Abstract:

We report on the comparative growth and spectroscopy of Eu^{3+} -doped $\text{Y}_3\text{Al}_5\text{O}_{12}$ (YAG) and $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals grown by the micro-pulling-down (μ -PD) method. The structure of the as-grown crystals was determined by X-ray diffraction (XRD) and Raman spectroscopy. The spectra of the crystals are dominated by a strong line centered at 395 nm, matching well with the emission of commercial ultraviolet laser diodes. The Eu:YAG and Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals exhibit strongest red emission centered at 710 nm and the full width at half maximum (FWHM) was calculated to be 2.03 and 3.19 nm, respectively. The fluorescence decay curves of $^5\text{D}_0$ levels were measured and discussed. All the results indicate that the Eu:YAG and Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals are promising candidates for red luminescent/laser materials.

Keywords: Eu:YAG; Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$; Micro-pulling-down technique; Spectral property

1. Introduction:

In recent years, the red luminescent materials have attracted much attention because of their potential applications in white light-emitting diodes (W-LEDs), field emission display (FED), vacuum fluorescent displays (VFDs), plasma display panels (PDP) [1-4]. As one of the most popular used red emitting activators, the trivalent europium ion (Eu^{3+}) exhibits characteristic emissions which are associated to the f-f transitions from the excited level $^5\text{D}_0$ to lower levels $^7\text{F}_J$ ($J=0, 1, 2, 3, 4$). Up to now, the Eu^{3+} -doped phosphors, such as $\text{Eu}:\text{YAG}$ [5], $\text{Eu}:\text{Sr}_3\text{Bi}(\text{PO}_4)_3$ [6], $\text{Eu}:\text{Ca}_9\text{ZnK}(\text{PO}_4)_7$ [7], $\text{Eu}:\text{Na}_3\text{Sc}_2(\text{PO}_4)_3$ [8], and $\text{Eu}:\text{Ca}_3\text{Y}(\text{AlO})_3(\text{BO}_3)_4$ [9] have merited considerable attention due to potential applications in red emission. However, it is well known that phosphors have many drawbacks, such as lower uniformity, deficiency of red emission, light scattering and encapsulation difficulty. Therefore, in order to overcome the above disadvantages, search for new red luminescent materials which have better optical properties and chemical stability become an urgent task. The preparation and spectral properties of $\text{Eu}:\text{YAG}$ ceramics [10], $\text{Eu}:\text{Gd}_3\text{Sc}_2\text{Ga}_3\text{O}_{12}$ nanocrystalline [11], $\text{Eu}:\text{CaGdAlO}_4$ crystal [12], $\text{Eu}:\text{YAl}_3(\text{BO}_3)_4$ crystal [13], $\text{Er}:\text{KGd}(\text{WO}_4)_2$ crystal [14] and $\text{Eu}:\text{Bi}_4\text{Ge}_3\text{O}_{12}$ crystal [15] have been reported for exploring new luminescent/laser materials.

$\text{Y}_3\text{ScAl}_4\text{O}_{12}$ belongs to the disordered material in which the Sc^{3+} and Al^{3+} ions randomly occupy the same lattice site, which leads to inhomogeneous broadening of absorption and emission spectra [16-19]. $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ has been realized as a valuable material thanks to its high optical, excellent chemical and mechanical characteristics. To the best of our knowledge and in spite of the possibilities to crystallize this material from the melt, up to now there has no research about the growth and performance of $\text{Eu}:\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystal.

In this paper, we select to study two Eu^{3+} -doped garnet hosts (YAG and $\text{Y}_3\text{ScAl}_4\text{O}_{12}$). They crystallize in $\text{Ia}3\text{d}$ of the cubic crystal system. In these two materials, Y^{3+} and Al^{3+} can be substituted by different types of cations with different sizes and valences up to certain concentration. In this work, attention was focused to grow Eu^{3+} -doped YAG and $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals were by the micro-pulling-down (μ -PD) technique for the first time. The structure of two crystals were studied by X-ray diffraction (XRD). The spectroscopic properties of two crystals were also investigated.

2. Experimental

The Eu^{3+} -doped YAG and $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ single crystals were grown by the μ -PD method [20-23]. The Eu_2O_3 , Sc_2O_3 , Y_2O_3 and Al_2O_3 powders with high purity of 99.999% were used as raw materials. The starting materials were weighed according to the formula $(\text{Eu}_{0.02}\text{Y}_{0.98})_3\text{Al}_5\text{O}_{12}$, $(\text{Eu}_{0.02}\text{Y}_{0.98})_3\text{ScAl}_4\text{O}_{12}$, respectively, and then ground and mixed thoroughly in an agate mortar. The mixtures were shaped into a rod and pressed by cold isostatic at 160 MPa for 2 min, then sintered at 1300 °C for 20 h in air. A $\langle 111 \rangle$ oriented YAG crystal was used as seed, the pulling rate was 0.3 mm/min and the growth atmosphere was high-purity flowing argon. A small portion of as-grown crystals were ground into powders and the powders were carried out in the 2θ range of 20° – 90° by X-ray diffraction method (XRD, Bruker-D2, Germany) at room temperature. The Raman spectra were obtained with a laser Raman spectrometer (Omni- λ 300i, Zolix) in the range of 16 – 900 cm^{-1} at 30 MV with a 785 nm excitation light source. The absorption spectra of $\text{Eu}:\text{YAG}$ and $\text{Eu}:\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals

were recorded with a UV–VIS–NIR spectrophotometer (Lambda 900, Perkin -Elmer UV-VIS-NIR) in the range of 300-450 nm. The fluorescence spectra, as well as the lifetime were recorded using Edinburgh Instruments FLS980 spectrophotometer under 394 nm excitation. All the measurements were taken at room temperature. The samples were cut from the as-grown crystals and two surfaces perpendicular to the $\langle 111 \rangle$ -growth axis was polished for spectral measurements. The spectral measurements were detected in the core (diameter of 0.5 mm) of the samples.

3. Results and discussions

3.1 Crystal growth

After growth the crystals were cooled to room temperature during 3 h. As shown in Fig. 1, as-grown Eu:YAG and Eu:Y₃ScAl₄O₁₂ crystals with diameter of about 2 mm were crystallized. We obtain blue transparent Eu³⁺-doped YAG crystal (Fig.1a) and slightly dark brown Eu³⁺-doped Y₃ScAl₄O₁₂ crystal (Fig.1b), with homogeneous diameter and free of macroscopic defects. During the growth process, the melt meniscus thickness under the capillary die did not exceed 250 μm, it is considered a good value for a stable growth. The length of the grown fibers reached 10 cm while 100% of the melt in the crucible was crystallized. We did not record any macro-scale shift from the $\langle 111 \rangle$ initial orientation.

(a)

(b)

Fig. 1. Photographs of the as-grown Eu:YAG (a) and Eu:Y₃ScAl₄O₁₂ (b) crystals.

3.2 Crystal structure

The corresponding XRD patterns are shown in Fig. 2. All the diffraction peaks matched well with the standard card of YAG (PDF#88-2048), and no impurity peaks were found in the patterns, indicating that the Eu³⁺ ions were well diffused in the host lattices and did not change the crystalline structure. The Eu³⁺ is expected to substitute Y³⁺ into the distorted dodecahedral site and to be coordinated to eight O²⁻ ions because of their comparable ionic size. The calculated cell parameters of Eu³⁺-doped YAG and Y₃ScAl₄O₁₂ single crystals were $a=11.957 \text{ \AA}$, and $a= 12.053 \text{ \AA}$, respectively. The increase in the lattice parameter of YSAG is

attributed to the larger ionic radius of Sc^{3+} (0.75 Å) compared to Al^{3+} ions (0.39 Å).

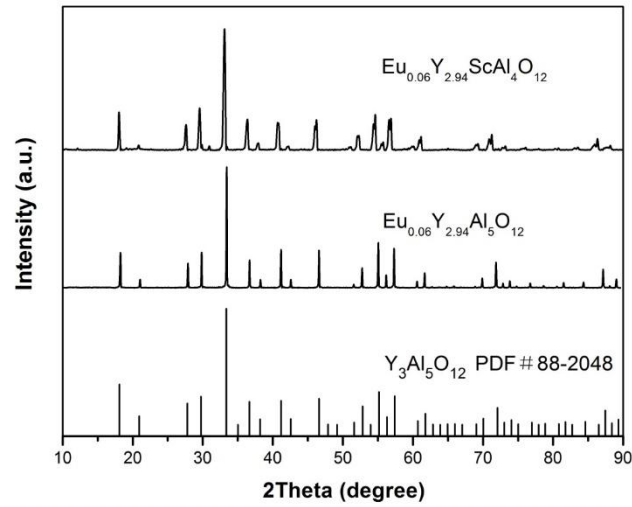

Fig. 2. XRD patterns of Eu:YAG and Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals with a standard pattern of YAG (PDF#88-2048).

The Raman spectra of Eu^{3+} -doped YAG and $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ single crystals are shown in Fig. 3. The Raman spectra are in consistent with the spectra of Yb:YAG [24] and Nd: $\text{Y}_3\text{Sc}_2\text{Al}_3\text{O}_{12}$ crystal [25]. The Raman peaks position and intensity are changed after the introduction of Sc^{3+} ions in YAG crystal. However, no distinct changes in the modes are observed, which suggests that the crystal structure remains the same. Additionally, the maximum phonon energy of Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ was determined to be 768 cm^{-1} from the Raman spectra, which is lower than that of Eu:YAG (780 cm^{-1}).

Fig. 3. The Raman spectra of Eu:YAG and Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals.

3.3 Optical characterization

The room temperature absorption spectra of Eu^{3+} -doped YAG and $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals in the range from 300 to 450 nm are shown in Fig. 4. The corresponding transitions from the $^7\text{F}_0$, $^7\text{F}_1$ ground state to excited state were assigned and marked. The absorption spectra of Eu:YAG and Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals are dominated by a strong line occurring at 395 nm, corresponding to the $^7\text{F}_0 \rightarrow ^5\text{L}_6$ transition, matching well with the emission of commercial ultraviolet laser diodes. In addition, the absorption coefficient at 395 nm of Eu:YAG and Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ was calculated to be 1.07 and 1.12 cm^{-1} , and the full width at half maximum (FWHM) of absorption band at 395 nm was calculated to be 1.89 and 2.21 nm respectively, which is higher than that of Eu: CaGdAlO_4 (1.62 nm) [12], but smaller than that of Eu: $\text{Bi}_4\text{Ge}_3\text{O}_{12}$ (3.1 nm) [15].

Fig. 4. The absorption spectra of Eu:YAG and Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals.

The fluorescence spectra of Eu:YAG and Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals in the wavelength range of 550-770 nm excited by 394 nm at room temperature are shown in Fig. 5. It's clear that emission bands centered around 591 nm, 610 nm, 650 nm, 710 nm, 743 nm are corresponding to transitions from $^5\text{D}_0$ excited level to $^7\text{F}_1$, $^7\text{F}_2$, $^7\text{F}_3$, $^7\text{F}_4$ and $^7\text{F}_5$ energy level, respectively, and these peaks split into some stark components. The emission in the range (580-600 nm) of Eu^{3+} due to the magnetic dipole transition of $^5\text{D}_0 \rightarrow ^7\text{F}_1$ is not affected much by the site symmetry, because they are partly allowed, while the red emission (605-630 nm) due to the electric dipole transition of $^5\text{D}_0 \rightarrow ^7\text{F}_2$ is sensitively affected by the site symmetry of Eu^{3+} . In Eu: CaGdAlO_4 crystal, the emission of $^5\text{D}_0 \rightarrow ^7\text{F}_2$ transition is dominant because Eu^{3+} ions are located at a non-inversion symmetry position in CaGdAlO_4 crystal [12]. However, in Eu:YAG and Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ crystals, Eu^{3+} ions occupy a site with inversion symmetry, which induces the relative weak emission of the $^5\text{D}_0 \rightarrow ^7\text{F}_2$ transition at 610 nm. Furthermore, the ratio between the integrated intensity of $^5\text{D}_0 \rightarrow ^7\text{F}_2$ and $^5\text{D}_0 \rightarrow ^7\text{F}_1$ transitions ($^5\text{D}_0 \rightarrow ^7\text{F}_2 / ^5\text{D}_0 \rightarrow ^7\text{F}_1$) is called asymmetric ratio (R_{21}), which gives information about the surrounding and environmental changes around the Eu^{3+} ions. The higher the asymmetric ratio is, the more apart from a centrosymmetric geometry luminescent center is located [26]. The asymmetric ratio R_{21} of Eu:YAG and Eu: $\text{Y}_3\text{ScAl}_4\text{O}_{12}$ was calculated to be 0.49 and 0.48, which is much higher than that of Eu-doped

SnO₂ xerogels with low concentration (0.01 [27]), but smaller than that of Y_{0.7}BO₃:Eu_{0.3}³⁺@SiO₂ nanophosphors (6.71 [28]), Eu:YAG microcrystals (1.0 [29]) and Eu:YAG nanocrystals (average value 0.75 [29]). The observed difference can be explained with more symmetric local environment in Eu:YAG monocrystals compared with Eu:YAG nanocrystals and microcrystals.

The intense emission of the ⁵D₀→⁷F₄ transition at 710 nm suggests that Eu:YAG and Eu:Y₃ScAl₄O₁₂ crystals have potential application in red emission. Besides, The full width at half maximum (FWHM) of emission band at 710 nm was calculated to be 2.03 and 3.19 nm for Eu:YAG and Eu:Y₃ScAl₄O₁₂, respectively. It can be clearly observed that the emission bandwidth of Eu:Y₃ScAl₄O₁₂ crystal is significantly broader than that of Eu:YAG crystal due to the partially disordered crystalline structure in Eu:Y₃ScAl₄O₁₂.

Fig. 5. The emission spectra of Eu:YAG and Eu:Y₃ScAl₄O₁₂ crystals under 394 nm excitation

The CIE-1931 chromaticity coordinates for Eu:YAG and Eu:Y₃ScAl₄O₁₂ crystals were calculated and the results are illustrated in Fig. 6. The CIE coordinate of Eu:YAG and Eu:Y₃ScAl₄O₁₂ samples were determined to be (0.615, 0.385) and (0.635, 0.365), respectively, which was close to that of the standard value of National Television Standard Committee (NTSC) for red phosphor (0.670, 0.330).

Fig. 6. CIE-1931 chromaticity diagram of Eu:YAG and Eu:Y₃ScAl₄O₁₂ crystals.

To further investigate the fluorescence mechanism, the room temperature fluorescence decay curves of the ⁵D₀ level excited by 394 nm were presented in Fig. 7. The measured decay curves showed a single exponential decaying behavior, and the fluorescence lifetimes of Eu:YAG and Eu:Y₃ScAl₄O₁₂ crystals were measured to be 3.19 and 2.97 ms, respectively, which is much longer than that of Eu:CaGd₄O₇ phosphors (700 μs) [30]. The incorporation of Sc³⁺ in YAG decrease the life time of the excited state (⁵D₀) in Eu-doped Y3SAG around 7%. The incorporation of Sc in Eu-doped YAG can slightly affect lattice parameter inducing lattice defects, which can strongly affect the life time. The Sc environment influence the lifetime of Eu³⁺ in garnet structure. Eu:tellurite glasses (0.93 ms) [31], Eu:CaGdAlO₄ crystal (1.02 ms) [12] and Eu:Bi₄Ge₃O₁₂ crystal (1.51 ms) [15]. The result shows that Eu:YAG and Eu:Y₃ScAl₄O₁₂ crystals are promising candidates for red luminescent/laser materials.

Fig. 7. Decay curves of 5D_0 level of Eu:YAG and Eu:Y₃ScAl₄O₁₂ crystals.

4. Conclusion

In this work, Eu³⁺-doped YAG and Y₃ScAl₄O₁₂ single crystals have been successfully grown by the μ -PD method for the first time. The optical properties including absorption spectra, fluorescence spectra and fluorescence decay curves of Eu:YAG and Eu:Y₃ScAl₄O₁₂ were characterized and compared. The FWHM of absorption band at 395 nm was calculated to be 1.89 and 2.21 nm for Eu:YAG and Eu:Y₃ScAl₄O₁₂, respectively. The most intense red emission centered at 710 nm corresponding to the transition $^5D_0 \rightarrow ^7F_4$, and the FWHM of emission band at 710 nm was calculated to be 2.03 and 3.19 nm for Eu:YAG and Eu:Y₃ScAl₄O₁₂, respectively. The lifetime of Eu:YAG and Eu:Y₃ScAl₄O₁₂ crystals was measured to be 3.19 and 2.97 ms, respectively. All the results show that the Eu:YAG and Eu:Y₃ScAl₄O₁₂ crystals are potential media for red luminescent emission.
