**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

The new species *Homo luzonensis* has recently been described based on a set of dental and post-cranial elements found at Callao Cave (Northern Luzon, Philippines) and dated to at least 50 ka. Seven post-canine maxillary teeth are attributed to this taxon, five of them belonging to the same individual (CCH6) and representing the holotype of *H. luzonensis*. All these teeth are characterized by their small dimensions (in the inferior range or below the modern human variation) and particularly large premolars relative to the molars. A small dentition is also found in *H. floresiensis*, another hominin having evolved in an insular environment of Southeast Asia, while large premolars (even if to a lesser extent than in *H. luzonensis*) are also found in *H. erectus*. The post-canine teeth from Callao Cave display a blend of modern-like features in the crown (with a simplified occlusal morphology) and more archaic traits in the roots (three-rooted premolars, large root volume). The internal tooth structural signature also supports an attribution to another species than those already recognized in the fossil record. The enamel-dentine junction (EDJ), demonstrated to be a reliable proxy to distinguish between taxa up to the sub-specific level, shows that the premolars and molars of *H. luzonensis* are intermediate between those of *H. erectus* and *H. floresiensis*, while they substantially differ from the modern human condition. Further analyses of the internal tooth structure, notably of the enamel thickness and pulp morphology, and comparisons with larger comparative samples will likely shed more lights on the phylogenetic relationship of this mysterious hominin. Altogether, the external and internal organization of the dental tissues of *H. luzonensis* teeth attest of the existence of this taxon and highlight the taxonomic diversity of Pleistocene hominins in Southeast Asia.
