### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

### Abstract

Messenger RNA (mRNA) has immense potential for developing a wide range of therapies, including immunotherapy and protein replacement. As mRNA presents no risk of integration into the host genome and does not require nuclear entry for transfection, which allows protein production even in non-dividing cells, mRNA-based approaches can be envisioned as safe and practical therapeutic strategies. Nevertheless, mRNA presents unfavorable characteristics, such as large size, immunogenicity, limited cellular uptake and sensitivity to enzymatic degradation, which hinder its use as therapeutic agent. While mRNA stability and immunogenicity have been ameliorated by direct modifications on the mRNA

1  
2  
3 1 structure, further improvements in mRNA delivery are still needed for promoting its activity in biological  
4  
5 2 settings. In this regard, nanomedicine has shown the ability for spatiotemporally controlling the function  
6  
7  
8 3 of a myriad of bioactive agents *in vivo*. Direct engineering of nanomedicine structures for loading,  
9  
10 4 protecting and releasing mRNA, and navigating in biological environments, can then be applied for  
11  
12 5 promoting mRNA translation toward the development of effective treatments. Here, we review recent  
13  
14 6 approaches aimed at enhancing mRNA function and its delivery through nanomedicines, with particular  
15  
16  
17 7 emphasis on their applications and eventual clinical translation.

Messenger RNA (mRNA) mediates the translation of genetic information from genes into proteins. Delivering exogenous mRNA into cells allows to transiently produce proteins in a precise manner. Such mRNA-mediated transfection offers an attractive alternative to plasmid DNA (pDNA)-based gene therapy by expressing proteins even in non-dividing and hard to transfect cells without the risks of genomic integration.<sup>1</sup> Moreover, while pDNA needs to be delivered inside the nucleus of targeted cells, the access of mRNA to the cytosol and the subsequent engagement with the translation machinery of the cells are sufficient to obtain the proteins of interest. The mRNA delivered inside the cells can also last for several days, which is convenient for developing efficient therapeutic strategies, as well as commercially viable approaches. On the other hand, mRNA presents inherent limitations for being used as a stand-alone drug, including fast degradation by nucleases, limited cellular uptake, and immunogenicity.<sup>2</sup> While the immunogenic signals triggered by mRNA could be exploited for vaccination or immunotherapy applications,<sup>3</sup> major efforts have been dedicated to reduce mRNA immunogenicity

1 and improve the stability of the molecule by either chemical modification or by RNA architectonics,  
 2 aiming at increasing the significance of mRNA as a therapeutic agent. Nevertheless, mRNA is still  
 3 susceptible to degradation and the cellular uptake of naked mRNA should be improve for eliciting  
 4 adequate amounts of proteins. Thus, the development of safe carrier systems capable of intracellular  
 5 delivery of intact mRNA molecules is fundamental for progressing into effective treatments.

7  
 8 **Figure 1. Nanomedicine approaches for mRNA delivery.** Various platforms are under intense research  
 9 and development for the delivery of mRNA based on their unique ability to promote navigation in  
 10 biological environments, intracellular delivery and engagement with the translation machinery of cells.

1  
2  
3 1  
4  
5 2 A wide range of nano-scaled carriers are under intense investigation for developing mRNA  
6  
7 delivery systems.<sup>1</sup> Viral vectors, which have been extremely useful for delivering other nucleic acids,  
8 3  
9 have been among the first carriers to be considered for developing mRNA delivery systems.<sup>4</sup>  
10 4  
11 Nevertheless, viral carriers present intrinsic limitations, such as small packing size, immunogenicity,  
12 5  
13 cytotoxicity and complex production processes,<sup>5</sup> which have spurred the development of safe and  
14 6  
15 effective non-viral vehicles.<sup>6, 7</sup> These non-viral vehicles can benefit from a myriad of biocompatible  
16 7  
17 synthetic and natural materials for attaining specific physicochemical and functional features directed to  
18 8  
19 develop mRNA-loaded nanomedicines with improved mRNA bioavailability, targeting to specific  
20 9  
21 tissues and cells, and enhanced cellular uptake and intracellular release of mRNA molecules (**Figure 1**).  
22 10  
23 Thus, various non-viral strategies have achieved major breakthroughs in the *in vivo* delivery of mRNA,  
24 11  
25 as well as in the clinical translation of mRNA-based therapies.<sup>1, 6, 7</sup>  
26 12  
27  
28  
29

30 13 Here, we present the recent progress in mRNA-loaded nanomedicine toward innovating  
31 14  
32 vaccination, immunotherapy, treatment of genetic disorders and protein replacement approaches. We  
33 15  
34 have focused on the different non-viral strategies with emphasis on the employed materials and the  
35 16  
36 advantages offered by each approach. Moreover, the mRNA modification methods are also reviewed,  
37 17  
38 highlighting opportunities for synergistically enhancing nanomedicine efficiency. Finally, the trends in  
39 18  
40 the application of mRNA-loaded nanomedicines and their future perspectives are discussed.  
41 19  
42  
43  
44

## 45 19 46 20 **2. Engineering mRNA for enhanced function**

47 21 mRNA modification by approaches that enhance the stability and promote its function have  
48 22  
49 been considered for improving mRNA biological activity, as well as reducing immunogenicity issues.  
50 23  
51 Notably, these modification methods do not affect the main structural features of mRNA, *i.e.* being a  
52 24  
53 negatively-charged macromolecule, which provides opportunities for developing orthogonal cooperative  
54 25  
55  
56  
57  
58  
59  
60

1  
2  
3 1 approaches in combination with nanomedicine with potential for synergistic enhancement of mRNA  
4  
5 2 function. We have categorized these methods as chemical modifications of mRNA, introduction of self-  
6  
7 3 replication functions to mRNA sequences, stabilization through RNA architectonics and circularization  
8  
9 4 of RNA. In the following sections, we review each of these approaches.  
10  
11  
12 5

## 14 6 **2.1. Chemical modifications of mRNA**

16  
17 7 Chemical modification of mRNA structure is an effective way for promoting mRNAs that are  
18  
19 8 more resistant to enzymatic degradation than their native counterparts, as well as mRNAs with decreased  
20  
21 9 immunogenicity. Major strategies have focused on the introduction of a m7G 5'-Cap structure<sup>8, 9</sup>,  
22  
23 10 modifications through poly(A) tails<sup>10, 11</sup>, incorporation of untranslated regions (UTRs)<sup>12, 13</sup>, and insertion  
24  
25 11 of modified nucleotides<sup>11</sup> to the structure of mRNA (**Figure 1**). In the following sections, we summarize  
26  
27 12 the advantages provided by these features.  
28  
29  
30  
31 13

### 33 14 **2.1.1. 5'-Cap structure**

35 15 During maturation of primary transcripts, a cap is added at the 5' extremity of pre-mRNA.<sup>14</sup>  
36  
37 16 This step occurs very early, before the addition of the first 30 nucleotides. The 5'-cap consists of an  
38  
39 17 inverted 7-methylguanosine connected to the rest of the eukaryotic mRNA via a 5'-5' triphosphate bridge  
40  
41 18 (m7GpppN, Cap 0). Besides Cap 0, the cap can be further modified by methylation at the 2'-O position  
42  
43 19 of the +1 ribonucleotide (m7GpppNm, Cap 1) or the +2 ribonucleotide (m7GpppNmNm, Cap 2),  
44  
45 20 respectively.<sup>15</sup> This methylation is necessary to distinguish self from viral RNA.<sup>16</sup> The presence of the  
46  
47 21 cap is first required for RNA export from the nucleus after binding to the cap binding complex.<sup>17</sup> Once  
48  
49 22 in the cytoplasm, the cap is required for initiation of translation and protection against nuclease  
50  
51 23 degradation.<sup>18, 19</sup> Accordingly, cap analogs are incorporated in synthetic mRNA by 2 strategies: post-  
52  
53 24 transcriptional capping or co-transcriptional capping.<sup>17</sup> In post-transcriptional capping, capping enzymes  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 1 from RNA viruses (mostly *Vaccinia*) are used to produce cap1-capped mRNA using GMP. Although  
4  
5 2 very effective, this strategy requires the expensive production and purification of capping enzymes and  
6  
7  
8 3 is limited to existing natural cap structures.<sup>17, 20</sup>  
9

10 4 In co-transcriptional capping, chemical cap analogs are incorporated during transcription. This  
11  
12 5 allows optimization of chemical analogs, a work well covered by Jemielity's group, as reviewed  
13  
14 6 elsewhere.<sup>8</sup> During transcription, the m7G cap analog can be incorporated either in correct orientation  
15  
16 7 with the methylated guanosine in 5' (m<sup>7</sup>GpppGpN) or inverted orientation (Gpppm<sup>7</sup>GpN), with a sharp  
17  
18 8 decrease in translation efficiency of mRNA with inverted cap.<sup>21</sup>  
19  
20

21 9 The ARCA (Anti Reverse Cap Analog) has been developed for obliged incorporation in the  
22  
23 10 correct orientation.<sup>22</sup> In this analog, the hydroxyls of the ribose have been substituted by OCH<sub>3</sub>, this stops  
24  
25 11 elongation in the incorrect orientation as it prevents bonds between nucleotides. ARCA-capped mRNAs  
26  
27 12 have 1.8-fold higher translation efficiency over uncapped- or m7G-capped mRNAs.<sup>23</sup>  
28  
29

30 13 Chemical cap analogs aimed at decreasing cleavage by Dcp1/2 decapping enzymes which  
31  
32 14 cleave the triphosphate bond. Analogues with the second phosphate replaced by an heteroatom have been  
33  
34 15 developed: either carbon<sup>24</sup> or nitrogen<sup>25</sup>. Bridging oxygens have also been substituted with  
35  
36 16 dihalogenmethylenbisphosphonate, and were superior to phosphate substitution both in terms of  
37  
38 17 resistance towards hydrolysis and translation.<sup>26</sup>  
39  
40

41 18 Analogues combining ARCA and phosphorothioated riboses have also been developed ( $\beta$ -S-  
42  
43 19 ARCA analogs).<sup>9, 27</sup> Such analogues allowed 3-fold higher expression *in vivo* in mice over ARCA-capped  
44  
45 20 mRNA resulting in superior immune response induction.<sup>28</sup> Increased translation of  $\beta$ -S-ARCA-capped  
46  
47 21 mRNA was related to increased affinity for the cap-binding translation initiation factor eIF4E and  
48  
49 22 increased resistance to Dcp2 or Dcps degradation over ARCA or m7G caps.<sup>9, 27, 29</sup>  
50  
51

52 23 A further refinement in cap design has been to optimize the first transcribed nucleotide. Indeed,  
53  
54 24 mammalian mRNA can be capped with cap1/cap2 with different first nucleotide (A,G,C,U).<sup>30</sup> Sirkoski  
55  
56  
57

1  
2  
3 1 *et al.* compared the translation efficiency of in vitro transcribed and HPLC-purified mRNA harboring  
4  
5 2 caps with different first nucleotides.<sup>31</sup> They synthesized trinucleotides cap analogs m7GpppNpG where  
6  
7 N is the unmethylated or methylated nucleotide and, used them for co-transcriptional capping. They  
8 3  
9 reported that guanine as the first transcribed nucleotide led to the lowest expression in JAWSII murine  
10 4  
11 dendritic cells: 20-fold lower expression of m7GpppGpG cap compared to m7GpppApG cap. This was  
12 5  
13 not due to increased affinity for eIF4E nor increased resistance to decapping enzymes and is in agreement  
14 6  
15 with the abundance of adenosine as first nucleotide in human cell lines.<sup>30</sup>  
16  
17 7

18  
19 8 One of the drawbacks of co-transcriptional capping is that, due to competition with GTP, not  
20  
21 all cap analogs are incorporated alongside transcription and, the efficiency of capping is around 80-  
22 9  
23 90 %.<sup>32</sup> To limit antiviral responses, uncapped mRNA is usually removed by Xrn1.<sup>14, 31, 33</sup>  
24 10  
25

### 26 11 27 28 12 *2.1.2 Poly(A) tail*

29  
30  
31 13 Another step of pre-mRNA maturation occurs after release from the RNA polymerase II.<sup>14</sup> At  
32  
33 14 the 3' extremity, pre-mRNA is cleaved at 20 nucleotides after a consensus polyadenylation sequence  
34  
35 15 (AAUAAA).<sup>34</sup> After cleavage, the polyA polymerase binds to the pre-mRNA and adds a 100 to 250  
36  
37 adenosines polyA tail. The presence of the poly(A) tail is required for translation and for protection  
38 16  
39 against degradation.<sup>1</sup>  
40 17  
41

42 18 Polyadenylation of synthetic mRNA can be achieved either by enzymatic polyadenylation of  
43  
44 capped mRNA or by cloning a poly(T) sequence in the plasmid template.<sup>35</sup> However, enzymatic  
45 19  
46 polyadenylation yields mRNAs with profound differences in poly(A) lengths resulting in a mixture of  
47 20  
48 mRNAs critically affecting reproducibility and purity of mRNA.<sup>35, 36</sup>  
49 21  
50

51 22 Electroporation of dendritic cells and cancer cells with mRNAs of different poly(A) lengths  
52  
53 (0, 16, 42, 51 or 120A) demonstrated the requirement of a poly(A) tail for *in cellulo* translation and a  
54 23  
55 critical impact of poly(A) length on translation efficiency.<sup>35</sup> GFP-120A mRNA resulted in a 4-fold higher  
56 24  
57

1  
2  
3 1 transcript level over 51A or 42A mRNA 24 h after electroporation. Increased transcript levels were  
4  
5 2 correlated with higher GFP protein levels. On the contrary, transcript and protein levels were negligible  
6  
7 3 after electroporation of untailed mRNA or mRNA with 16A. Following studies confirmed that the  
8  
9 4 optimal length of the tail is between 120A and 150A, and that is should not be masked by additional  
10  
11 5 bases.<sup>37-41</sup>  
12  
13  
14  
15 6  
16

### 17 7 *2.1.3. Untranslated regions*

18  
19 8 5' and 3' UTRs regulate both translation and stability of mRNA.<sup>14</sup> Therefore a strategy to  
20  
21 9 increase translation efficiency and half-life of synthetic mRNA is to include UTRs sequences from stable  
22  
23 10 and highly translated mRNA such as beta-globin, albumin, complement factor 3 (C3) and cytochrome  
24  
25 11 p4502E1 (CYP2E1).<sup>12, 13</sup> The 5' UTR plays a critical role in the initiation of translation as it controls both  
26  
27 12 mRNA scanning and the selection of the initiation codon.<sup>42</sup> Because of this role, highly structured 5'  
28  
29 13 UTR regions are avoided and more research has been focused on 3' UTRs. 3' UTRs derived from  $\alpha$ - or  
30  
31 14  $\beta$ -globin, which have long half-lives in erythrocytes (enucleated cells) are the most frequently used for  
32  
33 15 mRNA,<sup>10, 43</sup> particularly when two 2 sequential  $\beta$ -globin 3' UTRs are fused head to tail.<sup>35</sup> Since  
34  
35 16 homologous double UTR (dUTRs) are unstable and prone to recombination, heterologous dUTRs are  
36  
37 17 preferred.<sup>44, 45</sup> Sahin's group used a SELEX (Systematic Evolution of Ligands by Exponential  
38  
39 18 enrichment) to identify best dUTRs for vaccination and cell reprogramming.<sup>45</sup> They tested 64  
40  
41 19 combinations of dUTRs. The two best dUTRs identified were mtRNR1 (mitochondrially encoded 12S  
42  
43 20 rRNA) /  $\beta$ -globin and mtRNR1/ AES (Amino Enhancer of Split) with both 1.89-fold mRNA half-life  
44  
45 21 over double  $\beta$ -globin UTR in human dendritic cells (hDCs). Superior half-life was mirrored with  
46  
47 22 decreased miRNA binding. mtRNR1/AES dUTR also improved mRNA translation in hDCs by 1.6-fold  
48  
49 23 over double  $\beta$ -globin UTR. The intravenous injection of luciferase mRNA lipoplexes in mice revealed a  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 1 3-fold higher expression of mtRNR1/AES dUTR over double  $\beta$ -globin UTR, which resulted in superior  
4  
5 2 induction of antigen-specific T cells. For the reprogramming of human foreskin fibroblasts, the  
6  
7 3 AES/mtRNR1 dUTR was the best demonstrating a cell type specificity for optimal dUTR. Recently,  
8  
9 4 Asrani *et al.* evaluated a library of 10 variants of 5' and 3' UTRs in their ability to improve arginase 1  
10  
11 5 mRNA expression.<sup>12</sup> They reported higher dependence of mRNA translation on 5' UTR sequence relative  
12  
13 6 to 3' UTR variants. Moreover, improved protein production was associated with increased protein  
14  
15 7 translation efficiency, and not to an improved mRNA stability. UTR sequences from C3 and CYP2E1  
16  
17 8 were found to be the most efficient.  
18  
19  
20  
21

22 9 Besides optimization of 5' UTR and 3' UTR regions, sequence engineering of the coding  
23  
24 10 sequence is also required for maximal expression.<sup>46</sup> Whereas AU-rich motifs are prone to exosome-  
25  
26 11 mediated degradation of mRNA, GC-rich mRNAs have increased expression.<sup>47-49</sup> Accordingly, mRNA  
27  
28 12 sequences have been optimized to be GC-rich.<sup>50-52</sup>  
29  
30  
31  
32

#### 33 14 2.1.4 Modified nucleotides

34  
35 15 The first generation of synthetic mRNA lacked the diversity of natural nucleotides present in  
36  
37 16 mammalian mRNA with natural modified nucleotides such as pseudouridine ( $\Psi$ ), 5-methylcytidine  
38  
39 17 (5meC), N6-Methyladenosine (m6A), 5-methyluridine (m5U), or 2-thiouridine (S<sup>2</sup>U).<sup>11, 53</sup> This led to  
40  
41 18 recognition of mRNA as foreign mRNA by intracellular sensors, such as Toll Like Receptors (TLRs) 7  
42  
43 19 and 8, resulting in the induction of type I interferon (INF  $\alpha/\beta$ ) expression and associated anti-viral  
44  
45 20 responses. These signals resulted in mRNA translation suppression and degradation, and even host cell  
46  
47 21 apoptosis.<sup>54, 55</sup>  
48  
49  
50

51  
52 22 Incorporation of  $\Psi$  is the most frequent modification of synthetic mRNA.<sup>56</sup>  $\Psi$ -modified mRNA  
53  
54 23 resists RNase degradation<sup>57</sup> and lacks TLR activation<sup>54</sup> resulting in improved translation in cell lysates  
55  
56 24 and cultured cells.<sup>58, 59</sup> Then, combination of modifications have been preferred to mirror the diversity  
57  
58  
59  
60

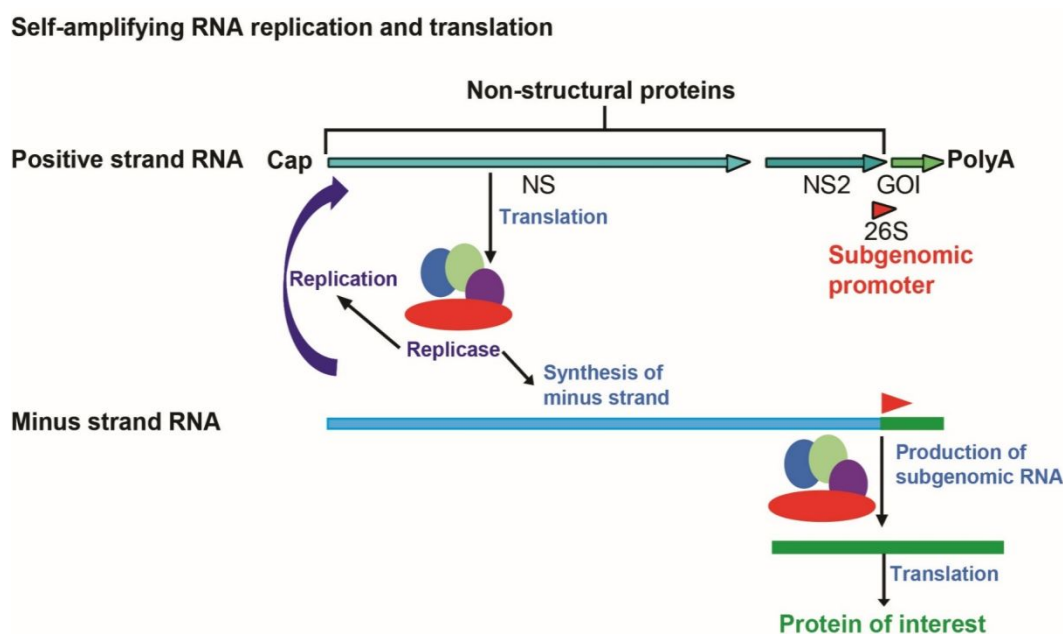

1  
2  
3 1 of natural mRNA. Andries *et al.* reported that mRNA harboring both N methyl  $\Psi$  (m1  $\Psi$ ) and m5C  
4  
5 2 outperformed mRNA with single  $\Psi$  modification or m5C and  $\Psi$  modifications in several cell lines and  
6  
7  
8 3 *in vivo*.<sup>60</sup> Notably, they showed that after intramuscular or intradermal injection of luciferase mRNA  
9  
10 4 lipoplexes, m1  $\Psi$ -mRNA yielded 13-fold higher expression over  $\Psi$ -mRNA and 4-fold higher expression  
11  
12  
13 5 over m5C/  $\Psi$ - or m5C/m1  $\Psi$ -modified mRNA suggesting m1  $\Psi$  as a new standard for chemically  
14  
15 6 modified mRNA.

16  
17 7 Importantly, the incorporation of modified nucleotides is cell-type and mRNA sequence-  
18  
19 8 dependent, requesting application-based screening of modifications.<sup>61-63</sup> For instance, Li *et al.*, re-ported  
20  
21  
22 9 that, in THP-1 macrophages, 5meC/  $\Psi$  modified Fluc mRNA resulted in significantly higher Fluc  
23  
24  
25 10 expression, while 5meC/  $\Psi$  modified eGFP mRNA resulted in a decreased GFP expression; m1  $\Psi$   
26  
27 11 modified Fluc in THP-1 cells generated 8-fold more Fluc than that in hepatocellular carcinoma Hep 3B  
28  
29 12 cells.<sup>62</sup>

## 30 31 32 13 33 34 14 **2.2. Self-amplifying RNA**

35  
36 15 Another approach to increase the activity of mRNA comes from mimicry of RNA viruses.  
37  
38 16 Indeed, RNA viruses need to replicate their genome in the host cell for virion production.<sup>64</sup> Accordingly,  
39  
40  
41 17 researchers have used strategies derived from RNA viruses for vaccination as early as 1999.<sup>65</sup> These  
42  
43 18 RNA with self-amplification capacity are called self-amplifying RNA (saRNA) or replicons.<sup>64, 66, 67</sup> In  
44  
45 19 most studies, saRNA are derived from alphaviruses.<sup>39, 65, 66, 68-72</sup> In alphaviruses, on part of the genome  
46  
47  
48 20 codes for non-structural proteins which assemble to form the RNA-dependent RNA polymerase  
49  
50 21 (replicase), the other part for structural proteins (capsid and envelope proteins).<sup>73</sup> After infection,  
51  
52 22 replicase is expressed from the positive strand RNA genome to synthesize the minus RNA strand, which  
53  
54  
55 23 serves as template to amplify the genomic RNA and, for subgenomic RNA synthesis (**Figure 2**). It is

important to notice that saRNA is amplified after a first round of translation to assemble the replicase, highlighting similar bottlenecks for the early steps of mRNA and saRNA transfection.<sup>74, 75</sup>

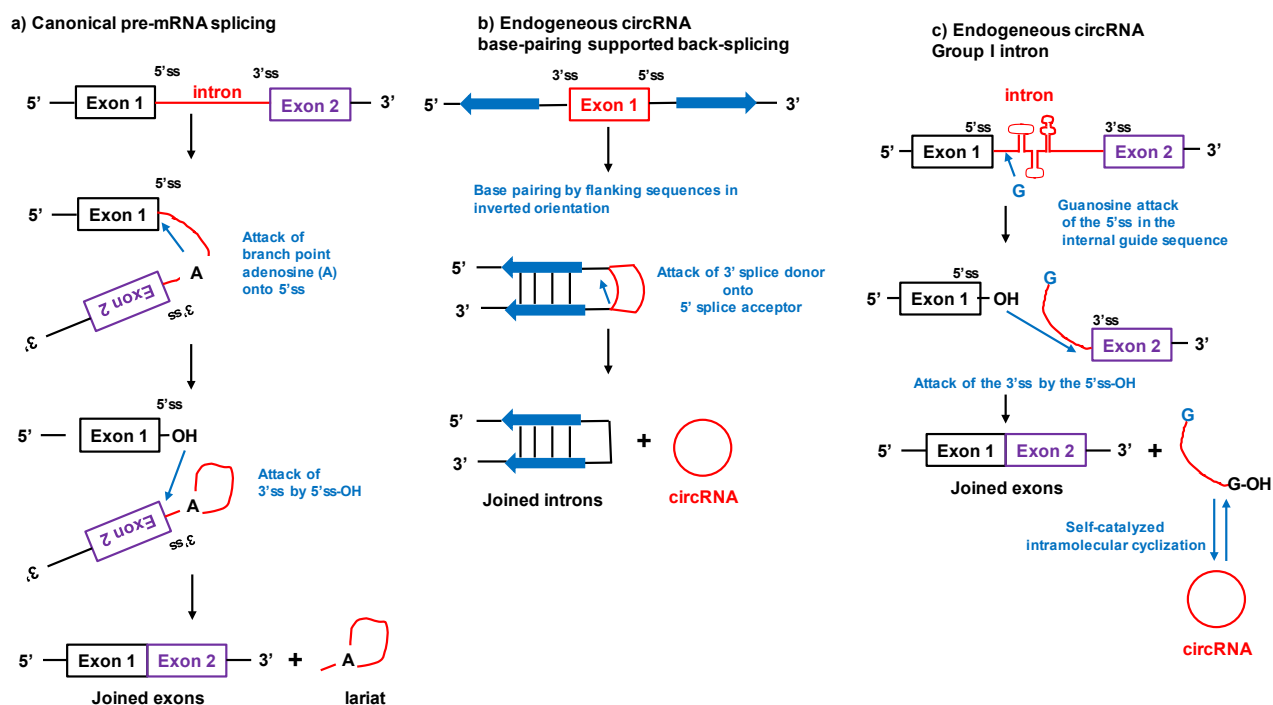

**Figure 2. Replication and translation of saRNA.** Early after infection the non-structural proteins (NS) are translated and self-assemble to form the replicase. The replicase both amplifies the genome and synthesizes the minus strand RNA. Finally, the replicase translated subgenomic RNA which contains virulence genes allowing production of virions. In synthetic saRNA virulence genes (e.g. capsid) are replaced by the gene of interest. The figure is based on information from a reference<sup>73</sup>.

### 2.3. Circular RNA

Another solution to face the degradation of RNA by exonucleases is the circularization of RNA.<sup>76-79</sup> This strategy was inspired by the endogenous circular RNA with covalently linked ends found in viruses<sup>80</sup>, archaea<sup>81</sup>, all eukaryotes<sup>82</sup> among which humans.<sup>83</sup> CircRNA is formed by the pre-mRNA splicing machinery from introns<sup>84, 85</sup> or from exons<sup>71, 86</sup> and its biogenesis is regulated by several factors<sup>87</sup>. circRNA is generated by back-splicing to join a splice donor to an upstream splice acceptor (**Figure**

1 3).<sup>87</sup>

2

3

**Figure 3. Canonical splicing, back-splicing and self-splicing.** **A.** For pre-mRNA, the spliceosome binds to 5' and 3' splice sites (5'ss and 3'ss). The then 2'OH of a 3'ss branchpoint nucleotide performs a nucleophilic attack on the first nucleotide of the 5'ss. This results in the formation of an exon1-3'OH and a lariat intermediate-exon2. Finally, 5'ss-OH attack of exon 2 3'ss joins exons and releases a lariat. **B.** In back-splicing, 5'ss and 3'ss are in reverse orientation. As back-splicing is not sterically favorable, it is supported by complementary base pairing of flanking exons which juxtaposes 5'ss and 3'ss. Then 3'ss attack of the 5'ss splice acceptor joins the two introns and releases circRNA. **C.** An exogenous guanosine (G) attacks the 5'ss separating exon1 5'ss-OH from G-intron 3'ss-exon2. The, 5'ss attack of the 3'ss results in exon joining and release of a linear intron. Group I introns possess a 3' terminal G and this 3'G-OH performs a self-catalyzed nucleophilic attack close to the exogenous G resulting in the formation of circRNA. The figures are based on information from references <sup>87-91</sup>.

15

For pre-mRNA canonical splicing, the spliceosome recognizes consensus intron/exon boundary sites: 5' splice site (5'ss) and 3' splice site (3'ss) to remove introns in two steps: 1) formation

17

1  
2  
3 1 of a free hydroxyl at the 5'ss, 2) attack of the 3'ss by the 5'ss-OH resulting in exon joining and an excised  
4  
5 2 lariat (**Figure 3A**).<sup>89</sup>  
6

7  
8 3 Endogenous circRNA is generated when splicing occurs not between 5'ss of exon 1 and 3'ss  
9  
10 4 of exon 2 but between 3'ss of exon 2 and 5'ss of exon 2 that is, back-splicing (**Figure 3B**).<sup>90, 92</sup> circRNA  
11  
12 5 formation is not frequent due to the low efficiency of the process as upstream 5'ss-3'ss ligation by the  
13  
14 6 spliceosome is sterically unfavorable.<sup>93</sup> Thus, circRNA formation is reinforced by repetitive flanking  
15  
16 7 sequences, particularly Alu repetitive sequences in an inverted orientation.<sup>87, 94</sup>  
17  
18

19 8 The most frequent method used for *in vitro* production of synthetic circRNA derives from group from  
20  
21 9 *Tetrahymena* or *Anabena* containing end-to-end fused exons that interrupt half intron sequences.<sup>90</sup> As  
22  
23 10 the exon sequences do not participate in the back-splicing they can be replaced by a sequence of interest.<sup>90,</sup>  
24  
25 11  
26 95  
27

28 12 Group I introns self-splice by recruiting a guanosine (G) which, in the presence of Mg<sup>2+</sup>,  
29  
30 13 performs a nucleophilic attack on the 5'ss phosphate resulting in covalent linkage of G to the end of the  
31  
32 14 intron and generation of a reactive OH on the 5'ss.<sup>88, 90</sup> The site of G attack is defined by an internal guide  
33  
34 15 sequence present in a duplex formed between the last nt of the 5'ss and the first nt of the intron. The  
35  
36 16 second step involves attack of the 3'ss by the 5'ss-OH. This ligates the 5' and 3' exons and releases a  
37  
38 17 linear intron. Finally, the linear intron undergoes a self-catalyzed intramolecular cyclization reaction  
39  
40 18 (**Figure 3C**).<sup>96</sup>  
41  
42  
43

44 19 CircRNA is resistant to exonucleases and highly stable with a median half-life of 24h.<sup>97</sup> Due  
45  
46 20 to the low efficiency of back-splicing<sup>93</sup>, most circRNA have been categorized as side products of pre-  
47  
48 21 mRNA splicing<sup>98</sup> or miRNA sponges.<sup>95</sup> Only few circRNA have been proven to bind and regulate  
49  
50 22 specific miRNA<sup>95, 99, 100</sup> or express proteins.<sup>101, 102</sup>  
51  
52

53  
54 23 Progression of RNA therapeutics in preclinical and clinical studies<sup>103, 104</sup> supported the demand  
55  
56 24 for circRNA to benefit from its enhanced stability.<sup>76-79, 105</sup> Synthetic circRNA is prepared by  
57  
58  
59  
60

1 intramolecular ligation of a linear precursor followed by elimination of linear RNA using RNase R  
2 (RNA circularization strategies reviewed in <sup>90, 92</sup>). Use of exogenous circRNA for protein expression in  
3 mammalian cells is recent (2018).<sup>78</sup> Authors used a permuted intron-exon method for RNA  
4 circularization. This strategy had been applied in 1994 for circRNA production in yeast and bacteria  
5 using group I intron of phage T4.<sup>106</sup> Wesselhoeft et al used the group I intron in the thymidylate synthase  
6 gene of the T4 phage.<sup>78</sup> They took advantage of exon-joining by Group I introns and inserted a cassette  
7 between 5'ss and 3'ss. Their construct contains 5' and 3' introns. They permuted 5'ss and 3'ss on both  
8 sides of the cassette to circularize the insert between splicing sites by group I intron mediated exon  
9 joining. The cassette contains an EMCV IRES (encephalomyocarditis virus internal ribosomal entry site)  
10 for cap-independent translation followed by Gaussia luciferase with a 3'ss in 5' and a 5'ss in 3' (**Figure 4**).  
11 Contrary to group I introns where intron is between two exons, in their construct the 5'ss and 3'ss are  
12 separated by the inserted cassette, a distance unfavorable to group I intron self-splicing. Accordingly,  
13 authors added homology arms (in green in **Figure 4**) in 5' and 3' to bring introns closer to 5'ss and 3'ss.  
14 Using this strategy, they reported circularization of RNA up to 5, 000 nt with close to 100 %  
15 circularization efficiency.

### Group I intron and base-pairing inspired production of synthetic circRNA

**Figure 4. Production of exogenous circRNA by a Group I intron-based strategy.** The I intron-based strategy, the 3'ss and 5'ss are too far from each other to allow splicing. Thus, homology arms are added on both sides to bring the two splicing sites closer. Exogenous G attack of the 5'ss releases the 5' intron-homology arm and produces an exon1-OH. This is followed by 5'ss-OH attack of the 3'ss to form a circRNA and release the 3' intron-homology arm. The figures are based on information from a reference <sup>78</sup>.

Transfection of human cancer cells (HEK293) with circRNA complexed with Lipofectamine Messenger Max (Invitrogen) resulted in 8-fold more luciferase expression over unmodified luciferase mRNA and 50 % more than nucleoside-modified mRNA. This was accompanied with a doubling of luciferase production half-life reaching 80 h compared to 40 h for linear mRNA. Two critical improvements of linear mRNA: HPLC purification and incorporation of modified nucleotides<sup>107</sup> have

1  
2  
3 1 also been applied to circRNA and further enhanced its translation and decreased its immunogenicity.<sup>76</sup>  
4  
5 2 <sup>78</sup> Circularization of RNA followed by HPLC purification reduces TLR and RIG-1 sensing.<sup>78</sup> Concerning  
6  
7 3 incorporation of modified nucleotides it appears that the circRNA production method needs to be adapted  
8  
9 4 as replacement of uridine by methyl pseudo uridine or replacement of adenosine by N-methyl adenosine  
10  
11 5 greatly decreased splicing efficiency.<sup>79</sup>  
12  
13

14 6 Along with the stabilization against exonuclease, RNA circularization strategy has a potential  
15  
16 7 to improve the efficiency of protein production. Among the three protein translational processes,  
17  
18 8 initiation, elongation and termination, initiation is the rate-limiting phase. In circular RNA without stop  
19  
20 9 codon, ribosomes continue translation with low frequency of detachment from RNA, thereby skipping  
21  
22 10 rate-limiting re-initiation step. Indeed, circular RNA without stop codon improved the efficiency of  
23  
24 11 protein production compared to linear mRNA and circular RNA with stop codon in cell-free translational  
25  
26 12 system from *E. Coli*, and also in human cells.<sup>108, 109</sup> For application of this strategy to mRNA therapeutics,  
27  
28 13 additional mechanism is needed to post-translationally cleave large protein translated from circular RNA  
29  
30 14 without stop codon for obtaining intended protein.  
31  
32  
33  
34  
35  
36  
37

#### 38 16 ***2.4. mRNA engineering with RNA architectonics***

39  
40 17 While chemical methods have provided improved translational activity and decreased mRNA  
41  
42 18 immunogenicity,<sup>54, 58, 60, 110</sup> only a few types of modified nucleosides allow to preserve mRNA  
43  
44 19 translational activity, and even widely used modified nucleoside species induce negative effect on  
45  
46 20 translational processes, depending on their introduction ratio and target cell types (see *Section 2.1.4* for  
47  
48 21 detail).<sup>61, 62</sup> Thus, other approaches are needed to expand the options of mRNA engineering.  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

**Figure 5. mRNA engineering with RNA architectonics.** A, B. Introduction of (A) cholesterol moieties,<sup>111</sup> and (B) PEG.<sup>112</sup> C. mRNA nanoassemblies.<sup>113</sup> D. mRNA hybridized with poly U for mRNA vaccination.<sup>114</sup>

We proposed an original approach of mRNA architectonics for introducing various functional moieties to mRNA, through hybridization of mRNA with functionalized RNA oligonucleotides (OligoRNAs) (Figure 5). Although formation of double stranded RNA structure resulting from OligoRNA hybridization may impair mRNA translational processes and increase mRNA immunogenicity, these unfavorable outcomes were successfully avoided by limiting OligoRNA hybridization length to 17 nt.<sup>111</sup> This finding motivated us to functionalize mRNA carriers, such as polymeric micelles (PMs) and lipid nanoparticles (LNPs), using OligoRNAs introduced with functional moieties. For structural stabilization of PMs, OligoRNAs introduced with hydrophobic cholesterol (Chol) moiety (Chol-OligoRNAs) was hybridized to mRNA (Figure 5A), and then resulting mRNA was mixed with  $\omega$ -cholesteryl poly(ethylene glycol) (PEG)-polycation block copolymers to prepare PMs (see Section 3.5 for detail about PMs). Hybridization of just one or a few Chol-OligoRNAs provided drastic

1  
2  
3 1 effect on tightening mRNA structure in PM core, presumably through stacking between Chol moieties  
4  
5 2 on mRNA and those on the block copolymers. As a result, PMs became stabilized against nuclease  
6  
7 3 attacks and polyion exchange reaction. Eventually, the stabilized PMs showed efficient mRNA  
8  
9 4 introduction in mouse lung with minimal toxicological responses, after intratracheal administration,  
10  
11 5 demonstrating *in vivo* utility of Chol-OligoRNA hybridization strategy.  
12  
13

14 6 The hybridization-based mRNA engineering approach is versatile to improve bioavailability  
15  
16 7 of other types of carriers, such as LNPs (see *Section 3.1* for detail about PMs). Although mRNA LNPs  
17  
18 8 have demonstrated their high potential especially in delivery to the liver and the spleen,<sup>115-117</sup> arduous  
19  
20 9 processes, including the use of microfluidics, are needed for mRNA preparation, especially for  
21  
22 10 preventing LNP aggregation after the mixture of cationic lipids with mRNA.<sup>118</sup> To tackle this issue, we  
23  
24 11 developed a simple and robust strategy through hybridization of mRNA with PEGylated OligoRNAs  
25  
26 12 (**Figure 5B**).<sup>119</sup> This strategy allowed to prevent aggregation after mixing mRNA with commonly used  
27  
28 13 LNPs, including lipofectamine LTX and DOTAP/Chol liposomes, with minimal influence on mRNA  
29  
30 14 translational activity. The PEGylated LNPs thus prepared exhibited high structural stability even in  
31  
32 15 physiological environment, without forming aggregates in mouse blood circulation, while unPEGylated  
33  
34 16 LNPs formed several micrometer-sized aggregates in blood, and caused lung embolism.  
35  
36  
37  
38  
39

40 17 Other applications of OligoRNA hybridization strategy include mRNA structuring to improve  
41  
42 18 its nuclease stability. Growing field of RNA nanotechnology revealed that nuclease attack to RNA is  
43  
44 19 weakened by structuring RNA, presumably through steric hindrance, and this strategy was applied to  
45  
46 20 siRNA delivery.<sup>120, 121</sup> Meanwhile, precise sequence designing is needed to obtain intended base-pairing  
47  
48 21 for structuring RNA. This issue hampers direct application of this technology to the delivery of mRNA,  
49  
50 22 which possesses limited sequence flexibility with fixed structure containing a 5'-cap, 5'- and 3'-  
51  
52 23 untranslated regions, a coding region, and a poly-A tail. To prepare structured mRNA possessing all of  
53  
54 24 these endogenous mRNA components without sequence optimization, we crosslinked mRNA strands  
55  
56  
57  
58  
59  
60

1  
2  
3 1 using linker OligoRNAs, which possess two complementary arms for hybridization (**Figure 5C**).<sup>122</sup> Each  
4  
5 2 mRNA nanoassembly thus prepared was comprised of 7.7 strands of mRNA on average, with average  
6  
7 3 size below 100 nm, and the nanoassemblies exhibited around 100-fold increase in nuclease stability  
8  
9 4 compared to naïve mRNA, with preserved translational activity. Intriguingly, this result suggests that  
10  
11 5 nanoassemblies remained accessible to translational factors, although the recognition by nucleases is  
12  
13 6 effectively weakened presumably through steric hinderance. In mechanistic analysis, nanoassemblies  
14  
15 7 from mRNA with 5' cap were selectively dissociated in the environment mimicking intracellular space,  
16  
17 8 while those from mRNA without 5' cap failed to dissociate. This result suggests that translational factors  
18  
19 9 recognize 5' cap in nanoassemblies to trigger translation, and then nanoassemblies dissociate through  
20  
21 10 endogenous mRNA unwinding mechanism of translational complexes, which facilitates further  
22  
23 11 translation. Similar unwinding mechanism might contribute to protein translation from mRNA  
24  
25 12 hybridized with Chol-OligoRNAs or PEG-OligoRNAs. Nanoassemblies exhibited efficient mRNA  
26  
27 13 introduction to mouse brain, demonstrating their *in vivo* utility. Rolling circle transcription of plasmid  
28  
29 14 DNA, a widely-used method, can also provide structured RNA with protein expressing capability, and  
30  
31 15 this approach resulted in improvement of RNA nuclease stability,<sup>123</sup> which is consistent with our finding  
32  
33 16 of mRNA nanoassemblies. However, protein translation from RNA prepared by rolling circle methods  
34  
35 17 relies on an internal ribosomal entry site, which tends to yield a much lower level of translational  
36  
37 18 efficiency compared to cap-dependent translation.<sup>124</sup> Other strategies to improve mRNA nuclease  
38  
39 19 stability includes the preparation of long double stranded structure in mRNA by hybridizing long  
40  
41 20 antisense strand.<sup>125</sup> Although this strategy was effective in facilitating mRNA delivery to the liver after  
42  
43 21 hydrodynamic injection, its versatility is unclear, because long RNA hybridization to mRNA resulted in  
44  
45 22 impaired translational activity and enhanced mRNA immunogenicity.<sup>111, 114</sup>  
46  
47  
48  
49  
50  
51  
52

53  
54 23 Interestingly, in RNA hybridization to poly A region, even 120 nt poly U RNA attachment  
55  
56 24 resulted in only modest decrease in translational activity,<sup>114</sup> whereas hybridization of 23 nt or longer  
57  
58  
59  
60

1  
2  
3 1 OligoRNA to protein coding region led to the decrease in translational activity.<sup>111</sup> Meanwhile, mRNA  
4  
5 2 hybridized with 120 nt poly U (mRNA:pU) induced strong innate immune responses, especially when  
6  
7 3 the poly U strand possesses triphosphate structure at its 5' end, which is a substrate of an innate immune  
8  
9 4 receptor, retinoic acid-inducible gene (RIG)-I.<sup>126, 127</sup> We utilized these unique properties of mRNA:pU,  
10  
11 5 preserved translational activity and enhanced immunogenicity, for mRNA vaccine, to obtain antigen  
12  
13 6 expression and immunostimulatory adjuvant function simultaneously (**Figure 5D**). After introduction to  
14  
15 7 cultured mouse and human dendritic cells, mRNA:pU induced enhanced expression of dendritic  
16  
17 8 activation markers, CD86 and CD40, compared to naïve mRNA. Mechanistic analyses indicate the  
18  
19 9 involvement of RIG-I and Toll-like receptor (TLR)-3 for the immunostimulation by mRNA:pU.  
20  
21 10 Eventually, in mouse vaccination experiment using a model antigen, ovalbumin (OVA), mRNA:pU  
22  
23 11 formulation induced cellular and humoral immunity against OVA more efficiently compared to naïve  
24  
25 12 mRNA. Together, mRNA engineering approach based on OligoRNA hybridization is versatile to  
26  
27 13 improve bioavailability of naked mRNA and various types of mRNA carriers, and also enhance the  
28  
29 14 activity of mRNA vaccine, opening up broad opportunities for expanding the potential of mRNA  
30  
31 15 therapeutics.

### 40 17 **3. Nanomedicine-approaches for mRNA delivery**

41  
42 18 The application of nano-scaled carriers is necessary for allowing mRNA molecules to endure  
43  
44 19 in the harsh *in vivo* environments, as well as promote the intracellular delivery of mRNA. Various  
45  
46 20 materials have been employed for constructing such mRNA-loaded nanomedicines, allowing  
47  
48 21 physicochemical and functional control. By engineering the interaction with mRNA and the carrier  
49  
50 22 components, it is then possible to obtain nanomedicines capable of maximizing the stability of mRNA  
51  
52 23 in biological settings, obtaining optimal translation in targeted cells for therapeutic purposes, and reduce  
53  
54 24 the side effects from mRNA molecules or off-target translation. The choice of the carrier components  
55  
56  
57  
58  
59  
60

will depend on the eventual route of administration and therapeutic purpose of the nanomedicines. In the following sections, we review major nanomedicine approaches for mRNA delivery categorized by the materials used to make the carriers. The delivery systems highlighted in this section are summarized in

#### Table 1.

**Table 1 Nanomedicine-approaches for mRNA delivery**

Category	Key component(s)	Core technologies	Size (nm)	Delivery route(s)	Gene(s)	Ref
Lipid-based nanoparticles	DLin-MC3-DMA <sup>a)</sup>	Clinically approved ionizable lipid	75-85	i.v., i.c.v. (mouse)	Luc, frataxin	133
	Lipid 5	Optimized ionizable lipids	86	in vitro, i.v. (mouse, rat, NHP)	Luc, EPO, IgG	135
	TT3 <sup>a)</sup>	Orthogonal array optimization	110	in vitro, i.v. (mouse)	Luc, hFIX	136
	A18-Iso5-2DC18 <sup>a)</sup>	cyclic head group in ionizable lipid for STING activation	96	in vitro, s.c.	Luc, Cre, OVA, tumor antigens	137
	C12-200 <sup>a)</sup>	A large scale <i>in vivo</i> screening of mixture ratio	152	i.v. (mouse)	Luc, EPO	139
	SORT lipid (DLin-MC3-DMA <sup>a)</sup> , C12-200 <sup>a)</sup> , 5A2-SC8 <sup>a)</sup> , DOTAP <sup>a)</sup> , 18PA <sup>a)</sup> , etc.)	Addition of cationic, anionic and ionizable lipid to change tissue tropism	70-200	i.v. (mouse)	Cre, EPO, IL-10, Cas9	141
	C-24 alkyl phytosterols <sup>a)</sup>	Optimized cholesterol	102	in vitro	Luc, GFP, Cas9	143
5A2-SC8 <sup>a)</sup>	Dendrimer LNP	100	in vitro, i.v. (mouse)	Luc, FAH	147	
Polyplexes	PEtOx-PEI	Optimization of Mw and charge density	80-450	in vitro	Luc	152
	hyperbranched PBAE	Hyperbranched polycation for nebulization.	150	inhalation (mouse)	Luc, GFP, Cre	153
	Dimannose-PGA/PBAE	Macrophage targeting	100	in vitro, i.p., i.v. (mouse)	IRF5, IKK $\beta$	154
	PAsp(EDA), PAsp(TET)	Polyplex stabilization	82, 93	in vitro	Luc	155
	PAsp(TET), PAsp(TEP)	Efficient translation	62, 51	in vitro	Luc	156
	PAsp(DPT), PAsp(TET)	Pre-complexation with eIF4E to facilitate translation	100	in vitro, i.v. (mouse)	Luc	157
Lipopolyplexes	HpK-PEG + HDHE/chol	Protonable histidylated lipids	100	i.v. (mouse)	MART1	38
	PEI + Chol/DOPA/DOPE/DSPE-PEG/Man-lip	Neutral and mannosylated LPP	160-190	i.m., i.v. (mouse)	Luc, HA	39
	HpK-PEG + KLN25/MM27	Mannosylated and histidylated lipids	100-140	i.v. (mouse)	MART1	158
	HpK-PEG +	Histidylated lipids and a tri-	100-	i.v. (mouse)	E7	164

	KLN25/MM27/TriMan-lip	mannosylated diether lipid	150			
	PBAE + EDOPC/DOPE/DSPE-PEG	Biodegradable polymer	n.d.	s.c. (mouse)	OVA	167

Lipid5, ; Heptadecan-9-yl 8-((2-hydroxyethyl)(8-(nonyloxy)-8-oxooctyl)amino)octanoate PEtOx, poly(2-ethyl-2-oxazoline); PEI, poly(ethylene imine); PBAE, poly(beta amino esters); PGA, poly(glutamic acid); PAsp(EDA), poly[N-(2-aminoethyl)aspartamide]; PAsp(TET), poly(N-{N'-[N''-(2-aminoethyl)-2-aminoethyl]-2-aminoethyl}aspartamide); PAsp(TEP), poly-[N-(N'-{N''-[N'''-(2-aminoethyl)-2-aminoethyl]-2-aminoethyl]-2-aminoethyl)aspartamide]; PAsp(DPT), poly{N'-[N-(3-aminopropyl)-3-aminopropyl]aspartamide}; HpK, Histidylated polylysine; HDHE, L-Histidine-(N,N-di-n-hexadecylamine)ethylamide; Chol, Cholesterol; DOPA, 1,2-dioleoyl-sn-glycero-3-phosphate; DOPE, 1,2-dioleoyl-sn-glycero-3-phosphatidylethanolamine; DSPE, 1,2-distearoyl-sn-glycero-3-hosphoethanolamine; Man-lip, 16:0 1,2-dipalmitoyl-sn-glycero-3-phospho((ethyl-1',20,30-triazole)triethyleneglycolmannose; TriMan-lip, trimannosylated archeal diether lipid; EDOPC, 1,2-dioleoyl-sn-glycero-3-ethylphosphocholine; PLGA, poly(lactic-co-glycolic acid); n.d., not determined; i.v., intravenous injection; i.c.v., intra-cerebroventricular injection; s.c.; subcutaneous injection; i.c., intracisternal injection; i.n., intranasal delivery; HTVi, hydrodynamic tail-vein injection; i.t., intratracheal delivery; NHP, non-human primate; Luc, luciferase; EPO, erythropoietin; OVA, ovalbumin; IL-10, interleukin 10; FAH, fumarylacetoacetate hydrolase; hFIX, human factor IX, IRF5, interferon regulatory factor 5; IKK $\beta$  inhibitor of nuclear factor kappa- $\beta$  kinase subunit  $\beta$ ; MART-1, Melanoma antigen recognized by T cells 1; E7, human papillomavirus 16 oncoprotein E7; HA, Hemagglutinin; eIF4E, eukaryotic translation initiation factor 4E; BDNF, brain-derived neurotrophic factor; Bcl-2, B-cell lymphoma-2; sFlt-1, soluble fms-like tyrosine kinase-1; PGC1 $\alpha$ , proximosome proliferator- activated receptor  $\gamma$  coactivator 1  $\alpha$ ; PTEN: phosphatase and tensin homolog.

### 3.1. Lipid-based nanoparticles

1  
2  
3 1 LNP are one of the most advanced mRNA delivery systems (reviewed in <sup>46, 103</sup>). LNP are  
4  
5 2 prepared by microfluidic mixing of lipids in ethanol and mRNA in acidic buffer (pH 3.0-4.0).<sup>128</sup> Lipids  
6  
7 3 include an ionizable lipid (pKa < 7) that will be protonated at acidic pH to condense mRNA and release  
8  
9 4 it inside the cells, cholesterol for stabilization, an helper lipid for endosomal escape (usually DOPE,  
10  
11 **Figure 6**) and a PEGylated lipid to prevent aggregation of LNPs.<sup>129</sup> Using an ionizable cationic lipid for  
12  
13 5 mRNA complexation instead of a permanently charged one limits toxicity *in vivo* and increases half-life  
14  
15 6 of the mRNA.<sup>130</sup> The rapid mixing leads to the formation of an electron dense core surrounded by a lipid  
16  
17 7 monolayer.<sup>131</sup> Mixing is followed by dialysis against a neutral buffer to remove ethanol.

18  
19 8  
20  
21 9 LNP were first developed for siRNA delivery, mostly to the liver. The system has produced  
22  
23 10 an FDA-approved siRNA LNP called Onpattro, which includes the DLin-MC3-DMA (MC3, **Figure 6**)  
24  
25 11 ionizable lipid.<sup>132</sup> Accordingly, earlier studies on mRNA LNPs used ionizable lipids with a structure  
26  
27 12 similar to DLin-MC3-DMA.<sup>46, 133</sup> LNPs are internalized by clathrin-mediated endocytosis, resulting in  
28  
29 13 their accumulation in endosomes and possible clearance by exocytosis.<sup>134, 135</sup> Protonation of the ionizable  
30  
31 14 lipid at endosomal pH (5.5-6.5) and presence of fusogenic lipids such as DOPE disrupts the endosomal  
32  
33 15 membrane allowing intracellular delivery of mRNA and its translation.<sup>46, 135</sup>

34  
35 16 Biodegradability is an important parameter for the clinical translation of mRNA LNPs. Sabnis  
36  
37 17 *et al.* screened a library of different amino lipid-based LNPs and compared their safety and expression  
38  
39 18 levels in rodents and non-human primates to MC3-LNPs.<sup>135</sup> They identified ethanolamine as the best  
40  
41 19 headgroup and their library included ethanolamine with different lipid tails. Intravenous administration  
42  
43 20 of all the variants led to expression in the liver of mice. By measuring lipid levels in the liver along time,  
44  
45 21 they reported that ester linkages accelerated liver clearance. Whereas primary esters increased pKa and  
46  
47 22 decreased mRNA expression, secondary esters improved mRNA expression. The best lipid, lipid 5  
48  
49 23 (Heptadecan-9-yl 8-((2-hydroxyethyl)(8-(nonyloxy)-8-oxooctyl)amino)octanoate), contains one lipid  
50  
51 24 chain with a primary ester and one lipid chain with a secondary ester and provided 3-fold higher  
52  
53  
54  
55  
56  
57  
58  
59  
60

expression over MC3-LNP. Higher expression was correlated with enhanced endosomal escape with 6-fold more cytosolic mRNA after transfection of HeLa cells with lipid 5-LNPs over MC3-LNPs. Lipid 5-LNPs were more rapidly cleared from liver, spleen and plasma than MC3-LNPs and, contrary to MC3-LNPs did not accumulate in the heart, arguing for better biosafety. Evaluation of the LNPs then moved to Cynomolgus monkeys. Intravenous injection of 0.01 mg/kg of mRNA encoding either human erythropoietin or anti-human IgG influenza antibody resulted in 5-fold higher protein levels of lipid 5-LNPs over MC3-LNPs, with minimal activation of immune markers.

**Figure 6. Common lipid and small surfactant structures for preparing LNPs.**

Dong *et al.* introduced LNPs where the ionizable lipid is based on TT ( $N^1, N^3, N^5$ -tris(2-aminoethyl)benzene-1,3,5-tricarboxamide, **Figure 6**), a group consisting of a phenyl ring, three amide linkers and three amino lipid chains.<sup>136</sup> LNPs were prepared with TT3 (T3, DOPE, Cholesterol, DMG-

1  
2  
3 1 PEG2000 at molar ratios of 20/30/40/0.75). Intravenous injection of TT3-LNPs resulted in 6-fold higher  
4  
5 2 bioluminescence in mice spleen over C12-200 LNPs (**Figure 6**). They also prepared LNPs using mRNA  
6  
7 3 coding human factor IX (hFIX), a blood clotting factor deficient in hemophilia. Intravenous injection of  
8  
9 4 hFIX mRNA TT3-LNPs at a dose of 1.1 mg/kg was able to restore FIX levels to normal physiological  
10  
11 5 values in FIX knockout mice, suggesting a broad potential for protein replacement therapies.  
12  
13

14 6 A further improvement over MC3-LNPs was to use a cyclic lipid headgroup instead of a linear  
15  
16 7 one.<sup>137</sup> The Anderson group screened a library of LNPs formed with headgroups containing linear or  
17  
18 8 heterocyclic amines (dimethylamino, dimethylaminopropyl, dibutylaminopropyl, dipropylaminopropyl)  
19  
20 9 which were benchmarked against MC3-LNPs. Irrespective of the number of carbon bonds, subcutaneous  
21  
22 10 injection of OVA mRNA LNPs with heterocyclic polar heads showed superior activation of murine  
23  
24 11 splenocytes compared to linear polar heads. Piperazin and azepanyl polar heads induced the highest  
25  
26 12 levels of specific lymphocytes. LNPs with the A18 polar head increased IFN- $\gamma$  secretion by 10-fold over  
27  
28 13 MC3-LNPs and 75-fold over LNPs with a linear tertiary amine polar head (**Figure 6**). This was explained  
29  
30 14 by enhanced affinity of cyclic lipids towards the binding pocket of the STING protein, resulting in  
31  
32 15 superior expression of the dendritic cell activation markers CD40, CD86 and HLA-DR (Human  
33  
34 16 Leukocyte Antigen DR isotype). A18-LNPs achieved superior protection against tumor growth and  
35  
36 17 extended survival over MC3-LNPs in two murine cancer models.  
37  
38  
39  
40  
41

42 18 Helper lipids such as DOPE and cholesterol are critical components of LNPs (**Figure 6**).<sup>46, 103</sup>  
43  
44 19 DOPE is preferred to DSPC as helper lipid as presence of DSPC leads to the formation of protrusions on  
45  
46 20 the surface of LNPs and mRNA LNPs enriched in DSPC have low transfection efficiency *in cellulo* and  
47  
48 21 lower expression *in vivo*.<sup>131, 137-139</sup> mRNA LNPs containing DSPC were also reported to induce  
49  
50 22 inflammation at the injection site.<sup>140</sup>  
51  
52  
53

54 23 All mRNA LNPs to date include cholesterol as a stabilizer and to promote membrane fusion.<sup>135,</sup>  
55  
56 24 <sup>137, 139-144</sup> Substitution of cholesterol by natural analogues has been proposed to increase the potency of  
57  
58  
59  
60

1  
2  
3 1 mRNA LNPs.<sup>143</sup> Authors prepared LNPs with MC3:sterol:DSPC:DMG-PEG at 50:38.5:10:1.5 molar  
4  
5 2 ratios using three groups of cholesterol analogs. Group I included Vitamin D analogs (*e.g.* Vitamin D3),  
6  
7 3 group II analogs included phytosterols (*e.g.*  $\beta$ -Sitosterol, **Figure 6**), group III included pentacyclic  
8  
9 4 terpenoids (*e.g.* botulin). LNPs containing group I analogs had similar size and mRNA encapsulation  
10  
11 5 efficiency as cholesterol LNPs but low transfection efficiency. Inclusion of group III analogs decreased  
12  
13 6 encapsulation efficiency by  $\geq 50$  % and increased the size of LNPs resulting in poor transfection  
14  
15 7 efficiency. The group II analog  $\beta$ -Sitosterol did not alter LNPs size nor encapsulation efficiency but  
16  
17 8 improved translation efficiency by 48-fold in cancer cells. This enhancement in transfection efficiency  
18  
19 9 was even observed in primary cells, with a 14-fold enhancement in *ex vivo* transfected human peripheral  
20  
21 10 blood macrophages over MC3-LNPs. Improved transfection was due to differences in both  
22  
23 11 microstructure of LNPs and intracellular trafficking. Whereas cholesterol-LNPs presented a smooth  
24  
25 12 surface,  $\beta$ -Sitosterol-LNPs' surface was highly faceted suggesting phase separation of lipid domains<sup>145</sup>,  
26  
27 13 packing defects suggested to improve fusion with membranes and thus intracellular delivery.<sup>146</sup> Confocal  
28  
29 14 microscopy imaging of transfected cells highlighted a higher rate of cellular uptake and retention of  $\beta$ -  
30  
31 15 Sitosterol-LNPs, with a no significant enhancement in endosomal escape but higher cytoplasmic mobility  
32  
33 16 of  $\beta$ -Sitosterol-LNPs.

34  
35  
36  
37  
38  
39  
40 17 Cheng *et al.* developed LNPs for mRNA delivery and gene editing in lungs, spleen or liver  
41  
42 18 after intravenous injection.<sup>141</sup> The tissue tropism of these particles is based on modulation of the internal  
43  
44 19 charge of the LNPs by addition of an additional sorting lipid. LNPs consisted of ionizable lipid (11.9-  
45  
46 20 50%), DOPE as co-lipid (5-23.8 %), cholesterol (19.3-47.6 %), DMG-PEG (1,2-dimyristoyl-rac-  
47  
48 21 glycerol-methoxy(poly(ethylene glycol, 0.8-4.8 %) (**Figure 6**) and an increasing percentage of sorting  
49  
50 22 lipid (0-50%). They compared three different ionizable lipids: the 5A2-SC8 dendrimer (**Figure 6**) which  
51  
52 23 allowed FAH (fumarylacetoacetate hydrolase) mRNA delivery in the hepatocytes of FAH knockout mice  
53  
54 24 and extended their survival<sup>147</sup>, the MC3 lipid and the same lipid composition as the FDA-approved  
55  
56  
57  
58  
59  
60

1  
2  
3 1 siRNA LNP Onpattro<sup>132</sup>, the C12-200 lipid (**Figure 6**) which allowed mRNA delivery in the liver.<sup>139</sup> For  
4  
5 2 LNPs prepared with these 3 different ionizable lipids, expression of mRNA in organs was controlled by  
6  
7 3 the content of DOTAP (1,2-dioleoyl-3-trimethylammonium-propane, **Figure 6**) permanently charged  
8  
9 4 cationic lipid. LNPs without DOTAP were expressed in the liver, LNPs with intermediate DOTAP  
10  
11 5 content (10-15%) were expressed in the spleen and LNPs with 50 % DOTAP were expressed in the lungs.  
12  
13 6 Measurements of surface charge showed that DOTAP is in the core of LNPs together with the mRNA as  
14  
15 7 zeta potentials were close to 0. Interestingly, the type of lipid dictated organ specificity. Using an  
16  
17 8 ionizable lipid as sorting lipid reinforced the liver tropism of LNPs. Adding an extra 20 % of 5A2-SC8  
18  
19 9 increased mRNA expression in the liver by 3-fold. Using a zwitterionic sorting lipid favored spleen  
20  
21 10 targeting with exclusive distribution to the spleen of LNPs containing 80% DSPC (1,2-distearoyl-sn-  
22  
23 11 glycerol-3-phosphocholine) or 50% DOPC (2-((2,3-bis(oleoyloxy)propyl)dimethylammonio)ethyl ethyl  
24  
25 12 phosphate). Negatively charged sorting lipids also favored spleen targeting with exclusive expression in  
26  
27 13 the spleen of LNPs with 10-40% 18PA (1,2-dioleoyl-sn-glycerol-3-phosphate) (**Figure 6**). Selective  
28  
29 14 organ targeting (SORT) LNPs achieved high expression of erythropoietin and interleukin 10 after  
30  
31 15 intravenous injection and nearly 100 % gene editing in murine hepatocytes after a single intravenous  
32  
33 16 injection of 0.3 mg/kg of mRNA.  
34  
35  
36  
37  
38  
39  
40  
41

### 42 18 **3.2. Polyplexes**

43  
44 19 Polymer-mRNA complexes (polyplexes), particularly using PEI (polyethylenimine) is one of  
45  
46 20 the earliest strategies used for nucleic acid delivery.<sup>148</sup> Whereas the high cationic density of PEI allows  
47  
48 21 RNA complexation and endosomal escape by “proton-sponge” effect,<sup>149</sup> this also induces cytotoxicity<sup>150</sup>  
49  
50 22 and alters cellular homeostasis.<sup>151</sup> Formation of conjugates of low molecular weight PEI with lipids  
51  
52 23 decreases the cytotoxicity while preserving transfection efficiency.<sup>149</sup> Using a library of poly(2-ethyl-2-  
53  
54 24 oxazoline) with varying molar mass and charge densities identified the optimal  $M_w$  of PEI for pDNA or  
55  
56  
57  
58  
59  
60

1  
2  
3 1 mRNA delivery, the EI content being controlled by hydrolysis kinetics.<sup>152</sup> Whereas large and densely  
4  
5 2 charged polymer (83 kDa and 100 % hydrolysis) was optimal for pDNA transfection of HEK 293T cells,  
6  
7 3 the optimal polymer for mRNA was smaller and with lower charge density (45 kDa and 80 % hydrolysis).  
8  
9  
10 4 This polymer has not been used *in vivo* yet.

11  
12 5 Poly( $\beta$ -amino) esters (PBAEs) are biodegradable polymers that are less toxic than PEI and  
13  
14 6 showed efficient mRNA delivery *in vivo*.<sup>153, 154</sup> An hyperbranched PBAEs (hPBAEs) formulation has  
15  
16 7 been designed for nebulized mRNA delivery to the lungs.<sup>153</sup> To evaluate the influence of PBAEs  
17  
18 8 structure on mRNA inhalation, Authors compared linear PBAEs (lPBAEs) and hPBAEs. Whereas  
19  
20 9 lPBAEs and hPBAEs showed similar transfection of A549 lung cells in culture, only hPBAEs were suited  
21  
22 10 for nebulization. Indeed, size of lPBAEs increased from 150- to 1200-nm after nebulization with high  
23  
24 11 polydispersity. Oppositely, hPBAEs size remained stable under 200 nm with low polydispersity.  
25  
26 12 Nebulization of luciferase mRNA polyplexes prepared with hPBAEs resulted in 16-fold higher luciferase  
27  
28 13 protein levels in mice lungs compared to 25 kDa branched PEI polyplexes. Notably, hPBAEs allowed  
29  
30 14 mRNA delivery to all lung lobes and the transfection of 24.6 % of lung epithelial cells with no  
31  
32 15 transfection of lung immune cells nor alveolar damage. This technology holds potential for future clinical  
33  
34 16 application of mRNA polyplexes.  
35  
36  
37  
38  
39

40 17 The control of the structure of the polycations may also provide opportunity for intracellular  
41  
42 18 navigation. For example, polyplexes made from *N*-substituted polyaspartamides having odd number of  
43  
44 19 repeats, *i.e.* polyaspartamides modified with ethylene diamine (P(Asp(EDA))) or triethylamine  
45  
46 20 (P(Asp(TET))), showed higher and prolonged expression *in vitro* compared to polyaspartamides having  
47  
48 21 even number of repeats, *i.e.* polyaspartamides modified with diethylenetriamine P(Asp(DET)) or  
49  
50 22 tetraethylenepentamine (P(Asp(TEP))).<sup>155</sup> This effect was associated with the protonation behaviors of  
51  
52 23 the aminoethylene groups in response to changes in pH during endosomal uptake, which direct the  
53  
54 24 endosomal escape and the stability of the polyplexes. Thus, despite the polyaspartamides with even  
55  
56  
57  
58  
59  
60

1  
2  
3 1 number of repeats promoted endosomal escape, they showed lower stability of mRNA in the cytosol of  
4  
5 2 cells, which may lead to mRNA degradation and less protein translation. On the other hand,  
6  
7 polyaspartamides having odd number of repeats facilitated a rapid escape from endosomes, though their  
8 3  
9 higher stability in the cytosol resulted in prolonged protein translation. Thus, the stability of these  
10 4  
11 polyplexes in the cytosol appears to correlate with the protonation of the primary amino groups at the  
12 5  
13 side chains. These primary amines are almost fully protonated for polyaspartamides having odd number  
14 6  
15 of repeats, while for polyaspartamides having even number of repeats, the protonation is lower.  
16  
17 7

18  
19 8 The polycation structure may also affect the initiation of mRNA translation. For example, by  
20  
21 9 evaluating the translation of polyplexes from a series of polyaspartamides in cell free conditions, it was  
22  
23 found that the translation efficiency of polyplexes formed from polymers having higher number of  
24 10  
25 aminoethylene repeating units, *i.e.* (P(Asp(TET))) and (P(Asp(TEP))), was comparable to that of naked  
26 11  
27 mRNA. On the other hand, the efficiency of polyplexes from polyaspartamides having less repeating  
28 12  
29 units, *i.e.* P(Asp(EDA)) and P(Asp(DET)) was significantly decreased.<sup>156</sup> This behavior was explained  
30 13  
31 by the high negative charge of the triphosphate of the m<sup>7</sup>G group in the cap of mRNA. Thus,  
32 14  
33 polyaspartamides presenting higher number of aminoethylene repeating units may bind to the  
34 15  
35 triphosphates in the caps more strongly, and promote binding to eIF4E. Such binding profile was  
36 16  
37 confirmed in a separate study by using FRET imaging studies of Cy5-mRNA/Cy3-eIF4E complexes  
38 17  
39 electrostatically stabilized by polyaspartamides,<sup>157</sup> showing that P(Asp(DPT)) and P(Asp(TET)) keep the  
40 18  
41 co-localization of mRNA and eIF4E inside cells. These findings indicate the relevance of the polycations  
42 19  
43 design for regulating intracellular delivery and targeting to the translational machinery of cells.  
44 20  
45  
46  
47 20  
48  
49 21  
50

### 51 22 **3.3. Lipopolyplexes**

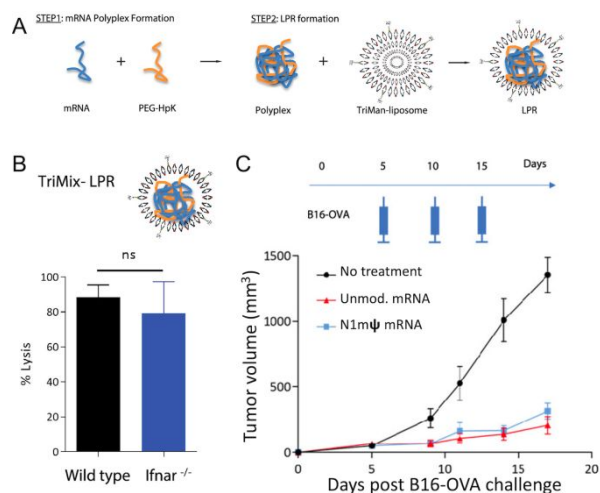

52  
53  
54 23 Lipopolyplexes (LPP) are ternary Lipid-Polycation-nucleic acid complexes.<sup>39, 158, 159</sup> These  
55  
56 24 ternary complexes were introduced by Leaf's group by complexation of DNA by protamine or polylysine  
57  
58  
59  
60

1  
2  
3 1 into polyplexes before interaction with DOTAP cationic liposomes.<sup>160, 161</sup> Lipopolyplexes allowed a  
4  
5 2 better protection against DNAses and a superior gene expression *in vivo* over DOTAP liposomes / DNA  
6  
7 3 lipoplexes. This technology was later applied to RNA delivery by Pichon's group.<sup>162</sup>  
8  
9

10 4 We used LPP where mRNA is first complexed with PEGylated and histidylated polylysine  
11  
12 5 (PEGHpK) before interaction with cationic liposomes made of cholesterol/HDHE (L-Histidine-(N,N-di-  
13  
14 6 nhexadecylamine)ethylamide).<sup>38</sup> The interesting feature of this formulation is the spleen targeting  
15  
16 7 obtained following intravenous administration. Vaccination of mice with LPP prepared with mRNA  
17  
18 8 (termed LPR) coding a melanoma antigen resulted in superior inhibition of melanoma tumor growth  
19  
20 9 compared to mRNA polyplexes or mRNA lipoplexes. To better target dendritic cells harboring mannose  
21  
22 10 receptors on their surface, liposomes harboring mannose moieties have been synthesized. In this second  
23  
24 11 set of study, liposomes were made with bio-inspired lipids: N-methyl imidazolium lipophosphoramidate  
25  
26 12 (cationic lipid, KLN25) and histamine lipophosphoramidate (protonable lipid, MM27), and a  
27  
28 13 mannosylated lipid. These cationic lipopolyplexes made of PEGHpK polymer and KLN25/MM27  
29  
30 14 mannosylated liposomes were designated LPR. Following IV injection, they allowed a better *in vivo*  
31  
32 15 transfection of DCs over unmannosylated LPR resulting in superior tumor growth inhibition and  
33  
34 16 extended survival of mice bearing B16F10 melanoma.<sup>158</sup> To further increase the transfection of DCs *in*  
35  
36 17 *vivo*, a second generation of mannosylated LPR were also formed with the PEG-HpK polymer and  
37  
38 18 KLN25/MM27 liposomes but included a glycolipid containing a tri-antenna of  $\alpha$ -D-mannopyranoside  
39  
40 19 instead of a monovalent mannose for improved endocytosis by DCs.<sup>163</sup> LPR prepared with the tri-antenna  
41  
42 20 targeting motif allowed better transfection of DCs *in vitro* and a stronger tumor growth inhibition in mice  
43  
44 21 compared to untargeted LPRs or LPRs with a mannosylated lipid harboring only one mannose.<sup>164, 165</sup>  
45  
46 22 Indeed, knowing the structure of oligosaccharides on the ligands recognized by mannose receptors on  
47  
48 23 dendritic cells, having more than one moiety leads to an increase of the receptor avidity and an improved  
49  
50 24 targeting.<sup>166</sup> One of the interesting feature of this formulation is the fact that mRNA lipopolyplexes e did  
51  
52

57  
58  
59  
60

not rely on type I IFN for effective T-cell immunity by contrast to lipopolyplexes (**Figure 7A**). This property led to a similar protection against melanoma growth after vaccination with unmodified or m1 $\Psi$ -modified mRNA encoding a tumor antigen (**Figure 7B**)

**Figure 7. Cationic and trimannosylated lipopolyplexes induce protection against melanoma. A.**

LPP have also been prepared using other polymers such as PBAE and PEI.<sup>39, 167</sup> 4 kDa PBAE/mRNA polyplexes were encapsulated in (1,2-dioleoyl-sn-glycero-3-ethylphosphocholine/1,2-dioleoyl-sn-glycero-3-phosphatidyl-ethanolamine/1,2-distearoyl-sn-glycero-3-hosphoethanolamine-N-[amino(polyethyleneglycol)-2000, EDOPC/DOPE/DSPE-PEG) liposomes.<sup>167</sup> Subcutaneous injection of these LPP resulted in stronger stimulation of DCs and better antigen presentation over lipopolyplexes or polyplexes confirming the superiority of the ternary platform. Importantly, LPP formulation has a potential to improve the functionalities of existing polyplexes and LNPs. For example, PBAE-based polymer was installed with alkyl tail to anchor PEG-lipids, which allowed efficient mRNA introduction to the lung after systemic delivery.<sup>168</sup> Incorporation of poly(lactic-co-glycolic acid) (PLGA) to TT3-

1  
2  
3 1 based LNP (**Figure 6**) was effective in increasing mRNA introduction efficiency to several human cell

### 10 4 **3.5. Polymeric Micelles**

11  
12 5 Polymeric micelles (PMs) based on polyion complexation have also shown high potential for  
13  
14 6 delivering mRNA.<sup>170, 171</sup> The PMs are self-assembled in aqueous conditions by ionic and hydrogen  
15  
16 7 bonding between the negatively charged mRNA and block cationomers, having a neutral segment and  
17  
18 8 polycation block. Thus, PMs form a nano-compartmentalized structure with a hydrophilic protective  
19  
20 9 shell surrounding the mRNA payload in the polyion complex core.<sup>172</sup> The mRNA inside the PMs is  
21  
22 10 packaged in globular shape,<sup>40, 173</sup> probably due to the flexibility of single stranded mRNA. The cationomers  
23  
24 11 can then be engineered to elicit effective protection of the loaded mRNA against enzymatic degradation,  
25  
26 12 as well as promote the cellular uptake by endocytosis and the eventual endosomal escape and access to  
27  
28 13 the cytosol. PMs also allowed to suppress immune responses of mRNA, probably by inhibiting the  
29  
30 14 interaction of mRNA with TLRs and/or hindering TLR mediated signals by endosomal disruption.<sup>40, 174</sup>  
31  
32 15 These features indicate PMs as promising carriers for dealing with major challenges of mRNA therapy,  
33  
34 16 *i.e.* instability, immunogenicity and translation efficiency.  
35  
36  
37  
38  
39

40 17 The potential of PMs for effective mRNA delivery has been demonstrated *in vivo* after local  
41  
42 18 or systemic administration. mRNA-loaded micelles based on the block cationomer poly(ethylene glycol)-  
43  
44 19 *b*-poly{N'-[N-(2-aminoethyl)-2-aminoethyl]aspartamide} (PEG-P(Asp(DET))) showed successful  
45  
46 20 transfection in the nasal epithelium,<sup>175</sup> the central nervous system,<sup>40</sup> and the liver.<sup>176</sup> The PEG-  
47  
48 21 P(Asp(DET)) block copolymer was designed to protect mRNA from rapid degradation and improve the  
49  
50 22 intracellular delivery of mRNA by polyion complexation and shielding with the PEG blocks. Moreover,  
51  
52 23 the polyaspartamide block, *i.e.* P(Asp(DET)), presents 2 pKas, *i.e.* 6.2 and 8.9, which allow for effective  
53  
54 24 polyion complexation at pH 7.4 and enhance endosomal escape after protonation at endosomal pH (pH  
55  
56  
57  
58  
59  
60

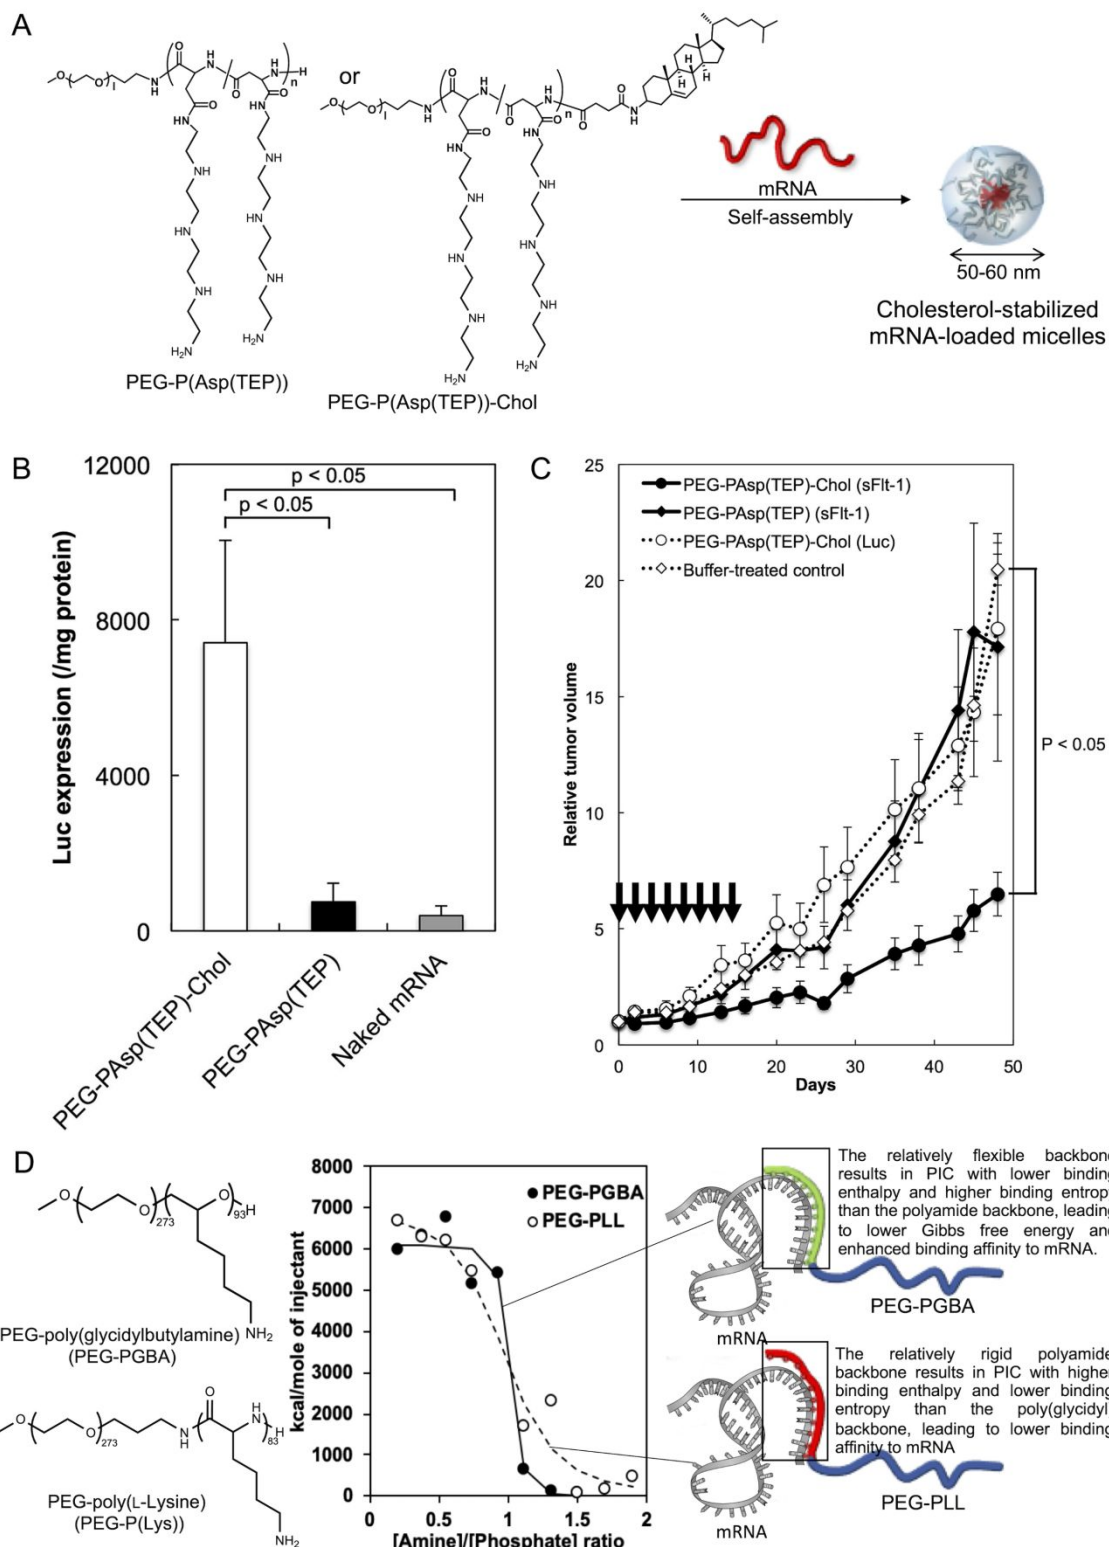

1  
2  
3 1 5-6.5).<sup>171</sup>  
4

5 2 While mRNA-loaded PMs are stable under physiological salt conditions, polyelectrolytes in  
6  
7 3 biological environments can disrupt them by interfering with the polyion complex between polymers and  
8  
9 4 mRNA.<sup>177</sup> Thus, efforts directed to stabilize mRNA-loaded PMs have focused on maintaining the micelle  
10  
11 5 structure by cross-linking the core with stimuli-sensitive covalent bonds,<sup>178</sup> or by introducing  
12  
13 6 hydrophobic moieties in polycation segments or nucleic acids.<sup>41, 111</sup> For example, PMs prepared by block  
14  
15 7 copolymers having cholesteryl group at the end (**Figure 8A**), as well as a relatively large PEG segment  
16  
17 8 of 23 kDa and polycation blocks for endosomal escape, showed improved blood circulation upon  
18  
19 9 intravenous injections, achieving 3-orders of magnitude higher concentration in blood compared to naked  
20  
21 10 mRNA. The high stability and extended bioavailability of these micelles promoted their tumor targeting,  
22  
23 11 which resulted in high translation of a mRNA encoding luciferase (**Figure 8B**). The ability of these  
24  
25 12 micelles to elicit antitumor effects was tested by using mRNAs producing the anti-angiogenic sFlt-1 in  
26  
27 13 a model of pancreatic cancer. The enhanced delivery by the cholesterol modified micelles significantly  
28  
29 14 improved the efficacy compared to the micelles without cholesterol (**Figure 8C**).<sup>41</sup> PMs having their core  
30  
31 15 crosslinked *via* reduction-sensitive disulfide bonds by using cyclic-RGD peptide-modified PEG-poly(L-  
32  
33 16 Lysine-thiol) copolymers (cRGD-PEG-P(Lys(SH))) showed improved stability compared to PMs  
34  
35 17 prepared from PEG-P(Lys) block copolymers. Moreover, by adding a hydrophobic layer of  
36  
37 18 thermoresponsive blocks into these micelles just by mixing with poly(N-isopropylacrylamide)-  
38  
39 19 poly(lysine-thiol) (PNIPAM-P(Lys(SH))) copolymers at a temperature below the lower critical solution  
40  
41 20 temperature (LCST) of PNIPAM and then incubating the micelles at physiological temperature, it was  
42  
43 21 possible to further improve the bioavailability of polyion complex micelles 3-orders of magnitude higher  
44  
45 22 compared to PMs prepared from PEG-P(Lys) block copolymers.<sup>179</sup> The enhanced stability of the PMs  
46  
47 23 from cRGD-PEG-P(Lys(SH))/PNIPAM-P(Lys(SH)), as well as the tumor targeting by the cRGD ligand  
48  
49 24 on the surface of the PMs improved the mRNA accumulation in a mouse model of glioblastoma.<sup>173</sup>  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 1 Besides crosslinking and increasing the hydrophobicity of the core, the stability of PMs could  
4  
5 2 be enhanced by improving the affinity of the polymers to the mRNA. In this regard, controlling the  
6  
7 3 rigidity of the main chain of the cationomers could provide a straightforward approach for promoting the  
8  
9 4 stability of mRNA-loaded PMs. In fact, molecular dynamics simulations have shown that polycations  
10  
11 5 with higher flexibility may have stronger binding to DNA and double stranded RNAs (dsRNAs) by  
12  
13 6 increasing the entropic gain through water release.<sup>180</sup> We have recently demonstrated this possibility by  
14  
15 7 using 2 cationomers having similar structure, except for their polycation backbone, *i.e.* the standard PEG-  
16  
17 8 P(Lys) bearing a relatively rigid polycation backbone composed of peptide bonds and PEG-poly(glycidyl  
18  
19 9 butylamine) (PEG-PGBA) block copolymer, which has a relatively flexible polycation block comprised  
20  
21 10 of a polyether backbone (**Figure 8D**).<sup>181</sup> While both copolymers spontaneously formed PMs after mixing  
22  
23 11 with mRNA in aqueous conditions, PMs made from PEG-PGBA required less polymers to stabilize the  
24  
25 12 micelle structure. By isothermal titration calorimetry measurements (**Figure 8D**), PEG-PGBA was found  
26  
27 13 to have 50-fold higher binding to mRNA than PEG-P(Lys) due to the decreased in the binding enthalpy  
28  
29 14 and the increase in the binding entropy, which leads to lower Gibbs free energy and enhanced the binding  
30  
31 15 affinity to mRNA (**Figure 8D**). The stronger binding of PEG-PGBA resulted in PMs with significantly  
32  
33 16 enhanced the protection against enzymatic attack and disassembly by polyanions. The PMs from PEG-  
34  
35 17 PGBA showed higher intracellular delivery of mRNA, resulting in higher protein translation *in vitro* and  
36  
37 18 *in vivo*. When systemically injected, the PMs from PEG-PGBA were able to circulate in the bloodstream  
38  
39 19 longer time than the PMs from PEG-P(Lys).

40  
41  
42 20 These observations indicate the possibility to construct stable and functional mRNA-loaded  
43  
44 21 PMs for systemic applications through precise control of the chemical structure of the cationomers. Such  
45  
46 22 nanomedicine platforms could allow guiding mRNA molecules into hard to reach tissues and cells for  
47  
48 23 eliciting unprecedented therapies. The development of such advanced PM formulations will be associated  
49  
50 24 with systems capable of enduring harsh *in vivo* settings, promoting extravasation in through the blood  
51

### 36 37 38 39 40 17 **3.6. Exosomes**

41  
42 18 In the search for biocompatible mRNA delivery systems, exosomes secreted by almost cell types have  
43  
44 19 been proposed as biological nanocarriers (Reviewed in <sup>182, 183</sup>). Exosomes are 50-150 nm vesicles  
45  
46 20 originating from the fusion of multivesicular bodies with the plasma membrane.<sup>184</sup> These vesicles are a  
47  
48 21 means of exchanging proteins, lipids and nucleic acids between producing and receiving cell types<sup>182</sup>  
49  
50 22 with as much as 1, 300 different mRNAs in mast cell-derived exosomes.<sup>185</sup> Thanks to their cellular origin,  
51  
52 23 the surface of exosomes presents membrane proteins, transmembrane proteins and immunoglobulins  
53  
54 24 which are “don't eat me” signals decreasing their clearance from the circulation.<sup>186, 187</sup> In addition, these

1  
2  
3 1 endogenous membrane proteins promote their fusion with cells allowing intracellular delivery of  
4  
5 2 cargo.<sup>182, 188</sup> Nucleic acids can be loaded in exosomes either indirectly or directly. For indirect loading,  
6  
7 3 cells are transfected with nucleic acids before isolation of exosomes: transfection using pDNA to obtain  
8  
9 4 mRNA-loaded exosomes. For direct loading, purified exosomes in suspension are electroporated with  
10  
11 5 nucleic acids, this method is called bulk electroporation (BEP). Cell-derived exosomes are isolated and  
12  
13 6 purified from conditioned media of cells transfected with pDNA coding the desired mRNA or from  
14  
15 7 biological (e.g. blood) by ultracentrifugation or sucrose gradient ultracentrifugation and then stored at -  
16  
17 8 80 °C until use.<sup>182</sup>

19  
20  
21 9 To decrease the expression of delivered mRNA in undesired tissues, Sun *et al.* applied tissue-  
22  
23 10 specific miRNA-controlled mRNA expression to exosome borne mRNA as an alternative to tissue  
24  
25 11 targeting.<sup>189</sup> In their system, the mRNA IRES contains two specific miRNA binding sites and binding of  
26  
27 12 the miRNA induces a conformational change resolving tertiary structures inhibiting translation. Using  
28  
29 13 luciferase mRNA harboring miR-21 binding sites they reported a 6-fold increase in luciferase expression  
30  
31 14 in the presence of miR-21. They later moved to adipocyte-targeted expression. They produced exosomes  
32  
33 15 by transfection of HEK293T packaging cells with a plasmid coding PGC1 $\alpha$  (Peroxisome proliferator-  
34  
35 16 activated receptor Gamma Coactivator 1  $\alpha$ ) harboring two miR-148 binding sites. PGC1 $\alpha$  is an essential  
36  
37 17 transcription factor for fat browning<sup>190</sup> and miR-148 an adipose tissue specific miRNA.<sup>191</sup> Exosomes  
38  
39 18 isolated from cell culture media contained 50-70 mRNA copies per 100 exosomes. Exosomes were  
40  
41 19 intravenously injected to fat diet-induced obesity mice and they proved that PGC1 $\alpha$  expression was  
42  
43 20 increased in adipose tissue but not in liver and lungs, common off-target accumulation organs of  
44  
45 21 exosomes after intravenous injection. Moreover, overexpression of PGC1 $\alpha$  in adipocytes promoted fat  
46  
47 22 browning suggesting promising applications for obesity therapy.

48  
49 23 Using microfluidics and multiple transfections, Yang *et al.* were able increase the production  
50  
51 24 of mRNA-loaded exosomes and decorate them with a targeting peptide for anti-glioma therapy.<sup>192</sup> They

1  
2  
3 1 developed a microfluidic cellular nanoporation biochip (CNP) where pDNA enters cells through 500 nm  
4  
5 2 channels at the bottom and secreted exosomes are collected from the top, followed by isolation using  
6  
7 3 sequential ultracentrifugation. As secretion of exosomes is a stress response, they compared exosome  
8  
9 4 production after stress by starvation, hypoxia, heat or electrical pulses. Electrical pulses generated 10-  
10  
11 5 fold more exosomes than all the other stress signals with a maximal secretion of 150 exosomes per 10<sup>4</sup>  
12  
13 6 mouse embryonic fibroblasts (MEFs) at 200V. Using a plasmid coding the tumor suppressor PTEN  
14  
15 7 (Phosphatase and TENsin homolog) and RT-qPCR quantitation, they demonstrated that exosomes  
16  
17 8 produced by CNP and electrical pulses stimulation contained 1,000-fold more intact mRNA over BEP  
18  
19 9 cells or Lipofectamine 2000<sup>®</sup>-transfected cells. To target glioma cells, they used a CDX-CD47 plasmid  
20  
21 10 coding the glioma targeting peptide CDX<sup>193</sup> fused to the N terminus of the exosome-enriched  
22  
23 11 transmembrane protein CD47 to produce targeted exosomes (Exo-T). Adding the CDX-CD47 plasmid  
24  
25 12 resulted in the production of PTEN mRNA-loaded Exo-T harboring the CDX peptide on their external  
26  
27 13 surface. Presence of the targeting peptide increased cellular uptake and PTEN expression in murine U87  
28  
29 14 glioma cells over untargeted exosomes. Finally, intravenously injected Exo-T were able to cross the  
30  
31 15 blood-brain barrier and accumulate in mice brain leading to superior tumor growth inhibition and  
32  
33 16 extended survival of mice bearing orthotopic gliomas compared to untargeted exosomes. As CNP  
34  
35 17 improve the yield of mRNA loading in exosomes using a microfluidic platform and versatile targeting  
36  
37 18 can be implemented using a CD47 fusion plasmid, this technology shows high translational potential for  
38  
39 19 exosomal mRNA targeted delivery.  
40

## 49 21 **4. Applications**

### 50 22 **4.1. Vaccination**

51 23 Early applications of mRNA have been focused to the development of vaccines. This is because mRNA  
52  
53 24 presents several advantages for eliciting potent immunization, as well as the potential to fast and cheap  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 1 processing and easy handling.<sup>3</sup> Moreover, as variety of antigens can be encoded in the mRNA sequence,  
4  
5 2 it is possible to utilize the same carrier platform for eliciting effective immunization against a wide-range  
6  
7 of diseases. The carriers used for mRNA vaccination are designed to deliver the antigen-encoding mRNA  
8 3  
9 molecules to antigen presenting cells (APCs). Inside the APCs the mRNA molecules produce proteins  
10 4  
11 that are processed into peptide epitopes for presentation through the major histocompatibility complex  
12 5  
13 (MHC) class I. The efficiency of the immunization will depend on several aspects, including the route  
14 6  
15 of vaccination, the cellular targeting, and the translation efficiency and the toxicity of the carrier.  
16 7  
17  
18  
19 8

#### 21 9 **4.1.1. Carrier development for mRNA vaccines**

24 10 Among various mRNA carriers for mRNA vaccines, LNPs are most vigorously studied. In the  
25  
26 11 researches introduced in *Section 3.1*, LNP development was mainly directed to maximizing its protein  
27  
28 12 expression potential. Meanwhile, some researches optimized LNP formulations based on its vaccination  
29  
30 capability. Oberli *et al.* ranked LNPs on their ability to induce ovalbumin (OVA)-specific T cells 7 days  
31 13  
32 after subcutaneous injection.<sup>140</sup> They compared several ionizable lipids (C12-200, cKK-E12 and  
33 14  
34 503O13) and positively charged lipids combined with a lipid-anchored PEG, cholesterol and a helper  
35 15  
36 lipid (DSPC or DOPE). The best formulation, B11, was composed of cKK-E12/DOPE/Chol/C14-  
37 16  
38 PEG2000 (10/15/26/40.5/2.5 mol %) and induced 4.2 % OVA-specific T cells. Therapeutic vaccination  
39  
40 17  
41 of mice harboring established B16-F10 melanoma with B11 LNPs prepared with TRP2 (Tyrosinase  
42 18  
43 Related Protein 2) and gp100 (glycoprotein of 100 kDa) tumor antigen mRNAs extended their survival  
44 19  
45 compared to LNPs prepared with irrelevant mRNAs.  
46 20  
47  
48

49 21 Lutz *et al.* compared the vaccinal potency of LNPs to licensed influenza vaccines in non-human  
50  
51 22 primates.<sup>194</sup> They prepared LNPs using the ionizable lipid L319, DSPC, cholesterol and PEG-DMG at a  
52  
53 molar ratio of 555:10:32.5:2.5. They showed that intramuscular vaccination of cynomolgus monkeys  
54 23  
55 with LNPs formed with mRNA encoding the hemagglutinin antigen from the pandemic influenza strain  
56 24  
57

1  
2  
3 1 H1N1pdm09 induced functional antibody titers above protective levels for 5 months after vaccination.  
4  
5 2 Antibody titers were comparable to those obtained after vaccination of monkeys with the licensed Flud  
6  
7  
8 3 vaccine. In addition, the LNP vaccine induced antigen-specific CD4 and CD8 T cells which were absent  
9  
10 4 in the Flud<sup>®</sup> group.

11  
12 5 To advance the application of mRNA-LNP vaccines, the Coalition for Epidemic Preparedness  
13  
14 6 innovations initiated a partnership agreement worth up to US\$ 34 million with the German mRNA  
15  
16  
17 7 vaccine company Curevac to develop a downscaled and transportable facility called RNA Printer for the  
18  
19 8 production of several grams of mRNA LNPs in a few weeks. Altogether, these data show that the LNP  
20  
21 9 technology is a powerful and biocompatible mRNA delivery platform and warrants clinical trials in the  
22  
23  
24 10 near future. As of now few mRNA LNPs are under phase 1 clinical trial for several applications: SARS-  
25  
26 11 CoV-2 Infection (NCT04283461 in USA and BNT162 in Europe), a phase 1 melanoma trial (mRNA-  
27  
28 12 4157) and a phase 1 trial in several cancers (NCI-4650), phase 1 against cystic fibrosis (NCT03375047).

29  
30  
31 13 Besides LNPs, mRNA complexation with protamine, a small arginine-rich protein, provides a  
32  
33 14 promising platform.<sup>195</sup> Protamine/mRNA complex functions as an immunostimulatory adjuvant, by  
34  
35 15 stimulating TLR7 signaling. While tight complexation with protamine resulted in drastic reduction of  
36  
37  
38 16 protein translational capability of mRNA, translational efficiency was recovered by decreasing  
39  
40 17 protamine/mRNA ratio to prepare mixture of naked mRNA and protamine/mRNA complexes.<sup>196</sup> The  
41  
42 18 optimal formulation that balanced the properties of immunostimulation and protein translation was used  
43  
44 19 in clinical trials of vaccination against infectious diseases (NCT02241135),<sup>197</sup> and cancer  
45  
46 20 (NCT01915524).<sup>198</sup> While carriers were used in most researches of mRNA vaccine, even naked mRNA  
47  
48  
49 21 provided vaccination effects as described in the next section.

#### 51 52 53 54 23 **4.1.2. Route of vaccination**

55  
56 24 mRNA-based vaccines are usually administered through local or systemic injection depending

1  
2  
3 1 on the antigen expression localization requirements. Direct subcutaneous, intramuscular, or intradermal  
4  
5 2 injection of mRNA have been the main routes for vaccines directed to infectious diseases, while  
6  
7 3 intravenous injections are used when the systemic expression of antigens is required.  
8  
9

#### 10 4 11 12 5 *Intradermal*

13  
14 6 After intradermal delivery, mRNA-transfected resident DC need to migrate to lymph nodes to  
15  
16 7 present antigens to T cells and induce an adaptive immune response.<sup>199</sup> Intradermal injection of naked  
17  
18 8 mRNA resulted in the transfection of dermal DC with subsequent priming of antigen-specific CD8<sup>+</sup> T  
19  
20 9 cells.<sup>200</sup> Using fluorescently-labeled mRNA, authors could show mRNA expression occurred in the  
21  
22 10 dermis not the epidermis and, that dermal DCs and dermal macrophages internalized the mRNA.  
23  
24 11 Although mRNA was delivered to dermal DCs and macrophages to the same extent (5% mRNA positive  
25  
26 12 cells for both), using transgenic mice expressing the DC-specific integrin cD11c fused to the diphtheria  
27  
28 13 toxin receptor they could demonstrate that dermal DCs are the main contributor to mRNA expression in  
29  
30 14 the dermis. Internalization occurred *via* macropinocytosis as pre-conditioning the injection site with the  
31  
32 15 micropinocytosis inhibitor rottlerin dramatically decreased the expression of luciferase mRNA in the  
33  
34 16 dermis. Finally, T cell priming was reduced in rottlerin-treated animals confirming that intradermal  
35  
36 17 mRNA vaccination proceeds by macropinocytosis in dermal DCs. Feasibility of this administration route  
37  
38 18 for mRNA vaccine has already been demonstrated even in large animals, with mRNA LNP inducing the  
39  
40 19 production of antibodies against human immunodeficiency virus type 1 (HIV-1) in rhesus macaques.<sup>201</sup>  
41  
42  
43  
44  
45  
46  
47  
48

#### 49 21 *Intranodal*

50  
51 22 Because ultimately, the naked mRNA requires to reach a lymph node, some groups directly  
52  
53 23 inject the mRNA in the lymph nodes: by intranodal injection.<sup>46</sup> As the lymph nodes are rich in immune  
54  
55 24 cells, intranodal injection results in mRNA accumulation in both macrophages and dendritic cells,  
56  
57  
58  
59  
60

1  
2  
3 1 antigen-presenting cells capable of inducing an adaptive immune response.<sup>202</sup> However, in injections  
4  
5 2 need to be performed by highly-trained personnel: by surgically exposing the inguinal lymph node  
6  
7  
8 3 followed by injection and wound closure in mice,<sup>203</sup> by a radiologist guided by echography in inguinal  
9  
10 4 lymph nodes in humans.<sup>204</sup>

11  
12 5 Kreiter et al. compared the vaccine activity of naked mRNA administered by intranodal,  
13  
14 6 subcutaneous or intradermal routes in mice.<sup>205</sup> Using luciferase mRNA they showed highest  
15  
16  
17 7 bioluminescence after intranodal injection, 3-fold higher than intradermal injection at 16h whereas no  
18  
19 8 signal was detected after subcutaneous injection. By injecting mRNA coding the influenza antigen  
20  
21 9 hemagglutinin they reported that only intranodal injection led to the expansion of antigen-specific T cells  
22  
23  
24 10 both in lymph node, blood and spleen. Therapeutic evaluation as a preventive cancer vaccine  
25  
26 11 demonstrated superior survival of intranodally vaccinated mice over s.c. or i.d. vaccinated mice with s.c.  
27  
28 12 route offering no protection at all.

29  
30  
31 13 The same authors then evidenced that naked mRNA selectively accumulated in lymph node  
32  
33 14 DCs after intranodal injection *via* macropinocytosis highlighting the importance of this endocytic  
34  
35 15 pathway for naked mRNA vaccination both by intradermal and intranodal routes.<sup>202</sup>

36  
37  
38 16 Joe et al. compared intranodal mRNA vaccination to intramuscular pDNA vaccination against  
39  
40 17 influenza.<sup>203</sup> Intramuscular pDNA vaccination was used as a benchmark. mRNA vaccination induced  
41  
42 18 more antigen-specific cytotoxic T lymphocytes both in the lymph nodes and the spleen over pDNA.  
43  
44 19 Intranodal mRNA also partially protected mice from viral challenge.

45  
46  
47 20 Intranodal mRNA vaccination recently reached Phase 1 clinical trial in HIV patients.<sup>204</sup> HIV  
48  
49 21 patients received three intranodal doses of mRNA coding HIV immunogen sequences. This vaccine was  
50  
51 22 well tolerated in patients and induced a moderate HIV-specific T cell response supporting the ongoing  
52  
53  
54 23 Phase 2 clinical trial.

### 1 *Intravenous*

2  
3  
4  
5 2 Successful outcomes obtained by intranodal administration provided proof of concept to the  
6  
7  
8 3 strategy of targeting lymphoid organs for effective vaccination. Intravenous administration allows for  
9  
10 4 targeting multiple lymphoid organs throughout the body, with an easier and less invasive procedure,  
11  
12 5 compared to intranodal administration. While uptake of mRNA carriers by reticuloendothelial system  
13  
14 6 typically induced negative influence on their application to disease treatment, this process provides  
15  
16  
17 7 beneficial outcomes in mRNA vaccine. After intravenous administration of cationic mRNA LNPs based  
18  
19 8 on DOTAP, efficient protein expression was obtained in CD11<sup>+</sup> antigen presenting cell in the spleen.<sup>206</sup>  
20  
21 9 In addition, this formulation activated APCs in several organs, including the spleen, liver, bone marrow  
22  
23  
24 10 and lymph nodes. As a result, intravenous administration of the LNPs loading model antigen mRNA  
25  
26 11 induced enhanced cellular immunity compared to their intradermal and subcutaneous administration.  
27  
28 12 Another group also demonstrated the advantage of intravenous administration over intramuscular and  
29  
30  
31 13 subcutaneous administration, using negatively charged mRNA LNPs based on lipofectamine RNAi  
32  
33 14 Max.<sup>207</sup> Several reports attempted to improve the efficacy of intravenous mRNA vaccination by  
34  
35 15 introducing (tri-)mannose ligands to LNPs for targeting dendritic cell,<sup>208, 209</sup> or by incorporating lipid-  
36  
37  
38 16 based immunostimulatory adjuvant to LNPs.<sup>210</sup> In another report,  $\alpha$ -galactosylceramide was co-  
39  
40 17 encapsulated to LNPs with mRNA encoding tumor antigens to activate natural killer T cells, leading to  
41  
42 18 improved efficiency of cancer vaccines.<sup>211</sup>  
43

44  
45 19 Intravenous mRNA vaccination was tested also in patients with advanced malignant melanoma,  
46  
47 20 in a phase I clinical trial. In the study, LNPs with various surface charges were prepared by tuning  
48  
49 21 LNP/mRNA mixture ratio, for optimization in animal experiments. As a result, LNPs with slightly  
50  
51 22 negative charge induced efficient protein expression from mRNA in the spleen, bone marrow and lymph  
52  
53  
54 23 nodes, with histological observation showing efficient protein expression in dendritic cells. This  
55  
56 24 formulation showed efficient anti-tumor activity in several mouse models, and successfully induced  
57

1  
2  
3 1 antigen-specific T cell responses in a clinical trial.<sup>116</sup> A subsequent study indicated successful immune  
4  
5 2 activation in the spleen of patients, using [<sup>18</sup>F]Fluoro-2-deoxy-2-D-glucose positron emission  
6  
7 3 tomography (FDG-PET).<sup>212</sup> The same group recently used this LNP formulation to potentiate chimeric  
8  
9 4 antigen receptor (CAR)-T cell therapy against solid tumor in an animal study.<sup>213</sup> In many cases of CAR-T  
10  
11 5 cell therapy against solid tumors, CAR-T cells are inactivated rapidly after transplantation due to low  
12  
13 6 accessibility to target cells, leading to reduced proliferative signal in CAR T cells. To solve this problem,  
14  
15 7 mRNA expressing cancer antigen that CAR-T cells target was administered using LNPs to obtain its  
16  
17 8 expression in APCs throughout lymphoid tissues in the body. Through interaction with APCs expressing  
18  
19 9 the cancer antigen, CAR-T cells proliferated with preserved activity, thereby inducing efficient anti-  
20  
21  
22  
23  
24 10 cancer effect in mouse models.  
25  
26  
27  
28  
29

### 30 12 **4.1.3. saRNA vaccines**

31 13 saRNA vaccines were first used in the form of Virus RNA Particles (VRPs).<sup>214, 215</sup> In VRPs the  
32  
33 14 structural proteins have been replaced by the antigen, they are provided *in trans* in packaging cells to  
34  
35 15 produce replication-defective VRPs.<sup>215, 216</sup> As reviewed previously,<sup>216</sup> alphavirus-based VRPs showed  
36  
37 16 promising results, among which protection against Meta pneumonia virus, respiratory syncytial virus and  
38  
39 17 dengue in primates.<sup>217, 218</sup> However, VRPs face the same biosafety and production limits as viral  
40  
41  
42 18 vectors.<sup>219</sup>  
43  
44

45 19 Synthetic saRNA has been developed as an alternative to VRPs and, since synthetic saRNA do  
46  
47 20 not use packaging cells delivery systems are required. Delivery of saRNA faces the size challenge of  
48  
49 21 saRNA: as saRNA code for the replicase and the antigen(s) they are longer than mRNA: 10, 000 nt vs  
50  
51 22 1,000 nt for mRNA. Despite this increased length saRNA are produced by *in vitro* transcription from a  
52  
53  
54 23 DNA template with yields similar to mRNA.<sup>39</sup>  
55

56 24 Because synthetic saRNA are more recent than mRNA, fewer formulations have been  
57  
58  
59  
60

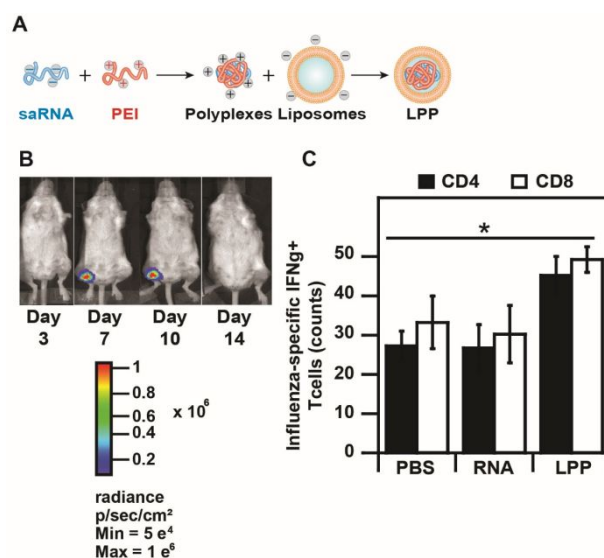

1  
2  
3 1 developed for their delivery.<sup>56, 104, 220</sup> saRNA has been used for vaccination both by intradermal injection  
4  
5 2 of naked or complexed saRNA followed by electroporation<sup>74</sup>, as intramuscular injection of saRNA  
6  
7 3 lipopolyplexes<sup>39</sup>, intramuscular injection of saRNA complexes with dendrimers.<sup>69</sup> In these studies,  
8  
9 4 saRNA demonstrated higher expression and extended duration of expression over mRNA.<sup>66, 67, 71</sup> A few  
10  
11 5 examples will be detailed.

12  
13  
14 6 Vogel et al. used PEI polyplexes to deliver saRNA coding an influenza antigen.<sup>66</sup> Using  
15  
16 7 luciferase reporter gene they evidenced extended saRNA expression after intramuscular injection of  
17  
18 8 polyplexes over mRNA polyplexes with an expression delay of saRNA attributable to the necessary  
19  
20 9 production of replicase, minus strand RNA and translation of minus strand RNA. saRNA gave equivalent  
21  
22 10 protection as mRNA at 64-fold lower dose. Moreover, combining saRNA coding hemagglutinin from  
23  
24 11 three strains of influenza protected against sequential viral challenges. They later reported the induction  
25  
26 12 of CD4 and CD8 specific T cells against conserved HIV-1 regions after vaccination with saRNA  
27  
28 13 polyplexes.<sup>221</sup> These results validate the versatility and therapeutic potential of saRNA polyplexes.

29  
30  
31  
32  
33 14 A dendrimer platform has been used for multipurpose intramuscular saRNA vaccination.<sup>69, 222</sup>  
34  
35 15 VEEV-derived saRNA was complexed using Modified Dendrimer Nanoparticles (MDNPs) into c.a. 100  
36  
37 16 nm stable in human serum. Intramuscular injection of MDNPs resulted in the induction of antigen-  
38  
39 17 specific T cells *in vivo*. Interestingly, when authors injected MDNPs prepared with luciferase saRNA,  
40  
41 18 they reported an increase in luciferase activity between 36 h and 60 h post injection suggesting *in situ*  
42  
43 19 replication of the saRNA. MDNPs formed with antigen-coding saRNA protected against lethal influenza  
44  
45 20 challenge, ebola virus, Zika virus and *Toxoplasma gondii*.<sup>69, 222</sup>

46  
47  
48  
49 21 We introduced neutral targeted lipopolyplexes (LPP) for the delivery of VEEV-derived saRNA  
50  
51 22 to dendritic cells.<sup>39</sup> Here, saRNA was first complexed in positively-charged polyplexes using PEI  
52  
53 23 (polyethylenimine) before interaction with anionic PEGylated liposomes to form neutral LPP (**Figure**  
54  
55 24 **9A**). A mannosylated lipid (16:0 PA-PEG3-mannose 1,2-dipalmitoyl-sn-glycero-3-phospho((ethyl-

1 1',2',3'-triazole)triethyleneglycolmannose) was included in liposomes to engage the mannose receptor on  
 2 dendritic cells.<sup>158, 159</sup> LPP were capable of transfecting a murine dendritic cell line *in vitro*. Intramuscular  
 3 injection of LPP prepared with luciferase saRNA resulted in durable expression in the quadriceps (**Figure**  
 4 **9B**). Vaccination with LPP formed with saRNA coding influenza antigens led to the induction of antigen-  
 5 specific CD4 and CD8 T cells (**Figure 9C**). Another benefit of using saRNA, particularly saRNA derived  
 6 from Venezuelan equine encephalitis virus has another advantage as the non-structural proteins also  
 7 inhibit type I IFN signaling.<sup>74, 223</sup>

9 **Figure 9. Formation of LPP-saRNA and activity *in vivo*.** **A.** To form neutral Lipopolyplexes, saRNA  
 10 is first complexed with branched PEI to form positively charged polyplexes. Then, positively charged  
 11 polyplexes are mixed with anionic liposomes resulting in the formation of neutral LPP. **B.** Intramuscular  
 12 injection of LPP- luciferase saRNA complexes allowed sustained expression *in vivo*. **C.** Vaccination of  
 13 mice by intramuscular injection of LPP- hemagglutinin saRNA induced antigen-specific IFN- $\gamma$  secreting  
 14 cells with superior immunogenicity over naked RNA or unvaccinated mice. Adapted with permission  
 15 from reference <sup>39</sup>. Copyright 2019 Elsevier.

## 1 2 3 1 **4.2 Protein replacement therapy**

4  
5 2 Alongside with vaccine, mRNA delivery was widely used for supplying therapeutic peptides  
6  
7  
8 3 or proteins, which is called as protein replacement therapy. As early as 1992, *in vivo* protein replacement  
9  
10 4 therapy was reported, in which vasopressin mRNA was injected to hypothalamus of model rats that lacks  
11  
12 5 vasopressin expression, to treat diabetes insipidus.<sup>224</sup> However, over 20 years after the report, therapeutic  
13  
14 6 application of mRNA was focused on vaccine and immunotherapy, with very few reports addressing the  
15  
16  
17 7 potential of mRNA for protein replacement. A major challenge for mRNA-based protein replacement is  
18  
19 8 the control of mRNA immunogenicity, as inflammatory responses after mRNA delivery would hamper  
20  
21  
22 9 the therapeutic processes and pose safety concerns. This is in sharp contrast to the cases of vaccine and  
23  
24 10 immunotherapy, in which induction of innate immune responses is essential to obtain preventive or  
25  
26 11 therapeutic outcomes. To control mRNA immunogenicity, various techniques have been developed.  
27  
28 12 Among them, replacement of mRNA nucleosides with chemical modified species, such as m5C, t2C,  
29  
30  
31 13 ΨU and m1ΨU, is the most common approach, which inhibits the recognition of mRNA by innate  
32  
33 14 immune receptors (see *Section 2.1.4* for detail).<sup>54, 110</sup> High performance liquid chromatography (HPLC)  
34  
35 15 purification to remove dsRNA contaminants was also reported to be effective in reducing mRNA  
36  
37  
38 16 immunogenicity.<sup>225</sup> Along with these approaches focusing on mRNA, fine-tuned designing of mRNA  
39  
40 17 carriers allows for the inhibition of mRNA recognition by immune receptors. After encapsulation of  
41  
42 18 mRNA into PEGylated polymeric micelles (PMs), its recognition by TLR7 in endosome was suppressed,  
43  
44  
45 19 presumably through steric repulsive effect of PEG, leading to efficient *in vivo* delivery of mRNA with  
46  
47 20 minimal inflammatory responses (see *Section 3.5* for detail).<sup>40, 174</sup> Notably, even without mRNA  
48  
49 21 chemical modification and HPLC purification, mRNA PMs exhibited successful outcome in tissue  
50  
51  
52 22 regenerative treatment to several diseases in model animals, such as osteoarthritis, intravertebral disc  
53  
54 23 disease and spinal cord injury.<sup>226-228</sup> Such immune regulation approach without relying on mRNA  
55  
56 24 chemical modification is practically important, because mRNA chemical modification often leads to

1  
2  
3 1 impaired translational activity, compromising therapeutic potential of mRNA.<sup>61-63, 229</sup>

4  
5 2 These technology advances for alleviating mRNA immunogenicity opened the door for mRNA  
6  
7  
8 3 application to protein replacement therapy. In the past decade, numerous reports demonstrated the  
9  
10 4 potential of mRNA for this therapeutic approach, with following 5 fields vigorously pursued: (1) Single  
11  
12 5 gene disorder treatment using mRNA encoding deficient genes, e.g. treatment of lung surfactant protein  
13  
14 6 deficiency,<sup>110</sup> hemophilia,<sup>230</sup> cystic fibrosis,<sup>231, 232</sup> ornithine transcarbamylase deficiency,<sup>233</sup> acute  
15  
16  
17 7 intermittent porphyria,<sup>234</sup> Fabry disease,<sup>235</sup> and acute intermittent porphyria;<sup>236</sup> (2) Production of  
18  
19 8 antibody, including single chain antibody (scFv),<sup>237</sup> whole antibody,<sup>238-240</sup> and bi-specific antibody,<sup>241</sup>  
20  
21 9 targeting amyloid deposition, toxin, infectious diseases, and cancers; (3) Tissue repair and regeneration  
22  
23  
24 10 using growth factors,<sup>227, 242-244</sup> and transcriptional factors;<sup>226, 227</sup> (4) Cellular reprogramming (see *Section*  
25  
26 11 *4.3*); (5) Cancer therapy (see *Section 4.4*).

27  
28 12 While details of these applications were extensively reviewed elsewhere,<sup>1, 245-247</sup> here, we  
29  
30  
31 13 discussed therapeutic application of mRNA, by focusing on following 3 advantages of mRNA over DNA  
32  
33 14 in protein replacement therapy. (1) mRNA provides earlier onset of protein expression compared to DNA,  
34  
35 15 because mRNA does not require the processes of nuclear transport and transcription for protein  
36  
37  
38 16 production (**Figure 10A**).<sup>40, 248</sup> This time-dependent protein expression profile of mRNA is attractive for  
39  
40 17 targeting acute diseases. (2) Duration of protein expression from mRNA is at most one week, allowing  
41  
42 18 the use of mRNA to express therapeutic factors that would induce detrimental effects after prolonged  
43  
44  
45 19 expression. (3) mRNA tends to induce protein expression in higher percentage of target cells compared  
46  
47 20 to DNA (**Figure 10B**), presumably because nuclear entry of DNA becomes a barrier for protein  
48  
49 21 expression in a large percentage of cells.<sup>176, 248</sup> In the use of gene expressing secreted factors, their  
50  
51 22 expression in a small percentage of the target cells is sufficient for obtaining therapeutic outcome,  
52  
53  
54 23 because untransfected cells also receives therapeutic factors secreted from transfected cells. On the  
55  
56 24 contrary, in the delivery of genes encoding intracellular factors, untransfected cells would obtain less

1 beneficial effect compared to transfected cells. Thus, mRNA is a more suitable option in this case,  
 2 because of its capability to induce protein expression in a large percentage of cells (**Figure 10B**).

**Figure 10. Comparison of mRNA and pDNA delivery.** A. Time dependent protein expression profile.

PEG-PAsp(DET)-based polyplex micelles (PMs, see *Section 3.5.*) loading luciferase mRNA or pDNA

were injected to cerebrospinal fluid (CSF) of rats, followed by measurement of luciferase levels in CSF.

The figure is adapted from [In Vivo Messenger RNA Introduction into the Central Nervous System Using](#)

[Polyplex Nanomicelle](#) by S. Uchida, *et al.*<sup>40</sup> to show pDNA and mRNA. The figure is licensed under

<https://creativecommons.org/licenses/by/2.0/>. B. Tissue distribution of protein expression from mRNA

1 (upper panels) and pDNA (lower panels). Left panels: GFP expression in mouse liver observed 24 h after  
2 hydrodynamic injection of PMs loading GFP mRNA or pDNA. Green: GFP, Blue: cell nuclei (DAPI).  
3 Scale bar: 100  $\mu\text{m}$ . The figure is adapted from [Messenger RNA-based therapeutics for the treatment of](#)  
4 [apoptosis-associated diseases](#) by A. Matsui *et al.*<sup>176</sup> to show the difference between mRNA and pDNA.  
5 The figure is licensed under <https://creativecommons.org/licenses/by/4.0/>. Middle panels: Therapy using  
6 gene encoding secreted proteins. Protein expression in a small percentage of the target cells is sufficient  
7 for obtaining therapeutic outcome, because untransfected cells also receives therapeutic factors secreted  
8 from transfected cells. Left panels: Therapy using gene encoding intracellular proteins. Protein  
9 expression in a large percentage of the cells is required for therapy, as untransfected cells typically failed  
10 to receive therapeutic effects. C. Primary hepatocytes were transfected with Bcl-2 mRNA or pDNA for  
11 measuring of Bcl-2 protein expression levels (left). Bcl-2 mRNA and pDNA showed comparable levels  
12 of Bcl-2 protein expression from day 1 to day 2 after the transfection (highlighted with gray). In this  
13 period, cell death was induced by deprivation of oxygen and glucose. Bcl-2 mRNA showed enhanced  
14 pro-survival effect compared to Bcl-2 pDNA, although total Bcl-2 expression levels were comparable  
15 between these two groups. This result highlights the importance of obtaining Bcl-2 expression in a large  
16 percentage of cells. Reprinted with permission from reference<sup>249</sup>. Copyright 2018 Elsevier. D. Treatment  
17 of mouse model of fulminant hepatitis using Bcl-2 mRNA and pDNA. Liver sections 4 h post-treatment.  
18 Red: apoptotic cells (TUNEL). Blue: cell nuclei (DAPI). Scale bar: 100  $\mu\text{m}$ . The figure is adapted from

9  
10 4  
11  
12 5 These three advantages of mRNA provide strong rationale for the use of mRNA in some  
13  
14 6 therapeutic settings. For example, the treatment of acute myocardial infarction using *vascular endothelial*  
15  
16 7 *growth factor (VEGF)-A* mRNA utilized the advantages (1) and (2).<sup>242</sup> While both of *VEGF-A* mRNA  
17  
18 8 and plasmid DNA (pDNA) were effective in reducing infarct area through their angiogenic effects, only  
19  
20 9 mRNA improved the survival of model animals. Surprisingly, *VEGF-A* pDNA decreased the survival  
21  
22 10 even when compared to control groups, due to edema caused by prolonged VEGF-A expression. Thus  
23  
24 11 transient protein expression profile of mRNA was advantageous in this application.

25  
26 12 mRNA delivery is also a preferable method to introduce pro-survival genes, as DNA-based  
27  
28 13 introduction might cause prolonged expression of pro-survival factors after genomic integration of the  
29  
30 14 gene, which is cancer promoting. In our previous report, mRNA encoding Bcl-2, an intracellular pro-  
31  
32 15 survival factor, was used for the treatment of acute hepatitis in mouse model, which utilizes 3 advantages  
33  
34 16 of mRNA described above.<sup>176</sup> When *Bcl-2* mRNA and pDNA was introduced *in vitro* to primary  
35  
36 17 hepatocytes treated with cell death stimuli, mRNA provided enhanced pro-survival effects to hepatocytes  
37  
38 18 compared to pDNA (**Figure 10C**).<sup>249</sup> The enhanced potential of *Bcl-2* mRNA is attributed to its  
39  
40 19 capability to provide Bcl-2 protein expression and pro-survival effects to a larger percentage of cells  
41  
42 20 compared to *Bcl-2* pDNA. As a result, in the treatment of acute hepatitis, mRNA showed enhanced anti-  
43  
44 21 apoptotic effect in the liver compared to pDNA (**Figure 10D**). Along with such *in vivo* administration,  
45  
46 22 *Bcl-2* mRNA is applicable for *ex vivo* administration to improve the engraftment efficiency after cell  
47  
48 23 transplantation therapy<sup>249</sup>. In hepatocyte transplantation to mouse liver, *ex vivo Bcl-2* mRNA introduction  
49  
50 24 provided up to 5-fold increase in the hepatocyte engraftment efficiency with improved outcome in liver  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 1 functional support to mouse model of chronic hepatitis. Together, *Bcl-2* mRNA provides a safe and  
4  
5 2 effective option to prevent cell death in a variety of therapeutic settings.  
6  
7  
8 3

### 10 4 **4.3 Cell reprogramming**

12 5 mRNA therapeutics also provide an excellent tool for converting cell fates, *i.e.* generation of  
13  
14 6 induced pluripotent cells (iPSCs), differentiation of stem cells, direct reprogramming, and genome  
15  
16  
17 7 editing, with several advantages over the other commonly used methods, such as the use of viral gene  
18  
19 8 transduction.<sup>252, 253</sup> iPSCs were firstly generated using retrovirus gene vectors,<sup>254</sup> which cause random  
20  
21 9 integration of the encapsulated genes into host genome. Genomic integration may result in the activation  
22  
23  
24 10 of oncogenes near the integration sites, as reported in a clinical trial.<sup>255</sup> Moreover, prolonged expression  
25  
26 11 of Yamanaka factors after genomic integration may hamper differentiation of iPSCs and also cause tumor  
27  
28 12 formation.<sup>256-258</sup> Although adenovirus vectors and non-viral pDNA transfection also allowed iPSC  
29  
30  
31 13 generation in a manner less prone to cause genomic integration,<sup>259, 260</sup> thorough examination of genome  
32  
33 14 sequence of iPSCs would still be required before clinical usage, to check the genomic integration, which  
34  
35 15 occurs at certain rates after introduction of adenovirus vector and pDNA.<sup>261, 262</sup> This issue of genomic  
36  
37  
38 16 integration also poses problems in gene transfection for stem cell differentiation, direct reprogramming,  
39  
40 17 and genome editing. On the contrary, mRNA delivery would provide a safer option to cell  
41  
42 18 reprogramming. In addition, transient protein expression profile of mRNA allows precise temporal  
43  
44  
45 19 control of protein expression, which is often needed for (trans-)differentiation of cells.

46  
47 20 For iPSC generation, repeated mRNA transfection is needed due to short duration of protein  
48  
49 21 expression from mRNA and relatively short intracellular half-life of transcriptional factor proteins. In  
50  
51 22 repeated transfection, toxicity of each transfection procedure should be minimized to preserve cell  
52  
53  
54 23 viability and obtain efficient and prolonged protein expression. Thus, in the first successful report of  
55  
56 24 mRNA-based iPSC generation, chemically modified mRNA with 100% substitution of C and U with  
57

1  
2  
3 1 5mC and ΨU was used with supplementation of B18R protein, a decoy receptor for type I interferon, to  
4  
5 2 reduce immunogenicity of mRNA.<sup>263</sup> Further, 5' triphosphate of uncapped mRNA contaminants, a  
6  
7 3 potential substrate for an innate immune receptor, RIG-I, was enzymatically removed, and low oxygen  
8  
9 4 culture was performed to improve iPSC generation efficiency. In subsequent researches, this protocol  
10  
11 5 was modified to include additional reprogramming mRNA or micro RNA (miRNA).<sup>264, 265</sup> Despite these  
12  
13 6 advances, daily dosing of mRNA is still needed. To circumvent this troublesome procedure, self-  
14  
15 7 amplifying RNA (saRNA) encoding all four Yamanaka factors were employed (see *Section 2.2* for detail  
16  
17 8 about saRNA), which induced protein expression for more than a week.<sup>266</sup> With supplementation of  
18  
19 9 B18R protein to reduce immune responses, single administration of saRNA successfully generated iPSCs.

20  
21  
22  
23  
24 10 mRNA also demonstrated its potential for differentiation of stem cells. In the first report of  
25  
26 11 mRNA-based iPSC generation described above, *MyoD* mRNA transfection to iPSCs allowed their  
27  
28 12 differentiation to myotube.<sup>263</sup> Several reports succeeded in osteogenic differentiation of mesenchymal  
29  
30 13 stem cells (MSCs) *in vitro* using mRNA encoding *bone morphogenetic protein-2 (BMP-2)*, and also *in*  
31  
32 14 *vivo* bone regeneration after *BMP-2* mRNA delivery to the region of bone defect in animal models.<sup>243,</sup>  
33  
34 15 <sup>267</sup> Alongside with such *in vivo* delivery of differentiation factor mRNA, transplantation of cells after *ex*  
35  
36 16 *vivo* differentiation using mRNA transfection is a promising approach of regenerative therapy. As three-  
37  
38 17 dimensional (3D) culturing is a wide-spread method to potential cell transplantation therapy,<sup>268-270</sup> we  
39  
40 18 undertook *ex vivo* differentiation of 3D-cultured cells using mRNA. Interestingly, in osteogenic  
41  
42 19 differentiation of MSC spheroids using runt-related transcription factor 2 (*Runx2*), transfection of *Runx2*  
43  
44 20 mRNA exhibited improved outcomes compared to that of *Runx2* pDNA.<sup>251</sup> In mechanistic analysis using  
45  
46 21 a reporter gene, reporter protein expression efficiency from mRNA in MSC spheroids was higher than  
47  
48 22 that from pDNA (**Figure 10E**), while both of mRNA and pDNA induced comparable level of the protein  
49  
50 23 expression in MSCs in monolayer culture. This result is explained by the observation that MSCs in  
51  
52 24 spheroids showed lower rate of cell division compared to those in monolayer culture, and mRNA induced  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 1 more efficient protein expression in non-dividing cells compared to pDNA. This study demonstrated  
4  
5 2 additional advantage of mRNA over pDNA in transfection to 3D culture cells.  
6  
7

8 3 Various reports demonstrated the utility of mRNA for direct reprogramming, *e.g.* from  
9  
10 4 fibroblasts to hepatocyte-like cells,<sup>271</sup> endothelial progenitor cells,<sup>272</sup> neurons,<sup>273</sup> and neural precursor  
11  
12 5 cells,<sup>274</sup> from pancreatic exocrine cells to insulin-producing cells,<sup>275</sup> and from MSCs to neural stem  
13  
14 6 cells.<sup>276</sup> Notably, *in vivo* direct reprogramming to neurons was achieved by injection of 4 types of mRNA  
15  
16 7 to brain parenchyma, leading to alleviation of Parkinson's disease symptoms in mouse models.<sup>273</sup> Other  
17  
18 8 exciting targets of cell programming include hematopoietic and immune cells. In CAR-T cell therapy,  
19  
20 9 *Foxo1* mRNA was used to increase the fraction of central memory T cells before transplantation, which  
21  
22 10 resulted in improved anticancer activity of CAR T cells.<sup>277</sup> *Musashi-2* mRNA facilitated *ex vivo*  
23  
24 11 proliferation of hematopoietic stem cells (HSCs) without differentiation, which would solve the problem  
25  
26 12 of HSC shortage for clinical use.<sup>277</sup> Because prolonged overexpression of *Musashi-2* is cancer  
27  
28 13 promoting,<sup>278</sup> its transient expression using mRNA is desirable, as is the case in *Bcl-2* (see Section 4.2).<sup>176,</sup>  
29  
30 14 <sup>249</sup> Regulation of macrophage polarization attracts much attention in various therapeutic fields, with M1  
31  
32 15 macrophages desirable for cancer treatment, and M2 macrophages for tissue regeneration. Several reports  
33  
34 16 succeeded in M1-to-M2 and M2-to-M1 transition *in vivo*, providing a new tool for macrophage  
35  
36 17 polarization.<sup>279, 280</sup> Other interesting strategies of macrophage potentiation include mRNA-based  
37  
38 18 introduction of anti-microbial peptide in lysosome for treating bacterial infection.<sup>281</sup> In this strategy,  
39  
40 19 mRNA encodes anti-microbial peptide connected with a cathepsin B, which translocates the peptide to  
41  
42 20 lysosome after its translation in cytoplasm, and transplantation of the mRNA-treated macrophages was  
43  
44 21 effective in treatment of multidrug-resistant bacteria-induced sepsis in mice.  
45  
46  
47  
48  
49  
50

51 22 Genome editing is another promising strategy of cellular reprogramming. Transient protein  
52  
53 23 expression profile of mRNA is beneficial for genome editing, because prolonged expression increases  
54  
55 24 the rate of off-target genome cleavage.<sup>282</sup> In clinical trials, gene encoding *C-C chemokine receptor 5*  
56  
57  
58  
59  
60

1  
2  
3 1 (*CCR5*), a receptor for HIV entry, was disrupted *ex vivo* using zinc finger nucleases (ZFN) mRNA, for  
4  
5 2 making the transplanted cells resistant to HIV infection (ClinicalTrials.gov Identifier: NCT02500849,  
6  
7 3 NCT02225665). Recently, research focus was shifted to RNA-based delivery of clustered regularly  
8  
9 4 interspaced short palindromic repeat (CRISPR)/CRISPR-associated protein (Cas) 9. In co-delivery of  
10  
11 5 *Cas9* mRNA and single guide RNA (sgRNA), sgRNA was degraded in cytoplasm before translation of  
12  
13 6 sufficient amount of Cas9 protein, leading to reduced genome editing efficiency.<sup>283</sup> Intracellular  
14  
15 7 degradation of sgRNA was effectively prevented by chemical modification of sgRNA, which provided  
16  
17 8 a boost in genome editing efficiency.<sup>115, 284</sup> By *in vivo* co-delivery of *Cas9* mRNA and sgRNA, several  
18  
19 9 reports succeeded in the disruption of disease-related genes in the liver, such as *proprotein convertase*  
20  
21 10 *subtilisin/kexin (PCSK9)*, a target gene of familial hypercholesterolaemia,<sup>115, 285, 286</sup> *transthyretin (TTR)*,  
22  
23 11 a target gene of TTR amyloidosis,<sup>287</sup> and hepatitis B virus (HBV) DNA.<sup>288</sup> Notably, up to 60% of indel  
24  
25 12 in the liver was achieved even after single administration of *Cas9* mRNA and sgRNA,<sup>115, 286</sup> while  
26  
27 13 achieving such a high efficiency is difficult in pDNA delivery.<sup>289</sup> This may be partially attributed to  
28  
29 14 mRNA capability to induce protein expression in higher percentage of cells compared to pDNA  
30  
31 15 transfection (see *Section 4.2*).<sup>176, 248, 249</sup>

#### 4.4. Cancer

42 18 mRNA-based vaccines were the first application to be considered for using mRNA against  
43  
44 19 tumors.<sup>116, 290-293</sup> After the vaccination, the immune system can recognize cancer cells to elicit cell-  
45  
46 20 mediated antitumor responses. Thus, mRNA-based cancer vaccines can be directed to promote immunity  
47  
48 21 against tumor-associated antigens,<sup>294</sup> or against neoepitopes due to cancer mutations.<sup>295</sup> As the  
49  
50 22 neoepitope signature, *i.e.* mutanome, is exclusive for each patient and the mRNA molecules can encode  
51  
52 23 several neoantigen epitopes in their sequence, Sahin et al. proposed to use mRNA-based vaccines as  
53  
54 24 personalized therapeutics.<sup>295, 296</sup> This concept was demonstrated in first-in-human application by

1  
2  
3 1 immunizing metastatic melanoma patients against 10 epitopes.<sup>297</sup> This initial success has triggered  
4  
5 2 several clinical trials against melanoma and other tumors, as reviewed elsewhere.<sup>3</sup>  
6  
7

8 3 mRNA can also be used to produce therapeutic proteins with antitumor activity, such as anti-  
9  
10 4 angiogenic proteins or antibodies,<sup>41, 241</sup> thereby, using the organs and cells in the body as temporary  
11  
12 5 factories. This approach could be used to promote the bioavailability of agents that otherwise are rapidly  
13  
14 6 cleared from the body, thereby, reducing the number of injections and decreasing the burden for patients.  
15  
16 7 Moreover, producing the proteins *in situ* could avoid cumbersome procedures for synthesizing and  
17  
18 8 purifying protein drugs in clinical grade. For example, Stadler et al. developed mRNA-loaded  
19  
20 9 lipopolyplexes encoding bispecific tandem single-chain variable fragments (scFv), *i.e.* bi-(scFv)<sub>2</sub>  
21  
22 10 proteins, directed to simultaneously target both CD3 expressed on T cells and tumor-associated antigens,  
23  
24 11 *i.e.* claudin 6, claudin 18.2, and the epithelial cell adhesion molecule (EpCAM)).<sup>241</sup> These bi-(scFv)<sub>2</sub>  
25  
26 12 work by connecting T cells to cancer cells for improving the cell killing efficiency. The mRNA-loaded  
27  
28 13 nanomedicines accumulated in liver to achieve effective mRNA translation and sustained release of bi-  
29  
30 14 (scFv)<sub>2</sub> for around 7-days. The nanomedicines encoding bi-(scFv)<sub>2</sub> directed to CD3 and claudin 6  
31  
32 15 eradicated large ovarian tumors, and their activity was comparable to that of the clinical recombinant  
33  
34 16 bispecific antibody. However, the nanomedicines required 3-fold less frequency than the antibodies to  
35  
36 17 exert the same antitumor effect.  
37  
38  
39  
40  
41

42 18 mRNA-loaded nanomedicines can be applied to introduce specific proteins into cancer cells.  
43  
44 19 Such approach can be exploited to reduce cancer malignancy or sensitize cancer cells to other treatments.  
45  
46 20 For example, by using polymer-lipid hybrid nanoparticles comprised of PAMAM (generation 0)  
47  
48 21 dendrimer for complexation with mRNA, poly(lactic-co-glycolic acid) (PLGA) for increasing  
49  
50 22 hydrophobicity and ceramide-PEG for coating, it was possible to deliver mRNA encoding the tumor-  
51  
52 23 suppressor gene phosphatase and tensin homologue (*PTEN*) to tumors. The resulting expression of  
53  
54 24 functional PTEN in PTEN-null prostate cancer cells suppressed the phosphatidylinositol 3-kinase  
55  
56  
57  
58  
59  
60

1  
2  
3 1 (PI3K)–AKT pathway and increased apoptosis.<sup>298</sup> In another report, mRNA encoding *p53*, a tumor  
4  
5 2 suppressor gene, was introduced to *p53*-deficient tumors using polymer-lipid hybrid nanoparticles,  
6  
7 3 comprised of cationic lipid-like molecules for mRNA complexation, disulfate-containing polymers for  
8  
9 4 mRNA release in reductive intracellular environment and PEGylated lipids.<sup>299</sup> The treatment with *p53*  
10  
11 5 mRNA suppressed the growth of *p53*-deficient tumors, potentiated the function of a mammalian target  
12  
13 6 of rapamycin (mTOR) inhibitor and ultimately exhibited successful outcomes in mouse models of  
14  
15 7 orthotopic hepatocellular carcinoma and disseminated non-small cell lung cancer. More recently, PEI-  
16  
17 8 based polyplexes were used to introduce mRNA encoding vascular endothelial growth factor-C (VEGF-  
18  
19 9 C) into brain tumor cells to promote lymphangiogenesis and induce the infiltration of CD8 T cells into  
20  
21 10 the tumors.<sup>300</sup> The combination of these mRNA-loaded polyplexes with immune checkpoint inhibitors  
22  
23  
24 11 allowed the effective treatment of mice models of brain tumors.  
25  
26  
27  
28  
29  
30

## 31 13 **5. Future perspectives**

32  
33 14 mRNA therapeutics are now gradually moving toward clinical applications. Vaccination  
34  
35 15 against cancer is one of the most advanced fields, with the first report of the clinical trials dating back to  
36  
37 16 2002.<sup>301</sup> Targeting neoantigens, which are expressed only in cancer cells, is a good approach to improve  
38  
39 17 the efficacy of vaccines by circumventing immune tolerance mechanisms. A recent clinical trial provided  
40  
41 18 a proof of concept to this approach, by preparing mRNA expressing neoantigens, which were determined  
42  
43 19 by deep sequencing of cancer samples from each patient.<sup>297</sup> With advances in mRNA vaccine  
44  
45 20 technologies, including RNA design, administration routes and delivery system, further improvement of  
46  
47 21 therapeutic outcomes are expected. Such personalized therapy has the potential to revolutionize the  
48  
49 22 methodology of cancer treatment.  
50  
51  
52

53  
54 23 Vaccine against infectious disease is another important field. In the pandemic of COVID-19  
55  
56 24 caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV2), several companies have  
57

1  
2  
3 1 launched or planned to start clinical trials of mRNA vaccine against the viral spike protein  
4  
5 2 (ClinicalTrials.gov Identifier: NCT04283461, NCT04368728), based on their promising results in  
6  
7 3 preclinical or clinical studies of mRNA vaccine against other viruses, including Zika, influenza and  
8  
9 4 rabies viruses.<sup>197, 302-305</sup> Importantly, mRNA vaccine against a new infectious disease can be easily  
10  
11 5 prepared just by changing the mRNA sequence in vaccine formulations developed for other viruses,  
12  
13 6 which allowed fast start of clinical trials within a few months after sequencing of SARS-CoV2 genome.  
14  
15 7 The utility of mRNA vaccine against pandemic will be evaluated within a year in large clinical trials.  
16  
17 8 Notably, competing technologies of nucleic acid vaccines, such as electroporation of pDNA and  
18  
19 9 adenovirus vector administration, are also being pursued for vaccination against SARS-CoV2.<sup>306, 307</sup> Pros  
20  
21 10 and cons of each technology should be assessed from wide perspectives, including effectiveness, adverse  
22  
23 11 effects, production costs, quality control and large-scale production.  
24  
25  
26  
27

28 12 Clinical trials of mRNA therapeutics were conducted also for protein replacement therapy and  
29  
30 13 genome editing, with *VEGF-A* mRNA injection for heart regeneration (ClinicalTrials.gov Identifier:  
31  
32 14 NCT03370887), cystic fibrosis transmembrane conductance regulator (CFTR) supplementation for  
33  
34 15 cystic fibrosis (ClinicalTrials.gov Identifier: NCT03375047), and *ex vivo* ZFN-mediated disruption of  
35  
36 16 *CCR5* gene for HIV treatment, as extensively reviewed elsewhere.<sup>308, 309</sup> However, clinical trials in these  
37  
38 17 fields are still much fewer than that those for mRNA vaccines, which may be partially due to the issues  
39  
40 18 of mRNA delivery. Protein replacement therapies and genome editing often targets larger organs  
41  
42 19 compared to the case of mRNA vaccine, which makes mRNA delivery difficult. While various delivery  
43  
44 20 systems exhibited successful outcomes in small animals, their functions should be evaluated using larger  
45  
46 21 animals for clinical translation. Because tremendous advances have been made in the core technologies  
47  
48 22 of mRNA delivery as reviewed here, combination of these technologies may provide effective systems  
49  
50 23 for clinical usage.  
51  
52  
53  
54

55  
56 24 Target diseases and genes should be properly selected based on advantages of mRNA  
57

therapeutics over competing methodologies, including viral gene therapy and protein therapeutics. As described above, mRNA provided a more proper option compared to viral gene vectors, when prolonged gene expression induces detrimental effects (see *Sections 4.2, 4.3*). Acute diseases are a promising target of mRNA therapeutics, as the onset of protein expression from mRNA is as early as a few hours after the transfection.<sup>40,248</sup> A major problem of viral gene therapy is the production of neutralizing antibody, which hampers repeated systemic administration of viral vectors.<sup>310</sup> mRNA delivery is less prone to produce neutralizing antibody, allowing multiple systemic injection without reduction of delivery efficiency.<sup>233, 234</sup> On the other hand, transient profile of protein expression from mRNA should be taken into account in selecting target diseases. Repeated injections would be required for a long term to treat chronic diseases. When compared to protein therapeutics, mRNA therapeutics are more cost-effective due to their ability to produce numerous copies of proteins from single mRNA.<sup>311</sup> While global market of antibody therapeutics is growing,<sup>312</sup> mRNA may provide an inexpensive and effective option for antibody-based treatment.<sup>237-241</sup> Moreover, mRNA delivery is an easier approach to introduce intracellular and membrane proteins compared to protein delivery, expanding the candidates of therapeutic proteins for disease treatment.

## 6. Conclusion

Vigorous efforts were devoted to solve the problems of mRNA therapeutics, such as immunogenicity, short duration of protein expression, rapid enzymatic degradation, and limited cellular uptake. The strategies are classified into two orthogonal approaches, mRNA designing and nanomedicines, which cooperatively function to facilitate mRNA delivery and minimize safety issues. These technological advances allowed various therapeutic applications of mRNA including vaccinations, protein replacement therapy, cancer therapy and cell reprogramming in preclinical and clinical studies. Through further development of delivery system and proper selection of target diseases, mRNA

1  
2  
3 1 nanomedicines will solve various medical problems, which are intractable using conventional approaches,  
4  
5 2 as well as promote unprecedented therapeutic strategies.
