $h(j) < |\sigma_i|$ entirely defines $\sigma_i$. Therefore, $F_0^\wedge = F_1^\wedge$ and $F_0 = F_1$.

For the second part, let $H \subseteq T$ be a coded Joyce order isomorphic to $F$. We claim that $H$ is included in some $E \in \mathcal{S}_{2n-1}(T)$. Let $H^\wedge = \{ \sigma \land \tau : \sigma, \tau \in H \}$ be the $\land$-closure of $H$. In particular, $H^\wedge$ is a finite tree of height $2n - 1$ with exactly one string at each level. Since $T \in \mathcal{S}_\omega(2^{<\omega})$ and $H \subseteq T$ then $H^\wedge \subseteq T$. Let $L = \{ \ell_0 < \cdots < \ell_{2n-2} \}$ be the set of levels of the nodes of $H^\wedge$ in $T$. Let $E$ be the largest (in the sense of inclusion) subtree of $T$ of height $2n - 1$ containing $H^\wedge$ such that for every $i < 2n - 1$, $E(i) \subseteq T(\ell_i)$. We claim that for every $i < 2n - 2$, every node $\sigma \in E(i)$ is 2-branching in $E$. Since $E \subseteq 2^{<\omega}$ is a tree, it is $\land$-closed, $\sigma$ is at most 2-branching. Since $T \in \mathcal{S}_\omega(2^{<\omega})$, every node in $T$ is 2-branching. Then $\sigma$ has two extensions $\tau_0, \tau_1 \in T(\ell_{i+1})$ such that $\tau_0 \land \tau_1 = \sigma$. By maximality of $E$, $\sigma$ is 2-branching in $E$. Thus $E \in \mathcal{S}_{2n-1}(T)$. □

THEOREM 5.21 (ACA$_0$). Let $X$ be a countable DLO Joyce structure, and $\mathbb{F}$ be a finite Joyce structure. Then, the big Ramsey number of $\mathbb{F}$ in $X$ is 1.

PROOF. Let $X$ be a countable coded DLO Joyce order and $F$ be a finite coded Joyce order of size $n$. Fix a coloring $f : (\overline{X}) \to k$. Here, $(\overline{X})$ denotes all the subcopies of $F$ in $X$.

Let $h : 2^{<\omega} \to X$ be a Joyce order diagonalization, which exists by Corollary 5.19. Let $g : \mathcal{S}_{2n-1}(2^{<\omega}) \to k$ be defined for every $E \in \mathcal{S}_{2n-1}(2^{<\omega})$ by $g(E) = f(h(H))$ where $H \subseteq E$ is the unique element coded Joyce order isomorphic to $F$, if it exists. Otherwise let $g(E) = 0$. This coloring is well-defined by Lemma 5.20.

By Milliken’s tree theorem for height $2n - 1$, there is a strong subtree $S \in \mathcal{S}_\omega(2^{<\omega})$ such that $g$ restricted to $\mathcal{S}_{2n-1}(S)$ is monochromatic for some color $i < k$. In particular, by Lemma 5.20, for every coded Joyce order $H \subseteq S$ isomorphic to $F$, there is some $E \in \mathcal{S}_{2n-1}(S)$ containing $H$, and $g(E) = f(h(H)) = i$.

Since $S \in \mathcal{S}_\omega(2^{<\omega})$, there is an injective function $\phi : 2^{<\omega} \to S$ such that $\phi[X]$ is a coded Joyce order isomorphic to $X$. In particular, since $h$ is a Joyce diagonalization, $Y = h[\phi[X]]$ is a DLO coded Joyce order isomorphic
to $X$, hence a subcopy of $X$. Note that $Y$ is a coded Joyce order since it is a subset of $X$ which is a coded Joyce order.

We claim that $f$ restricted to $\left( \frac{Y}{F} \right)$ is monochromatic for color $i$. Let $\bar{H}$ be a copy of $F$ in $Y = h[\phi[X]]$. Let $H \subseteq \phi[X]$ be such that $h[H] = \bar{H}$. In particular since $\phi[X]$ is a coded Joyce order, so is $H$, so since $h$ is a Joyce order diagonalization, $\bar{H} = h[H]$ is a coded Joyce order isomorphic to $H$. In other words, $H$ is a copy of $F$ in $\phi[X] \subseteq S$, so $H$ is a copy of $F$ in $S$. By Lemma 5.20, there is some $E \in S_{2n-1}(S)$ containing $H$, and by definition of $g$, $g(E) = f(h(H))$. By choice of $S$, $g$ restricted to $S_{2n-1}(S)$ is homogeneous for color $i$, so $g(E) = f(h[H]) = i$, so $f(\bar{H}) = i$. □

**Statement 5.22** (Joyce Devlin’s theorem for $n$-tuples and $\ell$ colors). JD$T^n_{k,\ell}$ is the statement: “For any Joyce structure $X$ and coloring $f : [X]^n \rightarrow k$, there exists a strong subcopy of $X$ such that $f$ uses at most $\ell$ colors”.

**Corollary 5.23** (Tight bounds on Joyce Devlin’s theorem). For any $n$,

$(\forall k)JD^n_{k,\ell}$ holds, $\ell$ being the number of Joyce orders with $n$ elements, and this bound is tight.

**Proof.** Let $\ell$ be the number of Joyce order structures with $n$ elements. Let $F_0, \ldots, F_{\ell-1}$ be a finite enumeration of all the finite coded Joyce orders of size $n$.

We first prove that $(\forall k)JD^n_{k,\ell}$ holds. Fix a coloring $f : [X]^n \rightarrow k$ for some countable DLO Joyce structure $(X, <, R)$. By Theorem 5.21, build a finite decreasing sequence of subsets $X = X_0 \supseteq X_1 \supseteq \cdots \supseteq X_\ell$ of $X$ such that for every $s < \ell$:

1. $(X_{s+1}, <, R)$ is a subcopy of $(X_s, <, R)$;
2. every copy of $F_s$ in $(X_{s+1}, <, R)$ is monochromatic for $f$ for some color $i_s < k$.

The Joyce structure $(X_\ell, <, R)$ is a subcopy of $(X, <, R)$. Moreover, for every $E \subseteq [X]^n$, $(E, <, R)$ is isomorphic to $F_s$ for some $s < k$, so $f(E) = i_s$. It follows that $f[X_\ell]^n \subseteq \{i_s : s < \ell\}$, hence $|f[X_\ell]^n| \leq \ell$.

We now show that the bound is tight. Let $f : [X]^n \rightarrow k$ be defined by $f(E) = s$ for the unique $s < \ell$ such that $(E, <, R)$ is isomorphic to $F_s$. Let $(Y, <, R)$ be a subcopy of $(X, <, R)$. In particular, $(Y, <, R)$ is a DLO Joyce structure, so by Theorem 5.15, for every $s < \ell$, there is an embedding of $F_s$ into $(Y, <, R)$. Therefore, $|f[Y]^n| \geq \ell$. □

It is clear that Joyce Devlin’s theorem for $n$-tuples and $\ell$ colors implies Devlin’s theorem for $n$-tuples and $\ell$ colors: indeed, by the existence of a DLO Joyce structure and computable categoricity of dense linear orders without endpoints, any such order can be turned into a DLO Joyce structure (see Corollary 5.8). The following theorem shows the converse:

**Theorem 5.24** (RCA$_O$). Let $X = (X, <, R)$ be a DLO Joyce structure. Let $X' = (X', <)$ be an isomorphic subcopy of $(X, <)$, that is, a dense linear
order with no endpoints. Then, there exists a subcopy $(X''',<)$ of $(X',<)$ such that $(X''',<,\mathbb{R})$ is a subcopy of $X$.

PROOF. The structure $\overline{X}' = (X',<,\mathbb{R})$ is a DLO Joyce structure, even if it might not be isomorphic to $X$. By Theorem 5.15, there exists an embedding of $X$ into $\overline{X}'$. The image of the embedding is $X''$. \hfill \Box

Corollary 5.25 (RCA$_0$). Devlin’s theorem for $n$-tuples and $\ell$ colors implies Joyce Devlin’s theorem for $n$-tuples and $\ell$ colors.

Corollary 5.26 (RCA$_0$). The tight bound for Devlin’s theorem and Joyce Devlin’s theorem for $n$ elements are the same, that is, the number of Joyce structures with $n$ elements, or the number of Joyce trees with $n$ leaves, or the odd tangent number of $n$.

PROOF. Let $b_0$ and $b_1$ be the tight bound for Devlin’s theorem and Joyce Devlin’s theorem for $n$ elements, respectively.

We first claim that $b_0 \leq b_1$. Let $(X,<)$ be a dense linear order with no endpoints. By Corollary 5.8, one can enrich this order with a relation $R$ so that $(X,<,R)$ is a DLO Joyce structure. Let $f : |X|^n \to k$ be a coloring. By choice of $b_1$, there is a Joyce subcopy $(Y,<,R)$ of $(X,<,R)$ such that $|f[Y]^n| \leq b_1$. In particular, $(Y,<)$ is a subcopy of $(X,<)$ so $b_0 \leq b_1$.

We then claim that $b_1 \leq b_0$. Let $(X,<,R)$ be a DLO Joyce structure. Let $f : |X|^n \to k$ be a coloring. By choice of $b_0$, there is a subcopy $(Y,<)$ of $(X,<)$ such that $|f[Y]^n| \leq b_0$. By Theorem 5.24, there is a subcopy $(Z,<)$ of $(Y,<)$ such that $(Z,<,R)$ is a Joyce subcopy of $(X,<,R)$. In particular, $|f[Z]^n| \leq b_0$. Thus $b_1 \leq b_0$.

It follows that $b_0 = b_1$. Moreover, by Corollary 5.23, this tight bound is the number of Joyce structures with $n$ elements, that is, the odd tangent number of $n$ (see [47, p. 147]). \hfill \Box

5.3. Lower bounds on Devlin’s theorem

A coloring that witness the need for 2 colors for Devlin’s theorem for pairs is the coloring $f_0$ defined as follows. Let $(q_n)_{n \in \mathbb{N}}$ be an enumeration of the rationals, and define $f_0 : |\mathbb{Q}|^2 \to 2$ by letting $f_0(q_n,q_m) = 0$ if $q_n < q_m$ and $f_0(q_n,q_m) = 1$ otherwise. Now every subset $S \subseteq \mathbb{Q}$ of order-type $\mathbb{Q}$ (or even $\mathbb{Z}$) must contain pairs of both colors under $f_0$, as every element of a dense linear order has infinitely many element both below it and above it.

Definition 5.27 (the ordering $<_\mathbb{Q}$ on $2^{<\omega}$). Given two strings $\sigma, \tau \in 2^{<\omega}$, define $\sigma <_{\text{lex}} \tau$ if and only if one of the following holds:

1. $\sigma < \tau$ and $|\sigma| = 1$;
2. $\tau < \sigma$ and $|\tau| = 0$;
3. $\sigma$ and $\tau$ are incomparable and $\sigma <_{\text{lex}} \tau$, where $<_{\text{lex}}$ is the lexicographical order.
5.3. Lower bounds on Devlin’s theorem

Intuitively, if \( \sigma <_Q \tau \) then \( \sigma \) lies to the left of \( \tau \) if one draws the standard picture of the tree \( 2^{<\omega} \), growing upwards from the root. (See, e.g., Figure 5.2.) From this, the claim that this ordering is order-isomorphic to \( Q \) is clear. An explicit embedding of \( <_Q \) into \( Q \) is given by the following function: \( \sigma \mapsto \sum_{i<|\sigma|} \left( \sigma(i) - \frac{1}{2} \right) 2^{-i} \). Thus, the \( i \)th bit of \( \sigma \) contributes to the sum either \(-2^{-i-1}\) or \( 2^{-i-1} \), depending as it is 0 or 1.

**Theorem 5.28.** There is a computable instance of \( \text{DT}^2_{4,3} \) all of whose solutions compute the halting set.

**Proof.** Recall the order \( <_Q \) from Definition 5.27, and that \((Q, <) \cong (2^{<\omega}, <_Q)\) via a computable bijection. Therefore, the rationals will now be considered as finite strings.

Let \( f_{<_Q} : [2^{<\omega}]^2 \to 2 \) be the function such that \( f_{<_Q}(\sigma, \tau) = 1 \) if and only if \(|\sigma| < |\tau| \iff \sigma <_Q \tau \). Any dense (in the sense of \( <_Q \)) subset of \( 2^{<\omega} \) must contain a pair with both 0, and a pair with color 1. Let also \( f_J : [\mathbb{N}]^3 \to 2 \) be such that for any \( x < y < z \), \( f_J(x, y, z) = 1 \) if and only if \( K_y \upharpoonright x = K_z \upharpoonright x \), where \( K \) is a complete \( \Sigma^0_1 \) set with fixed computable enumeration \((K_n)_{n \in \omega}\).

(The function \( f_J \) was devised by Jockusch [22, Theorem 5.7] to show the analogue of the present theorem for Ramsey’s theorem for triples.)

The function of interest for us is the product function \( f = f_{<_Q} \times f_J : (\sigma, \tau) \mapsto (f_{<_Q}(\sigma, \tau), f_J(|\sigma \land \tau|, |\sigma|, |\tau|)) \). This is a 4-coloring, so by \( \text{DT}^2_{4,3} \) let \( S \subseteq 2^{<\omega} \) be a dense linear ordering for \( <_Q \) such that \( f \) uses at most three colors on \([S]^2\). Suppose for instance that for some \( c \in 2 \) and for every \( \sigma, \tau \in S \), we have \( f(\sigma, \tau) \neq (1, 1 - c) \). (The case where the color \((0, 1 - c)\) is avoided is symmetric.) This means that any \( \sigma_0 <_Q \sigma_1 \) in \( S \) with \(|\sigma_0| < |\sigma_1| \) must have color \( c \) under \( f_J \).

The remainder of the proof consists of two parts. The first is the proof that \( c \) must be 1, and the second is an argument to show how to compute \( K \) from \( S \). The main ingredient will be the fact that for every \( n \in \mathbb{N} \), we can find arbitrarily long strings \( \sigma \) and \( \tau \) in \( S \) with \(|\sigma \land \tau| > n \). This is depicted in Figure 5.2.

Given two strings \( \sigma <_Q \tau \), define \(|\sigma, \tau| = \{ \rho \in 2^{<\omega} : \sigma <_Q \rho <_Q \tau \}. \) Note that if \( I \subseteq 2^{<\omega} \) is a dense linear ordering without endpoints under \( <_Q \), then so is \( I \cap |\sigma, \tau| \). Also, note that if \( \xi, \rho \in |\sigma, \tau| \) then \( \xi \land \rho = \sigma \land \tau \).

**Fact 5.29.** If \( I \subseteq 2^{<\omega} \) is a dense linear ordering without endpoints under \( <_Q \), then \( I \) contains a pair of incompatible strings, \( \sigma \) and \( \tau \). Moreover, for every \( n \in \mathbb{N} \), we can find such \( \sigma \) and \( \tau \) so that \(|\sigma \land \tau| > n \).

**Proof.** Fix \( n \in \mathbb{N} \). As \( I \) is infinite but \( 2^n \) is finite, there exist \( \rho_0, \rho_1 \in I \) such that \( \rho_0 \upharpoonright n = \rho_1 \upharpoonright n \). If \( \rho_0 \) and \( \rho_1 \) are incompatible, then these can serve as \( \sigma \) and \( \tau \). So suppose otherwise, say \( \rho_0 <_Q \rho_1 \). Fix any \( \xi \in I \cap |\rho_0, \rho_1| \). Since \( I \cap |\rho_0, \rho_1| \) is a dense linear order without endpoints, there are infinitely many \( \sigma, \tau \in I \cap |\rho_0, \rho_1| \) with \( \sigma <_Q \xi <_Q \tau \), so these can be chosen so that \(|\sigma| > |\xi| \) and \(|\tau| > |\xi| \). But now, if \( \sigma \) and \( \tau \) were compatible, then by definition of \( <_Q \) they would both be above or both below \( \xi \), a contradiction.
Thus, $\sigma$ and $\tau$ are incomparable elements of $I$. Furthermore, since $\rho_0 <_Q \sigma <_Q \tau <_Q \rho_1$, we have $|\sigma| \upharpoonright n = \tau \upharpoonright n$, so $|\sigma \wedge \tau| > n$.

**Fact 5.30.** If $I \subseteq 2^{<\omega}$ is a dense linear ordering without endpoints under $<_Q$, then for every $n \in \mathbb{N}$ there exists four pairwise incompatible strings $\alpha_j^i \in I$ for $i, j \in 2$ such that $\alpha_0^0 <_Q \alpha_1^0 <_Q \alpha_0^1 <_Q \alpha_1^1$, the strings $\alpha_0^0 \wedge \alpha_1^0$ and $\alpha_0^1 \wedge \alpha_1^1$ are incompatible, and $|\alpha_0^0 \wedge \alpha_1^0 \wedge \alpha_0^1 \wedge \alpha_1^1| > n$. (See Figure 5.2.)

**Proof.** Fix $n \in \mathbb{N}$. First, suppose that whenever $\rho_0, \rho_1 \in I$ satisfy $|\rho_0 \wedge \rho_1| > n$ then they are incompatible. Since $I$ is infinite and $2^n$ is finite, we can then pick $\alpha_j^i <_Q \alpha_j^i <_Q \alpha_j^i <_Q \alpha_j^i$ in $I$ with $|\alpha_j^0 \wedge \alpha_j^0 \wedge \alpha_j^0 \wedge \alpha_j^0| > n$.

Then by assumption, all the $\alpha_j^i$ must be pairwise incompatible, as must $\alpha_0^0 \wedge \alpha_1^0$ and $\alpha_0^1 \wedge \alpha_1^1$.

So suppose otherwise, and fix $\rho_0 <_Q \rho_1$ with $|\rho_0 \wedge \rho_1| > n$. Fix $\gamma \in S \cap |\rho_0, \rho_1|$ (represented in grey in Figure 5.2). As $S \cap |\rho_0, \gamma|$ and $S \cap |\gamma, \rho_1|$ are two dense linear orderings without endpoints, we can apply the preceding fact to find incompatible $\alpha_0^0, \alpha_1^0 \in S \cap |\rho_0, \gamma|$ and incompatible $\alpha_0^1, \alpha_1^1 \in S \cap |\gamma, \rho_1|$ with $|\alpha_0^0 \wedge \alpha_0^1| > |\gamma|$ and $|\alpha_1^0 \wedge \alpha_1^1| > |\gamma|$.

Since $|\alpha_j^i \wedge \alpha_j^i| > |\gamma|$ for each $i \in 2$, we have $|\alpha_j^i| > |\gamma|$ for all $i, j \in 2$.

Hence, $\alpha_j^0$ and $\alpha_j^1$ are incompatible for each $j \in 2$, being on opposite sides of $\gamma$ under $<_Q$.

Since $\alpha_0^0 \wedge \alpha_0^1 <_Q \gamma <_Q \alpha_1^0 \wedge \alpha_1^1$, we have necessarily $\alpha_0^0 \wedge \alpha_0^1 \leq_Q \gamma \leq_Q \alpha_1^0 \wedge \alpha_1^1$, but since $|\alpha_0^0 \wedge \alpha_0^1| > |\gamma|$ for each $i \in 2$ these inequalities must be strict. It follows that $\alpha_0^0 \wedge \alpha_0^1$ and $\alpha_0^1 \wedge \alpha_1^1$ are incompatible, as desired.

Finally, as $\rho_0 <_Q \alpha_j^i <_Q \rho_1$ for all $i, j \in 2$, we have $\rho_0 \leq_Q \alpha_0^0 \wedge \alpha_0^1 \wedge \alpha_0^1 \wedge \alpha_1^1 \leq_Q \rho_1$, meaning that $\alpha_0^0 \wedge \alpha_0^1 \wedge \alpha_0^1 \wedge \alpha_1^1 = \rho_0 \wedge \rho_1$ and hence $|\alpha_0^0 \wedge \alpha_0^1 \wedge \alpha_0^1 \wedge \alpha_1^1| > n$.

We now use Fact 5.30 to prove that the color 1 for $f_j$ cannot be avoided. Fix any $n$, and find $\alpha_j^i \in S$ for $i, j \in 2$ as in Fact 5.30. Fix $l$ such that $K_l \upharpoonright N = K \upharpoonright N$, where $N = |\alpha_0^0 \wedge \alpha_0^1 \wedge \alpha_0^1 \wedge \alpha_0^1|$. Pick $\sigma_n \in S \cap |\alpha_0^0, \alpha_0^1|$ and $\sigma_m \in S \cap |\alpha_0^0, \alpha_0^1|$ such that $n < m$ and $|\sigma_n|, |\sigma_m| > l$. Now, as $\sigma_n \wedge \sigma_m = \alpha_0^0 \wedge \alpha_0^1 \wedge \alpha_0^1 \wedge \alpha_0^1$, we have $f_j(|\sigma_n \wedge \sigma_m|, |\sigma_n|, |\sigma_m|) = 1$ as the approximation for $K \upharpoonright N$ does not change after stage $l$. Therefore, the product coloring $f$ assigns $(\sigma_n, \sigma_m)$ the color $(1, 1)$. In particular, $c = 1$, as desired.

It remains to show that $K$ is $S$-computable. Given $n$, we uniformly compute $K \upharpoonright n$ from $S$. First, search for four strings $(\alpha_j^i)_{i,j \in 2}$ in $S$ satisfying Fact 5.30, which will be found as they exist. Then, output $K_{|\alpha_j^i|} \upharpoonright n$. Indeed, if it were the case that $K_{|\alpha_j^i|} \upharpoonright n \neq K \upharpoonright n$, then it would also be true that $K_{|\alpha_j^i|} \upharpoonright n \neq K_l \upharpoonright n$ for all sufficiently large $l$. But then we would have $f_j(\alpha_j^i, \sigma) = 0$ for any $\sigma \in S \cap |\alpha_j^i, \alpha_j^i|$ with $|\sigma|$ sufficiently big, contradicting that fact that $c = 1$.

**Corollary 5.31.** Over RCA$_0$, DT$_{1,3}^2$ implies ACA.

**Theorem 5.32.** For every $k, \ell \geq 1$, RT$_{k,\ell}^2 \leq_c$ DT$_{2k,2\ell+1}^2$.
PROOF. Let \( f : [\omega]^2 \to k \) be an instance of \( \text{RT}^2_{k,\ell} \). Let \( Q = \{ x_0, x_1, \ldots \} \) be a computable enumeration of all the rationals. Define \( g : [Q]^2 \to 2k \) for every pair \( \{ x_p, x_q \} \in [Q]^2 \) by \( g(x_p, x_q) = (0, f(p, q)) \) if \( x_p <_Q x_q \) and \( g(x_p, x_q) = (1, f(p, q)) \) otherwise. Let \( U \subseteq Q \) be a solution to the instance \( g \) of \( \text{DT}^2_{2k,2\ell+1} \), that is, \((U,<_Q)\) is a DLO order and \(|g[U]^2| \leq 2\ell + 1\). Let \( d < 2 \) and \( I \subseteq \{ 0, \ldots, 2k-1 \} \) with \(|I| \leq \ell \) be such that \( \{ i : (d, i) \in g[U]^2 \} \subseteq I \). Say \( d = 0 \), the other case is symmetrical. Build \( U \)-computably an infinite sequence \( x_{p_0} <_Q x_{p_1} <_Q \ldots \) such that \( p_n < p_{n+1} \). Such a sequence exists since \((U,<_Q)\) has no endpoints. For every \( s < t \in \omega \), \( f(x_{p_s}, x_{p_t}) = (0, f(p_s, p_t)) \). Since \( \{ i : (d, i) \in g[U]^2 \} \subseteq I, f(p_s, p_t) \in I \). Thus, letting \( H = \{ p_s : s \in \omega \} \), \( f[H]^2 \subseteq I \) so \(|f[H]^2| \leq \ell \).

We now give a better lower bound to Devlin’s theorem for pairs by constructing a computable instance of it with no \( \Sigma^0_3 \) solution.

**Definition 5.33.** A set \( H \subseteq \mathbb{N} \) is thin for a \( \sigma \in \kappa^{<\mathbb{N}} \) is there exists some \( i < 2 \) such that for all \( n \in H, n < |\sigma| \implies \sigma(n) \neq i \). It is thin for a tree \( T \subseteq 2^{<\mathbb{N}} \) if the tree \( \{ \sigma \in T : H \text{ is thin for } \sigma \} \) is infinite.

Whenever \( k = 2 \), a thin set is also called homogeneous.

**Definition 5.34.** A \( \Delta^0_0 \) approximation of a sequence \( \sigma \in \kappa^{<\omega} \) is a sequence \( (\sigma_s)_{s \in \mathbb{N}} \) of finite sequence such that for every \( n \), \( \lim_{s \to n} (\sigma(n)) \) exists and has value \( \sigma(n) \).

A \( \Delta^0_3 \) approximation of a sequence \( \sigma \) is a sequence \( (\sigma_{s,t})_{s,t \in \mathbb{N}} \) such that for every \( s \in \mathbb{N} \), \( (\sigma_{s,t})_{t \in \mathbb{N}} \) is a \( \Delta^0_0 \) approximation of a sequence \( \sigma_s \), and \( (\sigma_s)_{s \in \mathbb{N}} \) is a \( \Delta^0_2 \) approximation of \( \sigma \).

**Theorem 5.35.** Let \( F \) be a finite Joyce order with two elements, \( \mathcal{J} \) be a DLO Joyce structure and \( k \) be an integer. For every \( \Delta^0_3 \) approximation of
an infinite tree $T \subseteq k^{<\omega}$, there exists a coloring $f : (\frac{3}{4}) \to k$ such that for every DLO Joyce suborder $S \subseteq \mathbb{J}$, if $f$ avoids 1 color in $(\frac{5}{6})$ then $S$ computes a thin set for $T$.

**Proof.** We can always suppose $\mathbb{J}$ is a coded Joyce order. Let $m, M$ be such that $\{m; M\} = F$, and $|m| < |M|$. Let $(T_{s,t})_{s,t \in \mathbb{N}}$ be a $\Delta_0^0$ approximation of an infinite tree, that is for every $s \in \mathbb{N}$, $T_{s} = \lim_{t} T_{s,t}$ exists and $T = \lim_{t} T_{s,t}$ exists. Let $P_{s,t}$ be the leftmost path of $T_{s,t}$ of length $s$. Note that $P_{s} = \lim_{t} P_{s,t}$ is the leftmost path of $T_{s}$ of length $s$, and $P = \lim_{s} P_{s}$ is the leftmost path of $T$. If $\{\sigma, \tau\} \in (\frac{7}{8})$ with $|\sigma| > |\tau|$, define

$$f(\sigma, \tau) = P_{|\sigma|, |\tau|}((|\sigma| \wedge |\tau|)),$$

a computable coloring of $\left(\frac{1}{2}\right)$ in $k$ colors.

Now, suppose that $S \subseteq 2^{<\omega}$ is of order-type $\mathbb{Q}$ and such that $\left(\frac{8}{9}\right)$ avoids some color $i < k$ for $f$. The claim is that the set

$$H = \{\pi \in (\frac{1}{2}) : (\exists a, b, c, d \in S)(a <_{\text{lex}} b <_{\text{lex}} c <_{\text{lex}} d \wedge |a \wedge c| < |a \wedge b|, |c \wedge d|)\}$$

is thin for $P$, and thus for $T$.

Here, we suppose $m <_{\text{lex}} M$, so that if $x, y \in \mathbb{J}$ satisfies $|x| < |y|$, then $\{x, y\} \in (\frac{1}{2})$ if $x <_{\text{lex}} y$. Let $\ell \in H$, fix $a, b, c, d$ witnessing it. Let $s_0 > \ell$ be such that $P_{s_0}(\ell)$ has settled for every $s \geq s_0$. Let $\sigma \in S$ in the interval with bounds $a$ and $b$ such that $s_1 = |\sigma| \geq s_0$, which exists are there are infinitely many elements of $S$ in this interval. Let $t_0$ be such that $P_{s_1, t_0}(\ell)$ has settled for every $t \geq t_0$, and let $\tau \in S$ be in the interval with bounds $c$ and $d$ with $t_1 = |\tau| \geq \max(t_0, \ell, s_1)$. Then, $\{\sigma, \tau\} \in (\frac{5}{6})$ and $f_P(\sigma, \tau) = P_{s_1, t_1}(\ell) \neq i$ as $\left(\frac{5}{6}\right)$ avoids color $i$. By our choice of $t_1$, $P_{s_1, t_1}(\ell) = P_{s_1}(\ell)$, and by our choice of $s_1$, $P_{s_1}(\ell) = P(\ell) \neq i$, that is, $H$ is thin for $P$, and thus for $T$.

If $m \geq_{\text{lex}} M$, we do the same argument, but we take $\sigma$ in the interval with bounds $c$ and $d$, and $\tau$ in the interval with bound $a$ and $b$, to get the same conclusion.

We proved that $H$ is thin for $T$. As $H$ is c.e. in $S$, it contains an infinite computable subset, which is thin for $T$ as well. \hfill \Box

**Corollary 5.36.** Let $k$ be an integer. For every $\Delta_0^0$ approximation of an infinite tree $T \subseteq k^{<\omega}$, there exists a coloring $f : [\mathbb{Q}]^2 \to 2k$ such that for every DLO Joyce suborder $S \subseteq \mathbb{J}$, if $f$ takes only $2k - 1$ color on $[S]^2$ then $S$ computes a thin set for $T$.

**Proof.** Let $F_0$ and $F_1$ be the two Joyce structure with two elements. Let $f_0$ and $f_1$ be given by Theorem 5.35 for $F_0$ and $F_1$. Define $f : \mathbb{Q} \to 2k$ by enriching $\mathbb{Q}$ to a Joyce order, and if $\sigma, \tau \in \mathbb{Q}$, then $f(\sigma, \tau) = (i, f_i(\sigma, \tau))$ if and only if $\{\sigma, \tau\}$ is isomorphic to $F_i$.

If $S \subseteq \mathbb{Q}$ is an isomorphic substructure such that $f$ takes at most $2k - 1$ color on $[S]$, then let $(i, j)$ with $i < 2$ and $j < k$ be an avoided color. Then, $f_j$ avoids color $j$ on $\left(\frac{5}{6}\right)$, and by our choice of $f_j$, $S$ computes a thin set for $T$. \hfill \Box
Definition 5.37. A function $f : \omega \to \omega$ is DNC relative to $X$ if for every $e$, $f(e) \neq \Phi^X_e(e)$. Here, $f(e)$ can be any value if $\Phi^X_e(e) \uparrow$. A Turing degree is DNC relative to $X$ if it computes such a function.

Lemma 5.38. For every $k \geq 2$ and set $X$, there exists an $X$-computable tree $T \subseteq k^{<\omega}$ such that every infinite set thin for $T$ is of DNC degree relative to $X$.

PROOF. Let $T \subseteq k^{<\omega}$ be an infinite $X$-computable tree such that every infinite path is a Martin-Löf random relative to $X$ in base $k$. Let $H$ be an infinite set thin for $T$. In particular, there is some path $P \in [T]$ and some color $i < k$ such that $H \subseteq \{x : P(x) \neq i\}$. Let $Z$ be the Martin-Löf random $P$ in base 2. The set $H$ computes an infinite subset of $Z$ or of $\overline{Z}$, hence is of DNC degree relative to $X$. \hfill $\Box$

Corollary 5.39. For every $\ell \geq 2$, there exists a computable instance of $(\forall k)\text{DT}^2_{k,\ell}$ such that every solution is of DNC degree relative to $\emptyset''$.

PROOF. Fix $\ell \geq 2$. By Lemma 5.38 relativized to $\emptyset''$, there exists a computable $\Delta^0_2$-approximation of a tree $T \subseteq \ell^{<\omega}$ such that every infinite set thin for $T$ is of DNC degree relative to $\emptyset''$. By Theorem 5.35, let $f$ be a computable instance of $\text{DT}^2_{2\ell,\ell}$ such that every solution compute a set $H$ thin for $T$. Then every solution is of DNC degree relative to $\emptyset''$. \hfill $\Box$

Lemma 5.40. For every $X$-c.e. dense linear order with no endpoints $(D,<_D)$, there is an $X$-computable subset $S \subseteq D$ such that $(S,<_D)$ is a sub-copy of $(D,<_D)$.

PROOF. We build an $X$-computable $<_N$-increasing sequence $x_0 <_N x_1 <_N \ldots$ of elements of $D$ such that letting $S = \{x_n : n \in \mathbb{N}\}$, $(S,<_D)$ is a dense linear order without endpoints. Start with $x_0 \in D$ being any element. Having defined $F = \{x_0 <_N x_1, \ldots <_N x_n\}$, consider a minimal interval in $F \cup \{\neg\infty, +\infty\}$ with respect to $<_D$, that is, an interval $(a, b)$ with $a <_D b \in F \cup \{\neg\infty, +\infty\}$ such that $(a, b) \cap F = \emptyset$. Then wait until some element $x_{n+1}$ appears in $W \cap (a, b)$ with $x_{n+1} >_N x_n$. Such element must be found since, as $(D,<_D)$ is a DLO with no endpoints, there are infinitely many elements in $W \cap (a, b)$, so elements of arbitrary large value with respect to $<_N$. By choosing the minimal interval in an appropriate way, we can ensure that $(S,<_D)$ is a DLO with no endpoints. Since $D$ is $X$-c.e., searching for $x_{n+1}$ is done $X$-computably, so $S \leq_T X$. \hfill $\Box$

Corollary 5.41. For every $\ell \geq 2$, there exists a computable instance of $(\forall k)\text{DT}^2_{k,\ell}$ with no $\Sigma^0_3$ solution.

PROOF. By Corollary 5.39, there is a computable instance $f : [\mathbb{Q}]^2 \to k$ of $(\forall k)\text{DT}^2_{k,\ell}$ such that every solution is of DNC degree relative to $\emptyset''$. Suppose for the contradiction that there is a $\Sigma^0_3$ sub-copy $(U,<_Q)$ of $(\mathbb{Q},<_Q)$ such that $|f[U]^2| \leq \ell$. By Lemma 5.40, there is a $\Delta^0_3$ subset $H \subseteq U$ such that $(H,<_Q)$ is a sub-copy of $(\mathbb{Q},<_Q)$. Since $H$ is of DNC degree relative
to $0''$, is computes a function $f : \omega \to \omega$ such that for all $e$, $f(e) \neq \Phi^{0''}_e(e)$. Since $H$ is $\Delta^0_3$, so is $f$, hence there is some $e$ such that $\Phi^{0''}_e = f$. But then $f(e) = \Phi^{0''}_e(e)$, contradiction. \(\square\)

5.4. Above the big Ramsey number of Devlin’s theorem

In the case of Devlin’s theorem for pairs, the existence of the big Ramsey number implies ACA$_0$. By Corollary 5.31, this is also the case when weakening the statement by allowing 3 instead of 2 colors in the solution. We shall now conclude the chapter about Devlin’s theorem by proving that this bound is tight, in that the statement $(\forall k)\text{DT}^2_{k,4}$ does not imply ACA$_0$ over RCA$_0$. The proof consists essentially of replacing the use of Milliken’s tree theorem for height 3 by the statement $(\forall k)\text{PMTT}^3_{k,2}$ which admits cone avoidance by Theorem 4.28. The cost of this substitution is an increase in the number of colors allowed in the solution.

**Theorem 5.42** (RCA$_0 \land (\forall k)\text{PMTT}^3_{k,2}$). Let $X$ be a DLO Joyce structure and $F$ be a Joyce structure of size 2. Then for every $k \in \omega$ and every coloring $f : \binom{X}{F} \to k$, there is a subcopy $Y$ of $X$ such that $f$ uses at most 2 colors over $\binom{Y}{F}$.

**Proof.** The proof is exactly the same as the one of Theorem 5.21, but replacing an application of Milliken’s tree theorem for height 3 by $(\forall k)\text{PMTT}^3_{k,2}$. \(\square\)

**Theorem 5.43.** $(\forall k)\text{PMTT}^3_{k,2}$ implies $(\forall k)\text{DT}^2_{k,4}$ over RCA$_0$.

**Proof.** Let $F_0$ and $F_1$ be the two coded Joyce orders of size 2. Let $X$ be a coded DLO Joyce order and let $f : [X]^2 \to k$ be a coloring. By Theorem 5.42, there is a subcopy $X_0$ of $X$ such that $f$ uses at most 2 colors $i_0, i_1$ over $\binom{X_0}{F_0}$. Again by Theorem 5.42, there is a subcopy $X_1$ of $X_0$ such that $f$ uses at most 2 colors $j_0, j_1$ over $\binom{X_1}{F_1}$. We claim that $f[X]^2 \subseteq \{i_0, i_1, j_0, j_1\}$. Let $E \in [X]^2$. In particular, $E$ is isomorphic to $F_0$ or $F_1$. In the first case, $f(E) \in \{i_0, i_1\}$ and in the second case, $f(E) \in \{j_0, j_1\}$. Thus $X_1$ is a subcopy of $X$ such that $|f[X]^2| \leq 4$. \(\square\)

**Corollary 5.44.** $(\forall k)\text{DT}^2_{k,4}$ admits cone avoidance.

**Proof.** By Theorem 4.28, $(\forall k)\text{PMTT}^3_{k,2}$ admits cone avoidance hence so does $(\forall k)\text{DT}^2_{k,4}$ by Theorem 5.43. \(\square\)

**Corollary 5.45.** $(\forall k)\text{DT}^2_{k,4}$ does not imply ACA$_0$ over RCA$_0$.

**Proof.** By Theorem 4.28, $(\forall k)\text{PMTT}^3_{k,2}$ admits cone avoidance, hence there is a model $Mc$ of RCA$_0 \land (\forall k)\text{PMTT}^3_{k,2}$ which is not a model of ACA$_0$. In particular, $Mc \models (\forall k)\text{DT}^2_{k,4}$ by Theorem 5.43. \(\square\)
5.5. The Erdős Rado theorem

Erdős and Rado proved that it is always possible to obtain either a copy of \( \mathbb{Q} \) of one color, or else an infinite homogeneous set (in the sense of Ramsey’s theorem) of the other color.

**Theorem 5.46 (Erdős Rado theorem).** For every \( f : [\mathbb{Q}]^2 \to 2 \), there exists a subset \( S \subseteq \mathbb{Q} \) such that either \( S \) is infinite and \( f \)-homogeneous of color 0, or \( S \) is of order-type \( \mathbb{Q} \) and \( f \)-homogeneous of color 1.

**Statement 5.47.** \( \text{ER}^2 \) is the statement denoting the Erdős Rado theorem.

This statement was studied by [5, 15, 14] in the setting of reverse mathematics. One would expect it to be a consequence of Devlin’s theorem by the optimality of the bounds noted above. We give a direct combinatorial proof of \( \text{ER}^2 \) from Devlin’s theorem for pairs of rationals.

**Theorem 5.48.** \( \text{DT}^2_{4,2} \) implies \( \text{ER}^2 \).

**Proof.** Let \( f : [\mathbb{Q}]^2 \to 2 \) be a coloring of pairs of rationals, regarded as a given instance of \( \text{ER}^2 \). Let \( f_0 \) be the 2-coloring of \( [\mathbb{Q}]^2 \) witnessing the fact that big Ramsey degree of the pairs of rationals is 2, that is, \( f_0 \) is such that for every sub-copy \( S \) of the rationals, \( |f_0[S]^2| = 2 \). An explicit construction of \( f_0 \) is given at the start of Section 5.3.

Apply \( \text{DT}^2_{4,2} \) to the 4-coloring \( f \times f_0 : (q, r) \mapsto (f(q, r), f_0(q, r)) \) to get a subcopy of the rationals \( S \) such that \( f \times f_0 \) uses at most \( \text{DT}(2) = 2 \) colors on \( [S]^2 \). As \( [S]^2 \) must have two colors for \( f_0 \), the two colors of \( [S]^2 \) for \( f \times f_0 \) must be of the form \((c_0, 0)\) and \((c_1, 1)\). The rest of the proof is split into 3 cases.

**Case 1:** \( c_0 = c_1 = 1 \). In this case, \( [S]^2 \) is monochromatic with color 1 for \( f \), and since \( S \) has order-type \( \mathbb{Q} \) it is a solution to \( f \) as an instance \( \text{ER}^2 \).

**Case 2:** \( c_0 = 0 \) and \( c_1 = 1 \). Then \( f_0(q, r) = 0 \) implies \( f(q, r) = 0 \), for all \( q, r \in S \). We build an infinite set \( T = \{ q_n : i \in \mathbb{N} \} \) such that \( |T|^2 \) is monochromatic for \( f_0 \) with color 0, and therefore also for \( f \) with color 0. To this end, we build an increasing sequence of rationals \( (q_{n_i})_{i \in \mathbb{N}} \) in \( S \), such that \( (n_i)_{i \in \mathbb{N}} \) is also increasing. Fix any \( q_{n_0} \in S \), and suppose \( q_{n_i} \) has been defined. As there exists infinitely many rationals in \( S \) above \( q_{n_i} \), there exists \( n_{i+1} > n_i \) such that \( q_{n_{i+1}} > q_{n_i} \) and \( q_{n_{i+1}} \in S \). This completes the construction. Now, \( T \) is an infinite \( f \)-homogeneous set with color 0, and hence a solution to \( f \) as an instance \( \text{ER}^2 \).

**Case 3:** \( c_1 = 0 \) and \( c_0 = 0 \). Symmetric to Case 2.

However, \( \text{ER}^2 \) admits cone avoidance. As a warm-up before the proof of this result, we prove the following:

**Lemma 5.49.** Let \( f_J : [2^{< \omega}]^2 \to 2 \) be such that \( f_J(\sigma, \tau) = 1 \) iff \( \emptyset'[|\sigma]| \upharpoonright |\sigma \land \tau| = \emptyset'[|\tau|] \upharpoonright |\sigma \land \tau| \). Then, there exists two computable infinite sets \( X_0 \) and \( X_1 \) such that \( [X_i]^2 \) is monochromatic of color \( i \) for \( f_J \).
PROOF. First, we do the construction for \( i = 0 \). The set \( X_0 \) is defined as \( \{0^{n+1} : i \in \omega \} \) for an increasing sequence \((n_i)_{i \in \omega} \) verifying that \( \emptyset'[n_i+1] \upharpoonright n_i \neq \emptyset'[n_{i+1}+1] \upharpoonright n_i \). Suppose that \( n_i \) is defined. Then \( n_{i+1} \) is the first integer \( n > n_i \) found such that \( \emptyset'[n+1] \upharpoonright n \neq \emptyset' \upharpoonright n \) and \( \emptyset'[n_i+1] \upharpoonright n_i \neq \emptyset'[n+1] \upharpoonright n_i \), which must exists as otherwise \( \emptyset' \) would be computable. Then, \([X_0]^2 \) is monochromatic of color 0 by construction.

For the other case, define \( X_1 = \{ \emptyset'[n] \upharpoonright n : n \in \omega \} \), we claim that \([X_1]^2 \) is monochromatic for \( f_J \) of color 1. Let \( \sigma_0, \sigma_1 \in X_1 \) and for \( i < 2 \), the length \( n_i = |\sigma_i| \) is such that \( \sigma_i = \emptyset'[n_i] \upharpoonright n_i \). We have \( f_J(\sigma_0, \sigma_1) \iff \emptyset'[|\sigma_0|] \upharpoonright |\sigma_0 \land \sigma_1| = \emptyset'[|\sigma_1|] \upharpoonright |\sigma_0 \land \sigma_1| \), which we claim is true. Indeed, as \( |\sigma_0| > |\sigma_0 \land \sigma_1| \), we have
\[
\emptyset'[|\sigma_0|] \upharpoonright |\sigma_0 \land \sigma_1| = (\emptyset'[n_0] \upharpoonright n_0) \upharpoonright |\sigma_0 \land \sigma_1| = \sigma_0 \upharpoonright |\sigma_0 \land \sigma_1|
\]
and as \( |\sigma_1| > |\sigma_0 \land \sigma_1| \):
\[
\emptyset'[|\sigma_1|] \upharpoonright |\sigma_0 \land \sigma_1| = (\emptyset'[n_1] \upharpoonright n_1) \upharpoonright |\sigma_0 \land \sigma_1| = \sigma_1 \upharpoonright |\sigma_0 \land \sigma_1|.
\]
By definition of the meet operator, \( \sigma_0 \upharpoonright |\sigma_0 \land \sigma_1| = \sigma_1 \upharpoonright |\sigma_0 \land \sigma_1| \), therefore \( f_J(\sigma_0, \sigma_1) = 1 \) and \([X_1]^2 \) is monochromatic of color 1.

THEOREM 5.50. The statement \( \text{ER}^2 \) admits cone avoidance.

PROOF. Let \( Z \), and \( C \) with \( C \not\leq_T Z \). Let \( f : [2^{<\omega}]^2 \rightarrow 2 \) be a \( Z \)-computable coloring, seen as an instance of \( \text{ER}^2 \) as \((\mathbb{Q}, \lhd)\) and \((2^{<\omega}, \lhd)\) are computably isomorphic. Define \( i_\omega = 0 \) and \( i_\Q = 1 \), so that the goal is to find either an infinite set homogeneous for color \( i_\omega \), or a set of order-type \( \mathbb{Q} \) homogeneous for color \( i_\Q \).

The proof goes as follows: first, we build a set \( G \) such that \( C \not\leq_T Z \oplus G \) but \( C \leq_T (Z \oplus G)' \). Then, we apply cone avoidance of \( \text{DT}^2_{<\omega,<\omega} \) to the product of three colorings: the initial instance of \( \text{ER}^2 \), the Jockush coloring relativized to \( Z \oplus G \), and the coloring witnessing the fact that at least two colors must remain. Finally, we reason depending on which are the four remaining colors, with the two main constructions being linked with the two constructions of lemma 5.49. Let us start with the existence of \( G \).

CLAIM 5.51. There exists \( G \) such that \( C \not\leq_T Z \oplus G \) but \( C \leq_T (Z \oplus G)' \).

PROOF. Define a forcing, whose conditions are the tuples \((p, n)\) where \( p : \omega \times \omega \rightarrow 2 \) has finite domain, and \( n \) is an integer. A condition \((q, m)\) extends a condition \((p, n)\) if \( q \supseteq p \), and for every \((x, y) \in \text{dom}(q) \setminus \text{dom}(p)\), if \( x < n \) then \( q(x, y) = C(x) \). It is clear that if \( G \) is generic enough for this forcing, then \( G' \geq_T C \): Indeed, for every \( i \), the set of conditions \( \{(p, n) : n \geq i\} \) is dense. Therefore, \( \lim_{n \rightarrow \infty} G(i, n) \) is always defined with value \( C(i) \).

It remains to show that \( C \not\leq_T Z \oplus G \). We prove that for every \( e \), the set of conditions \((p, n)\) for which there is an \( i \) such that \( \Phi^{Z \oplus p}_e(i) \downarrow \neq C(i) \) or there is an \( i \) such that for all \((q, m)\) extending \((p, n)\), \( \Phi^{Z \oplus q}_e(i) \uparrow \), is dense. Indeed,
5.5. THE ERDŐS RADO THEOREM

fix \((p_0, n_0)\). If there exists \((p, n) \leq (p_0, n_0)\) and \(i\) such that \(\Phi^Z \oplus G(i) \downarrow \neq C(i)\), then \((p, n_0)\) extends \((p_0, n_0)\) and forces \(\Phi_e^Z \oplus G\) not to compute \(C\). If there is an \(i\) such that no \((q, n) \leq (p_0, n_0)\) are such that \(\Phi_e^Z \oplus G(i) \downarrow\), then already \((p_0, n_0)\) forces partiality of \(\Phi_e^Z \oplus G\). If none of the two previous cases happen, then \(Z\) computes \(C\): to know the value of \(C(i)\), guess the first \(n_0\) values of \(C\), using these find a \((q, n) \leq (p_0, n_0)\) such that \(\Phi_e^Z \oplus G(i) \downarrow\), we have \(\Phi_e^Z \oplus G(i) = C(i)\). This contradicts that \(C \not \leq_T Z\).

Let \(f_G^f\) be the coloring defined in the proof of Theorem 5.28 relativized to \(Z \oplus G\), that is, \(f_G^f(\sigma, \tau) = 1\) if \((Z \oplus G)'[|\sigma|]' | \sigma \wedge \tau| = (Z \oplus G)'[|\tau|]' | \sigma \wedge \tau|\). If \(|\tau| > |\sigma|\), we can see color 1 for \(f_G^f\) as saying: \(|\tau|\) witness that the interval from \(|\sigma \wedge \tau|\) to \(|\sigma|\) is “large” (relatively to \(Z \oplus G\)). To reflect this, we define \(i_s = 0\) the “small” color, and \(i_l = 1\) the “large” color. As in Theorem 5.28, let also \(f_{<Q}(\sigma, \tau) = 1\) if \((Q \preceq \tau) \iff |\sigma| < |\tau|\), note that \(f_{<Q}\) can be seen as the coloring which outputs the finite Joyce structure of \(\{\sigma, \tau\}\). For the colors of \(f_{<Q}\), we will use the variable \(i_{<Q}\).

Finally, define \(g : [2^{<\omega}]^2 \to (2 \times 2 \times 2)\) by

\[
g(\sigma, \tau) = (f(\sigma, \tau), f_G^f(\sigma, \tau), f_{<Q}(\sigma, \tau)).\]

We apply cone avoidance of \(DT^2_{<\omega,4}\), Corollary 5.45, to the coloring \(g\) to get a set \(S \subseteq 2^{<\omega}\) such that \(S \oplus G \oplus Z \not \leq_T C\) and \((S, <Q)\) is a dense linear order with no endpoints, and such that \(g\) takes at most 4 colors on \([S]^2\).

Recall that none of the colors of \(f_{<Q}\) can be avoided in a subset of \(2^{<\omega}\) of order-type \(Q\), therefore the two sets \(S_{<Q} = \{(\sigma, \tau) : f_{<Q}(\sigma, \tau) = i_{<Q}\}\) for \(i_{<Q} < 2\) must be non empty; and the sum of the number of colors taken by \(g\) on them is at most 4. Start by supposing that for each \(i_{<Q} < 2\), \(g\) takes at most 2 colors on \(S_{<Q}\).

We reason depending on the following cases:

**Case 1:** There exists \(i_{<Q} < 2\), such that \(S_{<Q}\) is monochromatic for \(f_G^f\).

**Case 2:** There exists \(i_{<Q} < 2\), such that on \(S_{<Q}\), \(f = f_G^f\).

**Case 3:** There exists \(i_{<Q} < 2\), such that on \(S_{<Q}\), either \(f\) is homogeneous of color \(i_{<Q}\), or \(f = 1 - f_G^f\).

**Case 4:** For all \(i_{<Q} < 2\), \(S_{<Q}\) is monochromatic of color \(i_{<Q}\) for \(f\).

We now prove the four cases in three different construction, Case 4 being trivial. The first construction is the one from Theorem 5.28, and shows that Case 1 cannot happen. The second and third construction correspond to the two constructions of Lemma 5.49. To separate them more clearly, the proof is divided in claims.

**Claim 5.52.** In Case 1, \(S \oplus Z \oplus G\) computes \((Z \oplus G)'\).
PROOF. The first paragraph after the proof of Fact 5.30 asserts that the function $f_f^G$ must be monochromatic for color $i_\ell$. The second paragraph asserts that in this case, $S \oplus G \oplus Z$ computes $(Z \oplus G)'$. □

By our choice of $G$, $(Z \oplus G)'$ computes $C$, and thus $S \oplus Z \oplus G \geq_T C$, a contradiction with our choice of $S$, so Case 1 cannot happen.

**Claim 5.53.** In Case 2, there exists a set $\hat{S} \subseteq S$ computable in $S \oplus Z \oplus G$, such that $[\hat{S}]^2 \subseteq S_{i_0}$ is an infinite subset monochromatic for color $i_\infty$.

PROOF. Note that by the fact that we are in Case 2, a set $\hat{S}$ with $[\hat{S}]^2 \subseteq S_0$ is such that $[\hat{S}]^2$ is monochromatic of color $i_\infty$ for $f$ if and only if it is monochromatic of color $i_s$ for $f_f^G$. The following construction corresponds to the first case of Lemma 5.49. We computably in $S \oplus G \oplus Z$ define a sequence $(F_n, A_n)$, where $F_n$ is a finite approximation to $\hat{S}$ and $A_n$ a reservoir for future addition to $F_n$, such that for all $n \in \omega$ the following holds:

1. $F_n$ is a finite set such that $[F_n]^2 \subseteq S_{i_0}$;
2. $A_n \subseteq S$ is of order-type $Q$;
3. $F_n \subseteq F_{n+1}$ and $A_{n+1} \subseteq A_n$;
4. for all $\sigma \in F_n$ and all $\tau \in F_n \cup A_n$, $(\sigma, \tau) \in S_{i_0}$ and $f_f^G(\sigma, \tau) = i_s$;
5. for all $\sigma \in F_{n+1} \setminus F_n$, $\sigma \in A_n$.

Suppose $F_n, A_n$ are defined. If there is no $\sigma, \tau_0, \tau_1 \in A_n$ with $(\sigma, \tau_i) \in S_{i_0}$ for $i < 2$ such that $(G \oplus Z)'[\sigma] \upharpoonright \ell \neq (G \oplus Z)' \upharpoonright \ell$ where $\ell = \min |\sigma \wedge \tau_0|, |\sigma \wedge \tau_1|$, then $A_n \oplus G \oplus Z$ would compute $(G \oplus Z)' \geq_T C$. Define $F_{n+1} = F_n \cup \{\sigma\}$ and

$$A_{n+1} = \{\tau \in A_n : (G \oplus Z)' \upharpoonright \ell = (G \oplus Z)'[\tau] \upharpoonright \ell \wedge \tau_0 \in Q \tau \in Q \tau = \tau_1\}.$$ 

By construction, all items are satisfied. Define $\hat{S} = \bigcup_n F_n$. By Item 3, $\hat{S}$ is infinite, and by Item 4 and 5, $[\hat{S}]^2$ is monochromatic of color $i_s$ for $f_f^G$, and thus monochromatic of color $i_\infty$ for $f$. □

**Claim 5.54.** In Case 3, there exists $\hat{S} \subseteq S$ such that $\hat{S} \oplus Z \not\geq_T C$ and $[\hat{S}]^2 \subseteq S_i$ is an infinite set monochromatic of color $i_\infty$ for $f$.

PROOF. If $f$ is homogeneous of color $i_\infty$ on $S_{i_0}$ then $S_{i_0}$ is already a witness of the claim. Otherwise, $f(\sigma, \tau) = i_\infty$ if and only if $f_f^X(\sigma, \tau) = i_\ell$, so all we need is to find a subset $\hat{S} \subseteq S$ such that $[\hat{S}]^2 \subseteq S_{i_0}$ and $[\hat{S}]^2$ is monochromatic of color $i_\ell$ for $f_f^G$.

The following construction is roughly analogous to the second case in the proof of Lemma 5.49, however the number of time we can take a lower meet to avoid having color $i_s$ is not anymore equal to the number of times we might have to do it. This prevents us from doing the construction computably, however we can still make it cone avoiding. We build $\hat{S}$ using the following forcing:
Definition 5.55. A condition is a couple \((F, D)\) such that \(F\) is a finite set with \([F]^2 \subseteq S_{i_0} \). and \(D \subseteq S\) is computable in \(S\) and of order-type \(Q\), and such that: for all \(\sigma \in F\) and all \(\tau \in F \cup D\), \((\sigma, \tau) \in S_{i_0}\) and \(f^G_\ell(\sigma, \tau) = i_\ell\).

A condition \((F_1, D_1)\) extends a condition \((F_0, D_0)\) if \(D_1 \subseteq D_0\) and for all \(\sigma \in F_1 \setminus F_0\), \(\sigma \in D_0\). We write \((F_1, D_1) \leq (F_0, D_0)\).

If \(\mathcal{F}\) is a filter for this forcing, then we let \(S_\mathcal{F} = \bigcup\{ F : (\exists D)[(F, D) \in \mathcal{F}] \}. We have that \([S_\mathcal{F}]^2 \subseteq S_{i_0}\) is monochromatic of color \(i_\ell\) for \(f^G_\ell\). So we need to find a filter ensuring that \(S_\mathcal{F}\) is infinite and \(S_\mathcal{F} \oplus Z\) does not compute \(C\).

Definition 5.56. Let \((F, D)\) be a condition and \(\varphi\) be a \(\Delta^0_0\) formula with a free set parameter \(\hat{S}\). We say that:

1. \((F, D) \models (\exists x)\varphi(\hat{S}, x)\) if \(\varphi(F, x)\) holds for some \(x \in \omega\);
2. \((F, D) \models (\forall x)\varphi(\hat{S}, x)\) if \(\varphi(F \cup E, x)\) holds for every \(x\), and for every \(E \subseteq D\) with \([F \cup E]^2 \subseteq S_{i_0}\) monochromatic of color \(i_\ell\) for \(f^G_\ell\).

We claim that for every Turing functional, for every condition \((F, D)\), there is a condition \((F', D') \leq (F, D)\) such that \((F', D') \models \Gamma^{S_\mathcal{F} \oplus Z} \neq C\). Let \(D_0 <_Q D_1\) be two subsets of \(D\) computable in \(S\) of order type \(Q\): For instance, pick \(x_0 <_Q x_1 <_Q x_2 \in D\), and define \(D_0 = \{ x \in D : x_0 <_Q x < Q x_1 \}\) and \(D_1 = \{ x \in D : x_1 <_Q x < Q x_2 \}\). Fix \(e \in \omega\).

Define the following c.e. set, where by “\(E\) is compatible with \(F\)” we mean that for all \(\sigma, \tau \in F \cup E\), \(f^G_\ell(\sigma, \tau) = i_\ell\) and \([F \cup E]^2 \subseteq S_{i_0}\):

\[
W = \{ (x, i) : (\exists E \subseteq F_{D_1-i_0}\) compatible with \(F)\} \bigcap \{ f^G_\ell(\sigma, \tau) = i_\ell \} \bigcap [F \cup E]^2 \subseteq S_{i_0}\}.
\]

We consider the three following cases.

Case 1: There exists \(x \in \omega\) such that \((x, 1 - C(x)) \in W\). Let \(E\) be a witness of this. The condition \((F \cup E, D_{i_0})\) forces \(\Phi_e\) to be different from \(C\), where \(D_{i_0}\) is \(D_{i_0}\) with a finite number of elements removed, so that for all \(\sigma \in E\) and all \(\tau \in D_{i_0}\), \((G \oplus Z) | | \sigma| = (G \oplus Z) | | \tau|\).

Case 2: There exists \(x \in \omega\) such that for each \(i \in 2\), \((x, i) \notin W\). The condition \((F, D_{1-i_0})\) already forces divergence of \(\Phi_e\).

Case 3: Otherwise. Thus, for every \(x\) there is an \(i\) such that \((x, i) \in W\) and \((x, i) \notin W\) \(\implies i = C(x)\). But as \(W\) is c.e., this implies that \(C\) is computable, a contradiction.

Finally, any sufficiently generic for this forcing is infinite: indeed, consider the functional \(\Gamma\) which halts if and only if its oracle has at least \(n\) elements. It is impossible to have a condition forcing \(\Gamma\) to halt, so any sufficiently generic has at least \(n\) elements, and so for every \(n\).

By the previous claims, Case 1 cannot happen, and Cases 2 and 3 validate the theorem with an infinite and cone avoiding set homogeneous for
color $i_\infty$. In Case 4, we are also done, as $S$ is a homogeneous set for color $i_Q$, of order-type $i_Q$.

In the making of the four cases, we supposed that each $S_{i_{<Q}}$ takes at most two colors. It remains the case when for some $i_{<Q}, S_{i_{<Q}}$ takes only one color by $g$, and $S_{1-i_{<Q}}$ takes three colors by $g$. But then, Case 1 holds for $i_{<Q}$, a contradiction.
CHAPTER 6

The Rado Graph theorem

6.1. A big Ramsey structure for the Rado Graph

Definition 6.1. A Joyce graph is a graph $G = (G, E)$ together with an order $<$ on $G$ and a symmetric function $[\cdot, \cdot] : G^2 \to \mathbb{N}$ such that $(G, <, [\cdot, \cdot])$ is a Joyce order and

(J4) for all $x, y, z \in G$, $[x, x] < [y, z] \implies (xEy \iff xEz)$.

As in the previous chapter, the function $[\cdot, \cdot]$ has to be taken as the height of a meet. The axiom (J4) states that if two elements have a meet above the height of a third element, they are both linked to it or none are linked to it. In this sense, the axiom states some compatibility between the $[\cdot, \cdot]$ operator and the edge relation. However, compared to the axiom (J2) which states a compatibility between the order and the $[\cdot, \cdot]$ operator, the crucial height is the one of the element and not of the meet. In other words, the relevant height to decide whether $x < y$ is at the level of the meet, while the relevant height to decide the edge relation between $x$ and $y$ is at the level of $x$ or $y$.

Definition 6.2. A Joyce Rado graph is a Joyce graph $(G, E, <, [\cdot, \cdot])$ such that $(G, E)$ is a Rado graph.

In what follows, define the relation $E_{pn}$ on strings of different length by $\sigma E_{pn} \tau$ if and only if $|\sigma| = 1$ and $|\tau| < |\sigma|$, or $|\sigma| = 1$ and $|\sigma| < |\tau|$.

Theorem 6.3 (RCA₀). There exists a Joyce Rado graph.

Proof. Consider $g : 2^{< \omega} \to 2^{< \omega}$ to be the function such that $g(\sigma) = \tau$, where $|\sigma| = 3|\sigma| + 2$, for all $n < |\sigma|$, $\tau(3n) = \tau(3n + 1) = \tau(3n + 2) = \sigma(n)$, and $\tau(3|\sigma| + 1) = 1$. The image of $g$ is a antichain. Fix an injective function $v : 2^{< \omega} \to \omega$ such that for every $\sigma, \tau \in 2^{< \omega}$, if $|\sigma| < |\tau|$ then $v(\sigma) < v(\tau)$, and for every $\sigma, \tau \in 2^{< \omega}$, define $\llbracket \sigma, \tau \rrbracket = v(\sigma \land \tau)$. Last, fix a cofinal set $S \subseteq 2^{< \omega}$ such that for all $\sigma, \tau \in S$, $|\sigma| \neq |\tau|$. The claim is that $(g[S], E_{pn}, <_{\text{lex}}, [\cdot, \cdot])$ is a Joyce Rado graph.

We prove that $(g[S], E_{pn}, <_{\text{lex}}, [\cdot, \cdot])$ satisfies axioms (J1), (J2), (J3) and (J4). Let $x, y, z, t \in g[S]$, not all equal, with $x \leq_{\text{lex}} y$ and $z \leq_{\text{lex}} t$.

(J1): Suppose $[x, y] < [x, z]$. By definition, $v(x \land y) < v(x \land z)$. By choice of the map $v$, $|x \land y| \leq |x \land z|$, so $x \leq_{\text{lex}} y$ if $z \leq_{\text{lex}} y$.

(J2): Suppose $[x, y] < [x, z]$. By definition, $v(x \land y) < v(x \land z)$. By choice of the map $v$, $|x \land y| \leq |x \land z|$, so $x \land y = z \land y$, hence $v(x \land y) = v(z \land y)$.

87
(J3): Suppose \([x, y] = [z, t]\). By definition, \(v(x \land y) = v(z \land t)\). By injectivity of the map \(v\), \(x \land y = z \land t\), so \(x \land y \prec x \land z\) and \(x \land y \prec y \land t\), hence \(v(x \land y) <_\mathbb{N} \min (v(x \land z), v(y \land t))\).

(J4): Let \(x, y, z \in g[S]\). Suppose \([x, x] < [y, z]\). By definition, \(v(x) = v(x \land x) < v(y \land z)\). By choice of the map \(v\), \(|x| \leq |y \land z|\), but as the length of elements of \(g[S]\) and the length of proper meets of \(g[S]\) are different by construction, \(|x| < |y \land z|\). Therefore \(y(|x|) = z(|x|)\) so \(x E_{p,n} y\) iff \(z E_{p,n} y\).

It remains to show that \((g[S], E_{p,n})\) is a Rado graph. Let \(F_0, F_1 \subseteq g[S]\) be finite disjoint sets. As \(S\) contains at most one element of each length, and is cofinal, let \(\sigma\) be a string in \(S\) such that \(\sigma(\ell) = i\) whenever there exists \(\tau \in S\) of size \(\ell\) with \(g(\tau) \in F_i\). By definition of \(g\), \(\sigma E_{p,n} \tau\) iff \(g(\sigma) E_{p,n} g(\tau)\), so \(g(\sigma)\) is linked with all of \(F_1\) and none of \(F_0\). Therefore, \((g[S], E_{p,n})\) is a Rado graph.

\[
\square
\]

**Corollary 6.4 (RCA₀).** Every Rado graph \(G = (G, E)\) can be ordered and equipped with a function \(\llbracket\cdot, \cdot\rrbracket: G^2 \to \mathbb{N}\) to form a Joyce Rado graph.

**Proof.** Let \((X, E_{p,n}, <_{\text{lex}}, \llbracket\cdot, \cdot\rrbracket_X)\) be the Joyce Rado graph of Theorem 6.3. By computable categoricity of the Rado graph, there exists a graph isomorphism \(f\) between \(G = (G, E)\) and \((X, E_{p,n})\). Define \(x < y\) for \(x, y \in G\) if and only if \(f(x) <_{\text{lex}} f(y)\). Also define \(\llbracket\cdot, \cdot\rrbracket: G^2 \to \mathbb{N}\) by \([x, y] = [f(x), f(y)]_X\). Then \((G, E, <, \llbracket\cdot, \cdot\rrbracket)\) is a Joyce Rado graph. \(\square\)

The first-order structure that is of interest for us is the following.

**Definition 6.5.** The Joyce (Rado) graph structure of a Joyce (Rado) graph \((G, E, <, \llbracket\cdot, \cdot\rrbracket)\) is the structure \((G, E, <, R)\) such that \((G, <, R)\) is the Joyce structure of the Joyce order \((G, <, \llbracket\cdot, \cdot\rrbracket)\).

We shall prove later that Joyce Rado graphs structures have big Ramsey degree 1 for every finite Joyce graph structure.

**Statement 6.6.** For all \(n, k, \ell \geq 1\), \(\text{JRG}^n_{k, \ell}\) is the assertion that for every Joyce Rado graph structure \(G\) and every coloring \(f: [G]^n \to k\), there exists an isomorphic substructure \(G'\) of \(G\) satisfying \(|f(G')^n| \leq \ell\).

As every Joyce graph is in particular a Joyce order, every finite Joyce graph of size \(n\) can be fully specified by a finite Joyce order and a finite graph, both of size \(n\), or equivalently by a finite Joyce tree with \(n\) leaves and a finite graph of size \(n\). In particular, for a fixed graph \(G\) of size \(n\), there are at most as many Joyce graphs isomorphic to it as there are Joyce trees with \(n\) leaves. On the other hand, as we shall see in Figure 6.1, if a finite graph \(G\) of size \(n\) is neither the clique, nor the anti-clique with \(n\) vertices, there are some Joyce orders of size \(n\) which cannot be enriched to form a Joyce graph isomorphic to \(G\).

**Theorem 6.7 (Joyce Rado graph theorem).** For all \(n, k \geq 1\), \(\text{JRG}^n_{k, \ell}\) holds, where \(J_n\) is the number of non isomorphic Joyce graphs with \(n\) elements. Moreover, this bound is tight: \(\text{JRG}^n_{k, \ell}\) does not hold for any \(\ell < J_n\).
Just as we did for the Joyce order, we can canonically represent any countable Joyce graph as a set of strings equipped with the lexicographic order and \(|\cdot \land \cdot|\), but also the relation \(E_{pn}\).

**Definition 6.8.** A **coded Joyce graph** is a Joyce graph of the form 
\[(X, E_{pn}, <_{\text{lex}}, |\cdot \land \cdot|)\]
such that for all \(\sigma, \tau, \rho \in X\) with \(\sigma \neq \tau\), \(|\rho| > |\sigma \land \tau|\) and \(\sigma \land \tau \neq \rho\), we have 
\[\rho(|\sigma \land \tau|) = 0.\]

Note that if \((X, E_{pn}, <_{\text{lex}}, |\cdot \land \cdot|)\) is a coded Joyce graph, that does not mean that \((X, <_{\text{lex}}, |\cdot \land \cdot|)\) is a coded Joyce order. Indeed, there is no restriction on \(\rho(|\sigma \land \sigma|)\) in the case of a coded Joyce graph, while this value must be 0 in the case of a coded Joyce order. The two notions thus coincides if and only if \(\neg \sigma E_{pn} \tau\) for every \(\sigma, \tau \in X\), by definition of \(E_{pn}\).

![Diagram of coded Joyce graphs](image)

**Figure 6.1.** In (a), a finite graph \(G = ([x_0, x_1, x_1], \{x_0, x_1\})\). In (b) and (c), two coded Joyce graphs isomorphic to \(G\). The trees (e) and (f) are Joyce trees corresponding the coded Joyce graphs (b) and (c), respectively. In (d), a Joyce tree which cannot represent the graph \(G\). Indeed, since there is an edge between \(x_0\) and \(x_1\) but not between \(x_0\) and \(x_1\), then for any coded Joyce graph \(\{\sigma_0, \sigma_1, \sigma_2\}\) representing \(G\), \(|\sigma_1 \land \sigma_2| < |\sigma_0|\).

**Theorem 6.9 (\(\text{RCA}_0\)).** Every countable Joyce graph is isomorphic to a coded Joyce graph.
PROOF. Let \((G, E, <, [\cdot, \cdot])\) be a countable Joyce graph. Let \(\sigma_x \in 2^{<\omega}\) be the unique string of length \([x, x]\), such that for any \(j < [x, x]\):

1. if \(j = \left[ x, y \right]\) for some \(y \in G\), then \(\sigma_x(j) = 1\) if and only if \(y < x\);
2. if \(j = \left[ y, y \right]\) for some \(y \in G\), then \(\sigma_x(j) = 1\) if and only if \(xEy\);
3. \(\sigma_x(j) = 0\) otherwise.

One first need to show that \(\sigma_x\) is well-defined. First, there is no \(y, z \in G\) such that \([y, z] = [z, z]\) by (J3), so Item 1 and Item 2 are compatible. Item 1 do not contradict itself as there is no \(y, z \in G\) such that \([y, y] = [z, z]\), also by (J3). It remains to show that Item 2 does not contradict itself: Let \(x, y, z \in G\) be such that \([x, y] = [x, z] < [x, x]\). Then, by (J3) \([x, y] < \mathbb{N} [y, z]\) and by (J1) we have \(x < z\) iff \(x < y\). So \(\sigma_x\) is well-defined.

Let \(X = \{\sigma_x : x \in G\}\). We claim that \((X, E_{\text{pr}}, <_{\text{lex}}, \cdot \land \cdot)\) is a Joyce graph whose structure is isomorphic to the Joyce structure of \((G, E, <, [\cdot, \cdot])\).

Let \(\sigma_x, \sigma_y \in X\). We have \(|\sigma_x| = [x, x] \neq [y, y] = |\sigma_y|\), we suppose \(|\sigma_x| < |\sigma_y|\). But then, \(\sigma_x E_{\text{pr}} \sigma_y\) iff \(|\sigma_x| = 1\) iff \(xEy\) by Item 2.

The rest of the proof follows the same argument that the construction in the proof of Theorem 5.10 works. We prove that for all \(x, y, z, t \in G\), \([x, y] < [z, t] \implies |\sigma_x \land \sigma_y| < \mathbb{N} |\sigma_x \land \sigma_t|\). We actually prove the stronger fact that for every \(x, y, z \in G\), \([x, y] = |\sigma_x \land \sigma_y|\). If \(x = y\), it is clear as by construction, \(\sigma_x\) is of length \([x, x]\). If \(x \neq y\), we first prove that \([x, y] \leq |\sigma_x \land \sigma_y|\): indeed, for all \(n < [x, y]\), by (J1), (J4) and the construction, we have \(\sigma_x(n) = 1\) iff \(\sigma_y(n) = 1\). It remains to show \([x, y] \geq |\sigma_x \land \sigma_y|\): if \(x < y\) we have that \(\sigma_x([x, x]) = 0 \neq 1 = \sigma_y([x, y])\) by Item 1, so \([x, y] \geq |\sigma_x \land \sigma_y|\), and similarly for \(x > y\).

Let \(x < y \in G\). Then, \([x, y] = |\sigma_x \land \sigma_y|\), thus \(\sigma_x(\sigma_x \land \sigma_y) = 0 \neq 1 = \sigma_y(\sigma_x \land \sigma_y)\) by Item 2. It follows that \(\sigma_x <_{\text{lex}} \sigma_y\).

\(\square\)

Corollary 6.10. There exists a computably coded Joyce Rado graph.

PROOF. Immediate by Theorem 6.9 and Theorem 6.3. \(\square\)

6.2. Joyce blossom graphs and an embedding theorem

Definition 6.11. A blossom tree is a pair \((f, g)\) where \(f : 2^{<\omega} \to 2^{<\omega}\) is a \(<\)-preserving, \(<_{\text{lex}}\)-preserving and \(\land\)-preserving function, such that for every \(\sigma, \tau \in 2^{<\omega}\):

1. \(g(\sigma) > f(\sigma)\);
2. if \(|\tau| > |\sigma|\) then \(|f(\tau)| > |g(\sigma)|\);
3. if \(|\tau| = |\sigma|\) then \(|f(\tau)| = |g(\sigma)|\).

A Joyce blossom graph is a structure \((g[S], E_{\text{pr}}, <_{\text{lex}}, \cdot \land \cdot)\) for some blossom tree \((f, g)\) and some set \(S\) cofinal in \(2^{<\omega}\) such that for all \(\sigma, \tau \in S^\omega, |\sigma| = |\tau|\).

Note that a Joyce blossom graph \(\mathcal{G}\) is a Joyce Rado graph: indeed, let \(F_0\) and \(F_1\) be two disjoint finite sets of vertices of \(\mathcal{G}\), and let \(f, g\) and \(S\) be the witnesses of the fact that \(\mathcal{G}\) is a Joyce blossom graph. By Item 3 of the
6.2. JOYCE BLOSSOM GRAPHS AND AN EMBEDDING THEOREM

definition, there exists \( \sigma \in f[2^{<\omega}] \) with \(|\sigma| > \max\{|\tau| : \tau \in F_0 \cup F_1\} \) and such that for every \( \tau \in F_0 \cup F_1 \) \( \sigma(|\tau|) = 0 \) iff \( \tau \in F_0 \). By the fact that \( S \) is cofinal, let \( \rho \succ f^{-1}(\sigma) \) in \( S \). Then, \( g(\rho) \succ \sigma \), and therefore \( g(\rho)E_{\text{pn}}\tau \) if \( \tau \in F_1 \) and \( -g(\rho)E_{\text{pn}}\tau \) if \( \tau \in F_0 \). The Joyce requirements are satisfied by the fact that the relations are \( E_{\text{pn}}, \prec_{\text{lex}} \) and \( |\cdot \land \cdot| \), and that for all \( \sigma, \tau \in S^\Delta \), \( |\sigma| \neq |\tau| \).

Note that if \((f,g)\) is a blossom tree, then letting \( B = g[2^{<\omega}] \) it follows by Item 1 that \((B, \preceq)\) is an antichain and \((B, \prec_{\text{lex}})\) contains a dense linear order with no endpoints. From a computability-theoretic viewpoint, \( \prec \)-preservation of \( f \) and Item 1 of Definition 6.11 ensures that if \((f,g)\) is computable, then so is \( g[2^{<\omega}] \). Conversely, Item 2 of Definition 6.11 implies that \((f,g)\) is computable from \( g[2^{<\omega}] \). One can therefore switch from one notion to the other in the computability realm.

**Lemma 6.12.** There exists a computable Joyce blossom graph, with a DLO induced order.

**Proof.** Let \( g \) and \( S \) be the objects defined in the proof of Theorem 6.3, and \( \mathcal{G} = (g[S], E_{\text{pn}}, \prec_{\text{lex}}, [\cdot, \cdot]) \) be the Joyce graph defined in the same proof. By Theorem 6.9, let \( \mathcal{G}' = (G', E_{\text{pn}}, \prec_{\text{lex}}, |\cdot \land \cdot|) \) be the coded Joyce Rado Graph computably isomorphic to \( \mathcal{G} \) via \( e \).

It remains to show that \( G' \) is a Joyce blossom graph. Define \( g' = e \circ g \) and \( f : \sigma \mapsto g'(\tau_0) \land g'(\tau_1) \). It is easy to check that \( f, g' \) and the set \( S \) are witnesses of the fact that \( G' \) is a Joyce blossom graph.

**Lemma 6.13 (RCA\(_0\)).** For every Rado graph \((G, E)\), there exists a graph embedding \( e : (2^{<\omega}, E_{\text{pn}}) \to (G, E) \).

**Proof.** Let \((\sigma_n)_{n < \omega}\) be an enumeration of \( 2^{<\omega} \) such that \(|\sigma_n| > |\sigma_m| \) implies \( n > m \). Suppose \( e(\sigma) \) is defined for every \( i < n \). Let \( F_0 = \{ e(\tau) : \tau \in 2^{<\omega}, |\sigma| < |\sigma_n|, \sigma(|\tau|) = 0 \} \) and \( F_1 = \{ e(\tau) : \tau \in 2^{<\omega}, |\tau| < |\sigma|, \sigma(|\tau|) = 1 \} \). By the fact that \((G, E)\) is a Rado graph, there exists an \( g \in G \) such that for all \( a \in F_0 \), \(-aEg\) and for all \( a \in F_1 \), \( aEg \), and \( g \) is not already in the image of \( e \). Define \( e(\sigma_n) = g \).

**Theorem 6.14 (ACA\(_0\)).** For every coded Joyce Rado graph \( \mathcal{G} = (G, E, <, [\cdot, \cdot]), \) there is an embedding from a Joyce blossom graph to \( G \).

**Proof.** We show the stronger result that there exists a blossom tree \((f,g)\) such that \((g[2^{<\omega}], E_{\text{pn}}, \prec_{\text{lex}}, |\cdot \land \cdot|) \) embeds into \( \mathcal{G} \). Thus, for any \( S \subseteq 2^{<\omega} \) such that for all \( \sigma, \tau \in S^\Delta \), we have \(|\sigma| \neq |\tau| \) iff \( \sigma \neq \tau \), we have \((g[S], E_{\text{pn}}, \prec_{\text{lex}}, |\cdot \land \cdot|) \) embeds into \( \mathcal{G} \).

Let \( e : (2^{<\omega}, E_{\text{pn}}) \to (G, E_{\text{pn}}) \) be the graph embedding constructed in Lemma 6.13. We say that \( L \subseteq 2^{<\omega} \) is large above \( \tau \in 2^{<\omega} \) if \( e^{-1}[L] \) is cofinal in \( 2^{<\omega} \) above \( \tau \). The set \( L \) is large if it is large above some \( \tau \in 2^{<\omega} \). Note that the collection of large sets is partition regular, that is, if \( L_0 \cup \cdots \cup L_{d-1} \) is large, then there is some \( j < d \) such that \( L_j \) is large. Moreover, if \( L \) is large above \( \tau \), then it is large above any \( \rho \geq \tau \). Last, \( G \) is large above \( e \).
Given a $\sigma \in 2^{<\omega}$, we write $G \models \sigma = \{ \tau \in G : \tau \geq \sigma \}$. Note that if $G \models \sigma$ is large above $\tau$, then so is $G \models \rho$ for every $\rho \preceq \sigma$.

The following claim is the combinatorial core of the theorem.

**Claim 6.15.** If $G \models \sigma$ is large, then for cofinitely many $\rho \in 2^{<\omega}$, there are some $\sigma_0, \sigma_1 \in G$ such that $G \models \sigma_0$ and $G \models \sigma_1$ are large, $\sigma \leq \sigma_0 \land \sigma_1$ and $\sigma_0(\ell) \neq \sigma_1(\ell)$, where $\ell = |e(\rho)|$.

**Proof.** Say $G \models \sigma$ is large above some $\tau$. Pick any $\rho \in 2^{<\omega}$ such that $|\rho| \geq |\tau|$. Since if $G \models \sigma$ is large above $\tau$, $G \models \sigma$ is large above any $\mu \geq \tau$, then we can assume that $|\tau| = |\rho|$. Unfolding the definition of largeness, the set $C = e^{-1}[G \models \sigma]$ is cofinal above $\tau$. Since $e : (2^{<\omega}, E_{pn}) \to (G, E_{pn})$ is a graph embedding and $|\tau| = |\rho|$, then for every $\mu \geq \tau_0$, $-e(\mu)E_{pn}e(\rho)$, hence $n(e(\mu)E_{pn}e(\rho))$ and for every $\mu \geq \tau_1$, $e(\mu)E_{pn}e(\rho)$. It follows that, letting $L_0 = \{ \nu \in G \mid \sigma : -e(\mu)E_{pn}e(\rho) \}$ and $L_1 = \{ \nu \in G \mid \sigma : e(\mu)E_{pn}e(\rho) \}$, then $C_0 = e^{-1}[L_0] = \{ \mu \geq \tau_0 : \mu \in C \}$ and $C_1 = e^{-1}[L_1] = \{ \mu \geq \tau_1 : \mu \in C \}$. Since C is cofinal above $\tau$, then $C_0$ and $C_1$ are cofinal above $\tau_0$ and $\tau_1$, respectively, so $L_0$ and $L_1$ are large above $\tau_0$ and $\tau_1$, respectively.

Let $\ell = |e(\rho)|$. Note that since $L_0$ and $L_1$ are both non-empty, then $\ell \geq |\sigma|$. $L_0 = \bigcup_{\nu \geq \tau_0} \nu \models e G \models e \nu \land 0$ and $L_1 = \bigcup_{\nu \geq \tau_1} \nu \models e G \models e \nu \land 1$. By partition regularity of largeness, there are some $\nu_0, \nu_1 \geq \sigma$ such that $|\nu_0| = |\nu_1| = \ell$, and $G \models e \nu_0$ and $G \models e \nu_1$ are large. Let $\sigma_0 = \nu_0 \land 0$ and $\sigma_1 = \nu_1 \land 1$. This proves our claim.

We are now ready to prove Theorem 6.14. Using Claim 6.15, we build a $\prec$-preserving and $\prec_{\text{lex}}$-preserving function $\phi : 2^{<\omega} \to 2^{<\omega}$, together with a function $g : 2^{<\omega} \to G$ such that for every $\sigma \in 2^{<\omega}$:

1. $G \models \phi(\sigma)$ is large; $g(\sigma) \succeq \phi(\sigma_0) \land \phi(\sigma_1)$;
2. for every $\rho \in 2^{\sigma_0}, \phi(\rho)(|g(\sigma)|) \neq \phi(\rho)(|g(\sigma)|)$.

Initially, $\phi(\varepsilon) = \varepsilon$ and $g$ is nowhere defined. Assume $\phi$ is defined over $2^{<k}$ and $g$ over $2^{<k}$ for some $k \in \omega$.

**Defining $\phi$.** Consider successively each $\sigma \in 2^k$. By partition regularity of largeness, $G \models e$ is large for some $\nu \succeq \phi(\sigma)$ such that $|\nu|$ is bigger than any value considered so far. By Claim 6.15, there is a $\rho$ two nodes $\mu_0, \mu_1$ extending $\nu$ such that, letting $\ell = |e(\rho)|$, $G \models \mu_0$ and $G \models \mu_1$ are large and $\mu_0(\ell) < \mu_1(\ell)$. Temporarily define $\phi(\sigma_0) = \mu_0$ and $\phi(\sigma_1) = \mu_1$. The actual value of $\phi(\sigma_0)$ and $\phi(\sigma_1)$ might change while defining $g$, but will be extensions of these strings. Since $\phi(\sigma_0) \land \phi(\sigma_1) = \mu_0 \land \mu_1 \succeq \varepsilon, \phi(\sigma_0) \land \phi(\sigma_1)$ is bigger than any value considered so far.

**Defining $g$.** Consider successively each $\tau \in 2^k$. We need to define $g(\tau)$ so that it satisfies Item 2. Since $G \models \phi(\tau)$ is large, it is infinite, so by Claim 6.15, there is a single $\rho$ such that $e(\rho) \succeq \phi(\tau)$ and $\ell = |e(\rho)|$ is bigger than any value considered so far, and for every $\sigma \in 2^k$ and $i < 2$ there are two extensions $\mu_0, \mu_1$ of $\phi(\sigma_i)$ such that $\mu_0(\ell) < \mu_1(\ell)$. Then let $\phi(\sigma_i) = \mu_i$ and $g(\tau) = e(\rho)$ and consider the next $\tau \in 2^k$. 

Defining \( f \). We now define \( f \) so that \((f,g)\) is a blossom tree. For every \( \sigma \in 2^{<\omega} \), let \( f(\sigma) = \phi(\sigma_0) \land \phi(\tau_0) \). Then \( f : 2^{<\omega} \to 2^{<\omega} \) is a \( \prec \)-preserving, \( \leq_{\text{lex}} \)-preserving and \( \land \)-preserving function such that for every \( \sigma \in 2^{<\omega} \):

1. \( g(\sigma) \geq f(\sigma) \geq \phi(\sigma) \);
2. for every \( \rho \in 2^{[\sigma]} \), \( f(\rho_0)(|g(\sigma)|) \neq f(\rho_1)(|g(\sigma)|) \).

Thus \((f,g)\) is a blossom tree, with \( g : 2^{<\omega} \to G \). Let \( S \subseteq 2^{<\omega} \) be a cofinal set such that \( S^\omega \) has at most one string of each length. The structure \((g[S],E_{\text{pn}},\leq_{\text{lex}},|\cdot \land \cdot|\) is a Joyce blossom graph.

**Theorem 6.16 (RCA0).** For every Joyce blossom graph \( \mathcal{G} \) and every (finite or infinite) Joyce graph \( \mathcal{F} \), there is a Joyce structure embedding from \( \mathcal{F} \) to \( \mathcal{G} \).

**Proof.** Let \((f,g)\) be the blossom tree and \( S \subseteq 2^{<\omega} \) such that \( \mathcal{G} = (g[S],E_{\text{pn}},\leq_{\text{lex}},|\cdot \land \cdot|) \). Let \( F \subseteq 2^{<\omega} \) be the domain of a coded Joyce graph isomorphic to \( \mathcal{F} \). Let \( D = \{ d_i : i \in |F^\omega| \} \) be an enumeration of \( F^\omega \) such that \( i < j \) implies \( |d_i| < |d_j| \). We first build a function \( \phi : D \to S \). Define \( \phi(d_0) \) to be any element of \( S \). Suppose \( \phi(d_i) \) is defined for \( i < n \). Then \( d_n \) is mapped to any element of \( S \) extending \( \sigma \), where \( \sigma \) is the string of length \(|\phi(n-1)| + 1 \), such that:

1. if \( k < |\sigma| \) and \( k \neq |\phi(d_i)| \) for any \( i < n \), then \( \sigma(k) = 0 \);
2. if \( d_i < d_n \), then \( \sigma(|\phi(d_i)|) = 1 \) iff \( d_i \prec d_n \);
3. Otherwise \( \sigma(|\phi(d_i)|) = j \) so that \( f(\sigma)(|g(\phi(d_i))|) = d_n(|d_i|) \).

The last item can be satisfy for a single \( j \) by Item 3 of Definition 6.11. The string \( \sigma \) is uniquely defined, and \( \phi(d_n) \in S \) extending \( \sigma \) exists as \( S \) is cofinal. Note that \( \phi \) is \( \prec \)-preserving: if \( d_n < d_m \), then by Item 1, for any \( k < |\phi(d_n)| \) if \( k \not\in \{ |\phi(d_i) | : i < n \} \), then \( \phi(d_n)(k) = \phi(d_m)(k) \). By Item 2 for any \( i \) such that \( d_i < d_n \), \( \phi(d_i)(|\phi(d_i)|) = \phi(d_m)(|\phi(d_i)|) \). By Item 3 and the fact that \( f \) is \( \prec \)-preserving, for \( i \) such that \( d_i \prec d_n \), we again have \( \phi(d_n)(|\phi(d_i)|) = \phi(d_m)(|\phi(d_i)|) \). So \( \phi \) is \( \prec \)-preserving.

Define \( \psi = g \circ \phi \). We claim that \( \psi : F \to g[S] \) preserves the Joyce graph structure. In order to show the claim, we have to prove that it preserves \( \leq_{\text{lex}} \), and that for any \( d_{n_0},d_{n_1},d_{m_0},d_{m_1} \in F \), \(|d_{n_0} \land d_{m_1}| < |d_{m_0} \land d_{m_1}| \) implies \( |\psi(d_{n_0}) \land \psi(d_{m_1})| < |\psi(d_{m_0}) \land \psi(d_{m_1})| \), and finally that for any \( d_n,d_m \in F \), \( d_nE_{\text{pn}}d_m \) implies \( \psi(d_n)E_{\text{pn}}\psi(d_m) \). The proof of these three facts are respectively in the three following paragraphs.

The fact that \( \phi \) is \( \prec \)-preserving implies that \( \phi(d_n \land d_m) < \phi(d_n) \land \phi(d_m) \). By Item 2, \( \phi(d_n \land d_m) \succ \phi(d_n) \land \phi(d_m) :\) indeed, \( \phi(d_n)(|\phi(d_n \land d_m)|) \neq \phi(d_m)(|\phi(d_n \land d_m)|) \). So \( \phi \) is \( \land \)-preserving, and by Item 2, it is also \( \leq_{\text{lex}} \)-preserving. The function \( g \) is also \( \leq_{\text{lex}} \)-preserving: \( f \) is \( \leq_{\text{lex}} \)-preserving, and \( f(\sigma) \prec g(\sigma) \) for every \( \sigma \in 2^{<\omega} \). So \( g = g \circ \phi \) is \( \leq_{\text{lex}} \)-preserving.

By the second item of Definition 6.11, for all \( \sigma,\tau \in 2^{<\omega} \) with \(|\sigma| \neq |\tau| \), \(|\sigma| < |\tau| \iff |g(\sigma)| < |g(\tau)| \iff |f(\sigma)| < |f(\tau)| \iff |g(\sigma)| < |f(\sigma)| \iff |g(\tau)| < |f(\tau)| \iff |f(\sigma)| < |g(\tau)| \). So \( |d_n| < |d_m| \iff |\psi(d_n)| < |\psi(d_m)| \). Now, suppose \(|d_{n_0} \land d_{m_1}| < |d_{m_0} \land d_{m_1}| \) for some \( d_{n_0},d_{n_1},d_{m_0}d_{m_1} \in F \). Let
$d_n = d_{m_0} \land d_{m_1}$ and $d_m = d_{m_0} \land d_{m_1}$. If $d_{m_0} \neq d_{m_1}$, then $\psi(d_{m_0}) \land \psi(d_{m_1}) = f(\phi(d_n))$, otherwise $\psi(d_{m_0}) \land \psi(d_{m_1}) = g(\phi(d_n))$; and similarly for $m_0, m_1, m$ with $d_m = d_{m_0} \land d_{m_1}$. So, depending whether $d_n, d_m \in F$, we use one of the previous equivalence to get that $|\psi(d_{m_0}) \land \psi(d_{m_1})| < |\psi(d_{m_0}) \land \psi(d_{m_1})|$.

Finally, for any $n < m$,

$$\psi(d_m)(|\psi(d_n)|) = g(\phi(d_m))(|g(\phi(d_n))|) = f(\phi(d_m))(|\psi(d_n)|)$$

as $g(\phi(d_m)) > f(\phi(d_m))$. By Item 3 $\phi(d_m)$ is chosen so that $f(\phi(d_m))(|\psi(d_n)|) = d_m(|d_n|)$. \(\square\)

**Corollary 6.17 (ACA₀)**. Let $G$ be a Joyce Rado graph, and $F$ be a (finite or infinite) Joyce graph. Then, there exists an embedding from $F$ to $G$.

**Proof.** By Theorem 6.9, we can assume that $G$ is a coded Joyce Rado graph. By Theorem 6.14, there is an embedding of a Joyce blossom graph $B$ to $G$. By Theorem 6.16, there is an embedding of $F$ to $B$. Thus there is an embedding of $F$ to $G$. \(\square\)

Recall that the *age* of a graph $G$ is the collection of all finite graphs that are isomorphic to a subgraph of $G$.

**Corollary 6.18.** The age of a Joyce Rado graph is the set of finite Joyce graphs.

**Theorem 6.19.** There is a computable Joyce Rado graph $G$ such that for every Joyce blossom graph $B$, every embedding of $B$ to $G$ computes $\Psi$.

**Proof.** The idea of the proof is to build a Joyce Rado graph with domain $G$ such that if $S \subseteq 2^{<\omega}$ is a cofinal set with at most one meet of each length, $f : 2^{<\omega} \to G^\wedge$ and $g : 2^{<\omega} \to G$ form a blossom tree, and $\sigma, \tau \in 2^{<\omega}$ are such that $|g(\sigma) \land g(\tau)| > 3j$, then $\theta'(j) = 1$ iff $g(\sigma)(3j + 2) = g(\sigma)(3j + 2)$.

Let $(G_0, E)$ be a Rado graph, and let $(g_n)_{n \in \omega}$ be an enumeration of $G_0$, and $(\theta'_n)_{n \in \omega}$ a computable approximation of $\theta'$. Define $\sigma_n$ to be the unique string of length $3n + 2$ such that:

1. $\sigma_n(3n) = 0$ and $\sigma_n(3n + 1) = 1$;
2. for any $j < n$, $\sigma_n(3j + 1) = 0$ and
   (a) if $\theta'_n(j) = 0$ and $g_n E g_j$ then $\sigma_n(3j) = 0$ and $\sigma_n(3j + 2) = 1$,
   (b) if $\theta'_n(j) = 0$ and $g_n E g_j$ then $\sigma_n(3j) = 1$ and $\sigma_n(3j + 2) = 0$,
   (c) if $\theta'_n(j) = 1$ and $g_n E g_j$ then $\sigma_n(3j) = 1$ and $\sigma_n(3j + 2) = 1$,
   (d) if $\theta'_n(j) = 1$ and $g_n E g_j$ then $\sigma_n(3j) = 0$ and $\sigma_n(3j + 2) = 0$.

Let $G = \{\sigma_n : n \in \mathbb{N}\}$. It is clear that $(G, E_{pa})$ is a Rado graph, as it is in bijection with $G_0$ via $g_n \mapsto \sigma_n$ since $g_n E g_m$ iff $\sigma_n E_{pa} \sigma_m$. Define $[\sigma_n, \sigma_m] = v(\sigma_n \land \sigma_m)$ where $v$ is a fixed injective function $2^{<\omega} \to \omega$ such that if $|\sigma| < \tau$ then $v(\sigma) < v(\tau)$. Then by construction, $G = (G, E_{pa}, <_{\text{lex}}, [\cdot, \cdot])$ is a Joyce Rado graph.
Now, suppose that \( f : 2^{<\omega} \to G \) and \( g : 2^{<\omega} \to G \) form a Joyce blossom graph. The claim is the following: if \( \sigma, \tau \in 2^{<\omega} \) are such that \( |g(\sigma) \land g(\tau)| > 3j \), then \( \emptyset'(j) = 1 \) if \( g(\sigma)(3j+2) = g(\sigma)(3j+2) \) iff \( g(\tau)(3j+2) = g(\tau)(3j+2) \).

Indeed, recall that \( g(\sigma) \land g(\tau) = f(\sigma) \land f(\tau) \). Let \( \rho \supset \sigma \) be such that \( |g(\rho)| \geq 3n+2 \) where \( \emptyset'(j) = \emptyset'(j) \). By construction, \( g(\rho)(3j) = g(\rho)(3j+2) \) iff \( \emptyset'(j) = 1 \). As \( \rho \supset \sigma \), we have \( g(\rho) \supset f(\sigma) < g(\sigma) \) so finally \( g(\sigma)(3j) = g(\sigma)(3j+2) \) iff \( \emptyset'(j) = 1 \).

Therefore, given \( g \), to know the value of \( \emptyset'(j) \), it suffices to find \( \sigma, \tau \in S \) such that \( |g(\sigma) \land g(\tau)| > 3j \), and answer according to whether \( g(\sigma)(3j) = g(\sigma)(3j+2) \).

\[\square\]

Corollary 6.20. Corollary 6.17 implies \( \text{ACA}_0 \).

6.3. A proof of the Rado Graph theorem

Definition 6.21. A Joyce graph diagonalization for some Joyce graph \((U, E_U, <_U, [\cdot, \cdot]_U)\) is a function \( h : 2^{<\omega} \to U \), such that for every coded Joyce graph \((X, (h[X], E_U, <_U, [\cdot, \cdot]_U))\) is isomorphic to \( X \).

Theorem 6.22 (\( \text{RCA}_0 \)). There exists a Joyce Rado graph \((2^{<\omega}, E_T, <_T, [\cdot, \cdot]_T)\) such that for every coded Joyce order \( X \), the Joyce structures of \((X, E_T, <_T, [\cdot, \cdot]_T)\) and \((X, E_{\text{pp}}, <_{\text{lex}}, [\cdot, \cdot])\) are isomorphic.

Proof. Let \((U, E_{\text{pp}}, <_{\text{lex}}, [\cdot, \cdot]_U)\) be the Joyce Rado graph defined in Theorem 6.3, that is, \( U = (000 \cup 101)^*01 \) and \([\sigma, \tau]_U = v(\sigma \land \tau)\) for some injective function \( v : 2^{<\omega} \to \omega \) such that for every \( \sigma, \tau \in 2^{<\omega} \), if \( |\sigma| < |\tau| \) then \( v(\sigma) < v(\tau) \).

Define the Joyce Rado graph \((2^{<\omega}, E_{\text{pp}}, <_T, [\cdot, \cdot]_T)\) as follows: Given \( \sigma \in 2^{<\omega} \), let \( \hat{\sigma} \) be the binary string of length \( 3|\sigma| + 2 \) defined for every \( j < |\sigma| \) by \( \hat{\sigma}(3j) = \sigma(j) \), \( \hat{\sigma}(3j+1) = \hat{\sigma}(3j+2) = 0 \), and \( \hat{\sigma}(3|\sigma|) = 0 \) and \( \hat{\sigma}(3|\sigma|+1) = 1 \). For instance, if \( \sigma = 0110 \) then \( \hat{\sigma} = 00010010000001 \). Then let \( \sigma <_T \tau \) if and only if \( \hat{\sigma} <_{\text{lex}} \hat{\tau} \) and \([\sigma, \tau]_T = [\hat{\sigma}, \hat{\tau}]_U\).

Let \( X \) be a coded Joyce order. We claim that \((X, E_{\text{pp}}, <_T, [\cdot, \cdot]_T)\) and \((X, E_{\text{pp}}, <_{\text{lex}}, [\cdot, \cdot])\) are isomorphic.

Fix \( \sigma, \tau \in X \). If \( \sigma <_{\text{lex}} \tau \), then \( \hat{\sigma} <_{\text{lex}} \hat{\tau} \), hence \( \sigma <_T \tau \). Conversely, if \( \sigma <_T \tau \), then \( \hat{\sigma} <_{\text{lex}} \hat{\tau} \), but since \( \sigma \) and \( \tau \) are incomparable with respect to the prefix relation, this implies that \( \sigma <_{\text{lex}} \tau \). Thus \( \sigma <_T \tau \) if and only if \( \sigma <_{\text{lex}} \tau \).

Fix \( \sigma, \tau, \rho, \mu \in X \). If \([\sigma \land \tau] \in \rho \land \mu \) then \( [\hat{\sigma} \land \hat{\tau}] \in [\hat{\rho} \land \hat{\mu}] \). If \( [\hat{\sigma} \land \hat{\tau}] \in [\hat{\rho} \land \hat{\mu}] \), then by definition of \( v \), \( [\sigma \land \tau] \in [\rho \land \mu] \), hence \( [\sigma \land \tau] \in [\rho \land \mu] \) if \([\hat{\sigma} \land \hat{\tau}] = [\hat{\rho} \land \hat{\mu}] \), then since \( X \) is a coded Joyce graph, \( \sigma \land \tau = \rho \land \mu \) so \( \sigma \land \tau = \rho \land \mu \) and \( v(\sigma \land \tau) = v(\rho \land \mu) \), contradiction.

\[\square\]

Corollary 6.23 (\( \text{ACA}_0 \)). Every Joyce Rado graph \((U, E_U, <_U, [\cdot, \cdot]_U)\) has a Joyce graph diagonalization.
Proof. Let \((2^{<\omega}, E_T, <_T, [[\cdot]_T])\) be the Joyce Rado graph of Theorem 6.22. By Corollary 6.17, there is an embedding \(h : 2^{<\omega} \to U\). By definition of an embedding, for every coded Joyce graph \(X \subseteq 2^{<\omega}, (h[X], E_U, <_U, [[\cdot]_U)\) is isomorphic to \((X, E_T, <_T, [[\cdot]_T)\). By Theorem 6.22, \((X, E_T, <_T, [[\cdot]_T)\) is isomorphic to \((X, F_{\text{em}}, <_{\text{lex}}, \cdot \wedge \cdot)\). Thus \(h\) is a Joyce graph diagonalization.

In the case of Joyce blossom graphs, the existence of a Joyce graph diagonalization holds in \(\text{RCA}_0\);

**Corollary 6.24 (\(\text{RCA}_0\)).** Every Joyce blossom graph has a Joyce graph diagonalization.

Proof. Similar to the proof of Corollary 6.23, but apply Theorem 6.16 instead of Corollary 6.17.

**Lemma 6.25.** Let \(F\) be a finite coded Joyce graph of size \(n\) and \(T \in \mathcal{S}_\omega(2^{<\omega})\). Then every \(E \in \mathcal{S}_{2n-1}(T)\) contains at most one coded Joyce graph isomorphic to \(F\). Moreover, every coded Joyce graph \(H \subseteq T\) isomorphic to \(F\) is included in some \(E \in \mathcal{S}_{2n-1}(T)\).

Proof. The proof is a straightforward adaptation of Lemma 5.20, mutatis mutandis.

**Theorem 6.26 (\(\text{ACA}_0\)).** Let \(G\) be a Joyce Rado structure, and \(F\) be a finite Joyce graph. Then, the big Ramsey number of \(F\) in \(G\) is 1.

Proof. Let \(X\) be a countable coded Joyce Rado graph and \(F\) be a finite coded Joyce Rado graph of size \(n\). Fix a coloring \(f : (X^k) \to k\). Here, \((X^k)\) denotes all the subcopies of \(F\) in \(X\).

Let \(h : 2^{<\omega} \to X\) be a Joyce graph diagonalization, which exists by Corollary 6.23. Let \(g : \mathcal{S}_n(2^{<\omega}) \to k\) be defined for every \(E \in \mathcal{S}_{2n-1}(2^{<\omega})\) by \(g(E) = f(h(H))\) where \(H \subseteq E\) is the unique element coded Joyce graph isomorphic to \(F\), if it exists. Otherwise let \(g(E) = 0\). This coloring is well-defined by Lemma 5.20.

By Milliken’s tree theorem for height \(2n - 1\), there is a strong subtree \(S \in \mathcal{S}_\omega(2^{<\omega})\) such that \(g\) restricted to \(\mathcal{S}_{2n-1}(S)\) is monochromatic for some color \(i < k\). In particular, by Lemma 6.25, for every coded Joyce graph \(H \subseteq S\) isomorphic to \(F\), there is some \(E \in \mathcal{S}_{2n-1}(S)\) containing \(H\), and \(g(E) = f(h(H)) = i\).

Since \(S \in \mathcal{S}_\omega(2^{<\omega})\), there is an injective function \(\phi : 2^{<\omega} \to S\) such that \(\phi[X]\) is a coded Joyce graph isomorphic to \(X\). In particular, since \(h\) is a Joyce graph diagonalization, \(Y = h[\phi[X]]\) is a coded Joyce Rado graph isomorphic to \(X\), hence a subcopy of \(X\).

We claim that \(f\) restricted to \((Y^k)\) is monochromatic for color \(i\). Let \(\hat{H}\) be a copy of \(F\) in \(Y = h[\phi[X]]\). Let \(H \subseteq \phi[X]\) be such that \(h[H] = \hat{H}\). In particular since \(\phi[X]\) is a coded Joyce graph, so is \(H\), so since \(h\) is a Joyce graph diagonalization, \(\hat{H} = h[H]\) is a coded Joyce graph isomorphic to \(H\).
In other words, $H$ is a copy of $F$ in $\phi[X] \subseteq S$, so $H$ is a copy of $F$ in $S$. By choice of $S$, $f(h[H]) = i$, so $f(H) = i$. This completes the proof of Theorem 6.26.

\[ \Box \]

**Corollary 6.27 (ACA\textsubscript{0}).** The statement $(\forall k)\mathrm{JRG}_{k,J_n}^n$ holds, where $J_n$ is the number of non isomorphic Joyce graph structure with $n$ elements, while $(\forall k)\mathrm{JRG}_{k,J_{n-1}}^n$ does not hold.

**Proof.** Let $\ell$ be the number of Joyce graph with $n$ elements. Let $F_0, \ldots, F_{\ell-1}$ be a finite enumeration of all the finite coded Joyce graph structures of size $n$.

We first prove that $\mathrm{JRG}_{k,\ell}^n$ holds. Fix a coloring $f : [X]^n \to k$ for some countable Joyce Rado graph structure $(X, E, <, R)$. By Theorem 5.21, build a finite decreasing sequence of subsets $X = X_0 \supseteq X_1 \supseteq \cdots \supseteq X_{\ell}$ of $X$ such that for every $s < \ell$:

1. $(X_{s+1}, E, <, R)$ is a subcopy of $(X_s, E, <, R)$;
2. every copy of $F$ in $(X_{s+1}, E, <, R)$ is monochromatic for $f$ for some color $i_s < k$.

The Joyce graph structure $(X_{\ell}, E, <, R)$ is a subcopy of $(X, E, <, R)$. Moreover, for every $E \in [X_{\ell}]^n$, $(E, <, R)$ is isomorphic to $F_s$ for some $s < k$, so $f(E) = i_s$. It follows that $f[X_{\ell}]^n \subseteq \{i_s : s < \ell\}$, hence $|f[X_{\ell}]^n| \leq \ell$.

We now show that the bound is tight. Let $f : [X]^n \to k$ be defined by $f(H) = s$ for the unique $s < \ell$ such that $(H, E, <, R)$ is isomorphic to $F_s$. Let $(Y, E, <, R)$ be a subcopy of $(X, E, <, R)$. In particular, $(Y, E, <, R)$ is a Joyce Rado graph structure, so by Corollary 6.17, for every $s < \ell$, there is an embedding of $F_s$ into $(Y, E, <, R)$. Therefore, $|f[Y]^n| \geq \ell$.

**Theorem 6.28 (ACA\textsubscript{0}).** Let $G = (G, E, <, R)$ be a Joyce graph structure. Let $G' = (G', E)$ be an isomorphic subcopy of $(G, E)$, that is, a Rado graph. Then, there exists a subcopy $(G'', E)$ of $(G', E)$ such that $(G'', E, <, R)$ is a subcopy of $G$.

**Proof.** The structure $\hat{X}' = (X', E, <, R)$ is a Joyce Rado graph structure, even if it might not be isomorphic to $\hat{X}$. By Corollary 6.17, there exists an embedding of $X$ into $\hat{X}'$. The image of the embedding is $\hat{X}''$.

Note that contrary to the case of Joyce orders, for which the proof that Devlin’s theorem implies the Joyce Devlin theorem holds in RCA\textsubscript{0}, the following corollary holds in ACA\textsubscript{0}. The difference comes from proof of Corollary 6.17 which is more complex than Theorem 5.15.

**Corollary 6.29 (ACA\textsubscript{0}).** The Rado graph theorem for $n$-tuples and $\ell$ colors implies the Joyce Rado graph theorem for $n$-tuples and $\ell$ colors.

**Corollary 6.30 (ACA\textsubscript{0}).** The tight bound for the Rado graph theorem and the Joyce Rado graph theorem for $n$ elements are the same, that is, the number of Joyce graph structures with $n$ elements.
6. THE RADO GRAPH THEOREM

PROOF. Let $b_0$ and $b_1$ be the tight bound for the Rado graph theorem and the Joyce Rado graph theorem for $n$ elements, respectively.

We first claim that $b_0 \leq b_1$. Let $(X, E)$ be a Rado graph. By Corollary 6.4, one can enrich this graph with an order $<$ and a relation $R$ so that $(X, E, <, R)$ is a Joyce Rado graph structure. Let $f : [X]^n \to k$ be a coloring. By choice of $b_1$, there is a Joyce subcopy $(Y, E, <, R)$ of $(X, E, <, R)$ such that $|f[Y]^n| \leq b_1$. In particular, $(Y, E)$ is a subcopy of $(X, E)$ so $b_0 \leq b_1$.

We then claim that $b_1 \leq b_0$. Let $(X, E, <, R)$ be a Joyce Rado graph structure. Let $f : [X]^n \to k$ be a coloring. By choice of $b_0$, there is a subcopy $(Y, E)$ of $(X, E)$ such that $|f[Y]^n| \leq b_0$. By Theorem 6.28, there is a subcopy $(Z, E)$ of $(Y, E)$ such that $(Z, E, <, R)$ is a Joyce subcopy of $(X, E, <, R)$. In particular, $|f[Z]^n| \leq b_0$. Thus $b_1 \leq b_0$.

It follows that $b_0 = b_1$. Moreover, by Corollary 5.23, this tight bound is the number of Joyce graph structures with $n$ elements.

6.4. Cone avoidance of the Rado Graph theorem for pairs

THEOREM 6.31. Fix two sets $C$ and $Z$ such that $C \not\subseteq T \ L$. Let

$$\mathcal{B} = (B, E_{\text{pr}}, <_{\text{lex}}, | \cdot \land \cdot|)$$

be a $Z$-computable Joyce blossom graph. For every $Z$-computable function $f : [B]^2 \to k$, there exists a subcopy $(U, E_{\text{pr}}, <_{\text{lex}}, n_{\cdot \lor \cdot}, n_{\cdot \land \cdot})$ of $\mathcal{B}$ and a finite set of colors $I \subseteq k$ such that $C \not\subseteq T \ U \oplus Z$, $|I| \leq 4$, and

$$(\forall \ell_0)(\forall^N \ell_1)(\forall^N \ell_2)\{f[U(\ell_0, \ell_1, \ell_2)]^2 \subseteq I\},$$

where $U(\ell_0, \ell_1, \ell_2)$ is the set of Joyce subgraphs of size 2 whose labels are exactly $\ell_0, \ell_1, \ell_2$, that is, $U(\ell_0, \ell_1, \ell_2) = \{\{\sigma, \tau\} \in [U]^2 : |\sigma \land \tau| = \ell_0, |\sigma| = \ell_1, |\tau| = \ell_2\}$.

PROOF. By Corollary 6.24, there is a $Z$-computable Joyce graph diagonalization $h : 2^{<\omega} \to B$. Let $\mathcal{F}_0, \mathcal{F}_1, \mathcal{F}_2, \mathcal{F}_3$ be the 4 Joyce graph structures of size 2.

For every $j < k$, let $g_j : S_3(2^{<\omega}) \to k$ be defined for every $E \in S_3(2^{<\omega})$ by $g(E) = f(h(H))$ where $H \subseteq E$ is the unique element coded Joyce graph isomorphic to $\mathcal{F}_j$, if it exists. Otherwise let $g(E) = 0$. This coloring is well-defined by Lemma 5.20.

By 4 successive applications of Theorem 4.11, there exists a strong subtree $R \in S_\omega(2^{<\omega})$ such that for each $j < 4$, $g_j$ restricted to $S_3(R)$ is stable. For each $j < 4$, let $\hat{g}_j : S_2(R) \to k$ be the (non-computable) limit coloring of $g_j$.

Again, by 4 successive applications of Theorem 4.11, there exists a strong subtree $S \in S_\omega(R)$ such that for each $j < 4$, $\hat{g}_j$ restricted to $S_2(S)$ is stable. For each $j < 4$, let $\mu_j : S \to k$ be the (non-computable) limit coloring of $\hat{g}_j$.

Last, by 4 successive applications of Theorem 3.21, there exists a strong subtree $T \in S_\omega(T)$ such that for each $j < 4$, $\mu_j$ restricted to $T$ is monochromatic for some color $i_j < 4$. Let $I = \{i_j : j < 4\}$. 
6.4. Cone Avoidance of the Rado Graph Theorem for Pairs

In particular, by Lemma 6.25, for every coded Joyce graph $H \subseteq T$ isomorphic to $F_j$, there is some $E \in S_3(S)$ containing $H$, and $g_j(E) = f(h(H))$.

Let $(X, E_{pn}, \preceq_{lex}, | \cdot \land \cdot |)$ be a $Z$-computable coded Joyce graph isomorphic to $B$, which exists by Theorem 6.9. Since $T \in S_\omega(2^{<\omega})$, there is an injective function $\phi : 2^{<\omega} \rightarrow T$ such that $\phi[X]$ is a coded Joyce graph isomorphic to $X$, hence to $B$. In particular, since $h$ is a Joyce graph diagonalization, $U = h[\phi[X]]$ is a coded Joyce Rado graph isomorphic to $X$, hence a subcopy of $B$.

We claim that the statement of the theorem holds for $U$, $f$ and $I$. Given any $\ell \in \omega$, there is at most one level $n \in \omega$ such that for every $\sigma, \tau \in T$ with $|\sigma \land \tau| = n$, $|h(\phi(\sigma)) \land h(\phi(\tau))| = \ell$. We call $n$ the preimage of $\ell$. Moreover, if $\ell$ is a level of $U$, that is, there is some $\rho, \nu \in U$ such that $|\rho \land \nu| = \ell$, then it has a preimage.

Fix $\ell_0 \in \omega$. If $\ell_0$ has no preimage, then $U(\ell_0, \ell_1, \ell_2) = \emptyset$ for every $\ell_1, \ell_2$ and the property is vacuously satisfied. Let $n_0$ be the preimage of $\ell_0$. Since for every $j < 4$, $\hat{g}_j$ is stable over $S_\omega(T)$ with limit color $i_j$, there is some threshold $t_0 \in \omega$ such that for every strong subtree $E$ of $U$ of height 2 whose first level is $n_0$ and second is higher than $t_0$, $\hat{g}_j(E) = i_j$. For all but finitely many $\ell_1$, the preimage of $\ell_1$, if it exists, is larger than $t_0$. Fix any such $\ell_1$ with preimage $n_1$. For every $j < 4$, since $\hat{g}_j$ is the limit coloring of $g_j$, there is a threshold $t_1 \in \omega$ such that for every strong subtree $E$ of height 3 whose first two levels are $n_0$ and $n_1$, respectively, and whose last level is higher than $t_1$, $g_j(E) = i_j$. For all but finitely many $\ell_2$, its preimage is larger than $t_1$.

Fix any such $\ell_2$, and let $\tilde{H} \in U(\ell_0, \ell_1, \ell_2)$. Let $j < 4$ be such that $\tilde{H}$ is isomorphic to $F_j$. Let $H \subseteq \phi[X]$ be such that $h[H] = \tilde{H}$. In particular since $\phi[X]$ is a coded Joyce graph, so is $H$, so since $h$ is a Joyce graph diagonalization, $\tilde{H} = h[H]$ is a coded Joyce graph isomorphic to $H$. In other words, $H$ is a copy of $\tilde{H}$ in $\phi[X] \subseteq T$, so $H$ is a copy of $F_j$ in $T$. By choice of $T$, $f(h[H]) = i_j$, so $f(\tilde{H}) = i_j \in I$. This completes the proof of Theorem 6.31.

**Theorem 6.32.** $(\forall k)\text{RG}_k^{2,4}$ admits cone avoidance.

**Proof.** Fix two sets $Z, C$ such that $C \not\leq_T Z$. Let $(V, E)$ be a $Z$-computable Rado graph and $h : [V]^2 \rightarrow k$ be a $Z$-computable coloring.

By computable categoricity of the Rado graph, $(V, E)$ is $Z$-computably isomorphic to the graph of a computable Joyce blossom graph $B = (B, E_{pn}, \preceq_{lex}, | \cdot \land \cdot |)$. This induces a $Z$-computable coloring $\hat{h} : [B]^2 \rightarrow k$ by composing the coloring $h$ with the isomorphism. By Theorem 6.31, there is a subcopy $(U, E_{pn}, \preceq_{lex}, | \cdot \land \cdot |)$ of $B$ and a finite set of colors $I \subseteq k$ such that $C \not\leq_T U \oplus Z$, $|I| \leq 4$, and

$$(\forall \ell_0)(\forall \ell_1)(\forall \ell_2)[\hat{h}[U(\ell_0, \ell_1, \ell_2)]^2 \subseteq I],$$

(6.1)
where \( U(\ell_0, \ell_1, \ell_2) \) is the set of Joyce subgraphs of size 2 whose labels are exactly \( \ell_0, \ell_1, \ell_2 \), that is, \( U(\ell_0, \ell_1, \ell_2) = \{ \sigma, \tau \} \in [U]^2 : |\sigma \land \tau| = \ell_0, |\sigma| = \ell_1, |\tau| = \ell_2 \}. \) Let \((f, g)\) be a \( U \oplus Z\)-computable blossom tree and \( D \subseteq 2^{<\omega} \) be a \( Z\)-computable set cofinal in \( 2^{<\omega} \) such that \( g[D] = B \). In particular, by Equation (6.1), the following holds:

\[
(\forall \rho \in 2^{<\omega})(\forall^\infty \sigma_0 \in D)(\forall^\infty \sigma_1 \in D)[|\sigma_0 \land \sigma_1 = \rho \Rightarrow \hat{h}(g(\sigma_0), g(\sigma_1)) \in I].
\]

We are going to build a by forcing infinite set \( G \subseteq D \) such that \((g[G], E_{pn})\) is a Rado graph and \( \hat{h}[g[G]]^2 \subseteq I \).

**Definition 6.33.** A string \( \sigma \in 2^{<\omega} \) witnesses a finite 2-partition \( F_0 \sqcup F_1 \subseteq 2^{<\omega} \) if for every \( i < 2 \) and every \( \rho \in F_i, \sigma(|\rho|) = i \).

In other words, \( \sigma \) witnesses \( F_0 \sqcup F_1 \subseteq 2^{<\omega} \) if in the graph \((2^{<\omega}, E_{pn})\), \( \sigma \) is connected to all the elements of \( F_1 \) and disconnected from all the elements of \( F_0 \). Note that if \( \sigma \) witnesses \( F_0 \sqcup F_1 \subseteq D \), then so does any \( \tau \succeq \sigma \).

**Lemma 6.34.** If \((G, E_{pn})\) is a Rado graph for some \( G \subseteq D \), then so is \((g[G], E_{pn})\).

**Proof.** Let \( \hat{F}_0 \sqcup \hat{F}_1 \subseteq g[G] \) be a finite 2-partition. Let \( F_0 = g^{-1}[\hat{F}_0] \) and \( F_1 = g^{-1}[\hat{F}_1] \). In particular, \( F_0 \) and \( F_1 \) are disjoint. Since \((G, E_{pn})\) is a Rado graph, then there is some \( \sigma \in G \) witnessing the 2-partition \( F_0 \sqcup F_1 \subseteq G \). We claim that \( g(\sigma) \) witnesses the 2-partition \( \hat{F}_0 \sqcup \hat{F}_1 \subseteq g[G] \). By definition of a blossom tree \((f, g)\), the function \( f \) is \( \land \)-preserving, so \( f(\sigma) \) witnesses the 2-partition \( \hat{F}_0 \sqcup \hat{F}_1 \subseteq g[G] \). Since \( g(\sigma) \succeq f(\sigma) \), then so does \( g(\sigma) \). \( \square \)

Given \( \sigma \in 2^{<\omega} \), we write \( D \upharpoonright 2^{<\omega} = \{ \tau \in D : \tau \succeq \sigma \} \). Given a finite set \( R \subseteq 2^{<\omega} \), we write \( D \upharpoonright R = \{ \tau \in D : (\exists \sigma \in R)[\tau \succeq \sigma] \} \).

**Definition 6.35.** A condition is a pair \((F, R)\) where \( F \subseteq D \) and \( R \subseteq 2^{<\omega} \) are both finite sets such that \( R \) is prefix-free and:

1. every finite 2-partition \( F_0 \sqcup F_1 = F \) is witnessed by some \( \sigma \in R \);  
2. for every \( \sigma \in F \) and \( \tau \in F \upharpoonright (D \upharpoonright R) \), \( \hat{h}(g(\sigma), g(\tau)) \in I \).

A condition \((E, S)\) extends \((F, R)\) (written \((E, S) \preceq (F, R))\) if \( F \subseteq E \), \( E \setminus F \subseteq D \upharpoonright R \) and for every \( \tau \in S \), there is some \( \sigma \in R \) such that \( \tau \succeq \sigma \).

One can see a condition \((F, R)\) as the Mathias condition \((F, D \upharpoonright R)\). In particular, for every filter \( F \) for this notion of forcing, letting \( G_F = \bigcup \{ F : (F, R) \in F \} \), if \((F, R) \in F \) then \( F \subseteq G_F \subseteq F \upharpoonright (D \upharpoonright R) \). Structurally, we ensured that \( \hat{h}[g[G_F]]^2 \subseteq I \). Note that \((\emptyset, \{ \epsilon \})\) is a valid condition.

**Lemma 6.36.** For every condition \((F, R)\), \((F \cup (D \upharpoonright R), E_{pn})\) is a Rado graph.

**Proof.** Fix any finite 2-partition \( E_0 \sqcup E_1 \subseteq F \cup D \upharpoonright R \). By definition of a condition, there is some \( \sigma \in R \) witnessing the 2-partition \( E_0 \cap F, E_1 \cap F \). Since \( D \) is cofinal in \( 2^{<\omega} \), there is some \( \tau \in D \) such that \( \tau \succeq \sigma \), and for
every \( i < 2 \) and \( \rho \in E_i \setminus F \), \( \tau(\rho) = i \). Thus \( \tau \) witnesses the 2-partition \( E_0 \sqcup E_1 \subseteq F \sqcup D \restriction R \). Moreover \( \tau \in D \restriction \sigma \), hence \( \tau \in D \restriction R \). \( \square \)

The following lemma shows that if \( \mathcal{F} \) is a sufficiently generic filter, then \((G_\mathcal{F}, E_{pn})\) is a Rado graph.

**Lemma 6.37.** For every condition \((F, R)\) and every 2-partition \( F_0 \sqcup F_1 \subseteq F \), an extension \((E, S)\) such that \( E \) contains an element witnessing the 2-partition.

**Proof.** Let \( \ell_0 \in \omega \) be larger than the length of any string in \( R \). Let \( \ell_1 \in \omega \) be sufficiently large with respect to \( \ell \) so that

\[
(\forall \rho \in 2^{<\ell_0})(\forall \sigma_0 \in D^{\geq \ell_1})(\forall \sigma_1 \in D)[\sigma_0 \land \sigma_1 = \rho \Rightarrow \hat{h}(g(\sigma_0), g(\sigma_1)) \in I].
\]

Such an \( \ell_1 \) exists by Equation (6.2). Let \( \hat{R} \) be obtained from \( R \) by extending each string \( \sigma \in R \) into a string \( \tau \) of length \( \ell_1 \) such that \( \tau(\ell_0) = 0 \). Then \((F, \hat{R})\) is again a condition.

By Lemma 6.36, since \((F \sqcup (D \restriction \hat{R}), E_{pn})\) is a Rado graph, there is some \( \tau \in F \sqcup (D \restriction \hat{R}) \) witnessing the 2-partition. If \( \tau \in F \) then we are done since \((F, \hat{R})\) then satisfies the lemma, so assume \( \tau \in D \restriction \hat{R} \). Let \( E = F \sqcup \{\tau\} \). Since \( |\tau| \geq \ell_1 \), by Equation (6.3), there is some \( \ell_2 \in \omega \) so that

\[
(\forall \rho \in 2^{<\ell_0})(\forall \mu \in D^{\geq \ell_2})[\tau \land \mu = \rho \Rightarrow \hat{h}(g(\tau), g(\mu)) \in I].
\]

For every \( \sigma \in R \), let \( \sigma_0, \sigma_1 \in R \) be strings of length at least \( \ell_2 \) such that \( \sigma_0(|\tau|) = 0 \), \( \sigma_1(|\tau|) = 1 \), \( \sigma_0(\ell_0) = \sigma_1(\ell_0) = 1 \), \( \sigma_0 \land \sigma_1 \succeq \sigma \), and define \( S = \{\sigma_0, \sigma_1 : \sigma \in R\} \).

We claim that \((E, S)\) is a condition. We first prove Item (1). Let \( F_0 \sqcup F_1 \subseteq E \) be a 2-partition. Since \((F, R)\) is a condition, there is some \( \sigma \in R \) witnessing the 2-partition \((F_0 \setminus \{\tau\}) \sqcup (F_1 \setminus \{\tau\})\). If \( \tau \in F_i \) for some \( i < 2 \), then \( \sigma_i \succeq \sigma \) witnesses the 2-partition \( F_0 \sqcup F_1 \subseteq E \). If \( \tau \notin F_0 \sqcup F_1 \), then any \( \sigma_i \succeq \sigma \) witnesses it.

We now prove Item (2). Fix \( \nu \in E \) and \( \mu \in E \setminus (D \restriction S) \) with \( |\nu| \leq |\mu| \). If \( \nu \neq \tau \), then \( \nu \in F \) and \( \hat{h}(g(\nu), g(\mu)) \in I \) by Item (2) for \((F, R)\). If \( \nu = \tau \), then \( \mu \in (D \restriction S) \). By choice of \( S \), \( \mu(\ell_0) = 1 \), and \( \nu(\ell_1) = 0 \). Thus, \( |\mu \land \nu| \leq \ell_0 \). Moreover, since every string in \( S \) has length at least \( \ell_2 \), \( |\mu| \geq \ell_2 \), so by Equation (6.4), \( \hat{h}(g(\nu), g(\mu)) \in I \). \( \square \)

**Definition 6.38.** Let \( c = (F, R) \) be a condition and let \( \varphi(G, x) \) be a \( \Delta^0_{\omega} \) formula with a free set parameter \( G \) and a free integer parameter \( x \).

1. \( c \models (\exists x) \varphi(G, x) \) if \( \varphi(F, x) \) holds for some \( x \in \omega \);
2. \( c \models (\forall x) \varphi(G, x) \) if \( \varphi(F \cup E, x) \) holds for every \( x \in \omega \) and every \( E \subseteq D \restriction R \) such that \( \hat{h}[g[E]]^2 \in I \).

In particular, the forcing relation is closed under extension, and if \( \mathcal{F} \) is a filter and \( c \models \varphi(G) \) for some \( \Sigma^0_{\omega} \) or \( \Pi^0_{\omega} \) formula and some \( c \in \mathcal{F} \),
then \( \varphi(G_F) \) actually holds. As usual, we write \( c \models \Gamma^{G \oplus Z} \neq C \) if either \( c \models \Gamma^{G \oplus Z}(x) \uparrow \) or \( c \models \Gamma^{G \oplus Z}(x) \downarrow \neq C(x) \) for some \( x \in \omega \).

**Lemma 6.39.** For every condition \( c \) and every Turing functional \( \Gamma \), there is an extension \( d \) of \( c \) such that \( d \models \Gamma^{G \oplus Z} \neq C \).

**Proof.** As in the proof of Lemma 6.37, let \( \ell_0 \) and \( \ell_1 \) be sufficiently large to satisfy Equation (6.3). Again, let \( \hat{R} \) be obtained from \( R \) by extending each string \( \sigma \in R \) into a string \( \tau \) of length \( \ell_1 \) such that \( \tau(\ell_0) = 0 \).

Let \( W \) be the set of all pairs \( (x, v) \in \omega \times 2 \) such that there is a finite set \( E \subseteq D \upharpoonright \hat{R} \) satisfying \( \hat{h}[g(E)]^2 \subseteq I \) and such that \( \Phi^{(F \cup E) \oplus Z}(x) \downarrow = v \). Note that the set \( W \) is \( Z \)-c.e. We have three cases.

**Case 1:** \( (x, 1 - C(x)) \in W \) for some \( x \in \omega \). Let \( E \subseteq D \upharpoonright \hat{R} \) witness that \( (x, 1 - C(x)) \in W \), that is, \( \hat{h}[g(E)]^2 \subseteq I \) and \( \Phi^{(F \cup E) \oplus Z}(x) \downarrow = 1 - C(x) \). Since for every \( \tau \in E \), \( |\tau| \geq \ell_1 \), then by Equation (6.3), there is some \( \ell_2 \in \omega \) so that

\[
(6.5) \quad (\forall \rho \in 2^{\leq \ell_0})(\forall \tau \in E)(\forall \mu \in D^{\geq \ell_2})[|\tau \land \mu = \rho \Rightarrow \hat{h}(g(\tau), g(\mu)) \subseteq I].
\]

For every \( \sigma \in R \), and every 2-partition \( E_0 \cup E_1 = E \), let \( \sigma_{E_0,E_1} \) be a string of length at least \( \ell_2 \) extending \( \sigma \), such that \( \sigma_{E_0,E_1}(|\tau|) = 0 \) for every \( \tau \in E_0 \) and \( \sigma_{E_0,E_1}(|\tau|) = 1 \) for every \( \tau \in E_1 \). Let \( S = \{ \sigma_{E_0,E_1} : \sigma \in R, E_0 \cup E_1 = E \} \).

We claim that \( (F \cup E, S) \) is a condition. We first prove Item (1). Let \( (F_0 \cup E_0) \cup (F_1 \cup E_1) \subseteq F \cup E \) be a 2-partition with \( F_0 \cup F_1 \subseteq F \) and \( E_0 \cup E_1 \subseteq E \). Since \( (F, R) \) is a condition, there is some \( \sigma \in R \) witnessing the 2-partition \( F_0 \cup F_1 \subseteq F \). By construction, \( \sigma_{E_0,E_1} \in S \) witnesses the 2-partition \( E_0 \cup E_1 \subseteq E \) and extends \( \sigma \), so \( \sigma_{E_0,E_1} \) witnesses the 2-partition \( (F_0 \cup E_0) \cup (F_1 \cup E_1) \subseteq F \cup E \).

We now prove Item (2). Fix \( \nu \in F \cup E \) and \( \mu \in F \cup E \cup (D \upharpoonright S) \) with \( |\nu| \leq |\mu| \). If \( \nu \in E \), then \( \hat{h}(g(\nu), g(\mu)) \in I \) by Item (2) for \( (F, R) \). If \( \nu \in E \) and \( \mu \in F \cup E \), then \( \mu \in E \) since \( |\nu| \leq |\mu| \), and \( \hat{h}(g(\nu), g(\mu)) \in I \) since \( \hat{h}[g(E)]^2 \subseteq I \). If \( \nu \in \tau \) and \( \mu \in (D \upharpoonright S) \), then by choice of \( S \), \( \mu(\ell_0) = 1 \), and \( \nu(\ell_1) = 0 \). Thus, \( |\mu \land \nu| \leq \ell_0 \). Moreover, since every string in \( S \) has length at least \( \ell_2 \), \( |\mu| \geq \ell_2 \), so by Equation (6.5), \( \hat{h}(g(\nu), g(\mu)) \subseteq I \).

Moreover, the condition \( (F \cup E, S) \) forces \( \Phi^{(F \oplus Z)}(x) \downarrow = 1 - C(x) \), thus satisfies the lemma.

**Case 2:** \( (x, C(x)) \notin W \) for some \( x \in \omega \). Then the condition \( (F, \hat{R}) \) is an extension of \( (F, R) \) forcing \( \Phi^{(F \oplus Z)}(x) \uparrow \lor \Phi^{(G \oplus Z)}(x) \downarrow \neq C(x) \), and we are done.

**Case 3:** otherwise. Then \( W \) is a \( Z \)-c.e. graph of the characteristic function of \( C \), hence \( C \) is \( Z \)-computable, contradicting the hypothesis. This case therefore cannot happen. This completes the proof of Lemma 6.39. \( \square \)

We are now ready to prove Theorem 6.32. Let \( F \) be a sufficiently generic filter for this notion of forcing. By definition of a forcing condition, \( \hat{h}[g(F)]^2 \subseteq I \) for every \( (F, \hat{R}) \in F \), so \( \hat{h}[G_F]^2 \subseteq I \). By Lemma 6.39, \( C \not \equiv_T G_F \oplus Z \). Since \( g \equiv_T Z \) then \( C \not \equiv_T g[G_F] \oplus Z \). By Lemma 6.37,
\( (G_x, E_{pa}) \) is a Rado graph, and by Lemma 6.34, so is \( (g(G_x), E_{pa}) \). The image of \( (g(G_x), E_{pa}) \) be the \( Z \)-computable isomorphism between the Rado graph \( (V, E) \) and the Joyce blossom graph \( \mathcal{B} \) yields a Rado subgraph \( (\hat{V}, E) \) of \( (V, E) \) such that \( h[\hat{V}] \subseteq I \) and \( C \not\subseteq \hat{V} \oplus Z \). This completes the proof of Theorem 6.32. \( \square \)

**Corollary 6.40.** \((\forall k)\text{RG}^2_{k,4} \) does not imply ACA\(_0\) over RCA\(_0\).

**Proof.** Immediate by Theorem 6.32 and Lemma 2.15. \( \square \)

### 6.5. Lower bound on the Rado Graph Theorem

In order to show lower bounds, we use the notion of Joyce blossom graph. Indeed, one can computably embed any Joyce graph in a Joyce blossom graph by Theorem 6.16, and there is a computable one by Lemma 6.12. The embeddings of a Joyce complete graph with order type \( \mathbb{N} \) or \( \mathbb{Q} \) allow to show that \( \text{JRG}^2_{k,7} \) implies respectively \( \text{RT}^2_2 \) and the Devlin Theorem. Even though it is weaker, we include the proof of \( \text{RT}^2_2 \) from \( \text{JRG}^2_{k,7} \) as it yields a computable reduction.

**Theorem 6.41.** For every \( k, n \), the statement \( \text{JRG}^2_{4k,4n+3} \) implies \( \text{RT}^2_{k,n} \). In particular, \( \text{JRG}^2_{2,7} \) implies \( \text{RT}^2_2 \).

**Proof.** We first give the insight about what \( 4n+3 \) corresponds to: if the union of \( 4 \) disjoints sets is of cardinality \( 4n+3 \), then one of them is of cardinality at most \( N \).

**Claim 6.42.** There exists a Joyce graph \( (G, E, <, [\cdot, \cdot]) \) such that \( (G, E) \) is the complete graph and for all \( a, b \in G \), \( a < b \iff [a, a] < [b, b] \).

**Proof.** Let \( G = \{1^{2n}: n \geq 1\} \), then \( (G, E_{pa}, <_{\text{lex}}, [\cdot, \cdot]) \) is a witness of the claim. \( \square \)

Let \( f : \mathbb{N}^2 \to k \) be a symmetric coloring. By Lemma 6.12, let \( \mathcal{G} = (G, E, <, [\cdot, \cdot]) \) be a computable Joyce blossom graph.

Let \( (\mathcal{F}_i)_{i<4} \) be an enumeration of the finite Joyce graph structures with two elements. If \( a, b \in G \), define \( g(a, b) = (f([a, a], [b, b]), i) \) where \( i \) is such that \( \{a, b\} \) is isomorphic to \( \mathcal{F}_i \). By \( \text{JRG}^2_{2,4n+1} \), let \( \mathcal{G}' \) be a subcopy of \( \mathcal{G} \) in \( \mathcal{G} \), using at most \( 4n+3 \) colors. Either \( \{(a, b) : aEb\} \) or \( \{(a, b) : \neg aEb\} \) uses at most \( 2n+1 \) colors, suppose for instance that it is the former. Similarly, either \( \{(a, b) : a < b \land [a, a] < [b, b] \land aEb\} \) or \( \{(a, b) : a < b \land [a, a] > [b, b] \land \neg aEb\} \) uses at most \( n \) colors, suppose that it is the former. By Claim 6.42 there exists a Joyce complete graph \( \mathcal{K} \) such that for all \( a, b \in \mathcal{K} \), \( a < b \iff [a, a] < [b, b] \). By Theorem 6.16, there exists a computable subcopy \( \mathcal{G}'' \) of \( \mathcal{K} \) inside \( \mathcal{G}' \). In particular, \( \mathcal{G}'' \) uses at most \( n \) colors for \( g \). As a consequence, \( \{[a, a] : a \in \mathcal{G}''\} \) uses at most \( n \) colors for \( f \). \( \square \)

**Theorem 6.43.** For every \( n, k \), the statement \( \text{JRG}^2_{2k,2n+1} \) implies \( \text{DT}^2_{k,n} \) and thus \( \text{JRG}^2_{2,7} \) implies ACA\(_0\).
PROOF. We start with a claim.

Claim 6.44. There exists a Joyce graph \((G, E, <, [\cdot, \cdot])\) such that \((G, E)\) is the complete graph and \((G, <)\) is a DLO.

PROOF. Let \((G, <, [\cdot, \cdot])\) be a DLO Joyce order. Define \(E = \{(a, b) : a, b \in G\}\). Then \((G, E, <, [\cdot, \cdot])\) is a witness of the claim.

Let \(X = (X, <_X)\) be a computable dense linear order with no endpoints, and \(f : X^2 \to k\) be a symmetric coloring. By Lemma 6.12, let \(G\) be a computable Joyce blossom graph. In particular, there exists an embedding \(e\) from \((G, <_{\text{lex}})\) to \(X\).

If \(a, b \in G\), define \(g(a, b) = (f(e([a; b])), 1)\) if \(aEb\) and

\[ g(a, b) = (f(e([a; b])), 0) \]

if \(\neg aEb\). By \(\text{JRG}_{2,2n+1}^{n}\), let \(G'\) be a subcopy of \(G\) in \(G\), using at most \(2n + 1\) colors. Either \(\{(a, b) : aEb\}\) or \(\{(a, b) : \neg aEb\}\) uses at most \(n\) colors, suppose for instance that it is the former. By Claim 6.44 there exists a Joyce complete graph \(K\) whose order is a DLO. By Theorem 6.16, there exists a computable subcopy \(G''\) of \(K\) inside \(G'\). In particular, \(G''\) is a DLO and uses at most \(n\) colors for \(g\). As a consequence, \(e[G''] \subseteq X\) is a DLO and uses at most \(n\) colors for \(f\).

Thus, \(\text{JRG}_{2,7}^{2}\) implies \(\text{DT}_{4,3}^{2}\) which implies \(\text{ACA}_0\). \(\square\)

Larson [27] computed the big Ramsey number for small subgraphs of the Rado graph. The sum of the big Ramsey numbers for subgraphs of size 3 is equal to the number of Joyce graphs of size 3, that is, 112. In other words, \((\forall k)\text{RG}_{k,112}^3\) holds, while \((\forall k)\text{RG}_{k,111}^3\) does not. In the particular case of the complete graph \(K_3\) of size 3, \((\forall k)\text{RG}_{k,16}^{K_3}\) holds, while \((\forall k)\text{RG}_{k,15}^{K_3}\) does not.

The proof technique for the following theorem stems from Jockusch [22] who constructed a computable instance of Ramsey’s theorem for triples whose solutions compute the halting set. It was later refined by Hirschfeldt and Jockusch [20, Theorem 2.1] who showed the existence of a computable such instance such that every solution is of PA degrees over \(\emptyset\). Although it is unknown whether the Rado graph statement for graphs of size \(n\) implies Ramsey’s theorem for \(n\)-tuples, we can adapt the argument of Hirschfeldt and Jockusch to graphs.

Theorem 6.45. Let \((G, E)\) be a computable Rado graph and \(F\) be a finite graph of size 3. Let \(b \in \omega\) be the Ramsey degree of \(F\) in the Rado graph theorem, that is, the number of Joyce graphs isomorphic to \(F\). There exists a computable coloring \(f : [G]_F \to 2b\), such that for every \(G \subseteq G\) for which \((\hat{G}, E)\) is a Rado graph and \(f\) restricted to \([\hat{G}]_F\) has at most \(b\) colors, \(\hat{G}\) is of PA degree over \(\emptyset\).

PROOF. By Corollary 6.4, there exists an order \(<_G\) over \(G\) and a function \([\cdot, \cdot] : G^2 \to \omega\) such that \((G, E, <, [\cdot, \cdot])\) is a Joyce Rado graph. Let
6.5. LOWER BOUND ON THE RADO GRAPH THEOREM

Let \( J_0, \ldots, J_{b-1} \) be an enumeration of all the Joyce graph structures of size 3 isomorphic to \( F \). Let \( g : (\tilde{G}) \to 2b \) be the coloring which to \( \{x, y, z\} \) associates the index \( i < b \) so that the Joyce graph structure of \( (\{x, y, z\}, E, <, [\cdot, \cdot]) \) is isomorphic of \( J_i \).

Let \( h : [\omega]^3 \to 2 \) be defined for every \( x < y < z \) by \( h(x, y, z) = 1 \) iff for every \( e < x, \Phi^\emptyset[y](e)[y] = \Phi^\emptyset[z](e)[z] \). Last, let \( f : (\tilde{G}) \to 2 \times b \) be defined by

\[
f(x, y, z) = (h([x, x], [y, y], [z, z]), g(x, y, z)).
\]

Let \( \tilde{G} \subseteq G \) be such that \((\tilde{G}, E)\) is a Rado graph and \( f \) restricted to \( (\tilde{G}) \) has at most \( b \) colors.

**Claim 6.46.** \( f(\tilde{G}) = \{(1, i) : i < b\}. \)

**Proof.** Let \( H \subseteq \tilde{G} \) be a (non-computable) set such that \((H, E)\) is a Rado graph, and \( H \) is sparse enough so that for every \( x, y \in H \) such that \([x, x] <_N [y, y]\), then for every \( e < x \) such that \( \Phi^\emptyset[y](e) \downarrow, \Phi^\emptyset[y](e)[y] \downarrow \). In particular, \([x, x] : x \in H\) is \( h \)-homogeneous for color 1. By Corollary 6.17, for every \( i < b \), \( J_i \) embeds into \((H, E, <, [\cdot, \cdot])\), so for every \( i < b \), there is a unique \( j < 2 \) such that \((j, i) \in f(\tilde{G})\). Moreover, by sparsity of \( H \), \( j = 1 \). Thus \( \{(1, i) : i < b\} \subseteq f(H) \subseteq f(\tilde{G}) \), and by cardinality, \( f(\tilde{G}) = \{(1, i) : i < b\} \). \( \Box \)

Let \( F_0 \) be the finite graph induced by the two first elements of \( F \).

**Claim 6.47.** For every \( \{x, y\} \in (\tilde{G}) \) with \([x, x] <_N [y, y] <_N [z, z] \), and every \( e < [x, x] \), if \( \Phi^\emptyset[e](e) \downarrow \) then \( \Phi^\emptyset[y][y](e)[[y, y]] \downarrow \).

**Proof.** Since \( \tilde{G} \) is a Rado graph, we can find a \( z \) with \([z, z] \) sufficiently large such that \( \{x, y, z\} \in (\tilde{G}) \) and for every \( e < [x, x] \), if \( \Phi^\emptyset[e](e) \downarrow \) then \( \Phi^\emptyset[[z, z]](e)[[z, z]] \downarrow \). By Claim 6.46, \( h([x, x], [y, y], [z, z]) = 1 \), so by definition of \( h \), for every \( e < [x, x] \), \( \Phi^\emptyset[y][y](e)[[y, y]] = \Phi^\emptyset[[z, z]](e)[[z, z]] \). In particular, if \( \Phi^\emptyset[e](e) \downarrow \) then \( \Phi^\emptyset[y][y](e)[[y, y]] \downarrow \). \( \Box \)

We are now ready to prove that \( \tilde{G} \) is of PA degree relative to \( \emptyset' \). For this, we prove that \( \tilde{G} \) computes a completion of the universal partial \( \emptyset' \)-computable function \( e \mapsto \Phi^\emptyset[e] \). Given \( e \), search \( \tilde{G} \)-computably for a pair \( \{x, y\} \in (\tilde{G}) \) such that \( e < [x, x] \), and return \( \Phi^\emptyset[y][y](e)[[y, y]] \) if it halts, otherwise return 0. Such a pair \( \{x, y\} \) is always found since \( \tilde{G} \) is a Rado graph. By Claim 6.47, if \( \Phi^\emptyset[y][y](e)[[y, y]] \) does not halt, then \( \Phi^\emptyset[e](e) \uparrow \), so this is a valid completion. This completes the proof of Theorem 6.45. \( \Box \)

**Corollary 6.48.** For every finite graph \( F \) of size 3, letting \( b \) be the number of Joyce graphs isomorphic to \( F \), \((\forall k)\text{RG}_{k,b}^F\) implies \( \text{ACA}_0 \) over \( \text{RCA}_0 \).

**Corollary 6.49.** \((\forall k)\text{RG}_{k,16}^{K_3} \) implies \( \text{ACA}_0 \) over \( \text{RCA}_0 \).
6. THE RADO GRAPH THEOREM

Theorem 6.50. For every \( n \geq 1 \), every finite graph \( F \) of size \( n \), let \( b_n \) be the tight bound of \((\forall k)\text{RG}^n_{k,b_n}\), and \( c_n \) be the tight bound of \((\forall k)\text{RG}^F_{k,c_n}\). That is, \( b_n \) is the number of Joyce graphs of size \( n \) and \( c_n \) is the number of Joyce graphs isomorphic to \( F \). Then \((\forall k)\text{RG}^n_{k,b_n}\) implies \((\forall k)\text{RG}^F_{k,c_n}\) over RCA_0.

Proof. Let \( f : \left(\begin{smallmatrix} G \\ F \end{smallmatrix}\right) \to k \) be an instance of \((\forall k)\text{RG}^F_{k,c_n}\). Let \( g : [G]^n \to b_n \) be the coloring witnessing the tightness of the bound \( b_n \). In particular, \( g \) restricted to \( \left(\begin{smallmatrix} G \\ F \end{smallmatrix}\right) \) uses exactly \( c_n \) many colors. Given \( H \in [G]^n \), let \( h(H) = (g(H), f(H)) \) if the graph \( H \) is isomorphic to \( F \), and \( h(H) = (g(H), \perp) \) otherwise. By \((\forall k)\text{RG}^n_{k,b_n}\), there is a Rado subgraph \( \hat{G} \subseteq G \) such that \( h(\hat{G})^n \) has at most \( b_n \) colors. By choice of \( g \), for every \( i < b_n \), there is some \( v \) such that \( (i, v) \in h(\hat{G})^n \). Thus for every \( i < b_n \), there is exactly one \( v \) such that \( (i, v) \in h(\hat{G})^n \). In particular, \( f \) restricted to \( \left(\begin{smallmatrix} G \\ F \end{smallmatrix}\right) \) has at most \( b_n \) many colors. \(\square\)

Corollary 6.51. \((\forall k)\text{RG}^3_{k,112}\) implies ACA_0 over RCA_0.

Proof. Immediate by Corollary 6.48 and Theorem 6.50. 112 is the tight bound for the Rado graph theorem for triples, and 16 the tight bound for the Rado graph theorem restricted to the complete graph of size 3. \(\square\)

We do not know whether \((\forall k)\text{RG}^2_{k,4}\) implies RT_2 over RCA_0. Theorem 6.55 however is a partial result towards that direction. Ramsey’s theorem for pairs RT_2^k was decomposed by Cholak, Jockusch and Slaman [3] into a stability version (SRT_2^k) and a cohesiveness principle (COH) in order to simplify the computability-theoretic analysis of the theorem.

Definition 6.52. An infinite set \( C \) is cohesive for a sequence of sets \( \mathcal{R}_0, \mathcal{R}_1, \cdots \subseteq \mathbb{N} \) if for every \( n \), \( C \subseteq^* \mathcal{R}_n \) or \( C \subseteq^* \overline{\mathcal{R}_n} \). A coloring \( f : [\omega]^2 \to k \) is stable if for every \( x \), \( \exists y \) such that \( f(x, y) \).

Statement 6.53 (Cohesiveness). COH is the statement “Every countable sequence of set has an infinite cohesive set”.

Statement 6.54 (Stable Ramsey’s theorem for pairs). SRT_2^k is the restriction of RT_2^k to stable colorings.

Cholak, Jockusch and Slaman [3, Lemma 7.11] and Mileti [28, Corollary A.1.4] proved the equivalence between RT_2^k and SRT_2^k ∧ COH over RCA_0. The following theorem shows that \((\forall k)\text{RG}^2_{k,4}\) implies SRT_2^k, hence any proof of separation would be a proof of separation of \((\forall k)\text{RG}^2_{k,4}\) from COH.

Theorem 6.55. \text{RG}^2_{8,4} implies SRT_2^k over RCA_0.

Proof. Let \( f : [\omega]^2 \to 2 \) be a stable coloring. Fix a computable coded Joyce Rado graph \((G, \leq_{\text{lex}}, E_{\text{ps}}, | \cdot \Box |)\), let \( F_0, F_1, F_2, \). be the 4 Joyce graphs of size 2, and define an instance \( g : [G]^2 \to 4 \times 2 \) of \text{RG}^2_{8,4} by
6.5. LOWER BOUND ON THE RADO GRAPH THEOREM

\( g(\{\sigma, \tau\}) = (i, f(\{\vert \sigma \vert, \vert \tau \vert\})) \) where \( F_i \) is the unique Joyce graph isomorphic to \( (\{\sigma, \tau\}, \prec_{\text{lex}}, E_{\text{pm}}, \cdot \wedge \cdot) \).

Let \( H \subseteq G \) be a RG\(_{8,4}^2\)-solution to \( g \), that is, \( (H, E_{\text{pm}}) \) is a Rado graph and \( \vert g[H] \vert^2 \leq 4 \). By Corollary 6.17, for every \( i < 4 \), there is an embedding from \( F_i \) to \( (H, \prec_{\text{lex}}, E_{\text{pm}}, \cdot \wedge \cdot) \), so for every \( i < 4 \), there is a unique value \( v(i) < 2 \) such that \( (i, v(i)) \in g[H] \). Thus \( g[H]^2 = \{(i, v(i)) : i < 4\} \).

**Claim 6.56.** \( g[H]^2 = \{(i, j) : i < 4\} \) for some \( j < 2 \).

**Proof.** Fix \( i_0 < i_1 < 4 \). We need to show that \( v(i_0) = v(i_1) \). By Corollary 6.17, there is an embedding \( h \) of a Joyce blossom graph \( B \) in \( (H, \prec_{\text{lex}}, E_{\text{pm}}, \cdot \wedge \cdot) \). One can find some \( \sigma \in B, \tau_0, \tau_1 \in B \) such that \( \{\sigma, \tau_0\}, \prec_{\text{lex}}, E_{\text{pm}}, \cdot \wedge \cdot \) and \( \{\sigma, \tau_1\}, \prec_{\text{lex}}, E_{\text{pm}}, \cdot \wedge \cdot \) are isomorphic to \( F_{i_0} \) and \( F_{i_1} \), respectively. Then \( g(\{h(\sigma), h(\tau_0)\}) = (i_0, v(i_0)) \) and \( g(\{h(\sigma), h(\tau_1)\}) = (i_1, v(i_1)) \). So \( f(\{h(\sigma), h(\tau_0)\}) = v(i_0) \) and \( f(\{h(\sigma), h(\tau_1)\}) = v(i_1) \). Moreover, \( \tau_0 \) and \( \tau_1 \) can be chosen so that \( \vert h(\tau_0) \vert \) and \( \vert h(\tau_1) \vert \) is large enough to witness stability of \( \lim_{s} f(\vert h(\sigma) \vert, s) \). Then \( f(\{h(\sigma), h(\tau_0)\}) = v(i_0) = f(\{h(\sigma), h(\tau_1)\}) = v(i_1) \).

Let \( j < 2 \) be such that Claim 6.56 holds. It follows that \( Y = \{\vert \sigma \vert : \sigma \in H\} \) is \( f \)-homogeneous for color \( j \). This completes the proof of Theorem 6.55. \( \square \)

We now prove that for every \( \ell \geq 1 \), RT\(_2^3\) does not imply \( (\forall k)\text{RG}_{k,\ell}^2 \) over RCA\(_0\). For this, we need two essential notions in computability theory, namely, lowness and hyperimmunity. Lowness is a weakness property over Turing degrees, saying informally that a low Turing degree behaves like the computable Turing degree from the viewpoint of the halting set. Hyperimmunity is an strength property about the ability to compute fast-growing functions, not dominated by any computable function.

**Definition 6.57.** A set \( A \) is low if \( A \equiv_T \emptyset' \). A set \( A \) is low relative to \( X \) for a set \( X \) if \( (A \oplus X)' \equiv_T X' \).

**Definition 6.58.** A function \( f : \mathbb{N} \to \mathbb{N} \) is hyperimmune relative to \( X \) if it is not dominated by any \( X \)-computable function. An infinite set \( H \subseteq \mathbb{N} \) is hyperimmune relative to \( X \) if its principal function, that is, the function which to \( n \) associates the \( n \)th element of \( H \), is hyperimmune relative to \( X \).

**Theorem 6.59.** Let \( P \) be low relative to \( \emptyset' \). For every \( \ell \), there exists a computable instance of \( \text{RG}_{\ell+1,\ell}^2 \) with no solution computable in \( P \).

**Proof.** We first need the following definition and lemma to build the instance.

**Lemma 6.60.** There exists a \( \Delta_0^0 \) coloring \( g : \mathbb{N} \to \ell + 1 \) such that for every \( k \leq \ell \), the set \( A_k = \{n \in \mathbb{N} : g(n) \neq k\} \) is hyperimmune relative to \( P \).

**Proof.** We prove that there exists a \( \Delta_0^0 \) coloring \( g : \mathbb{N} \to \ell + 1 \) such that for all \( k \), \( \{n : g(n) \neq k\} \) is hyperimmune. The relativization to \( P \) of
this proof yields the result of the lemma, as a $\Delta^0_3$ relative to $P$ is a $\Delta^0_3$ set by lowness relative to $\emptyset'$ of $P$.

We build uniformly in $\emptyset'$ a sequence $\sigma_s$ of compatible strings of increasing length. Start with $\sigma_0$ the empty string. Suppose $\sigma_s$ is defined, with $s = (k, e)$. Let $n_s = |\{i < |\sigma_s| : \sigma_s(i) \neq k\}|$ Using $\emptyset'$, we can decide if $\varphi_e(n_s) \downarrow$. If so we define $\sigma_{s+1}$ to be $\sigma_s$ followed by the string consisting of $\varphi_e(n_s) + 1$ times $k$. Otherwise, $\sigma_{s+1}$ is $\sigma_s$ followed by $0$.

Define $g = \bigcup_s \sigma_s$. By construction, for $s = (k, e)$, $\sigma_{s+1}$ diagonalizes against $\varphi_e$ dominating $\{n \in \mathbb{N} : g(n) \neq k\}$. Thus, for any $k < \ell$, $\{n \in \mathbb{N} : g(n) \neq k\}$ is hyperimmune.

Fix $g$ as in the lemma. Let $(g_s, t)_{s, t \in \mathbb{N}}$ be a $\Delta^0_3$ approximation of $g$. One can always arrange the approximation so that for every $s, t$, $g_{s, t}$ is a coloring of $\mathbb{N}$ in $\ell + 1$ colors. Let $\mathbb{G} = (G, E_{pn})$ with $G \subseteq 2^{<\omega}$ a coded Rado graph. Define $f$ to be the following: for every $\sigma, \tau \in 2^{<\omega}$ with $|\sigma| < |\tau|$, 

$$f(\sigma, \tau) = g[|\sigma|, |\tau|](|\sigma \wedge \tau|)$$

Let $S \subseteq 2^{<\omega}$ be such that $(S, E_{pn})$ is a Rado graph, and $f$ takes at most $\ell$ colors on $|S|^2$. Let $k$ be the avoided color. We prove that $S$ computes a function bounding the principal function of $A_k$, so by hyperimmunity relative to $P$ of $A_k$, $P$ cannot compute $S$.

Let $h \leq_T S$ be the function so that $h(n)$ is the smallest such that $S \cap 2^{<h(n)}$ has $n$ elements. We prove that for every $n$, $A_k$ contains at least $n$ elements smaller than $h(n)$. Indeed, let $e_0, \ldots, e_{n-1}$ be the $n$ elements of $S \cap 2^{<h(n)}$. Let $(\tau_j)_{j < 2^n}$ be an enumeration of the set $2^n$, we say that a string $\rho$ realize $\tau_j$ if for all $i < n$ ($\rho E_{pn} e_i$ $\iff$ $\tau_j(i) = 1$), note that for any $j$ there are infinitely many elements of $S$ realizing $\tau_j$, so there are some of arbitrarily big length. Let $\rho_0$ be the first element of $S$ such that $g_s(m) = g(m)$ for all $s \geq |\rho_0|$ and $m < h(n)$, and $\rho_0$ realizes $\tau_0$. If $\rho_j$ is defined, then define $\rho_{j+1}$ to be the first element of $S$ realizing $\tau_{j+1}$ such that for all $t \geq |\rho_{j+1}|$, $g_{|\rho_{j+1}|, t}(m) = g(m)$ for all $m < h(n)$.

This defines $2^n$ many different strings $\rho_j$ and thus $2^n - 1$ many meets, which must be of height below $h(n)$ by construction: given $\rho_{j_0} \wedge \rho_{j_1}$, they must differ at $|e_i|$ for some $i < n$ such that $\tau_{j_0}(i) \neq \tau_{j_1}(i)$. Moreover, as $\rho_j \in S$ for all $j$, if $|\rho_{j_0}| < |\rho_{j_1}|$, we have $g_{|\rho_{j_0}|, |\rho_{j_1}|}(|\rho_{j_0} \wedge \rho_{j_1}|) \neq k$, but also $g_{|\rho_{j_0}|, |\rho_{j_1}|}(|\rho_{j_0} \wedge \rho_{j_1}|) = g(|\rho_{j_0} \wedge \rho_{j_1}|)$ as $|\rho_{j_0} \wedge \rho_{j_1}| < h(n)$.

Thus, for every $j_0 \neq j_1 < 2^n$, $|\rho_{j_0} \wedge \rho_{j_1}| \in A_k$ and is below $h(n)$. There are $2^n - 1 > n$ many such meet. So $h$ is a function computable in $S$ that dominates the principal function of $A_k$. As $A_k$ is hyperimmune relative to $P$, $P$ cannot compute $h$, and so cannot compute $S$.

\textbf{Lemma 6.61 (Simpson [39, Theorem 6.5]).} For every pair of sets $A$ and $C$ such that $A$ is of PA degree over $C$, there is a set $B$ such that $A$ is PA over $B$ and $B$ is PA over $C$. 
6.5. LOWER BOUND ON THE RADO GRAPH THEOREM

Proof. Fix a universal $\Pi^0_1$ class functional $C \subseteq 2^\omega$ such that for every $X$, $C^X \neq \emptyset$ and all the members of $C^X$ are of PA degree relative to $X$. For example, take $C^X$ to be the class of all $\{0,1\}$-valued DNC functions relative to $X$. Then the class $D = \{B \oplus Z : B \in C^C \text{ and } Z \in C^B\}$ is a non-empty $\Pi^0_1$ class. In particular, $A$ computes some $B \oplus Z \in D$, and since $Z$ is of PA degree relative to $B$ and $B$ is of PA degree relative to $C$, the result follows.

Lemma 6.62. For every set $P$ of PA degree over $\emptyset'$, there exists an $\omega$-model $M_c$ of $RT^2_2$ such that for every $X \in M_c$, $X' \leq_T P$.

Proof. Fix $P$. We inductively define $A_0, A_1, \ldots \subseteq \mathbb{N}$ as follows. Let $A_0 = \emptyset$, and suppose we have defined $A_s$ for some $s \in \mathbb{N}$ and that $P$ is of PA degree above $A'_s$. By Lemma 6.61, there is some $Q$ be such that $P$ is PA relative to $Q$ and $Q$ is PA relative to $A'_s$. If $s \neq (e,t)$ for some $e \in \mathbb{N}$ and some $t < s$, or if $\Phi^e_t$ is not a coloring $f : [\omega]^2 \to 2$, then let $A_{s+1} = A_s$. Otherwise, by Cholak, Jockusch and Slaman [3] (see Hirschfeldt [19, Corollary 6.58] for an explicit formulation), there is an infinite $f$-homogeneous set $H$ such that $(H \oplus A_s)' \leq_T Q$. Let $A_{s+1} = A_s \oplus H$. In particular, $A'_{s+1} \leq_T Q$, so $P$ is of PA degree over $A'_{s+1}$. s

Let $S = \{Z : (\exists s)[Z \leq_T A_s]\}$, which is a Turing ideal since $A_t \leq_T A_s$ for all $t \leq s$. By construction, if $f : [\omega]^2 \to 2$ is any instance of $RT^2_2$ in $S$ then $S$ contains a solution to $f$. (Indeed, if $f = \Phi^e_t$, say, let $s = (e,t)$; then a solution to $X$ is computable from $A_{s+1}$.) It follows that $M_c = (\mathbb{N}, S)$ is a model of $RCA_0 \land RT^2_2$, and by construction, for every $X \in S$, $X' \leq_T P$.

We are now ready to prove our separation theorem.

Theorem 6.63. For every $\ell \geq 1$, $RT^2_2$ does not imply $(\forall k)RG^2_{k,\ell}$ over $RCA_0$.

Proof. By the low basis theorem relativized to $\emptyset'$ (see Jockusch and Soare [24, Theorem 2.1]), there is a set $P$ of PA degree over $\emptyset'$ such that $P' \leq_T \emptyset''$. By Lemma 6.62, there is an $\omega$-model $M_c$ of $RT^2_2$ such that for every $X \in M_c$, $X' \leq_T P$. By Theorem 6.59, there is a computable instance $f$ of $(\forall k)RG^2_{k,\ell}$ with no $P$-computable solution. In particular, $f \in M_c$, but $M_c$ does not contain a solution to $f$, so $M_c$ is not a model of $(\forall k)RG^2_{k,\ell}$.
CHAPTER 7

A generalized tree theorem

In this chapter, we study the principle $\text{CHMTT}^n_{k,l}$ stating that given a $k$-coloring of $[2^{<\omega}]^n$, there is a subtree $S \subseteq 2^{<\omega}$ such that $(S, \preceq)$ is isomorphic to $(2^{<\omega}, \preceq)$ and such that $[S]^n$ uses at most $l$ colors. Note that we do not require $S$ to be a strong subtree of $T$ or even $S$ to be meet-closed — thus enlarging a bit for this chapter the original definition of a tree given with definition 2.16.

The existence for every $n$ of a finite big Ramsey degree associated with these structures — a smallest number $l_n$ such that $\text{CHMTT}^n_{k,l_n}$ holds for every $k$ — easily follows from the Milliken’s tree theorem. We will try to identify more precisely the specific values of these big Ramsey degrees $l_n$, a new sequence of numbers, which does not seem to have appeared before in combinatorics.

In order to pursue this study, we introduce first a simpler principle, for which we now require the subtree to be a strong subtree.

**Theorem 7.1** (Strong generalized CHM tree theorem). For every $n \geq 1$ there exists $\ell \geq 1$ such that for every $k \geq 1$ and every $f : [2^{<\omega}]^n \to k$ there is a strong subtree $S \subseteq 2^{<\omega}$ such that $|f([S]^n)| \leq \ell$.

**Statement 7.2.** We call $\text{SCHMTT}^n_{k,l}$ the statement of the Strong generalized CHM tree theorem.

Note that both $\text{SCHMTT}^n_{k,l}$ and $\text{CHMTT}^n_{k,l}$ would work exactly the same way if we start from a coloring of any perfect tree $T$ rather than $2^{<\omega}$: via an isomorphism between $T$ and $2^{<\omega}$, the theorem applied to $2^{<\omega}$ also gives via the isomorphism a solution for $T$. We start by introducing the notion of embedding types, useful in the conduct of our study.

**7.1. Embedding types**

We shall try to identify what can be used by a coloring of $[2^{<\omega}]^n$ to identify some structure one will never be able to remove in any strong subtree. A first step for that is the identification of the concept of embedding type, for which we introduce the following preliminary notions.

**Definition 7.3.** Let $S$ be a set of strings.

1. $S$ is meet-closed if for every $\sigma, \tau \in S$, $\sigma \land \tau \in S$.
2. $S$ is level-closed if for every $\sigma, \tau \in S$, $\tau \upharpoonright |\sigma| \in S$. 

111
We will be interested in finite trees which are both meet-closed and level closed.

**Definition 7.4** (closure). Let $S$ be a set of strings.

1. The **meet closure** of $S$ is the set $S^\land = \{\sigma \land \tau : \sigma, \tau \in S\}$.
2. The **level closure** of $S$ is the set $S^{\text{lvl}} = \{\sigma \downarrow \tau : \sigma, \tau \in S\}$.
3. The **full closure** of $S$ is the set $S^{\text{cl}} = (S^\land)^{\text{lvl}}$.

Note that $S \subseteq S^\land$ and $S \subseteq S^{\text{lvl}}$ by taking $\sigma = \tau$ in the above definitions. Any strong subtree of $2^{<\omega}$ is meet-closed and level-closed but not conversely, as witnessed by the following example $S = \{e; 0; 00; 01; 11\}$. In Figure 7.1, we give an example of a subtree, and its full closure.

![Figure 7.1](image)

**Figure 7.1.** The set of nodes (a) is level-closed but not meet-closed. The set of nodes (b) is the meet-closure of (a). Note that it is now not level-closed. The set of nodes (c) is the level-closure of (b) which corresponds to the full closure of (a).

The idea is the following: given a set of strings $S = \{\sigma_1, \ldots, \sigma_n\} \in [2^{<\omega}]^n$, one can easily compute the tree $S^{\text{cl}}$. A coloring can then identify which type of tree arise from $S$ and give a different color to each of them. The number of these type is defined below as the embedding types that we now formally define.

**Definition 7.5.** Two finite fully closed trees $F_0, F_1 \subseteq 2^{<\omega}$ are **strongly isomorphic** if there is a bijection $f : F_0 \rightarrow F_1$ such that $\sigma \leq \tau \iff f(\sigma)i \leq f(\tau)$ for any $\sigma, \tau \in F_0$. The **embedding types** are the equivalence classes of the strong isomorphism relation on finite fully closed trees.

Any embedding type has a minimal element with respect its height. We usually use this minimal element as a canonical representative of the class.

Figures 7.2 to 7.4 illustrate the notion of embedding types. Figure 7.2 consists of example of different embedding types. Figure 7.3 shows several level-closed subtrees with the same embedding type. Figure 7.4 illustrates the height of an embedding type.

### 7.2. Strong generalized CHM tree theorem

No embedding type can be avoided in a strong subtree of $2^{<\omega}$. For this reason the number of colors that cannot be avoided by $n$-tuples of elements
of $2^{<\omega}$ is at least the number of embedding types that can be generated by these tuples.

**Definition 7.6.** Let $\epsilon_{\text{TT}} : \omega \to \omega$ be the function which to $n$ associates the number of embedding types that can be generated by $n$ distinct strings.

Let us provide an example with Figure 7.5: all the possible embedding types that are generated by two strings. We have $\epsilon_{\text{TT}}(2) = 7$.

Given an element of $[2^{<\omega}]^n$ one can computably recognize which embedding type it generates. It follows that given an enumeration $\epsilon_1, \epsilon_2, \ldots, \epsilon_{\epsilon_{\text{TT}}(n)}$ of the embedding types that can be generated by $n$ distinct strings, one can define the color $c$ on $[2^{<\omega}]^n$ which to each element generating the embedding type $\epsilon_i$ associates $i$. No strong subtree of $2^{<\omega}$ can avoid any embedding type
and thus at least \( e_{sTT}(n) \) colors are used by \( c \) within any strong subtree of \( 2^{<\omega} \).

We can in fact force even more colors: Given a finite strong subtree \( F \subseteq 2^{<\omega} \), there might be distinct tuples \( \overline{\sigma}_1, \overline{\sigma}_2 \in [F]^n \) such that \( \overline{\sigma}_1^cl = \overline{\sigma}_2^cl = F \). Note that such a phenomenon does not happen for \( n = 2 \) and below, but start to happen from \( n = 3 \). For instance the tuples \( \{\sigma_0, \sigma_1, \sigma_00\} \) and \( \{\sigma, \sigma_1, \sigma_00\} \) generate the same embedding type. This leads to the following definition:

**Definition 7.7.** A tuple type is an equivalence class on the following relation defined on \( \bigcup_n [2^{<\omega}]^n \times [2^{<\omega}]^n \): We say that \( \overline{\sigma}, \overline{\tau} \in [2^{<\omega}]^n \) are equivalent if there is a strong isomorphism \( f \) from \( \overline{\sigma}^cl \) to \( \overline{\tau}^cl \) which associates elements of \( \overline{\sigma} \) to elements of \( \overline{\tau} \).

Note that the tuple types are a refinement of the embedding types. Also for \( n > 2 \) this refinement is strict, by the example given above with \( \{\sigma_0, \sigma_1, \sigma_00\} \) and \( \{\sigma, \sigma_1, \sigma_00\} \): no strong isomorphism from \( \{\sigma_0, \sigma_1, \sigma_00\}^cl \) to \( \{\sigma, \sigma_1, \sigma_00\}^cl \) can map elements of \( \{\sigma_0, \sigma_1, \sigma_00\} \) to elements of \( \{\sigma, \sigma_1, \sigma_00\} \) as no string is a prefix of the other two in the former but one is in the latter.

**Definition 7.8.** Let \( t_{sTT} : \omega \rightarrow \omega \) be the function which to \( n \) associates the number of tuple types that can be generated by \( n \) distinct strings.

Just like a coloring on \( [2^{<\omega}]^n \) can recognize the generated embedding types, it can recognize the corresponding tuple types: the embedding type together with the role played by each string generating it. And just like no embedding type can be avoided in a strong perfect tree, also no tuple type can be avoided in a strong perfect tree. It follows that if \( c \) is a coloring of \( [2^{<\omega}]^n \) which associates to an element its corresponding tuple type, then any strong perfect subtree of \( T \) needs at least \( t_{sTT}(n) \) colors. In the next section we show that this number is optimal.

We are now ready to formally state and prove the strong generalized CHM tree theorem.

**Theorem 7.9** (Strong generalized CHM tree theorem). For every \( n \), the principle \( (\forall k)SCMHTT^n_{k,tTT(n)} \) is provable in \( ACA_0 \), and \( RCA_0 \) proves that the principle \( (\forall k)SCMHTT^n_{k,tTT(n)−1} \) is false.
7.3. AVOIDING TYPES

PROOF. We already saw that this principle is false when the maximal number of color is \( t_{\text{TT}}(n) - 1 \), with as an example the coloring on \([2^{<\omega}]^n\) which on each element associates an integer representing its tuple type.

Let us now show that one can prove the statement within ACA\(_0\) for \( t_{\text{TT}}(n) \) colors. Let \( t_1, t_2, \ldots, t_{t_{\text{TT}}(n)} \) be an enumeration of the tuple types of size \( n \). Let \( c \) be any coloring on the elements of \([2^{<\omega}]^n\).

Let \( T_0 = 2^{<\omega} \) and inductively for \( i < t_{\text{TT}}(n) \), let \( c_i \) be the embedding type that \( t_i \) belongs to. Let \( m_i \) be the height of the canonical representative of \( t_i \). Let \( c_i \) be the color on \( T_i \) which on any strong subtree \( F \) of height \( m_i \) associates the color \( c \) gives on the unique element of \([F]^n\) with tuple type \( t_i \). Using corollary 4.7 stating that Milliken theorem for height \( m_i \) is provable in ACA\(_0\), let then \( T_{i+1} \) be a strong perfect subtree of \( T_i \) which belongs to \( M_c \) and which is monochromatic for \( c_i \) and let \( k_i \) be the corresponding color. For this step, note that even if Milliken theorem is stated for strong subtrees of \( 2^{<\omega} \), we can also apply it for strong subtrees of \( T \) where \( T \) is itself a strong subtree of \( 2^{<\omega} \).

Let \( S = T_{t_{\text{TT}}(n)} \). By induction we have that \( S \) is a strong subtree of \( 2^{<\omega} \). Any \( \sigma \in [S]^n \) belongs to some tuple type \( t_i \) and thus has color \( k_i \). Thus at most \( t_{\text{TT}}(n) \) color are used in \( S \).

7.3. Avoiding types

We now turn to the study of CMHTT\(_k\). In particular we do not require our subtrees to be string anymore. As expected we need less colors, basically because we can avoid some embedding types, and within the embedding types which cannot be avoided, we can avoid some tuple types.

Note that one can easily create a perfect tree which avoids almost all embedding type. Suppose we force for instance every node to be of different length. Formally such a tree has only embedding types which consists of comparable nodes, because any embedding type with two incomparable nodes contains two distinct nodes of the same length. However, this does not help: what we want is to avoid the embedding types (resp. the tuple types) which can be generated by the \( n \)-tuples of the tree, even though elements in the strong closure of the \( n \)-tuple are not necessarily all in the tree.

We will show given any strong tree \( S \) how to compute a perfect subtree \( T \) of \( S \) which avoids as many tuple types as possible. We in fact give right away the syntactic property a tree must have to avoid as many tuple types as possible.

**Definition 7.10.** We say that a perfect tree \( T \) syntactically minimizes the number of tuple types if:

1. any two nodes of \( T^\land \) is of different length;
2. for any nodes \( \sigma, \tau \in T \) with \( \sigma < \tau \) we have \( \sigma 0 < \tau \);
3. for any nodes \( \sigma, \tau \in T^{cl} \) with \( \sigma \notin T^\land \) and \( \sigma < \tau \) we have \( \sigma 0 < \tau \).

Given (1), note that (3) in the previous definition is equivalent to have for any incomparable nodes \( \sigma, \tau \in T^\land \) with \( |\sigma| < |\tau| \) that \( \tau(|\sigma|) = 0 \).
Lemma 7.11. Given any strong perfect subtree $S \subseteq 2^{<\omega}$, there is an $S$-computable perfect subtree $T \subseteq S$ which syntactically minimizes the number of tuple types.

Proof. Without loss of generality we consider that we work with $S = 2^{<\omega}$. The subtree that we build can then be pulled back in $S$ using some isomorphism between $2^{<\omega}$ and $S$.

We start by computing a meet-closed subtree $T' \subseteq 2^{\omega}$ such that (1) and (3) are satisfied. We put in $T_0$ the root of $2^{<\omega}$. Then inductively suppose we have a finite perfect tree $T_n$ such that each of its leaf is of level $n$ and such that for $\tau_1, \tau_2 \in T_n$ we have $|\tau_1| + 1 < |\tau_2|$ or $|\tau_2| + 1 < |\tau_1|$. Let $\sigma_1, \ldots, \sigma_k$ be the leaves of $T_n$ such that $|\sigma_i| + 1 < |\sigma_{i+1}|$. We define $T_{n+1,0}$ to be $T_n$. Inductively for $i \leq k$ suppose we have defined a perfect tree $T_{n+1,i} \supseteq T_{n+1,0}$ such that for $\tau_1, \tau_2 \in T_{n+1,i}$, we have $|\tau_1| + 1 < |\tau_2|$ or $|\tau_2| + 1 < |\tau_1|$ and such that $|\sigma_i|$ is the smallest among the leaves of $T_{n+1,i}$. We let $\tau_0$ be the lexicographically smallest such that:

- $|\sigma_{i+1}0\tau_0| - 1$ is bigger than every string in $T_{n+1,i}$;
- for every string $\sigma \in T_{n+1,i}$ different from $\sigma_{i+1}$ we have $\sigma_{i+1}0\tau_0(|\sigma|) = 0$. Note that by the induction hypothesis we can find such a string.

Then let $\tau_1$ be the lexicographically smallest such that:

- $|\sigma_{i+1}1\tau_1| - 1$ is bigger than every string in $T_{n+1,i} \cup \{\tau_0\}$;
- for every string $\sigma \in T_{n+1,i} \cup \{\tau_0\}$ different from $\sigma_{i+1}$ we have $\sigma_{i+1}1\tau_1(|\sigma|) = 0$. Note that by the induction hypothesis we can find such a string.

Let us then define $T_{n+1,i+1} = T_{n+1,i} \cup \{\tau_0, \tau_1\}$. Note that $\sigma_{i+1}$ becomes the smallest leaf of $T_{n+1,i+1}$. Once we have defined $T_{n+1,i}$ for every $i \leq k$ we define $T_{n+1} = T_{n+1,k}$.

We finally define $T' = \bigcup_{n} T_n$. By construction $T'$ has the desired properties. Note that for any perfect subtree $T \subseteq T'$ then also every node is of different length, so (1) is preserved. Furthermore as $T'$ is meet closed then also for any perfect tree $T \subseteq T'$ and any two incomparable nodes $\sigma, \tau \in T'$ with $|\sigma| < |\tau|$ we have $\tau(|\sigma|) = 0$, so (3) is preserved.

We finally find a perfect subtree $T \subseteq T'$ such that for any $\sigma, \tau \in T$ with $\sigma < \tau$ we have $\sigma 0 \leq \tau$. Given an isomorphism $f : 2^{<\omega} \rightarrow T'$ we define $T$ to be the range of $f$ on strings of the form $\sigma 00$ or $\sigma 01$ for $\sigma \in 2^{<\omega}$. One can easily verify that $T$ is a perfect subtree of $T'$ on which (1) (2) and (3) are verified.

See Figure 7.6 for an illustration.

We shall see that the number above is optimal. Of course, it is not the case that one of the above types can never be omitted in a perfect tree and it is in fact one difficulty in showing that a tree $T$ syntactically minimizing the number of tuple types really does so: every tuple type can be omitted in some perfect tree. Of course omitting a type may force some other type to become unavoidable. In order to overcome this difficulty, we need to
introduce a third equivalence relation, within which we erase the part of a tuple type which can be omitted.

**Definition 7.12.** The *weak tuple types* are the equivalence classes of the following relation: \( \overline{\sigma}, \overline{\tau} \) have the same weak tuple type if there is a bijection \( f \) from \( \overline{\sigma}^d \) to \( \overline{\tau}^d \) such that:

- for \( \sigma_1, \sigma_2 \in \overline{\sigma}^d \) we have \( \sigma_1 \preceq \sigma_2 \) iff \( f(\sigma_1) \preceq f(\sigma_2) \);
- for \( \sigma_1, \sigma_2, \sigma_3 \in \overline{\sigma}^d \) we have \( \sigma_10 \preceq \sigma_2 \) and \( \sigma_11 \preceq \sigma_3 \) iff \( f(\sigma_1)0 \preceq f(\sigma_2) \) and \( f(\sigma_1)1 \preceq f(\sigma_3) \);
- elements of \( \overline{\sigma} \) are sent to \( \overline{\tau} \).

In other word, weak tuple types are tuple types, modulo the fact that whenever a node is not branching, it does not matter for its extension to go left or right. It is clear from the definition that the tuple types are a refinement of the weak tuple types. On the other hand neither the weak tuple types are a refinement of the embedding types, or the embedding types a refinement of the weak tuple types.

**Lemma 7.13.** Let \( T \) be a perfect tree which syntactically minimizes the number of tuple types. Then its tuple types and weak tuple types coincide.

**Proof.** We already have that the tuple types are a refinement of the weak tuple types. All we have to do is to show that restricted to \( T \), the weak tuple types are a refinement of the tuple types.

For any \( n \) consider any two \( n \)-tuples \( \overline{\sigma}, \overline{\tau} \) of \( T \). Suppose they are in the same weak tuple type via some bijection \( f : \overline{\sigma}^d \rightarrow \overline{\tau}^d \). Let us show that \( f \) in fact witnesses that \( \overline{\sigma} \) and \( \overline{\tau} \) are in the same tuple types. For that it is enough to show that \( \sigma_1i \preceq \sigma_2 \) implies \( f(\sigma_1)i \preceq f(\sigma_2) \) for \( \sigma_1, \sigma_2 \in \overline{\sigma}^d \). Let \( \sigma_1, \sigma_2 \in \overline{\sigma}^d \) with \( \sigma_1i \preceq \sigma_2 \).

Suppose first that we have a string \( \sigma_3 \in \overline{\sigma}^d \) such that \( \sigma_1(1-i) \preceq \sigma_3 \). Then by definition of a weak tuple type we have \( f(\sigma_1)i \preceq f(\sigma_2) \). Otherwise there are two possibilities: either \( \sigma_1 \in \overline{\sigma} \) or \( \sigma_1 \in \overline{\tau}^d \) but \( \sigma_1 \notin \overline{\sigma}^d \).

In the first case, note that we must have a string \( \sigma_3 \in \overline{\sigma} \) with \( \sigma_1i \preceq \sigma_2 \preceq \sigma_3 \). Note that as \( \sigma_1, \sigma_3 \in \overline{\sigma} \) then also \( \sigma_1, \sigma_3 \in T \). Then by property (2) in Definition 7.10 (the definition of syntactically minimizing the number of tuple type), we have \( \sigma_10 \preceq \sigma_2 \preceq \sigma_3 \). Note also that \( f(\sigma_1) \preceq f(\sigma_1) \preceq f(\sigma_3) \) and that by hypothesis on \( f \) we have \( f(\sigma_1), f(\sigma_3) \in \overline{\tau} \subseteq T \). Therefore also we have \( f(\sigma_1)0 \preceq f(\sigma_3) \) by (2) in Definition 7.10 and thus we have \( f(\sigma_1)0 \preceq f(\sigma_2) \).
In the second case we have $\sigma_1, \sigma_2 \in T^\varnothing$ and $\sigma_1 \notin T^\wedge$. Thus by property (3) in Definition 7.10 we have $\sigma_10 \preceq \sigma_2$. We shall argue that also $f(\sigma_1) \notin T^\wedge$.

Suppose for contradiction that $f(\sigma_1) \in T^\wedge$. Then also $f(\sigma_1) \in \overline{T}^\wedge$. Recall that by hypothesis $\sigma_1 \notin \overline{T}$ and thus $f(\sigma_1) \notin \overline{T}$ (as $f$ is a bijection between the two). It follows that $f(\sigma_1)$ must be the meet of two nodes in $\overline{T}$ and thus is branching in $\overline{T}^\varnothing$. On the other hand as $\sigma_1 \notin T^\wedge$ it is not branching in $\overline{T}^\varnothing$ which contradicts the properties of $f$. Thus $f(\sigma_1) \notin T^\wedge$ and it follows by property (3) in the definition of syntactically minimizes the number of tuple type that $f(\sigma_1)0 \preceq f(\sigma_2)$.

We then have that $\overline{T}$ and $T$ are in the same tuple types. 

We shall now identify the weak tuple types no perfect tree can omit. We shall then see that weak tuple types of a tree which syntactically minimizes the number of tuple types are all of this form. It will then follow that such a tree really minimizes the number of tuple types.

**Definition 7.14.** A tuple type (resp. a weak tuple type) $\overline{T}$ is *length-injective* if $\sigma_1, \sigma_2 \in \overline{T}^\wedge$ implies $|\sigma_1| \neq |\sigma_2|$.

**Definition 7.15.** A tuple type (resp. a weak tuple type) $\overline{T}$ is *meet-avoiding* if for any incomparable $\sigma_1, \sigma_2 \in \overline{T}$ we have $\sigma_1 \wedge \sigma_2 \notin \overline{T}$.

See Figure 7.7 for an illustration.

Up to symmetry and restricted to a tree which syntactically minimizes the number of types, these are the only tuple types generated by three strings and which are in the same embedding type. We will now see that the length-injective and meet-avoiding weak tuple types are exactly those which cannot be avoided by a perfect tree.

**Lemma 7.16.** Let $S$ be any perfect tree. Then $S$ has a member inside every length-injective and meet-avoiding weak tuple type.

**Proof.** Let $\overline{T}$ be a length-injective and meet-avoiding tuple type. Let us define first an injection $f$ from $\overline{T}^\wedge$ into $S^\wedge$ with the following properties:

1. $f(\overline{T}) \subseteq S$;
2. for $\sigma_1, \sigma_2 \in \overline{T}^\wedge$ we have $\sigma_1 \preceq \sigma_2$ iff $f(\sigma_1) \preceq f(\sigma_2)$;
3. if $\sigma_1$ is branching in $\overline{T}^\wedge$ then $f(\sigma_1)$ is branching in $S^\wedge$. Furthermore for $\sigma_1, \sigma_2, \sigma_3 \in \overline{T}^\wedge$ we have $\sigma_10 \preceq \sigma_2$ and $\sigma_11 \preceq \sigma_3$ iff $f(\sigma_1)0 \preceq f(\sigma_2)$ and $f(\sigma_1)1 \preceq f(\sigma_3)$;
(4) for \( \sigma_1, \sigma_2 \in \tau^\wedge \) we have \(|\sigma_1| < |\sigma_2| \) iff \(|f(\sigma_1)| < |f(\sigma_2)| \).

Let \( \sigma_1, \ldots, \sigma_n \) be a list of the elements of \( \tau^\wedge \) with \(|\sigma_1| < |\sigma_2| < \cdots < |\sigma_n| \). Note that we must have \( \sigma_i \preceq \sigma_j \) implies \( i \leq j \). Note also that as \( \tau \) is meet-avoiding we must have that \( \rho \in \tau^\wedge \) is branching in \( \tau^\wedge \) iff \( \rho \notin \tau \).

If \( \sigma_1 \in \tau \) then find the lexicographically first \( \tau \in S \) and let \( f(\sigma_1) = \tau \). Otherwise find the lexicographically first \( \tau \in S^\wedge \) which is branching in \( S^\wedge \) and let \( f(\sigma_1) = \tau \). Note that so far (1)(2)(3) and (4) are satisfied.

Suppose \( f(\sigma_1), \ldots, f(\sigma_k) \) have been defined with (1)(2)(3) and (4) satisfied so far. Consider \( \sigma_{k+1} \). Let \( j \leq k \) be the largest such that \( \sigma_j \prec \sigma_{k+1} \). Suppose first \( \sigma_j \) is branching in \( \tau^\wedge \). Then by induction hypothesis (3) we must have that \( f(\sigma_j) \) is branching in \( \tau^\wedge \). In this case let \( i \in \{0,1\} \) be such that \( \sigma_{j,i} \preceq \sigma_{k+1} \). If \( \sigma_{k+1} \in \tau \) then find the lexicographically first \( \tau \in S \) such that \(|\tau| > |f(\sigma_k)| \) and such that \( f(\sigma_{j,i}) \preceq \tau \). Then let \( f(\sigma_{k+1}) = \tau \). Otherwise find the lexicographically first branching \( \tau \in S^\wedge \), such that \(|\tau| > |f(\sigma_k)| \) and such that \( f(\sigma_{j,i}) \preceq \tau \). Then let \( f(\sigma_{k+1}) = \tau \). Note that in any case (1) (2) (3) and (4) are satisfied so far.

Suppose now \( \sigma_j \) is not branching in \( \tau^\wedge \). If \( \sigma_{k+1} \in \tau \) then find the lexicographically first \( \tau \in S \) such that \(|\tau| > |f(\sigma_k)| \) and such that \( f(\sigma_j) \preceq \tau \). Then let \( f(\sigma_{k+1}) = \tau \). Otherwise find the lexicographically first branching \( \tau \in S^\wedge \), such that \(|\tau| > |f(\sigma_k)| \) and such that \( f(\sigma_j) \preceq \tau \). Then let \( f(\sigma_{k+1}) = \tau \). Note that in any case (1) (2) (3) and (4) are satisfied so far. This ends the first part of the construction.

Note also that \( f \) is a bijection between \( \tau \) and \( f(\tau) \subseteq S \). In order to show that \( \tau \) and \( f(\tau) \) are in the same weak tuple type, we shall now extend \( f \) to \( \tau^d \) such that \( f \) becomes a bijection from \( \tau^d \) to \( f(\tau)^d \).

Let us first argue that so far \( f \) is a bijection from \( \tau^\wedge \) to \( f(\tau)^\wedge \). We have \( f(\tau) \subseteq f(\tau^\wedge) \). By design we also have that \( f(\tau^\wedge) \) is meet closed and thus we have \( f(\tau)^\wedge = f(\tau)^\wedge \). As \( f \) is injective it is a bijection from \( \tau^\wedge \) to \( f(\tau)^\wedge \) and then it is a bijection from \( \tau^\wedge \) to \( f(\tau)^\wedge \).

Let us now extend \( f \) to \( \tau^d \); for incomparable \( \sigma_1, \sigma_2 \in \tau^\wedge \) with \(|\sigma_1| < |\sigma_2| \) we assign \( f(\sigma_2 \upharpoonright |\sigma_1|) \) to \( f(\sigma_2 \upharpoonright |f(\sigma_1)|) \). Let us now show that \( f(\tau^d) = f(\tau)^d \). It is clear by definition of \( f \) that \( f(\tau^d) \subseteq f(\tau)^d \). Let us now show \( f(\tau)^d \subseteq f(\tau^d) \).

Suppose \( \tau \in f(\tau)^d \). Then as \( f(\tau)^d = (f(\tau)^\wedge)^d = f(\tau^\wedge)^d \) we have \( \tau \in f(\tau)^d \). Then there exists \( \sigma_1, \sigma_2 \in \tau^\wedge \) with \(|f(\sigma_1)| < |f(\sigma_2)| \) and with \( \tau = f(\sigma_2 \upharpoonright |f(\sigma_1)|) \). By (4) we have \(|\sigma_1| < |\sigma_2| \) and then \( \sigma_2 \upharpoonright |\sigma_1| \in \tau^d \). Thus \( \tau \in f(\tau^d) \) and then \( f(\tau)^d \subseteq f(\tau^d) \) and then \( f(\tau)^d = f(\tau^d) \).

Let us now show that \( f \) is injective on \( \tau^d \). Let \( \sigma_1, \sigma_2, \rho_1, \rho_2 \in \tau^\wedge \) with \( \sigma_1, \sigma_2 \) and \( \rho_1, \rho_2 \) incomparable, with \(|\sigma_1| < |\sigma_2| \) and with \(|\rho_1| < |\rho_2| \). Suppose \( \sigma_2 \upharpoonright |\sigma_1| \neq \rho_2 \upharpoonright |\rho_1| \). If \( \sigma_1 \neq \rho_1 \) then by (4) we must have \(|f(\sigma_1)| \neq |f(\rho_1)| \) and thus \( f(\sigma_2) \upharpoonright |f(\sigma_1)| \neq f(\rho_2) \upharpoonright |f(\rho_1)| \). Otherwise it must be that \( \sigma_2 \upharpoonright s \neq \rho_2 \upharpoonright s \) for \( s = |\sigma_1| = |\rho_1| \). By definition of \( f \) it must be that \( f((\sigma_2 \uparrow s) \land (\rho_2 \uparrow s)) = f(\sigma_2 \uparrow s) \land f(\rho_2 \uparrow s) \) and thus by (3) that \( f(\sigma_2 \uparrow s) \neq f(\rho_2 \uparrow s) \).
It follows that \( f \) is a bijection from \( \sigma^d \) to \( f(\sigma^d) \) and thus that it is a bijection from \( \sigma^d \) to \( f(\sigma)^d \).

It is clear that property (1) and (2) is still satisfied by \( f \) on \( \sigma^d \). Also as every branching node of \( \sigma^d \) is already branching in \( \sigma^1 \) property (3) is still satisfied on \( \sigma^d \). It follows that \( \sigma \) and \( f(\sigma) \) are in the same weak tuple type. \( \square \)

**Lemma 7.17.** Let \( T \) be a tree which syntactically minimizes the number of tuple types. Then every weak tuple type of \( T \) is length-injective and meet-avoiding.

**Proof.** By definition we have that \( \sigma_1, \sigma_2 \in T^\land \) implies \( |\sigma_1| \neq |\sigma_2| \). Thus the weak tuple types of \( T \) are length-injective. Suppose now \( \sigma_1, \sigma_2 \in T \) with \( \sigma_1, \sigma_2 \) incomparable. Suppose for contradiction that \( \sigma_1 \land \sigma_2 \in T \). Then we have \( (\sigma_1 \land \sigma_2) \leq \sigma_1 \) or \( (\sigma_1 \land \sigma_2) \leq \sigma_2 \). In any case we violate property (2) of syntactically minimizing the number of types. Thus for any \( \sigma_1, \sigma_2 \in T \) with \( \sigma_1, \sigma_2 \) incomparable we have \( \sigma_1 \land \sigma_2 \notin T \) which implies that the weak tuple types of \( T \) are meet-avoiding. \( \square \)

### 7.4. Generalized CHM tree theorem

We are now ready to study the generalized CHM tree theorem, where we do not necessarily required the subtree to be a strong subtree.

**Definition 7.18.** Given a perfect tree \( T \), let \( t_{TT}^T(n) \) be the number of tuple types generated by \( n \) distinct strings of \( T \). Let

\[
t_{TT}(n) = \min \{ t_{TT}^T(n) \mid T \text{ is a perfect tree} \}.
\]

**Theorem 7.19.** Suppose \( T \) syntactically minimizes the number of tuple types, then \( t_{TT}(n) = t_{TT}^T(n) \).

**Proof.** Suppose \( T \) syntactically minimizes the number of tuple types. Then by Lemma 7.13 the tuple types of \( T \) coincide with its weak tuple types. By Lemma 7.17 every weak tuple type of \( T \) is length-injective and meet-avoiding. By Lemma 7.16 we then have that every weak-tuple type of \( T \) is a weak-tuple type in any perfect tree \( S \). Using the fact that the tuple types are a refinement of the weak tuple types, we then have that given any \( n \), the number of tuple types of \( [S]^n \) is bigger than the number of weak tuple types of \( [S]^n \) and then bigger than the number of weak tuple types of \( [T]^n \) and then bigger than the number of tuple types of \( [T]^n \). Thus \( t_{TT}(n) = t_{TT}^T(n) \). \( \square \)

**Theorem 7.20** (Generalized CHM tree theorem). For every \( n \), the principle \( \text{CMHTT}^n_{k,TT} \) is provable in \( ACA_0 \) but \( \text{RCA}_0 \) proves that the principle \( \text{CMHTT}^n_{k,TT(n)-1} \) is false.

**Proof.** Let \( Mc \) be a model of \( ACA_0 \). Let \( T \in Mc \) be a perfect tree and \( c \in Mc \) be a color of \( [T]^n \). Using Theorem 7.9, there is a strong subtree \( S \subseteq T \) such that every tuple type of \( [S]^n \) is monochromatic for
7.4. GENERALIZED CHM TREE THEOREM

c. Using Lemma 7.11 let $R$ be a $S$-computable perfect subtree of $S$ which syntactically minimizes the number of tuple types. Note that $R \in Mc$ and that by Theorem 7.19 $[R]^n$ has at most $t_{TT}(n)$ many tuple types. It follows that $\epsilon$ uses at most $t_{TT}(n)$ many colors on $R$.

To show optimality, and given an enumeration $\{\epsilon_i\}_{i \leq t_{TT}(n)}$ of the tuple types generated by $n$ strings, let us define a color on $2^{<\omega}$ which associates $i$ to $\bar{\sigma}$ of tuple type $\epsilon_i$. By minimality of $t_{TT}(n)$ among $t_{TT}^T(n)$ for a perfect tree $T$ we have that every perfect subtree of $2^{<\omega}$ uses at least $t_{TT}(n)$ colors. □

**THEOREM 7.21** (CHM tree theorem for $n$-tuple and $k$-colors). *For every coloring of $n$-tuples of pairwise comparable strings, there exists a perfect tree on which the coloring is monochromatic.*

**PROOF.** This follows from the fact that given any $n$, there is only one weak tuple type of size $n$ which contains only comparable strings. □

It is easy to determine the number $e_n$ of embedding types of height $n$, which is given by the following induction:

\[
\begin{align*}
e_0 &= 1, \\
e_1 &= 1, \\
e_{n+1} &= 2 \times e_n \times (\sum_{i<n} e_i) + e_n^2.
\end{align*}
\]

The definition above is justified by the following observation: there is one tree of height 0 (the emptyset), there is one tree of height 1 (the empty string) and for any $n \geq 1$, the possibilities to build trees of height $n+1$ are as follow: having a left subtree of the root (the empty string) of height $n$ and a right subtree of the root of height $< n$, or the inverse of that, or have both a left and a right subtree of the root of height $n$.

The number of embedding types generated by $n$ strings, namely $e_{S_{TT}}(n)$ appears much harder to compute. It is the same for $t_{S_{TT}}(n)$ and $t_{TT}(n)$. We can also define the function $n \mapsto e_{TT}(n)$ which to $n$ associates the minimal number of embedding type within any perfect tree (which is the number of embedding types generated by $n$ strings of a tree which syntactically minimizes the number of tuple types).

We computed the first values of each with the help of a computer program:

<table>
<thead>
<tr>
<th>$e_{S_{TT}}$</th>
<th>$t_{S_{TT}}$</th>
<th>$e_{TT}$</th>
<th>$t_{TT}$</th>
</tr>
</thead>

</tbody>
</table>

None of these sequence appears in OEIS, The On-Line Encyclopedia of Integer Sequences [21]. It then seems that each of them is a new natural combinatorial sequence. Even if it seems that these sequences cannot be
computed with an easy mathematical induction like for the number of embedding types of height $n$, we conjecture each of them to be polynomial time computable.
CHAPTER 8

Open Questions

The computability-theoretic study of Milliken’s tree theorem and its applications being completely new, this work leaves many questions open. We collect some here that seem most promising for follow-up research directions.

8.1. Milliken’s tree theorem in the arithmetical hierarchy

When analyzing a mathematical problem from a computability-theoretic viewpoint, the first step usually consists in determining whether the computable instances of the problem admit arithmetical solutions, and if so, trying to identify the exact level in the arithmetical hierarchy where they stand. For example, Jockusch [22] proved that every computable instance of Ramsey’s theorem for $n$-tuples admits $\Pi^0_n$ solutions, and for each $n \geq 2$, constructed a computable instance of Ramsey’s theorem for $n$-tuples and 2 colors with no $\Sigma^0_n$ solutions. Thus, the status of Ramsey’s theorem with respect to the arithmetical hierarchy is fully determined.

The case of Milliken’s tree theorem is less clear. By Theorem 4.6, computable instances of Milliken’s tree theorem admit arithmetical solutions. More precisely, every computable instance of Milliken’s tree theorem for subtrees of height $n$ admits a $\Delta^0_{2n-1}$ solution. On the other hand, since Milliken’s tree theorem generalizes Ramsey’s theorem, for every $n \geq 2$, there exists a computable instance of Milliken’s tree theorem for trees of height $n$ with no $\Sigma^0_n$ solutions. This leaves a gap between the lower and upper bound.

**Question 1.** Does every computable instance of Milliken’s tree theorem for height $n$ admit a $\Delta^0_{n+1}$ solution?

The proof by Jockusch [22] of the existence of a $\Pi^0_2$ solution for every computable instance of Ramsey’s theorem for $n$-tuples is by an inductive argument based on the notion of prehomogeneous set. In particular, he proves that every PA degree relative to $\emptyset'$ is sufficient to compute a prehomogeneous set. Hirschfeldt and Jockusch [20, Theorem 2.1] actually proved a reversal, by constructing a computable instance of Ramsey’s theorem for triples such that every prehomogeneous set is of PA degree relative to $\emptyset'$. This bound on prehomogeneous sets is sufficient to make increasing the level in the arithmetical hierarchy only by one when increasing the size of the colored tuples by one, by taking prehomogeneous sets of low degree over $\emptyset'$.

Similarly, the current upper bound of Milliken’s tree theorem is proved using the corresponding notion of prehomogeneous tree, but Lemma 4.5
yields only a $\Delta^0_3$ solution, which makes increase the level in the arithmetical hierarchy by 2 instead of 1 when coloring larger tuples. The following questions are still open:

**Question 2.** Given a computable instance of the Milliken’s tree theorem for height $n$, does any PA degree relative to $\emptyset'$ compute a prehomogeneous infinite strong subtree? Is there always a prehomogeneous infinite strong subtree of low degree relative to $\emptyset'$?

A positive answer to either question would be sufficient to answer positively Question 1.

### 8.2. Larger degrees and cone avoidance

Cone avoidance is a central notion in the computability-theoretic analysis of theorems. It is the main tool for separating a theorem from ACA_0 over $\omega$-structures. It is in particular a desirable property to have, and given a statement which does not admit cone avoidance, one can ask whether there exists a natural weakening of it which admits it. The analysis of Ramsey’s theorem gives a good example: Jockusch [22] constructed for every $n \geq 3$ a computable instance of Ramsey’s theorem for $n$-tuples whose solutions compute the halting set. In particular, this shows that Ramsey’s theorem for 3-tuples does not admit cone avoidance. On the other hand, Wang [48, Theorem 3.2] proved that when weakening the notion of homogeneity in Ramsey’s theorem by allowing a larger number of colors, then the resulting statement admits cone avoidance. In particular, he proved that $(\forall k)\text{RT}^3_{k,2}$ admits cone avoidance, where $(\forall k)\text{RT}^n_{k,\ell}$ is the statement whose instances are colorings $f : [\omega]^n \to k$ for some $k$, and whose solutions are infinite sets $H$ such that $|H| \leq \ell$. In general, Wang proved that for every $n$, and every $\ell$ sufficiently large with respect to $n$, the statement $(\forall k)\text{RT}^n_{k,\ell}$ admits cone avoidance. Cholak and Patey [4] computed the exact bound where this threshold phenomenon happens, which happens to be $(\forall k)\text{RT}^n_{k,C_{n-1}}$, where $C_0, C_1, \ldots$ is the Catalan sequence, starting with 1, 1, 2, 5, 14, 42, \ldots

Milliken’s tree theorem behaves like Ramsey’s theorem with many respects. Milliken’s tree theorem for pairs admits cone avoidance, while there exists a computable instance of Milliken’s tree theorem for trees of height 3 whose solutions compute the halting set. By a similar investigation, we proved in Section 4.4 that $(\forall k)\text{PMTT}^3_{k,2}$ admits cone avoidance (Theorem 4.28), where $(\forall k)\text{PMTT}^n_{k,\ell}$ is the weakening of $(\forall k)\text{PMTT}^n$ where $\ell$ colors are allowed in the solutions.

The proof of Theorem 4.28 goes through the existence of a level-homogeneous strong subtree. Recall that a tree $T$ is level-homogeneous with respect to a coloring $f : \mathcal{S}_n(T)$ if strong subtrees with the same level function get assigned the same color. This notion reduces the problem of finding an infinite strong subtree monochromatic for $f$ to the problem of finding an infinite homogeneous set. Indeed, if $T$ is level-homogeneous with respect to $f$, the color
depends only on the levels, hence becomes a coloring of $[\omega]^n$. The known counter-examples to cone avoidance of Milliken’s tree theorem for trees of height at least 3 as all inherited from Ramsey’s theorem by defining a coloring which depends only on the levels. We proved that the statement which to a finite coloring of $S_3(T)$, associates an infinite level-homogeneous strong subtree, admits cone avoidance. This result goes towards the intuition that the strength of Milliken’s tree theorem is mainly inherited from Ramsey’s theorem. It is therefore natural to wonder whether the statement of the existence of a level-homogeneous infinite strong subtree admits cone avoidance, when considering colorings of finite subtrees of larger height. Since the proof from height $n$ to height $n + 1$ is usually inductive, by first proving cone avoidance for height $n$, then strong cone avoidance for height $n$, and then only cone avoidance for height $n + 1$, we wonder whether the statement of the existence of a level-homogeneous infinite strong subtree admits strong cone avoidance.

**Question 3.** Given two sets $C$ and $Z$ such that $C \not\leq_T Z$, and a finite sequence of $Z$-computable, $Z$-computably bounded, infinite trees with no leaves $T_0, \ldots, T_{d-1}$, does every coloring $f : S_0(T_0, \ldots, T_{d-1}) \rightarrow k$ admit a level-homogeneous tuple $(S_0, \ldots, S_{d-1}) \in S_\omega(T_0, \ldots, T_{d-1})$ such that $C \not\leq_T Z \oplus S_0 \oplus \cdots \oplus S_{d-1}$?

A positive answer to this question would enable to make it benefit from the computability-theoretic analysis for Ramsey’s theorem, and in particular would imply that $(\forall k)\text{PMTT}^n_{k,C_{n-1}}$ admits cone avoidance.

### 8.3. Comparing the statements for pairs in reverse mathematics

Ramsey’s theorem for pairs admits a special status with respect to full Ramsey’s theorem in reverse mathematics, as it admits cone avoidance, while Ramsey’s theorem for larger tuples is equivalent to ACA$_0$ over RCA$_0$. This threshold phenomenon was also satisfied by the Chubb-Hirst-McNicholl tree theorem (see Dzhafarov and Patey [14]) whose statement for pairs admits cone avoidance, while is equivalent to ACA$_0$ for larger tuples, or the Erdős-Rado theorem (see Chong, Liu, Liu and Yang [5]). We therefore naturally had a particular focus on the restriction of Milliken’s tree theorem for trees of height 2, and on the applications of Milliken’s tree theorem restricted to pairs.

As we can see in the proof of Devlin’s theorem and the Rado graph theorem using Milliken’s tree theorem, both Devlin’s theorem for $n$-tuples and the Rado graph theorem for graphs of size $n$ involve applications of Milliken’s tree theorem for strong subtrees of height $2n - 1$. This is essentially due to Lemma 5.20. Informally, when representing rational numbers as strings, any coloring of a pairs of rationals induces a coloring of strong subtrees of height 3, by considering the tree whose first level is the length of their meet, the second level is the length of the shortest of the two strings representing the rationals, and the third level is the longest length.
This yields two main questions, namely, (1) whether there exists another proof of these statements of size \( n \) involving only applications of Milliken’s tree theorem for trees of height \( n \), and (2) whether these statements should be more considered as statement about pairs or about triples. The latter question is more informal, and depends on the aspects considered.

One aspect separating Ramsey’s theorem for pairs from larger tuples is the existence of cone avoiding solutions. With this respect, Devlin’s theorem admits a computable instance whose solutions all compute the halting set, while the Rado graph theorem for graphs of size 2, the Erdős-Rado theorem and Milliken’s tree theorem for pairs are all cone avoiding. This proves in particular that Milliken’s tree theorem for pairs does not imply Devlin’s theorem for pairs in \( \text{RCA}_0 \), and answers the first question negatively for Devlin’s theorem. Another aspect which could better capture the difference between statements about pairs and about larger tuples, is the position in the arithmetical hierarchy. As explained, Jockusch [22] proved the existence of a computable instance of Ramsey’s theorem for triples with no \( \Sigma^0_3 \) solution, while every computable instance of Ramsey’s theorem for pairs admits a \( \Pi^0_2 \) solution. Here again, using this criterion, Devlin’s theorem for pairs does not seem to be a statement about pairs. Indeed, by Corollary 5.41 in a computable instance of Devlin’s theorem for pairs with no \( \Sigma^0_3 \) solution. The question for the Rado graph theorem for graphs of height 2 and for the Erdős-Rado theorem remains open:

**Question 4.** Is there a computable instance of the Rado graph theorem for graphs of size 2 with no \( \Sigma^0_3 \) solution? Same question for the Erdős-Rado theorem for pairs.

If the answer is yes, then this would answer negatively the corresponding part of the following question.

**Question 5.** Does \( \text{MTT}^2 \) imply \( (\forall k)\text{RG}_{k,4}^2 \) over \( \text{RCA}_0 \)? Same question for \( \text{ER}^2 \).

Milliken’s tree theorem for trees of height 2 is a natural generalization of Ramsey’s theorem for pairs, and so is the Erdős-Rado theorem. By Theorem 5.32, this is also the case of Devlin’s theorem for pairs. It is however unknown whether the Rado graph theorem for graphs of height 2 also implies Ramsey’s theorem for pairs. On the positive side, the Rado graph theorem for pairs implies a stable version of Ramsey’s theorem for pairs (see Theorem 6.55). Thus, by the decomposition of Ramsey’s theorem for pairs in its stable version and the cohesiveness principle (see Cholak, Jockusch and Slaman [3], Section 7), the question can be rephrased as whether the Rado graph theorem for pairs implies the \( \text{COH} \) over \( \text{RCA}_0 \).

**Question 6.** Does \( (\forall k)\text{RG}_{k,4}^2 \) imply \( \text{RT}^2_2 \) over \( \text{RCA}_0 \)? Equivalently, does \( (\forall k)\text{RG}_{k,4}^2 \) imply \( \text{COH} \) over \( \text{RCA}_0 \)?

Devlin’s theorem for pairs and the Erdős-Rado theorem are both statements about colorings of pairs of rationals. The former is symmetric, in
that the nature of the solution does not depend on value of the color, and is thus arguably more natural than the Erdös-Rado theorem. Since the statement $DT^2_{\leq \omega,2}$ is somehow combinatorially optimal with respect to coloring of pairs of dense linear orders with no endpoints, one could expect that it implies the Erdös-Rado theorem. This is actually the case by Theorem 5.48: $DT^2_{\leq 2}$ implies ER$^2$ over RCA$_0$. On the other hand, ER$^2$ admits cone avoidance, while $DT^2_{\leq 2}$ does not. This yields the following question: is there a natural statement which implies ER$^2$ and does admit cone avoidance? The notion of naturality is kept informal. When increasing the number of colors allowed in the solutions of Devlin’s theorem for pairs, the statement $DT^2_{\leq \omega,4}$ is the first one admitting cone avoidance (Corollary 5.44). This yields the following question:

**Question 7.** Does $DT^2_{\leq \omega,4}$ imply ER$^2$ over RCA$_0$?

We reproved in Section 5.5 cone avoidance of ER$^2$ (which was first proved by Chong, Liu, Liu and Yang [5]) using $DT^2_{\leq \omega,4}$. This is however not an answer to the question since it involved the existence of generic sets for a particular notion of forcing, which may not belong to the model of RCA$_0$.
