Abstract—In this paper, we present a simple way to design sext-band band-pass filter based on multi-shortened-stub resonators. Each sext-band resonator consists in the parallel association of five stepped-impedance resonators in a non-coupled structure and allows the control of transmission zeros and bandwidths. A second-order sext-band band-pass filter is synthesized and realized in microstrip technology, the final circuit successfully integrating five stubs per resonators into a single planar circuit. Compared with coupled structures, the solution proposed here can achieve good in-band responses, band-to-band isolation with a simple design procedure. It also needs less optimization. All of these merits make this filter an attractive solution for multi-band wireless communication systems.

Index Terms—Sext-band band-pass filter, shortened-stub resonators, Chebyshev filter, star-like topology.

I. INTRODUCTION

Multi-band band-pass filters (BPFs) with high performance are more and more needed in modern wireless communication systems. Nevertheless, their design is highly challenging when the number of bands increases. This paper focuses on the case of sext-band BPF for which only few papers were already published [1]–[4]. In [1], a sext-band BPF was constructed by using various quarter-wavelength stepped-impedance resonators (SIRs). By controlling the combinations of SIRs with different impedance ratios and electrical length ratios, several resonant frequencies were achieved to design the filter. In [2], authors developed a sext-band BPF by using semi-lumped resonators, which consist of two identical microstrip lines and a chip inductor at the center. Compared with half-wavelength resonators, these semi-lumped resonators are compact and allow a better control of the harmonic frequencies. In [3], a single multi-mode resonator was proposed to design a sext-band BPF with wide upper stop-band and high band-to-band isolation. Moreover, thanks to these multi-mode resonators, reflection zeros (RZ) and transmission zeros (TZ) can be controlled by adjusting the electrical lengths of two open-ended stubs. In [4], the use of SIR cascading stages, leads

to a miniaturized sext-band BPF. However, the band-to-band isolation and pass-band ripple level are not satisfying. All these sext-band BPFs are synthesized by coupled structures. However, multi-band (BPFs) based on coupled structures have some drawbacks. It is therefore difficult to obtain an adequate adjustment of the filter responses with most design methods. As a result, one may rarely meet all the design requirements for all pass-bands simultaneously. Such multi-band BPF also suffer from in-band or band-to-band poor performance and numerous optimization steps are often needed. Most of these drawbacks are also true for the rare published works on BPF with seven or more bands [5]–[8].

In this paper, we propose a non-coupled structure to design sext-band BPF based on Multi-Shorted-Stub Resonators (MSSR) implemented in a star-like topology. A simple but efficient method is then proposed to design the sext-band filter. Measurements validate the proposed theory and design techniques. Good simulation results and show that this MSSR topology is a good candidate for synthesizing sext-band BPFs.

II. THEORY OF NON-COUPLED MULTI-SHORTED-STUB RESONATORS

The proposed MSSR is constructed by combining several SIRs. As shown in Fig.1, such a resonator is composed of five short-ended branches on a star-like implementation. For simplicity, we assume that the electrical length of each part of the branch i ($i \in [1; 5]$) of the MSSR equals to $\lambda/4$ (or $\theta_i = \pi/2$ in Fig.1) at its resonant frequency f_{zi} which will, at the end, correspond to a transmission zero. So the total input admittance can be written as:

$$Y_{tot} = \sum_{i=1}^5 Y_i = j \sum_{i=1}^5 \frac{Z_{i2} \tan^2\left(\frac{f}{f_{zi}} \frac{\pi}{2}\right) - Z_{i1}}{Z_{i1}(Z_{i1} + Z_{i2}) \tan\left(\frac{f}{f_{zi}} \frac{\pi}{2}\right)} \quad (1)$$

where Y_{tot} denotes the total input characteristic admittance of the sext-band resonator, f is the frequency and Z_{i1} and Z_{i2}

Fig. 1. Proposed Multi-Shorted-Stub Resonators (MSSR) topology.

are the characteristic impedance of the first and the second parts of the i^{th} short-ended stub ($i \in [1; 5]$). It is easy to show that the TZ are obtained when $f = f_{zi}$. In this condition, the input admittance goes to infinity and each transmission zero f_{zi} determines the length of the associated branch i . So, firstly, five TZ are produced, one per SIR. In fact, one can also take into account two additional TZ: one at the origin ($f_{z0} = 0$ Hz) and another, called f_{z6} , which is the first harmonic of f_{z1} . Of course, these two additional TZ cannot be fixed independently. One reflection zero can be obtained between each TZ leading to a total of six pass-bands. These RZ appear when $Y_{tot} = 0$. One should notice that this equation is non-linear as the one associated to the slope parameter that can be easily deduced from (1). So to simplify the filter conception, an optimization was made to determine the impedances Z_{i1} and Z_{i2} , knowing that the firsts need to be higher than possible and the second relatively low to obtain narrow rejected bands between each pass-band frequency.

An example of such a sext-band resonator was designed with the following input parameters:

- *Transmission zeros*: $f_{z1} = 1.8$ GHz, $f_{z2} = 2.1$ GHz, $f_{z3} = 2.4$ GHz, $f_{z4} = 2.7$ GHz, $f_{z5} = 3.0$ GHz and so $f_{z6} = 2f_{z1} = 3.6$ GHz;
- *Reflection zeros*: $f_{01} = 1.650$ GHz, $f_{02} = 1.935$ GHz, $f_{03} = 2.245$ GHz, $f_{04} = 2.520$ GHz, $f_{05} = 2.815$ GHz, $f_{06} = 3.115$ GHz.

Its frequency response is presented in Fig.2. It was obtained from (1) after solving for Z_{i1} and Z_{i2} and exhibits the required performance of a sext-band filter with such narrow rejection bands.

An N -order sext-band band-pass filter could then be designed using N MSSR and J-inverters as presented schematically in Fig.3.

Fig. 2. Single resonator's S parameters with $Z_{11} = 138\Omega$, $Z_{12} = 23.1\Omega$, $Z_{21} = 137.8\Omega$, $Z_{22} = 30\Omega$, $Z_{31} = 136\Omega$, $Z_{32} = 22\Omega$, $Z_{41} = 24\Omega$, $Z_{42} = 23\Omega$, $Z_{51} = 138\Omega$, $Z_{52} = 22\Omega$.

III. DESIGN AND CHARACTERIZATION OF A SECOND-ORDER SEXT-BAND FILTER

As an example, a second-order sext-band band-pass filter has been designed. The two sext-band resonators used here are identical and are based on the one sizing in the previous section. The admittance value of the inverters are $J_{01} = 0.0125S$ and $J_{12} = 0.00862S$ respectively. The ideal frequency responses are presented in Fig.4 and again fulfill the initial requirements. All the pass-bands return losses are better than -20 dB and the bandwidths are equal to 56 MHz, 59 MHz, 55 MHz, 50 MHz, 48 MHz, 47 MHz respectively.

This filter was then implemented in microstrip technology. It was fabricated on Rogers RO4003 substrate of height $h = 0.508$ mm, relative permittivity $\epsilon_r = 3.55$ and loss tangent $\tan \delta = 0.0027$. The sext-band band-pass filter was designed using ADS 2017 from Keysight Technologies©. Mitigation of cross-coupling was realized by appropriate arrangement of all the resonators. A photograph of the fabricated filter is shown in Fig.5. For each sext-band resonators, the dimensions of the filter are the following (all in millimetres): $L_s = 20.00$, $W_s = 1.13$, $L_{01} = 18.55$, $W_{01} = 0.47$, $L_{02} = 19.00$, $W_{02} = 0.18$, $L_{11} = 26.64$, $W_{11} = 0.10$, $L_{12} = 23.81$, $W_{12} = 3.35$, $L_{21} = 22.83$, $W_{21} = 0.10$, $L_{22} = 20.73$, $W_{22} = 2.38$, $L_{31} = 0.11$, $W_{31} = 19.96$, $L_{32} = 17.60$, $W_{32} = 3.55$, $L_{41} = 17.73$, $W_{41} = 0.12$, $L_{42} = 15.60$, $W_{42} = 3.36$, $L_{51} = 15.98$, $W_{51} = 0.10$, $L_{52} = 13.8$, $W_{52} = 3.55$.

Fig. 4. S-parameters of the proposed sext-band BPF.

Fig. 5. Layout of the fabricated sext-band filter.

Fig.6 shows the simulated and measured S parameters of the sext-band BPF. A good correlation is obtained by EM simulation and measurement except in terms of insertion losses. Nevertheless, the important measured losses (between 3.3 and 5.5 dB according to the band) are mainly due to the internal low-cost laser etching realization process which alters the substrate characteristics. The adjacent band-to-band isolation are above -36.1dB, -41.1dB, -38.4dB, -41.7dB and -39.2dB respectively which shows we can achieve sharp and deep rejections between the adjacent pass-bands.

IV. CONCLUSION

In this paper, a non-coupled sext-band BPF with a star-shape Multi-Shorted-Stub Resonator has been presented. The design procedure is simple and fast and high band-to-band isolation can be easily obtained. The filter had been implemented in microstrip technology to validate the proposed theory. Good agreements have been achieved between simulation and measurements. The proposed Multi-Shorted-Stub Resonator can
