Here, the structural, electronic and optical properties of the GaP<sub>1-x</sub>Sb<sub>x</sub>/Si tandem materials association are determined in view of its use for solar water splitting applications. The GaPSb crystalline layer is grown on Si by Molecular Beam Epitaxy with different Sb contents. The bandgap value and bandgap type of GaPSb alloy are determined on the whole Sb range, by combining experimental absorption measurements with tight binding (TB) theoretical calculations. The indirect (X-band) to direct ( $\Gamma$ -band) cross-over is found to occur at 30% Sb content. Especially, at a Sb content of 32%, the GaP<sub>1-x</sub>Sb<sub>x</sub> alloy reaches the desired 1.7eV direct bandgap, enabling efficient sunlight absorption, that can be ideally combined with the Si 1.1 eV bandgap. Moreover, the band alignment of GaP<sub>1-x</sub>Sb<sub>x</sub> alloys and Si with respect to water redox potential levels has been analyzed, which shows the GaPSb/Si association is an interesting combination both for the hydrogen evolution and oxygen evolution reactions. These results open new routes for the development of III-V/Si low-cost high-efficiency photoelectrochemical cells.

**Keywords:** solar water splitting; III-V/Si photoelectrode; tandem material; 1.7/1.1eV bandgap combination; band alignment

### 1. Introduction

The conversion of solar energy into green hydrogen fuel is one significant milestone on the road to a sustainable energy future [1,2]. Especially under the current background of global energy and environmental crisis, the development of the photoelectrochemical (PEC) water splitting technology, where the sunlight falling on the semiconductor photoelectrode immersed, turns the liquid water into gaseous storable hydrogen that can be reused on demand for heat or electricity production, has driven much research in the past years [3].

However, numbers of challenges remain for the development of this technology, in terms of efficiency, profitability and sustainability. These challenges include many aspects such as the limitation of corrosion or photo-corrosion processes, the optimization of the design for solar energy harvesting, or the improvement of charge carriers transport properties in the semiconductor photoelectrodes. At the heart of the photoelectrochemical conversion process is the choice of an appropriate photoelectrode material with both good bandgap and good band alignment to harvest the largest portion of the solar spectrum and provide sufficient voltage to accomplish the water splitting reactions [4]. Due to the broadness of the solar spectrum, from infrared to ultra-violet light, the needs for combining monolithically different materials with different bandgaps and thus absorbing different wavelengths, is considered today as the main pathway to reach high solar-to-hydrogen (STH) conversion efficiency [5,6]. In the tandem association of two materials, the optimum combination of bandgaps has been widely discussed for different device configurations

[7]. Especially, the combination of a 1.7 eV top absorber bandgap with a 1.1 eV bottom absorber is recognized as one of the best tandem material configurations and gives rise to a theoretical maximum STH efficiency  $\eta_{\text{STH}}$  larger than 26% when neglecting water absorption [7]. Different device demonstrations were proposed with a III-V/III-V materials design, mostly based on the Ga(In)As/GaInP association, reaching  $\eta_{\text{STH}}$  larger than 15% [8-11]. In these works, high quality materials are achieved, thanks to the lattice-matching of these alloys on the expensive GaAs substrate [12]. A way to reduce the cost of tandem materials association is to monolithically integrate a III-V top absorber (1.7 eV bandgap) on the silicon substrate (because of its approximate 1.1eV band gap, earth abundance, low cost and prevalence in the electronics and PV industries) [7,13]. In this case, the overall cost of the electrochemical device depends also on the chemical and/or thermal preparation of the silicon surface. But by now there are only very few reports on Si-based tandem systems for water splitting, mainly due to the difficulty in growing high quality III-V epilayers on Si. The recent progress in the understanding of III-V/Si epitaxial processes and devices developments gives new hopes for the development of high efficiency III-V/Si PEC devices on the low-cost Si substrate [14,15]. Following this approach, pioneering works were performed on the development of bipolar configured 1.6eV AlGaAs on 1.1eV Si tandem association. Water splitting at a 18.3% conversion efficiency was reported [16]. Very recently, a single InGaN absorber photoanode monolithically integrated on silicon (where the Si (111)

substrate was used as a back contact) was proposed with an applied-bias photo-to-current efficiency of 4.1% [17]. GaP-based materials were also proposed as an ideal tandem association with Si for water splitting [18]. The optimum design of GaP/Si tunnel junctions was even considered [19]. TiO<sub>2</sub>-, CoO<sub>x</sub>- or Ni-based passivation strategies were found to be efficient for photoelectrode stability [20,21]. But this approach still suffers from the indirect and large bandgap (2.26 eV) nature of GaP. Therefore, alloying GaP with other group III-V atoms is needed to achieve a direct bandgap at 1.7 eV. Doscher H. et. al theoretically proposed GaPN/Si and GaPNAs/Si tandem lattice-matched materials for water splitting based on the experiments of GaP/Si photoelectrochemistry and GaPN/Si epitaxial growth [22]. But these N-including lattice-matched materials face the issue of excitons localization effects, which hamper easily charge transport in the developed devices. On the other hand, metamorphic III-V integration on Si is known to generate dislocations that may propagate in the volume and are detrimental for solar devices. Recently, the synthesis of GaPSb was proposed to reduce the bandgap of GaP with a STH efficiency of ~2% at zero bias [23]. The epitaxial growth of Sb-based III-V compounds on Si substrates is particularly interesting in this regard, as it allows relaxation of the crystal stress through a near-perfect misfit dislocation network localized at the III-V/Si interface [14] leading to efficient and stable photonic device demonstrations [24]. Recent work demonstrated efficient operation of a GaPSb/Si photoanode for water splitting, but a complete assessment of the alloy with different compositions for water splitting was not yet given [25].

In this study, we evaluate the potential of GaP<sub>1-x</sub>Sb<sub>x</sub>/Si tandem materials association for the development of efficient III-V/Si photoelectrodes. GaP<sub>1-x</sub>Sb<sub>x</sub> alloys with different compositions were directly grown on Si substrate by molecular beam epitaxy (MBE). The bandgaps and band alignments of the GaP<sub>1-x</sub>Sb<sub>x</sub> alloys were carefully and comprehensively studied over the whole Sb range, by combining the experimental data with tight binding (TB) theoretical calculations. We finally discuss the promises offered by such alloy for its use in photoelectrodes.

## 2. Material and device design for solar water splitting

Three GaP<sub>1-x</sub>Sb<sub>x</sub>/Si samples (named as GaPSb-1, GaPSb-2 and GaPSb-3, with increasing Sb amounts) were grown by Molecular Beam Epitaxy (MBE) on HF-chemically prepared n-doped (10<sup>17</sup>cm<sup>-3</sup>) Si(001) substrates, with a 6° miscut toward the [110] direction[26]. The substrates were heated at 800°C for 10 minutes to remove hydrogen at the surface. 1µm-thick GaP<sub>1-x</sub>Sb<sub>x</sub> layers were then grown at 500°C in a conventional continuous MBE growth mode, and at a growth rate of 0.24 ML/s, with a Beam Equivalent Pressure V/III ratio of 5.

The schematic diagrams of the proposed GaP<sub>1-x</sub>Sb<sub>x</sub>/Si tandem device for water splitting and the light absorption of the GaP<sub>1-x</sub>Sb<sub>x</sub>/Si tandem system with around 1.7/1.1eV bandgap combination are shown in Fig.1a and Fig.1b. The sun light first enters the top cell (1.7eV-bandgap targeted) GaP<sub>1-x</sub>Sb<sub>x</sub> layer, in which high-energy photons are absorbed and low-energy photons are transmitted and harvested by the Si substrate or bottom cell, leading to an overall very large light absorption (as shown in Fig.1b). Then the photo-induced charges (electrons and holes) are generated in both layers, and, depending on the doping, one kind of charges flows toward the illuminated surface (the top surface of GaPSb layer) to generate H<sub>2</sub> or O<sub>2</sub> and the other one flow toward the back contact which is connected to the Si substrate (as shown in Fig.1a) and is further extracted to feed the counter-electrode. In this configuration, the voltage would reach at the maximum - the sum of the two sub-cells (2.8 eV), enabling the splitting of the water molecules. Such operating principle is compatible with different concentrating or non-concentrating planar or tilted geometries [27].

Fig. 1. (a) Schematic of the proposed GaP<sub>1-x</sub>Sb<sub>x</sub>/Si tandem device for PEC water splitting. (b) Sunlight absorption illustration of GaP<sub>1-x</sub>Sb<sub>x</sub>/Si tandem system with around 1.7/1.1eV bandgap combination for water splitting.

## 3. Material characterizations and theoretical calculations

The detailed description of the methods for material characterizations and theoretical calculations are given in the supplemental materials.

Figure 2 shows the X-ray diffraction (XRD) patterns for the three samples. The miscut of around 6° is observed toward the [110] direction for the three samples based on the positions of Si Bragg peaks, which are in agreement with the substrate specifications. The ω/2θ scans exhibit well-defined GaP<sub>1-x</sub>Sb<sub>x</sub> Bragg peaks for the three samples. Reciprocal space maps (RSM) carried out on either (004) (the insets of Fig.2a, Fig.2b, Fig.2c) or (115) (Fig.S1 in supplemental materials) reflections show a full plastic relaxation of the GaP<sub>1-x</sub>Sb<sub>x</sub> layers for the three samples. GaP<sub>1-x</sub>Sb<sub>x</sub> lattice parameters were extracted from both reciprocal space maps and ω/2θ scans, leading to very similar values for each sample, confirming the full plastic relaxation rates and giving mean lattice parameters of 0.5665 nm, 0.5835 nm, 0.6093 nm, for the sample GaPSb-1, GaPSb-2, GaPSb-3, respectively. The Sb contents of 0.33, 0.60, and >0.99 are then inferred [28]. Sample

GaPSb-3 is almost pure GaSb. These RSM images also exhibit an important Bragg peak broadening due to a relatively large crystal defect density, in low Sb content samples. Furthermore, the XRD analysis does not give any evidence of a phase separation that could occur between GaP and GaSb in the  $\text{GaP}_{1-x}\text{Sb}_x$  alloys in these growth conditions.

Fig. 2. X-Ray Diffraction patterns of three MBE-grown  $\text{GaP}_{1-x}\text{Sb}_x/\text{Si}$  samples with different Sb contents: GaPSb-1 (a), GaPSb-2 (b) and GaPSb-3 (c). The insets show the reciprocal space maps around (004) for the three samples, correspondingly ( $S_x$  and  $S_z$  are the projected coordinates in the right handed Cartesian, with  $z$  axis parallel to the surface normal) [28].

Figure 3 shows the scanning electron microscopy (SEM) images of the three  $\text{GaP}_{0.67}\text{Sb}_{0.33}/\text{Si}$ ,  $\text{GaP}_{0.40}\text{Sb}_{0.60}/\text{Si}$ ,  $\text{GaSb}/\text{Si}$  samples on plane-view (Fig.3 a, c, e) and cross-section view (Fig.3 b, d, f). From these images, it can be observed that the samples  $\text{GaP}_{0.40}\text{Sb}_{0.60}/\text{Si}$  and  $\text{GaSb}/\text{Si}$  exhibit relatively smooth surfaces as compared with the other sample, the  $\text{GaP}_{0.67}\text{Sb}_{0.33}/\text{Si}$ . The roughness observed is attributed to both emergence of some crystal defects such

as residual dislocations and residual stress in the sample. The corresponding atomic force microscopy (AFM) images are given in the supplemental materials and the RMS (root-mean-square) roughnesses of the surfaces were found to be 22.80nm for  $\text{GaP}_{0.67}\text{Sb}_{0.33}$ , 9.32nm for  $\text{GaP}_{0.40}\text{Sb}_{0.60}$  and 7.91nm for GaSb. It suggests an improvement of the crystal quality with increasing Sb content. This is also confirmed by a very significant Bragg peak sharpening observed on reciprocal space maps (Fig.2). Even though the GaPSb/Si samples are defective, especially for the  $\text{GaP}_{0.67}\text{Sb}_{0.33}/\text{Si}$ , the high photocurrent and relatively long-lifetime stability with protecting layers measured with a  $\text{GaP}_{0.67}\text{Sb}_{0.33}/\text{Si}$  photoanode for water splitting [25] indicate that carriers pass through the GaPSb/Si interface efficiently without the need of a tunnel junction, and the corrosion impact on PEC performances can be reduced effectively by protections layers [20,21,25]. Moreover, there is a large room for the improvement of the material quality, because of the specific dislocation distribution in Sb-based compounds [14,24]. The influence of localized dislocations at the III-V/Si interface on transport and screening effects will be interesting to be explored in future work.

Fig. 3. Scanning electron microscopy (SEM) images of the  $\text{GaP}_{0.67}\text{Sb}_{0.33}$ ,  $\text{GaP}_{0.40}\text{Sb}_{0.60}$ ,  $\text{GaSb}$  three samples on plane view (a),(c),(e) and cross-section view(b),(d),(f).

Ellipsometry measurements were made for GaPSb bandgap determination, independently of the Si substrate. Chemical mechanical polishing (CMP) was performed to obtain smoother surfaces and avoid distortion on ellipsometry measurements. The SEM plane-view images of the three CMP-polished samples are shown in Fig.S2

(supplemental materials), which shows that the surface roughnesses of the three samples are much lower than the as-grown samples. The surface RMS (root-mean-square) roughnesses of the three CMP samples extracted from AFM measurements are 0.33nm ( $\text{GaP}_{0.67}\text{Sb}_{0.33}$ ), 0.28nm ( $\text{GaP}_{0.40}\text{Sb}_{0.60}$ ) and 0.56nm (GaSb), indicating the surfaces of the three samples become very smooth after CMP processes. Then the optical constants of the three  $\text{GaP}_{0.67}\text{Sb}_{0.33}/\text{Si}$ ,  $\text{GaP}_{0.40}\text{Sb}_{0.60}/\text{Si}$ , and GaSb/Si samples were measured by variable angle spectroscopic ellipsometry (VASE) at room temperature in the 0.58–5 eV photon energy region. The angles of incidence were set to  $60^\circ$  and  $70^\circ$ . A Tauc-Lorentz model with two oscillators was used to fit the ellipsometry data of the three samples (Fig.S5 in the supplemental materials). From this model, the refractive index (n), extinction coefficient (k) and absorption spectrum of the GaPSb layers of the three samples were extracted independently of the Si substrate, respectively, as shown in Fig.S6 (supplemental materials) and Fig.4 (the red curves). Besides, in order to further integrate and verify the experimental data, ellipsometry measurement was also performed on a GaP/Si sample and the corresponding optical constants extracted based on the Tauc-Lorentz model are shown in Fig.S7 (supplemental materials). The deduced absorption curves of the GaP and GaSb based on ellipsometry measurements show good agreements with both the experimental and theoretical data presented in ref. [29] (see Fig.S8 in the supplemental materials).

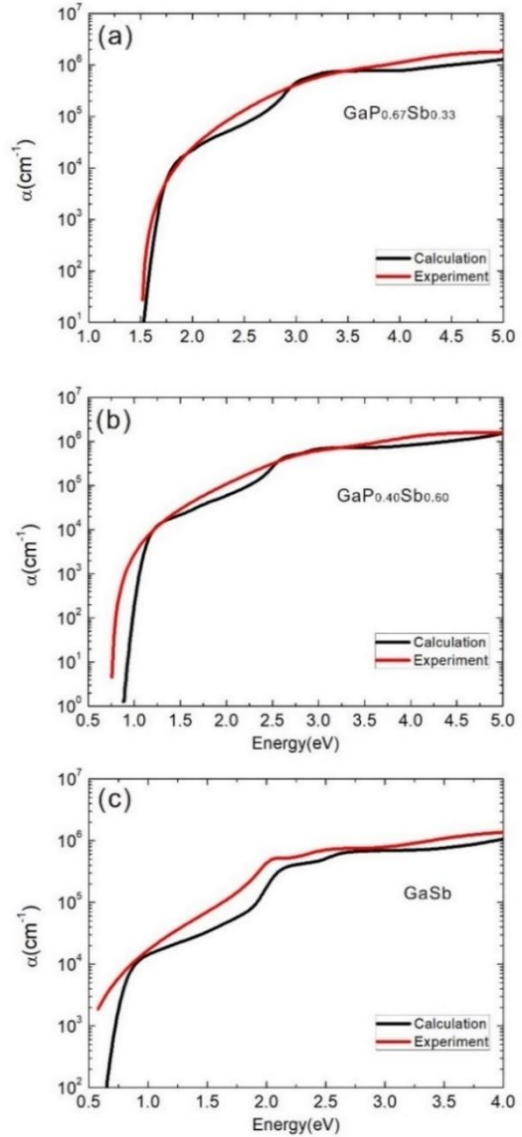

Fig. 4. Optical absorption spectra of the  $\text{GaP}_{0.67}\text{Sb}_{0.33}$  (a),  $\text{GaP}_{0.40}\text{Sb}_{0.60}$  (b), GaSb (c) semiconductors. The red lines were deduced from ellipsometry measurement and the black lines were obtained based on TB calculation.

Based on Tauc plot method, the band gap ranges of the four samples were obtained:  $E_g=2.25\pm0.04$  eV for GaP;  $E_g=1.70\pm0.06$  eV for  $\text{GaP}_{0.67}\text{Sb}_{0.33}$ ;  $E_g=1.04\pm0.08$  eV for  $\text{GaP}_{0.40}\text{Sb}_{0.60}$ , and  $E_g=0.68\pm0.09$  eV for GaSb (the details see the supplemental materials), which are consistent with bandgaps reported for the metamorphic growth of GaPSb on InP substrate [30]. In this study, we neglect the possible impact of alloy fluctuations and Sb ordering on the bandgap determination. Further experiments would be needed to assess quantitatively the influence of such effects.

The band structures of the unstrained  $\text{GaP}_{1-x}\text{Sb}_x$  alloys in the whole Sb compositional range have then been calculated by tight-binding (TB) calculation, using an extended basis  $sp^3d^5s^*$  tight binding Hamiltonian [31].

From the tight binding parameters of GaP and GaSb binary compounds [31], a virtual crystal approximation is performed to obtain the band structures of the different  $\text{GaP}_{1-x}\text{Sb}_x$  alloys at 0K as a function of the Sb content. Then the energies were shifted to take into account the influence of the temperature, in order to get room temperature band structures [32]. The calculated band structures of GaP,  $\text{GaP}_{0.67}\text{Sb}_{0.33}$ ,  $\text{GaP}_{0.40}\text{Sb}_{0.60}$ , and GaSb semiconductors are given in the Fig.S10. The bandgap evolutions obtained in the  $\Gamma$ , L and X valleys of the  $\text{GaP}_{1-x}\text{Sb}_x$  alloy for the whole Sb content range are presented in Fig.5, from which we can find both the band gap value and the band gap type (direct or indirect). For the GaP,  $\text{GaP}_{0.67}\text{Sb}_{0.33}$ ,  $\text{GaP}_{0.40}\text{Sb}_{0.60}$ , and GaSb semiconductors, tight-binding calculations are in good agreement with the experimental absorption measurements. The theoretical absorption curves of  $\text{GaP}_{0.67}\text{Sb}_{0.33}$ ,  $\text{GaP}_{0.40}\text{Sb}_{0.60}$ , GaSb semiconductors (corresponding to the three MBE grown samples) determined with tight-binding calculations are shown as black lines in Fig.4, which also shows good consistency with the experimental data. From this analysis, we deduce that the Sb content at which a 1.7 eV direct bandgap needed for tandem materials association obtained is 32%. Besides, the bandgap calculation of GaPSb were also investigated in previous works by density functional theory (DFT) calculations [33,34]. In these references, the bandgap values were underestimated (as compared to our TB calculation results and experimental data), which is a well-known issue with DFT calculations. Russell *et al.* performed DFT+U calculations [33], but this method is more adapted to transition metals and nitrides materials. Chen *et al.* also calculated the band gaps of different ordering structures of GaPSb based within the local-density approximation (LDA) with exchange correction function (LDA+C) [34], which compared to the general LDA results shows obvious improvement. The bandgap values reported in the literature for different ordering structures with different Sb contents are given in Fig. 5, with blue dots. It can be found that the bandgaps of the different ordering structures show obvious discrepancy. The bandgap of CA (layered tetragonal CuAu-I-like structure) with 50% Sb and FM (famatinite structure) with 75% Sb are close to our calculation data, and the CH (chalcopyrite structure) with 50% Sb and LZ (luzonite-like structure) with 25% and 75% Sb are lower than the results in the present work. Besides, the bandgaps of polycrystalline GaPSb with 3% and 10% Sb based on experimental measurement given in ref. [23] were also added in the Fig. 5, shown as the black star dots. The bandgap of polycrystalline  $\text{GaP}_{0.97}\text{Sb}_{0.03}$  shows good correspondence to the result obtained in this work, while the bandgap of  $\text{GaP}_{0.90}\text{Sb}_{0.10}$  is 0.6 eV lower than the value found in the present study, which may result from the inhomogeneity of the polycrystalline structure of the material demonstrated in ref. [23]. For the DFT calculation methods, DFT with hybrid functional and GW approximation [35] are more accurate methods for the

bandgap calculation of semiconductors and insulators, but they need high computational cost, especially for the bandgap calculation of alloyed semiconductors, such as GaPSb, which requests large structures to allow for random distribution of Sb and P atoms. Tight binding (TB) approach therefore appears as a reasonable way to achieve realistic bandgap calculation for GaPSb, and further study on band lineups.

Fig. 5. Room temperature bandgaps of  $\text{GaP}_{1-x}\text{Sb}_x$  alloys with different Sb contents. The green, red and purple solid lines are theoretical curves computed by tight-binding calculations, corresponding to  $\Gamma$ , L and X valleys, respectively. The separated error bar lines correspond to the bandgaps determined experimentally. The black square dots correspond to the bandgaps of GaP and GaSb given in ref. [36,37]. The blue circle dots correspond to the bandgaps of GaPSb with 25%, 50%, and 75% Sb content based on DFT+C calculation obtained from ref. [34], for different ordering structures: FM (famatinite structure), LZ (luzonite-like structure), CA (layered tetragonal CuAu-I-like structure), CH (chalcopyrite structure). The black star dots correspond to the bandgaps of polycrystalline GaPSb with 3% and 10% Sb based on experimental data obtained from ref. [23].

For efficient photoelectrochemical water splitting, another important aspect is to estimate the band edge location with respect to the redox potentials of water. The band alignment (no external electric field applied) of the  $\text{GaP}_{1-x}\text{Sb}_x/\text{Si}$  tandem architecture for water splitting is presented in Fig.6 as a function of the Sb content. The VBM (valence band maximum) energy ( $E_v$ ) of the  $\text{GaP}_{1-x}\text{Sb}_x$  alloy over the whole Sb content range was obtained based on the absolute bandlineup between VBM energy of GaP and GaSb [38], which follows the linear formula  $E_v(\text{GaP}_{1-x}\text{Sb}_x) = xE_v(\text{GaSb}) + (1-x)E_v(\text{GaP})$  [39]. In a first approximation, the evolution of the surface acidity with Sb content was neglected. The CBM (conduction band minimum) energy of the  $\text{GaP}_{1-x}\text{Sb}_x$  alloy was obtained by using the results from TB calculations presented in Fig. 5. For this alloy, the minimum of the conduction band is located in the X-valley between 0% and 11%. It then moves to the L valley for Sb contents between 11% and 30%. It finally reaches a direct bandgap configuration (minimum of

the CB in the  $\Gamma$  valley) beyond 30% of Sb incorporation. While the precise value predicted by the calculations for the X to L valleys crossover seems hard to confirm experimentally in this work, calculations clearly demonstrate that in any cases, an indirect to direct crossover is expected for this alloy at around 30% Sb, contrary to previously calculated band structures using density functional theory [23]. The VBM energy of bulk GaP is very close to the oxidation potential of water, which has been verified by many reports [38,40-42]. While, in the different papers, the energy differences (between the water redox levels and GaP VBM energy) have a little difference. So, here we show the redox levels of water based on the VBM position of GaP [38] and the energy differences [38,40-42] with error bars to analyze potential water splitting reactions more accurately and comprehensively (Fig.6).

Fig. 6. Band alignment of  $\Gamma$ , L and X valleys of  $\text{GaP}_{1-x}\text{Sb}_x$  and indirect bandgap of Si with respect to water oxidation and reduction potentials. The relative position of redox potentials of water are shown as green bars at  $\text{pH}=0$ .

From the Fig.5 and Fig.6, it can be observed first that, in order to benefit from a direct GaPSb bandgap larger than the one of the silicon (to absorb higher energy solar radiations), the Sb content should lie between 30% (indirect to direct cross-over) and 54% (bandgap equal to the Si one). In this Sb content range, it is also noticed that the band lineup is of type I, promoting the charge carrier extraction in the silicon under zero bias conditions. Now looking at the band lineups between GaPSb and the water redox potentials in the 30%-54% Sb content range, it is seen that GaPSb has a strong reduction ability due to its relatively higher CBM and it is around 0.9 eV higher than  $\text{H}^+/\text{H}_2$  potential at 32% Sb content. On the other hand, the VBM is higher than the  $\text{O}_2/\text{H}_2\text{O}$  potential in the 30%-54% Sb content range, and due to the linear increase of VBM with the Sb content, the GaPSb with low Sb content (around 30%) is thus more suitable for oxygen evolution reactions (about 0.43 and 0.46 eV higher than  $\text{O}_2/\text{H}_2\text{O}$  potential at 30% and 32% Sb content). Overall, addition of

Sb in GaP will therefore ease photocathode operation, although large currents densities were obtained with a GaPSb/Si photoanode, due to a strong direct bandgap absorption in this alloy [25]. The band lineups calculated in this work thus give a basis for further devices analysis, where the precise determination of Nernstian shifts and band bending will be needed, but it is beyond the scope of this article.

#### 4. Conclusions

In summary, the structural, electronic and optical properties of the III-V/Si-based tandem materials association  $\text{GaP}_{1-x}\text{Sb}_x/\text{Si}$  for photoelectrochemical water splitting was studied comprehensively for the whole range of Sb composition, and its potential for photoelectrochemical cell evaluated. The  $\text{GaP}_{1-x}\text{Sb}_x$  alloys were directly grown on the Si substrate with different Sb contents. The bandgap values and bandgap types of GaPSb alloys were determined on the whole Sb range, by combining the experimental data with tight binding (TB) theoretical calculations. The indirect (X-band) to direct ( $\Gamma$ -band) cross-over was found to occur at 30% Sb content. Especially, at a Sb content of 32%, the  $\text{GaP}_{1-x}\text{Sb}_x$  alloy reached the ideal 1.7eV direct bandgap, complementary to the Si 1.1eV one. Furthermore, the analysis of the band alignment of  $\text{GaP}_{1-x}\text{Sb}_x$  alloys and Si with respect to water potential levels shows that the GaPSb/Si association is an interesting combination both for the hydrogen evolution and oxygen evolution reactions, suggesting the  $\text{GaP}_{1-x}\text{Sb}_x/\text{Si}$  tandem material holds great promise for high-efficiency solar water splitting on the low cost silicon substrate.
