23	Abstract: We describe a large, nearly completely preserved sauropod humerus from the Lower
24	Cretaceous Xinlong Formation of Napai Basin, Fusui County, Guangxi Zhuang Autonomous
25	Region, southern China. It was excavated from the quarry that produced the holotypic specimen of
26	the titanosauriform Fusuisaurus zhaoi and is considered here to belong to the same individual as

27	the holotype of Fusuisaurus zhaoi. With a preserved length of 183.5 cm, the newly collected
28	humerus provides additional evidence suggesting the presence of a giant sauropod (i.e.,
29	Fusuisaurus zhaoi) during the late Early Cretaceous of Guangxi, China, which increases our
30	knowledge of the diversity of giant titanosauriforms from the late Early Cretaceous of Asia.
31	
32	Key words: Titanosauriformes; Early Cretaceous; Taphonomy; Asia; Fusuisaurus zhaoi
33	
34	1 Introduction
35	
36	The Lower Cretaceous Xinlong Formation in Guangxi Zhuang Autonomous region, which was
37	deposited in a non-marine, fluvial environment, has yielded a diverse assemblage of vertebrates
38	including hybodont sharks (Hybodus, Heteroptychodus, Khoratodus, Acrorhizodus and Thaiodus),
39	actinopterygians (Halecomorphi and Ginglymodi), turtles (the adocid Shachemys and the
40	carettochelyid Kizylkumenys), crocodilians (cf. Theriosuchus) and dinosaurs (the sauropods
41	Fusuisaurus and Liubangosaurus, carcharodontosaurid and spinosaurid theropods, iguanodontians
42	and a possible psittacosaurid) (Mo et al., 2016).
43	The holotype of the giant Fusuisaurus zhaoi, which comprises about 10% of a complete
44	sauropod skeleton, that of the medium-sized sauropod Liubangosaurus hei, and some unidentified
45	sauropod bones were excavated in 2001 by a team from the Natural History Museum of Guangxi
46	(NHMG) at the "Longcaoling" quarry, Liubang Village (Mo et al., 2006, 2010). In 2016-2017, a
47	joint team from the NHMG and the Bureau of Land and Resources of Fusui County (BLRF) re-
48	opened the Longcaoling quarry and uncovered nearly 100 disarticulated dinosaur bones within an

49 area of nearly 600 m^2 (Fig. 1). Most of these bones are probably derived from juvenile individuals

50	of hadrosauroid and sauropod dinosaurs, based on the disarticulated conditions of the vertebral
51	centra and neural arches. A large, nearly complete right humerus (183.5 cm in preserved length,
52	obviously belonging to a giant sauropod) was recovered from the fossil-bearing layer from which
53	the holotype of Fusuisaurus zhaoi was collected and it is positioned close to the latter (25 m), and
54	from the holotypic Fusuisaurus in the same bonebed, we conclude that this large humerus belongs
55	to the same individual of Fusuisaurus and consider it as the holotype (field number LCL 63).
56	
57	2 Taphonomy
58	
59	The Longcaoling site is located near the Liubang Village, about 70 km away from Nanning
60	City, Guangxi Zhuang Autonomous region. Dinosaur fossils were first excavated by local farmers
61	in 1960s, but all were lost due to a lack of relevant knowledge. In 2001, the Longcaoling site was

first excavated by a team organized by NHMG, and yielded the holotype of Fusuisaurus zhaoi and

of Liubangosaurus hei. In 2016-2017, the Longcaoling quarry was re-opened by a joint team from

NHMG and BRLF, and yielded nearly 100 dinosaur bones, most of which belong to juvenile

hadrosauroid and sauropod dinosaurs (Fig. 1).

62

63

64

65

Two layers of outcrops at the Longcaoling quarry include the fossil bearing deposit and the underlying deposit (the overlying deposit has been cultivated by local farmers). The fossil bearing deposit is exposed on the surface. It exhibits a succession of purple-red sandy gravels, fine sandstones, muddy sandstones and sandy mudstones. The layer of sandy gravels has a thickness of 15-60 cm in the northern part of the quarry (where LCL 63 was discovered), while it becomes thinner and finally disappears southward. The underlying deposit exhibits a succession of purplered, light-green mudstones, siltstones and fine-grained sandstones containing some calcareous concretions. The surface of this layer in the southern area is full of mud cracks. Some mud cracks are nearly 30 cm in depth and 8 cm in width. This indicates that the fossil site had experienced a prolonged dry period before the debris flow occurred and the dinosaurs were buried, compatible with the inferred environment and ecology, characterized by aridity (Amiot et al., 2015).

77 The underlying deposit is a lakeshore subfacies. It may have been submerged in the rainy 78 season, and exposed to the surface in the low water season, so that mud cracks formed when 79 the lake dried up for a long time. The fossil-bearing deposit was probably formed by a sudden 80 flood carrying gravels, sand, mud, and scattered dinosaur bones. Some dinosaur bones, such as an 81 ulna, pubis, and metacarpal were preserved in a steeply inclined position. The articulated 82 condition of the holotypic Liubangosaurus and the semidisarticulated condition of the holotypic 83 Fusuisaurus can be attributed to a rapid deposition before they were scattered. Many of the lost 84 dinosaur bones were either displaced before burial or destroyed by the local farmers prior to discovery. 85

86

87 3 LCL 63 as the holotypic material of *Fusuisaurus zhaoi*

As Mo et al. (2010) noted, there were three individuals of sauropods present at the Quarry A (Fig. 1A), a very large one (which pertains to *Fusuisaurus*), and two smaller ones (one of which pertains to *Liubangosaurus hei*, an adult, medium-sized sauropod, and the other is an unnamed, small-sized sauropod), based on the three left ilia present at the Qurry A, measuring 145 cm, 119 cm, and at least 67 cm in length, respectively. In addition, it is certainty that there are one giant sauropod (represented by the large humerus LCL 63), and one small, juvenile sauropod dinosaur present at the Quarry B (Fig. 1B), based on some disarticulated conditions of the vertebral centra

96	and neural arches. Therefore, there are at least three individuals of sauropod dinosaurs present at
97	the Quarry A and B, including a giant one, a medium-sized one, and a small, juvenile one, based
98	the absence of overlapping materials within these three sauropods. Fusuisaurus zhaoi was the only
99	giant sauropod recovered from Longcaoling site. Thus, we consider the humerus LCL 63
100	(obviously belongs to a giant sauropod) as the same individual of <i>F. zhaoi</i> .

106	Titanosauriformes Salgado, Coria & Calvo, 1997
107	Fusuisaurus zhaoi Mo, Wang, Huang, Huang & Xu 2006
108	
109	Holotype. NHMG 6729, a relatively complete left ilium, a complete left pubis, 3 incomplete
110	articulated anterior caudals, most of dorsal ribs, and distal end of the left femur. LCL 63 (field
111	number at "Longcaoling" quarry of Liubang Village), a nearly complete right humerus.
112	Type locality. Longcaoling quarry, Liubang Village, Shanxu Town, Fusui County, Guangxi
113	Zhuang Autonomous Region, southern China.
114	Type horizon. Napai Basin, Xinlong Formation, Early Cretaceous (possibly Aptian) (Mo et al.,
115	2016)
116	Emended Diagnosis. A gigantic basal titanosauriform (Mo et al., 2006) or Somphospondyli
117	(Mannion et al., 2013) diagnosed by the following characters: humerus with Slenderness Index
118	8.55 and Proximal Humeral Robusticity 2.63, anterior dorsal ribs lacking pneumatic foramina,

ilium with a prominent, pointed anteroventral process, ilium with a strongly dorsoventrally
expanded preacetabular blade, anterior caudal vertebrae with dorsoventrally flattened transverse
processes.

122

123 **Description**. The humerus is nearly completely preserved, missing only the anterior margins of 124 the distal and proximal parts of the shaft (including the deltopectoral crest), and the distomedial 125 portion (Fig. 2). Its preserved length is 183.5 cm, being the longest one for any known sauropod 126 from the Cretaceous (Table 1). The proximal, midshaft, and distal widths are 56.5 cm, 21.5 cm, 127 and about 54.0 cm, respectively. The humerus is gracile in anterior view, with the SI (Slenderness 128 Index, i.e., ratio of the proximodistal length to the midshaft width) value being about 8.55, which 129 is substantially greater than those of all other giant Cretaceous sauropods. The proximomedial 130 process is round and robust, pointing dorsomedially, with its apex lying well medial to the midshaft. The proximal end is robust relatively to the midshaft, with its PHR (Proximal Humeral 131 132 Robusticity, i.e., ratio of proximal to midshaft width) value being about 2.63, only smaller than 133 those of Ruyangosaurus and Notocolossus, and larger than those of other giant Cretaceous 134 sauropods. It is unknown whether the proximolateral corner was round or square due to the erosion of this part. The deltopectoral crest is not preserved, but appears to have continued to 135 136 about midshaft and does not appear to exhibit a significant transverse expansion. Medial to the 137 deltopectoral crest, the anterior margin of the proximal part of the shaft is greatly excavated. The 138 posterolateral bulge on the lateral margin of the proximal part of the shaft is not present. The proximal and distal transverse widths are significantly greater than the midshaft width. The shaft 139 140 is elliptical in cross-section, with its long axis oriented mediolaterally. The anterior surface and the 141 distal end of the distal part of the shaft were eroded during its fossilization.

143 **5 Discussion**

145 Fusuisaurus is based on a partial skeleton, including a relatively complete left ilium, a 146 complete left pubis, 3 incomplete articulated anterior caudals, most of the dorsal ribs, and the 147 distal part of the left femur. The left ilium is 145 cm in length, obviously longer than any other 148 known sauropod ilia. The incomplete left femur is 60 cm in distal width, with a probable restored 149 length of 200 cm. One anterior caudal centrum is about 40 cm in diameter. In addition, one 150 complete posterior dorsal rib measures 230 cm in length. The recently recovered right humerus, 151 the holotype of Fusuisaurus, is the longest one for any giant sauropod from the Cretaceous (Table 152 1). These available fossils suggest that *Fusuisaurus* was a typical gigantic titanosauriform (Fig. 3). 153 Titanosauriformes represent a diverse and globally distributed clade of neosauropod dinosaurs (D'Emic, 2012; Mannion et al., 2013). Although the number of named Asian Titanosauriformes 154 155 has dramatically increased in the last decade, most of them are represented by medium or large-156 sized animals (Azuma and Shibata, 2010; Ksepka and Norell, 2006; Li et al., 2014; Lü et al., 2008, 157 2009a, 2013a; Mo et al., 2008, 2010, 2017; Saegusa and Ikeda, 2014; Wang et al., 2007; Wu et al., 2006; Xu et al., 2006; You et al., 2006; You and Li, 2009; Zhang et al., 2009), only Huanghetitan 158 159 ruyangensis (Lü et al., 2007), Daxiatitan (You et al., 2008), Yunmenglong (Lü et al., 2013b), 160 Ruyangosaurus (Lüet al., 2009b, 2014) are comparable with Fusuisaurus in terms of gigantism. 161 Huanghetitan ruyangensis is based on a partial skeleton, including a nearly complete sacrum, 10 proximal caudals, haemal arches, dorsal ribs, and incomplete ischium, from the Early 162 163 Cretaceous Haoling Formation (Aptian-Albian, Xu et al., 2012), Ruyang Basin, Henan Province, 164 central China. The anteriormost caudal centrum is 26.9 cm and 32 cm in posterior height and

width, respectively, significantly smaller than that of *Fusuisaurus*. However, the longest preserved
dorsal rib in *Huanghetitan ruyangensis* is 293 cm in length, substantially larger than any known
dorsal rib of *Fusuisaurus*.

Daxiatitan is based on a postcranial skeleton, including the caudalmost 10 cervicals, 10 dorsals, 2 proximal caudals, partial cervical and dorsal ribs, one haemal arch, right scapulocoracoid, and right femur, from the Early Cretaceous of the Hekou Group, Gansu Province, northwestern China. The complete right femur measured 57 cm at its distal width, comparable to that of *Fusuisaurus*.

Yunmenglong is based on a partial skeleton, including 7 articulated anterior cervicals, 2
isolated posterior cervicals, one dorsal, 4 anterior caudals, and one complete right femur, from the
Early Cretaceous Haoling Formation, Ruyang Basin. The anterior caudal centrum measures 38cm
and 42cm in its posterior centrum height and width, respectively, comparable to that of *Fusuisaurus*. The complete right femur in *Yunmenglong* measures 192cm and 65 cm in its total
length and distal width, respectively, also comparable to that of *Fusuisaurus*.

179 Ruyangosaurus is known from two skeletons, including 9 cervicals, 13 dorsals, a dorsosacral, 180 articulated sacrum and ilia, 5 mid-posterior caudals, 7 incomplete cervical and dorsal ribs, a complete right humerus, a complete right femur, the proximal half of the right femur, and a 181 182 complete right tibia, from the Early Cretaceous Haoling Formation, Ruyang Basin. The estimated body length of Ruyangosaurus may have exceeded 35 m, with the maximum width of the 183 184 dorsosacral centrum, the length of the longest cervical centrum, and the length of the right tibia 185 reaching 68 cm, 124 cm, and 127 cm, respectively, being among the largest ones reported for any 186 known sauropods. Its ilium is 130 cm in length, smaller than that of *Fusuisaurus*. Its incomplete 187 right femur is 60 cm in proximal width, with its estimated length being 207 cm, comparable to that of *Fusuisaurus*. The complete right humerus of the smaller individual is 145 cm in its preserved
length, and the incomplete humerus of the bigger individual is 135 cm and 26 cm in its preserved
length and midshaft width, respectively, reaching nearly 190 cm in its reconstructed length, also
comparable to that of *Fusuisaurus*.

192 Interestingly, the above mentioned five gigantic Asian titanosauriforms are all from the late 193 Early Cretaceous (Abtian-Abian), implying a high diversity of giant Asian titanosauriforms from 194 this period. This raises the possibility that the late Early Cretaceous was a key period for the 195 evolution and diversity of giant titanosauriforms, corresponding to the simultaneous evolution 196 event of giant Patagonian titanosaurs in the Southern Hemisphere (Carballido et al., 2017).

197 During the Early Cretaceous, the global temperature was generally warm (Tremolada et al., 198 2006), with some short periods of cold temperature in some areas (Amiot et al., 2011). Seasonal 199 climatic changes were probably present in the Early Cretaceous (Steuber et al., 2005). On the 200 other hand, warm or seasonal climate may have resulted in the expansion of the angiosperms in 201 continental environments (Sun et al., 2002; Leng et al., 2003). These environmental conditions may have influenced the distribution and evolution of titanosauriforms, the dominant sauropod 202 203 clade in Asia during the Cretaceous (Barrett et al., 2002; Barrett and Wang, 2007), especially those gigantic forms from the late Early Cretaceous of Asia. 204
