This paper designs an optimal observer-based output feedback control for traffic breakdown to dissolve traffic congestion by means of backstepping method and optimization. The linearized ARZ model is used to represent the congested traffic dynamics resulting from traffic breakdown. Based on the factors leading to traffic breakdown, we take into account the boundary conditions consisting of a boundary with a constant density and a speed drop at the upstream inlet of a bottleneck, and a boundary with a disturbance of inflow (high traffic demand) at the inlet of the road segment under consideration. In order to dissolve traffic congestion, a dynamic feedback controller is designed at the upstream boundary. By using backstepping approach, an observer-based output feedback controller is computed to guarantee the iISS of the closed-loop system. Through establishing an optimization problem and solving it, the optimal values of the considered class of controller are obtained. The performance of the output feedback controller is also validated by numerical simulations.

INTRODUCTION

Traffic congestion resulting from traffic breakdown is an ubiquitous problem resulting in the increase of fuel consumption and unsafe driving conditions. In the real world, traffic breakdown usually arises from the combination of three factors: high traffic demand, bottlenecks, and disturbances caused by individual drivers [1]. High traffic demand is the inflow indicating the potential average traffic flow on the main road and exceeding the bottleneck capacity, such as during rush hours. The most bottlenecks include flow-conserving bottlenecks and non-flow-conserving bottlenecks with additional sources and sinks, for example, on-ramp and off-ramp bottlenecks, or permanent and temporary types such as the blocking effect resulted from the accidents or traffic lights. Local disturbances are caused by individual drivers, such as abrupt lane changes, braking maneuvers, or other un-anticipated actions. The disturbances often lead to a platoon of vehicles following each other at small time gaps which eventually becomes the first propagating upstream traffic wave of a triggered stop-and-go state.

There are several macroscopic models of traffic dynamics including first order Lighthill-Whitham-Richards (LWR) model (see [2] and [3]), second order Payne-Whitham (PW) model (see [4] and [5]) and second order Aw-Rascle-Zhang (ARZ) model (see [6] and [7]). The first-order LWR model represents density-velocity relation in equilibrium and fails to model stop-and-go traffic. PW model consists of momentum equation and conservation law, and it is a nonlinear second-order PDEs that describe deviations from density-velocity equilibrium. It is shown that disturbances in PW model travel faster than traffic velocity in [8] and [9]. Consequently, vehicles on freeway are effected by both behind and front. [7] showed that drivers mostly respond to the traffic in front of them. [6] and [7] separately brought forward a new velocity equation to solve this problem. Afterwards, ARZ model is derived from the combination of these two models through suitable definition and coefficients. Two-dimensional traffic dynamic model for large scale traffic networks is introduced in [10].

In order to stabilize hyperbolic systems of the highway traffic, it is natural to use boundary feedback control on available control signals as ramp metering or variable speed limits on a road. In order to design a boundary control law for the linearized ARZ traffic flow model, spectral analysis is applied in [11]. Paper [12] proves the local stability of a positive hyperbolic system and [13] designs a PI boundary feedback controller to stabilize the oscillations of the traffic parameters on a freeway by Lyapunov method. [14] presents explicit boundary conditions which guarantee the Lyapunov stability of the weak entropy solution to the scalar conservation law with convex flux.

In this paper, we use backstepping method to derive a boundary feedback controller to dissolve traffic congestion resulting from traffic breakdown. The rationale behind the backstepping method is the following: through constructing an appropriate Volterra integral transformation, the original PDE system is mapped to an integral input-to-state stable target system. The original system inherits the stability property thanks to the invertibility of backstepping transformation. The kernels derived from the backstepping transformation are adopted as gains of the original system feedback controller.

The backstepping method for hyperbolic PDEs was initially introduced by [15], [16] and [17]. For backstepping boundary control design of $2 \times 2$ coupled hyperbolic systems, there are some theoretical results obtained recently. [18] uses a backstepping transformation to design a full-state feedback control law and derives $H^2$ exponential stability for a quasilinear $2 \times 2$ system of first-order hyperbolic PDEs. Robust output regulation problem for boundary controlled linear $2 \times 2$ hyperbolic systems is solved in [19]. By implementing the finite-time state feedback regulator with disturbance observers, the finite-time output regulation problem is solved in [20]. Two closely related state feedback adaptive control laws are designed for stabilization of linear hyperbolic system with constant but uncertain in-domain and boundary parameters in [21]. In [22], a boundary observer for nonlinear ARZ traffic flow model is designed to estimate the information of traffic states using the backstepping method. An output feedback controller is designed
for the underactuated cascade network of interconnected PDE systems using backstepping in [23].

In consideration of the limits of technology and cost, there have been research inspired by [24], designing an observer-based output feedback control law for the linearized ARZ traffic flow model by using backstepping transformations (see also [25]). Although [26] has used the same method to deal with the disturbance rejection problem from the oil and gas industry, this paper in the first work to design an optimal observer-based output boundary control of traffic breakdown to remove or weaken the effect of high traffic demand acting as a given time-varying disturbance input with the fastest convergence rate. Moreover, we design a controller and an observer respectively with a time-depending integral term to reject disturbances by using backstepping transformation mapping the error system into an integral input-to-state stable target system with a time-varying disturbance term. We use Lyapunov approach to prove the iISS of this target system whose boundary control strategy is PI boundary control. Inspired by [27], we can compute the kernels of backstepping transformations using a general expression of the kernel functions.

This paper is organized as follows. In Section 2, the linearized ARZ traffic flow model with boundary disturbances for congested traffic deriving from traffic breakdown is derived by making use of coordinate transformation and linearization around the steady state. Using backstepping transformation to map the linearized ARZ traffic flow model into an integral input-to-state stable target system, we obtain a full state feedback controller in Section 3. An observer-based output feedback controller is designed in Section 4. In Section 5, the optimization problem is discussed and the results of numerical simulations are provided. The paper ends with concluding remarks in Section 6.

2 | TRAFFIC FLOW SYSTEM AND CONTROL PROBLEM

2.1 | ARZ traffic flow system and problem statement

The Aw-Rascle-Zhang model is a typically local second-order macroscopic traffic flow model composed of the following continuity and acceleration equations:

\[
\begin{align*}
\rho_t + (\rho v)_x &= 0, \\
v_t + (v - \rho p'(\rho)) v_x &= \frac{V_e(\rho) - v}{\tau},
\end{align*}
\]

with an independent space variable \(x\) in \((0, L)\) on a road section of length \(L\), and an independent time variable \(t\) in \([0, \infty)\). As the locally aggregated quantities, the traffic density \(\rho(x, t)\) is defined as the number of vehicles per unit length at time \(t\), the mean speed \(v(x, t)\) is the average speed of the vehicles passing the location \(x\) for a fixed time interval. The speed adaptation time \(\tau\) is a constant and corresponds to the inverse of the agility. In the previous model, the steady-state speed \(V_e(\rho)\) is the speed-density relation given by Greenshields model in [28] as

\[
V_e(\rho) = v_f \left(1 - \frac{\rho}{\rho_m}\right),
\]

where \(v_f\) is the free flow speed, \(\rho_m\) is the maximum density. The speed adaptation term or relaxation term located in the right side of equation (2) describes the mean acceleration of the vehicles in the local neighborhood for reaching the steady-state speed.

The traffic pressure \(p(\rho)\) is an increasing function of density defined as

\[
p(\rho) = v_f - V_e(\rho) = \frac{v_f}{\rho_m} \rho.
\]
Let $\omega = v + \frac{vr}{\rho m} D$, then (1) and (2) are written as

$$\omega_t + v \omega_x = \frac{vr - \omega}{\tau}, \quad (5)$$
$$v_t + (2v - \omega)v_x = \frac{vr - \omega}{\tau}. \quad (6)$$

In (6), the propagation velocity $2v - \omega > 0$ stands for the weak interactions between the vehicles, the traffic wave propagates with the traffic flow (downstream) at this characteristic velocity in free traffic. Usually, the propagation velocity of the traffic wave is slightly less than the average free-flow vehicle speed in free traffic. Reversely, the characteristic velocity $2v - \omega < 0$ represents the traffic waves moves against the traffic flow (upstream) in congested traffic due to the reaction of the drivers to their respective leading vehicles. In this paper, we take into account the control problem of perturbation in congested traffic situations.

Denote by $(\omega^*, v^*)^T$ in $C^1([0, L]; \mathbb{R}^2)$ a steady state of the system (5)-(6) such that $2v^*(x) - \omega^*(x) < 0$ for all $x \in [0, L]$ on a stable and inhomogeneous road (with speed and density gradients). Note that it depends on the space variable $x$ and the corresponding density is $\rho^*(x) = \frac{m}{\tau} (\omega^*(x) - v^*(x))$. The deviations from the system states $(\omega, v)^T$ are defined as

$$\check{\omega}(x, t) = \omega(x, t) - \omega^*(x), \quad (7)$$
$$\check{v}(x, t) = v(x, t) - v^*(x), \quad (8)$$

then the quasilinear deviation system is obtained,

$$\check{\omega}_t(x, t) + \Lambda_1(\check{\omega}, \check{v}, x)\check{\omega}_x(x, t) + \check{v}(x, t) \frac{d\omega^*(x)}{dx} + \frac{\check{\omega}(x, t)}{\tau} = 0, \quad (9)$$
$$\check{v}_t(x, t) + \Lambda_2(\check{\omega}, \check{v}, x)\check{v}_x(x, t) + (2\check{v}(x, t) - \check{\omega}(x, t)) \frac{d\omega^*(x)}{dx} + \frac{\check{\omega}(x, t)}{\tau} = 0, \quad (10)$$

with two characteristic velocities

$$\Lambda_1(\check{\omega}, \check{v}, x) = \check{v}(x, t) + v^*(x), \quad (11)$$
$$\Lambda_2(\check{\omega}, \check{v}, x) = 2\check{v}(x, t) - \check{\omega}(x, t) + 2v^*(x) - \omega^*(x), \quad (12)$$

where $\Lambda_1(\check{\omega}, \check{v}, x) > 0, \Lambda_2(\check{\omega}, \check{v}, x) < 0$.

As described in [1], beyond the deterministic factors causing the traffic breakdown, high traffic demand is the most effective ingredient. The disturbances caused by bottlenecks or individual drivers can not grow and propagate on account of unconditional stability, if the traffic load is low enough. However, in spite of the absolute stability, traffic breakdown will take place with inflow in excess of the capacity of bottlenecks on the considered road segment. The local capacity reduction is the decisive attribute of characterizing the obstructing effect of a bottleneck. Furthermore, we can not predict the time and location of individual traffic breakdown due to the stochastic and single-vehicle natures of disturbances caused by individual drivers.

In order to increase the efficiency and stability of traffic flow, we investigate the optimal control of high traffic demand by ramp metering in the presence of a bottleneck and disturbances on the road. Considering a road segment with a constant density $\rho^*_m$ and a speed drop $v_m(L, t) > v^*_m(L, t)$ at the boundary of the bottleneck, the diagram of the control model is illustrated in Figure 1. The control is defined as $U(t)$ and would depend only on $t$. 

To be more specific, the boundary condition at $x = L$ is, for all $t \geq 0$,

$$\rho_-(L, t) = \rho_+(L, t) = \rho_{\text{out}}^*.$$  \hspace{1cm} (13)

On the basis of the conservation of vehicle flows, the boundary condition with disturbances caused by high traffic demand at the upstream inlet $x = 0$ can be derived,

$$Q_{in}^* + Q_{rmp}^* + U(t) + \bar{p}(t) = \rho(0, t)v(0, t),$$  \hspace{1cm} (14)

where $Q_{rmp}^* > 0$ denotes the steady-state on-ramp flow at the segment boundary upstream, $Q_{in}^*$ denotes the steady-state inflow at the upstream boundary, and they satisfy $Q_{in}^* + Q_{rmp}^* = \rho^*(0)v^*(0)$; $\bar{p}(t)$ is the unknown disturbances of inflow serving as exogenous variable (externally given model input) depending on time $t$, the difference between the measured speed at the inlet $v(0, t)$ and the corresponding steady state $v^*(0) \geq 0$ acts as the model output, i.e.,

$$y(t) = v(0, t) - v^*(0).$$  \hspace{1cm} (15)

and the control law $U(t)$ is implemented by the on-ramp metering at upstream boundary of the main road. Ramp metering temporarily reduces the traffic throughput and delays to increase it to prevent a traffic breakdown and the associated capacity drop. We compute the optimal gains of controller $U(t)$ depending on the output $y(t)$ only, so that the system states converge to the steady state at the fastest speed, up to a constant depending on the size of the disturbance $\bar{p}$.

## 2.2 Coordinate transformation and linearization around steady state

In this section, in order to solve the previous problem, we perform a change of variables and we linearize the model. Define the coordinate transformation

$$e_1(x, t) = \psi_1(x)\tilde{\omega}(x, t),$$  \hspace{1cm} (16)

$$e_2(x, t) = \psi_2(x)\tilde{v}(x, t).$$  \hspace{1cm} (17)
with

\[ \psi_1(x) = \exp \left( \int_0^x \frac{1}{\tau \nu^*(s)} \, ds \right), \]  
\[ \psi_2(x) = \exp \left( \int_0^x \frac{2}{\nu^*(s) - \omega^*(s)} \, ds \right). \]  

for all \( x \) in \( (0, L) \), then the system (9)-(10) is rewritten as follows,

\[ \begin{align*}
\epsilon_{1t} + \Lambda_1(\epsilon_1, \epsilon_2, x)\epsilon_{1x} + c_1(x)\epsilon_2 &= \frac{\psi_2^{-1}(x)}{\tau \nu^*(x)} \epsilon_1 \epsilon_2 = 0, \\
\epsilon_{2t} + \Lambda_2(\epsilon_1, \epsilon_2, x)\epsilon_{2x} + c_2(x)\epsilon_1 &= \frac{d\nu^*(x)}{dx} \left( \frac{2\epsilon_2}{2\nu^*(x) - \omega^*(x)} \right) \left( 2\psi_2^{-1}(x)\epsilon_2 - \psi_1^{-1}(x)\epsilon_1 \right) = 0.
\end{align*} \]  

with

\[ \Lambda_1(\epsilon_1, \epsilon_2, x) = \psi_2^{-1}(x)\epsilon_2 + \nu^*(x), \]  
\[ \Lambda_2(\epsilon_1, \epsilon_2, x) = 2\psi_2^{-1}(x)\epsilon_2 - \psi_1^{-1}(x)\epsilon_1 + 2\nu^*(x) - \omega^*(x), \]  
\[ c_1(x) = \frac{d\omega^*(x)}{dx} \psi_1(x)\psi_2^{-1}(x), \]  
\[ c_2(x) = \left( \frac{1}{\tau} - \frac{d\nu^*(x)}{dx} \right) \psi_1^{-1}(x)\psi_2(x). \]  

From the linearization of the quasilinear equation (20)-(21), we can derive

\[ \begin{align*}
\epsilon_{1t}(x, t) + \lambda_1(\epsilon_1, \epsilon_2, x, t)\epsilon_{1x}(x, t) + c_1(x)\epsilon_2(x, t) &= 0, \\
\epsilon_{2t}(x, t) - \lambda_2(\epsilon_1, \epsilon_2, x, t)\epsilon_{2x}(x, t) + c_2(x)\epsilon_1(x, t) &= 0.
\end{align*} \]  

with

\[ \lambda_1(x) = \nu^*(x) > 0, \]  
\[ \lambda_2(x) = \omega^*(x) - 2\nu^*(x) > 0. \]  

Therefore, from (13) and the transformations (7)-(8) and (16)-(17), the boundary condition at \( x = L \) may be achieved as, for all \( t \geq 0 \),

\[ \epsilon_1(L, t) = \kappa \epsilon_2(L, t). \]  

with

\[ \kappa = \psi_1(L)\psi_2^{-1}(L). \]  

The following linearized boundary condition at \( x = 0 \) is derived from (14),

\[ \epsilon_1(0, t) = q_1 \epsilon_2(0, t) + q_2 \left( U(t) + \beta(t) \right). \]
with

\[ q_1 = \frac{2v^*(0) - \omega^*(0)}{v^*(0)}, \]  

(33)

and

\[ q_2 = \frac{\nu_f}{\rho_m v^*(0)}. \]  

(34)

We reformulate the previous control problem as follows. We seek the optimal parameters of an observer-based output feedback control law to attain the maximum throughput (inflow) at the upstream of considered road section in order to remove or weaken the effect of high traffic demand and stabilize the linearized ARZ traffic flow model. Inspired by [24], [18], but using different backstepping transformations due to different boundary conditions, we can design a new observer-based output feedback control law. Firstly, we derive a full-state feedback control law with kernels from the backstepping transformation mapping the original system to an integral input-to-state stable target system. An observer is designed to estimate the states of the linearized ARZ traffic flow system. The precise estimation to the states of the original system is guaranteed by the analytic expressions of injection gains which are obtained by the backstepping transformation mapping the error system (derived by subtracting the state-estimate system from the original system) to the same target system. Finally, the optimal parameters of the observer-based output feedback controller are derived by solving the optimization problem with the objective function, defined as the highest rate of exponential convergence.

3 | FULL-STATE FEEDBACK CONTROLLER

The main results of this section are the proof of the iISS of a target system with PI boundary conditions and obtaining a full-state feedback controller through backstepping transformation.

3.1 | Target system

Firstly, we introduce a target system,

\[ \alpha_t(x, t) + \lambda_1(x)\alpha(x, t) = 0, \]  

(35)

\[ \beta_t(x, t) - \lambda_2(x)\beta(x, t) = 0, \]  

(36)

\[ \alpha(L, t) = \kappa \beta(L, t), \]  

(37)

\[ \alpha(0, t) = q_1 \beta(0, t) + k_i \eta(t), \]  

(38)

where \( k_i \in \mathbb{R} \setminus \{0\} \) is an integral tuning parameter, and

\[ \eta(t) = \int_0^t (\beta(0, s) - \alpha(0, s)) \, ds + k_\eta^{-1} q_2 \bar{p}(t). \]  

(39)

According to the following theorem, the target system (35)-(39) is integral input-to-state stable for \( L^2 \)-norm. The symbol * stands for a symmetric block in the following content.
Theorem 1 (Integral Input-to-state Stability of Target System) Assume there exist positive constants $\mu$, $\theta$, $p_1$, $p_2$, $p_3$, $q_3$ and constant $p_3$ such that for all $x$ in $[0, L]$,

$$M_1 = \begin{bmatrix} M_1^{11} & M_1^{12} & M_1^{13} \\ M_1^{21} & M_1^{22} & M_1^{23} \\ M_1^{31} & M_1^{32} & M_1^{33} \end{bmatrix} \geq 0$$

with

$$M_1^{11} = p_1 e^{-\mu L} - \frac{p_2}{k^2} e^{\mu L}. \quad (41)$$

$$M_1^{12} = 0. \quad (42)$$

$$M_1^{13} = -\frac{p_4}{2k} e^{\frac{\theta}{2} L}. \quad (43)$$

$$M_1^{22} = -p_1 q_1^2 + p_2 - \frac{3q_4 L}{2} |p_3|(1 - q_1)^2. \quad (44)$$

$$M_1^{23} = -p_1 q_1 k_i + \frac{p_3}{2} \frac{1}{2} p_4 L(1 - q_1). \quad (45)$$

$$M_1^{33} = -p_1 k_i^2 - \frac{3q_4 L}{2} |p_3|k_i^2 + (1 - m) L(p_4 k_i - \frac{q_3}{2} |k_i^{-1}| q_2 p_4). \quad (46)$$

$$\begin{bmatrix} \frac{p_2}{2L(x)} & \frac{p_3}{2L(x)} & \frac{p_4}{2} \\ \frac{p_3}{2L(x)} & \frac{p_4}{2} & \theta L(x) \end{bmatrix} > 0, \quad (47)$$

$$m(k_i - \frac{q_3}{2} |k_i^{-1}| q_2) > \theta \frac{3}{2}, \quad (48)$$

$$\mu > \frac{\theta}{L_1(x)}, \quad (49)$$

and

$$\begin{bmatrix} \mu p_2 - |p_1| L_1(x) & \frac{\theta p_3}{2L_1(x)} \\ \frac{\mu p_3}{4} - \frac{\theta p_3}{2L_2(x)} & m(p_4 k_i - \frac{q_3}{2} |k_i^{-1}| q_2 p_4) \end{bmatrix} > 0. \quad (50)$$

Then there exists positive constants $\Omega_1$, $b_1$ such that, for any $z_0 = (x(t), \beta(t), \eta(t))^{\top}$ in $L^2((0, L); \mathbb{R}^3)$, and for any $\bar{\beta}$ such that $\bar{\beta} \in L^2[0, \infty)$, the solution $z = (x, \beta, \eta)^{\top}$ to the system (35)-(39) satisfies, for all $t \geq 0$,

$$\|z(\cdot, t)\|_{L^2((0, L); \mathbb{R}^3)}^2 \leq \Omega_1 e^{-\theta t} \|z_0\|_{L^2((0, L); \mathbb{R}^3)}^2 + b_1 \int_0^t \bar{\beta}^2(s) \, ds. \quad (51)$$

Remark Some observations follow

- From the inequality condition (48) in Theorem 1, it follows that the parameters $m$ and $k_i$ have the identical sign, i.e., $mk_i > 0$.
- Note that the first term at the right-hand side of inequality (51) is continuous, decreasing with respect to $t$ and converges to zero as $t$ goes to infinity. Since $b_1 > 0$, the second term is increasing and tends to the $L^2$ norm of $\bar{\beta}$. That is, the integral input-to-state stability of system (35)-(39) is verified by definition in [29] and [30].
Proof The following candidate Lyapunov function is proposed for the purpose of analyzing the stability of the system (35)-(39),

\[
V = \int_0^L \begin{bmatrix} \alpha(x, \cdot) \\ \beta(x, \cdot) \\ \eta(\cdot) \end{bmatrix}^T P(x) \begin{bmatrix} \alpha(x, \cdot) \\ \beta(x, \cdot) \\ \eta(\cdot) \end{bmatrix} \, dx = V_1 + V_2 + V_3 + V_4,
\]

with

\[
P(x) = \begin{bmatrix} \frac{p_1}{\lambda_1(x)} e^{-\mu x} & 0 & 0 \\ * & \frac{p_2}{\lambda_2(x)} e^{\mu x} & \frac{p_3}{2 \lambda_2(x)} e^{\mu x} \\ * & * & \frac{p_4}{2} \end{bmatrix}, \quad \text{for all } x \in [0, L]
\]

and

\[
\begin{align*}
V_1 &= p_1 \int_0^L \frac{e^{-\mu x}}{\lambda_1(x)} \alpha^2(x, \cdot) \, dx, \\
V_2 &= p_2 \int_0^L \frac{e^{\mu x}}{\lambda_2(x)} \beta^2(x, \cdot) \, dx, \\
V_3 &= p_3 \eta(\cdot) \int_0^L \frac{e^{\mu x}}{\lambda_2(x)} \beta(x, \cdot) \, dx, \\
V_4 &= \frac{p_4}{2} L \eta^2(\cdot).
\end{align*}
\]

On account of inequality (47) with \( p_1 > 0, \lambda_1(x) > 0 \), the following inequality holds for all \( x \) in \([0, L]\),

\[
\begin{bmatrix} \frac{p_1}{\lambda_1(x)} e^{-\mu x} & 0 & 0 \\ * & \frac{p_2}{\lambda_2(x)} e^{\mu x} & \frac{p_3}{2 \lambda_2(x)} e^{\mu x} \\ * & * & \frac{p_4}{2} \end{bmatrix} > 0.
\]

Using Schur complement with \( p_4 > 0 \), \( P(x) \) is symmetric positive definite for all \( x \) in \([0, L]\). Therefore,

\[
\lambda_{\min} \cdot \left( \int_0^L \left( \alpha^2(x, \cdot) + \beta^2(x, \cdot) \right) \, dx + L \eta^2(\cdot) \right) \leq V \leq \lambda_{\max} \cdot \left( \int_0^L \left( \alpha^2(x, \cdot) + \beta^2(x, \cdot) \right) \, dx + L \eta^2(\cdot) \right),
\]

where

\[
\lambda_{\min} = \min_{x \in [0, L]} \lambda(P(x)),
\]

\[
\lambda_{\max} = \max_{x \in [0, L]} \lambda(P(x)).
\]

In the previous equation, \( \lambda(P(x)) \) is the eigenvalue of \( P(x) \) and \( \lambda_{\min} > 0, \lambda_{\max} > 0 \).

From (39), one can derive

\[
\eta(t) = \beta(0, t) - \alpha(0, t) + k_i^{-1} q_2 \hat{v}(t).
\]

The time derivatives of (54)-(57) along the solutions to the system (35)-(39) are computed using integrations by parts
in (54)-(56), Young’s inequality in (56), and (62), for all \( t \geq 0 \),

\[
\dot{V}_1 = 2p_1 \int_0^L \frac{e^{-\mu x}}{\lambda_1(x)} \sigma(x,t)\alpha(x,t) \, dx \\
= -p_1 \sigma^2(x,t) e^{-\mu x} \bigg|_0^L - \mu p_1 \int_0^L \alpha^2(x,t) e^{-\mu x} \, dx \\
= p_1 (q_1 \beta(0,t) + k_i \eta(t))^2 - p_1 e^{-\mu x} \alpha^2(L,t) - \mu p_1 \int_0^L \alpha^2(x,t) e^{-\mu x} \, dx.
\]

(63)

\[
\dot{V}_2 = 2p_2 \int_0^L \frac{e^{\mu x}}{\lambda_2(x)} \beta(x,t) \beta_t(x,t) \, dx \\
= p_2 \beta^2(x,t) e^{\mu x} \bigg|_0^L - \mu p_2 \int_0^L \beta^2(x,t) e^{\mu x} \, dx \\
= \frac{p_2}{k^2} \sigma^2 \alpha^2(L,t) - p_2 \beta^2(0,t) - \mu p_2 \int_0^L \beta^2(x,t) e^{\mu x} \, dx.
\]

(64)

\[
\dot{V}_3 = p_3 \eta(t) \int_0^L \frac{e^{\mu x}}{\lambda_2(x)} \beta(x,t) \, dx + p_3 \eta(t) \int_0^L \frac{e^{\mu x}}{\lambda_2(x)} \beta_t(x,t) \, dx \\
= p_3 \left( \beta(0,t) - \alpha(0,t) + k_i^{-1} q_2 \hat{\beta}(t) \right) \int_0^L \frac{e^{\mu x}}{\lambda_2(x)} \beta(x,t) \, dx + p_3 \eta(t) \beta(x,t) e^{\mu x} \bigg|_0^L - \frac{\mu}{2} p_3 \eta(t) \int_0^L \beta(x,t) e^{\mu x} \, dx \\
\leq \frac{q_4 L}{2} |p_3| \left( \left( 1 - q_1 \right) \beta(0,t) - k_i \eta(t) + k_i^{-1} q_2 \hat{\beta}(t) \right)^2 + \frac{1}{2q_4} \left| p_3 \right| \int_0^L \frac{e^{\mu x}}{\lambda_2(x)} \beta^2(x,t) \, dx + p_3 \frac{\mu}{k} \eta(t) \alpha(L,t) \\
- p_3 \eta(t) \beta(0,t) - \frac{\mu}{2} p_3 \eta(t) \int_0^L \beta(x,t) e^{\mu x} \, dx.
\]

(65)

\[
\dot{V}_4 = \left( 1 - q_1 \right) p_4 L \eta(t) \beta(0,t) - k_i p_4 L \eta^2(t) + k_i^{-1} q_2 p_4 L \eta(t) \hat{\beta}(t) \\
\leq \left( 1 - q_1 \right) p_4 L \eta(t) \beta(0,t) - k_i p_4 L \eta^2(t) + \frac{3q_3}{2} \left| k_i^{-1} q_2 p_4 L \eta(t) \hat{\beta}(t) \right|.
\]

(66)

Using (63)-(66), for all \( t \geq 0 \),

\[
\dot{V} \leq -\theta V - \begin{bmatrix} \alpha(L) \end{bmatrix}^T M_1 \begin{bmatrix} \sigma(L) \\ \beta(0) \\ \eta(0) \end{bmatrix} - \int_0^L \begin{bmatrix} \alpha(x) \\ \beta(x) \\ \eta(x) \end{bmatrix}^T M(x) \begin{bmatrix} \sigma(x) \\ \beta(x) \\ \eta(x) \end{bmatrix} \, dx + \left( \frac{3q_4 L}{2} \right) |p_3| k_i^{-2} q_2^2 + \frac{1}{2q_3} |k_i^{-1} q_2 p_4 L| \hat{\beta}^2(\cdot).
\]

(67)

where \( M_1 \) is given by (40) and

\[
M(x) = \begin{bmatrix} A(x) & B^T(x) \\ B(x) & C \end{bmatrix}.
\]

(68)
with

\[
A(x) = \begin{bmatrix} \mu p_1 - \frac{\theta p_1}{\lambda_1(x)} & e^{-\mu x} \\ 0 & \mu p_2 - \frac{\theta p_2}{2q_2 \lambda_2(x)} \end{bmatrix},
\]

\[
B(x) = \begin{bmatrix} \mu p_3 - \frac{\theta p_3}{2q_4 \lambda_2(x)} & e^{\mu x} \\ 0 & \mu p_4 - \frac{\theta p_4}{2} \end{bmatrix},
\]

\[
C = m(p_4 k_i - \frac{q_3}{2} |k^{-1}_i| q_2 p_4) - \frac{\theta p_4}{2}.
\]

Therefore, using the Schur complement of \( C \) in \( M(x) \) and (48), (71), for all \( x \) in \([0, L]\), \( M(x) > 0 \) holds if and only if

\[
A(x) - B^T(x)C^{-1}B(x) = \begin{bmatrix} M^{11}(x) & M^{12}(x) \\ M^{21}(x) & M^{22}(x) \end{bmatrix} > 0
\]

with

\[
M^{11}(x) = \left( \mu - \frac{\theta}{\lambda_1(x)} \right) p_1 e^{-\mu x},
\]

\[
M^{12}(x) = 0,
\]

\[
M^{22}(x) = \left( \mu p_2 - \frac{\theta p_2}{2q_2 \lambda_2(x)} \right) e^{\mu x} - \left( m(p_4 k_i - \frac{q_3}{2} |k^{-1}_i| q_2 p_4) - \frac{\theta p_4}{2} \right)^{-1} \left( \mu p_3 - \frac{\theta p_3}{2q_4 \lambda_2(x)} \right) e^{\mu x}.
\]

Inequality (72) holds if and only if the conditions (48)-(50) are satisfied. Thus using (40), if \( M(x) > 0 \) holds,

\[
V \leq -\theta V + a_1 \beta^2(s),
\]

with \( a_1 = \frac{3q_4 L}{2} |p_3| k^{-2}_i q_2^2 + \frac{1}{2q_3} |k^{-1}_i| q_2 p_4 L > 0 \), and thus along the solutions to the system (35)-(39),

\[
V \leq e^{-\theta t} V(z_0) + a_1 e^{-\theta t} \int_0^t \beta^2(s) e^{\theta s} ds \leq e^{-\theta t} V(z_0) + a_1 \int_0^t \beta^2(s) ds.
\]

Combining this relation with (59), there exists positive constants \( \Omega_1 \geq \frac{\lambda_{\max}}{\lambda_{\min}}, b_1 \geq \frac{a_1}{\lambda_{\min}} \) such that

\[
\int_0^L \left( a^2(x, t) + \beta^2(x, t) \right) dx + L \eta^2(t)
\]

\[
\leq \frac{1}{\lambda_{\min}} V
\]

\[
\leq \frac{1}{\lambda_{\min}} \left( e^{-\theta t} V(z_0) + a_1 \int_0^t \beta^2(s) ds \right)
\]

\[
\leq \frac{1}{\lambda_{\min}} \left( e^{-\theta t} \cdot \lambda_{\max} \cdot \left( \int_0^L \left( a^2(x, 0) + \beta^2(x, 0) \right) dx + L \eta^2(0) \right) + a_1 \int_0^t \beta^2(s) ds \right)
\]

\[
\leq \Omega_1 e^{-\theta t} \left( \int_0^L \left( a^2(x, 0) + \beta^2(x, 0) \right) dx + L \eta^2(0) \right) + b_1 \int_0^t \beta^2(s) ds,
\]

completing the proof of Theorem 1.
3.2 | Backstepping transformation and control law

As in [18], consider the backstepping transformation

$$
\alpha(x, t) = e_1(x, t) - \int_x^L G^{11}(x, \xi) e_1(\xi, t) \, d\xi - \int_x^L G^{12}(x, \xi) e_2(\xi, t) \, d\xi,
$$

(79)

$$
\beta(x, t) = e_2(x, t) - \int_x^L G^{21}(x, \xi) e_1(\xi, t) \, d\xi - \int_x^L G^{22}(x, \xi) e_2(\xi, t) \, d\xi,
$$

(80)

where $G^{11}(x, \xi), G^{12}(x, \xi), G^{21}(x, \xi)$ and $G^{22}(x, \xi)$ in $L^2((0, L]^2; \mathbb{R})$ are kernels in the triangular domain $T_1 = \{(x, \xi) \in \mathbb{R}^2 | 0 \leq x \leq \xi \leq L\}$.

Take time derivative and spatial derivative on (79) and (80), and substitute them into (35)-(39) to get the following conditions of the kernels from (26)-(30). The kernels $G^{11}(x, \xi), G^{12}(x, \xi), G^{21}(x, \xi)$ and $G^{22}(x, \xi)$ should satisfy the following kernel equations,

$$
\lambda_1(x) G^{11}(x, \xi) + \lambda_1(\xi) G^{11}_\xi(x, \xi) = -\lambda'_1(\xi) G^{11}(x, \xi) + c_2(\xi) G^{12}(x, \xi),
$$

(81)

$$
\lambda_1(x) G^{12}(x, \xi) - \lambda_2(\xi) G^{12}_\xi(x, \xi) = \lambda'_2(\xi) G^{12}(x, \xi) + c_1(\xi) G^{11}(x, \xi),
$$

(82)

$$
\lambda_2(x) G^{21}(x, \xi) - \lambda_1(\xi) G^{21}_\xi(x, \xi) = \lambda'_1(\xi) G^{21}(x, \xi) - c_2(\xi) G^{22}(x, \xi),
$$

(83)

$$
\lambda_2(x) G^{22}(x, \xi) + \lambda_2(\xi) G^{22}_\xi(x, \xi) = -\lambda'_2(\xi) G^{22}(x, \xi) - c_1(\xi) G^{21}(x, \xi),
$$

(84)

and the boundary conditions

$$
G^{11}(x, L) = \frac{\lambda_2(L)}{\lambda_1(L)} G^{12}(x, L),
$$

(85)

$$
G^{12}(x, x) = \frac{c_1(x)}{\lambda_1(x) + \lambda_2(x)},
$$

(86)

$$
G^{21}(x, x) = -\frac{c_2(x)}{\lambda_1(x) + \lambda_2(x)},
$$

(87)

$$
G^{22}(x, L) = \frac{\lambda_1(L)}{\lambda_2(L)} G^{21}(x, L).
$$

(88)

The well-posedness of the kernel equations (81)-(88) and the boundedness of kernel variables follow from a coordinate change $(x, \xi) \mapsto (L - \xi, L - x)$ and an application of Theorem A.1 in [18] in the triangular domain $T_2 = \{(L - \xi, L - x) \in \mathbb{R}^2 | 0 \leq L - \xi \leq L - x \leq L\}$. Therefore, for system (26)-(34), the following control law can be deduced,

$$
U(t) = \frac{k_1}{q_2} \int_0^t (e_2(0, s) - e_1(0, s)) \, ds
+ \frac{k_1}{q_2} \int_0^t \int_0^L \left[ (G^{11}(0, \xi) - G^{21}(0, \xi)) e_1(\xi, s) + (G^{12}(0, \xi) - G^{22}(0, \xi)) e_2(\xi, s) \right] \, d\xi \, ds
+ \frac{1}{q_2} \int_0^t \left[ (G^{11}(0, \xi) - q_1 G^{21}(0, \xi)) e_1(\xi, t) + (G^{12}(0, \xi) - q_1 G^{22}(0, \xi)) e_2(\xi, t) \right] \, d\xi.
$$

(89)

Under the assumptions in the Theorem 1, the target system (35)-(39) is integral input-to-state stable. Thus, using the invertibility of backstepping transformation, the original system (26)-(34) is integral input-to-state stable in the $L^2$-norm with the control law (89).
Obviously, from (89), the practical implementation of the feedback control law needs the knowledge of the full state \((e_1(x, t), e_2(x, t))^\top\) over the whole spatial domain \([0, L]\). From (15), the output under coordinate transformation is

\[ y(t) = e_2(0, t). \]  \hspace{1cm} (90)

In the next section, the knowledge of the full state \((e_1(x, t), e_2(x, t))^\top\) in the control law \(U(t)\) can be provided by a boundary state observer that uses the output \(y(t)\) in (90) with a boundary measurement of \(v(0, t)\) only. The kernels \(G^{11}(0, \xi), G^{12}(0, \xi), G^{21}(0, \xi)\) and \(G^{22}(0, \xi)\) can be derived by solving the kernel equations (81)-(88). Through choosing an appropriate value of \(k_i\), the iISS of original system (26)-(34) is guaranteed with the control law (89).

### 4 | OBSERVER DESIGN AND OUTPUT FEEDBACK CONTROLLER

From (15), we note that the output \(y(t)\) can be obtained by the measurement of inlet speed \(v(0, t)\) of the considered road segment. In order to estimate the state \((e_1, e_2)^\top\), a boundary observer is designed as in [24] by constructing the system with the output injection terms:

\[
\begin{align*}
\dot{e}_1(x, t) + \lambda_1(x)\dot{e}_1(x, t) + c_1(x)e_2(x, t) &= r(x)(y(t) - \hat{e}_2(0, t)), \\
\dot{e}_2(x, t) - \lambda_2(x)\dot{e}_2(x, t) + c_2(x)e_1(x, t) &= s(x)(y(t) - \hat{e}_2(0, t)), \\
\dot{e}_2(L, t) &= \frac{1}{\kappa}\dot{e}_1(L, t), \\
\dot{e}_1(0, t) &= q_1\hat{e}_2(0, t) - L_i\int_0^t (e_2(0, \tau) - \hat{e}_2(0, \tau)) \, d\tau + q_2U(t).
\end{align*}
\]  \hspace{1cm} (91)-(94)

In the previous equations, \(\dot{e}_1\) and \(\dot{e}_2\) are the estimates of the state variables \(e_1\) and \(e_2\), the terms \(r(x)\) and \(s(x)\) are the output injection gains, and \(L_i \in \mathbb{R} \setminus \{0\}\) is an integral tuning parameter. In order to reject perturbation to guarantee the convergence of the estimated state to the real state, an integral term is added to a boundary condition of the observer.

The objective is to use the backstepping transformation to find \(r(x)\) and \(s(x)\) such that \((\dot{e}_1, \dot{e}_2)^\top\) converges to \((e_1, e_2)^\top\). The error system can be obtained by subtracting the estimate system (91)-(94) from the original system (26)-(34) and (32)-(30),

\[
\begin{align*}
\bar{e}_1(x, t) + \lambda_1(x)\bar{e}_1(x, t) + c_1(x)\bar{e}_2(x, t) &= -r(x)e_2(0, t), \\
\bar{e}_2(x, t) - \lambda_2(x)\bar{e}_2(x, t) + c_2(x)\bar{e}_1(x, t) &= -s(x)e_2(0, t), \\
\bar{e}_2(L, t) &= \frac{1}{\kappa}\bar{e}_1(L, t), \\
\bar{e}_1(0, t) &= q_1\bar{e}_2(0, t) + L_i\int_0^t \bar{e}_2(0, \tau) \, d\tau + q_2\bar{B}(t),
\end{align*}
\]  \hspace{1cm} (95)-(98)

where \(\bar{e}_1(x, t) = e_1(x, t) - \hat{e}_1(x, t)\), and \(\bar{e}_2(x, t) = e_2(x, t) - \hat{e}_2(x, t)\).

In order to guarantee the iISS of the error system (95)-(98), the target system (35)-(39) is mapped into the error system...
by using the backstepping transformation

\[ \tilde{e}_1(x, t) = \alpha(x, t) + \int_0^x F^{11}(x, \xi) \alpha(\xi, t) \, d\xi + \int_0^x F^{12}(x, \xi) \beta(\xi, t) \, d\xi, \tag{99} \]

\[ \tilde{e}_2(x, t) = \beta(x, t) + \int_0^x F^{21}(x, \xi) \alpha(\xi, t) \, d\xi + \int_0^x F^{22}(x, \xi) \beta(\xi, t) \, d\xi, \tag{100} \]

where the functions \( F^{ij}(x, \xi) \) in \( L^2((0, L)^2; \mathbb{R}) \), \( i, j = 1, 2 \) have to be determined on the triangular domain \( \Omega \).

Differentiating the transformation (99) and (100) with respect to \( t \) and \( x \), substituting the results into the error system (95)-(98) and using the equations of the target system (35)-(39), the following kernel equations can be derived,

\[ \lambda_1(x) F^{11}_{\xi}(x, \xi) + \lambda_1(\xi) F^{11}(x, \xi) = -\lambda_1'(\xi) F^{11}(x, \xi) - c_1(x) F^{21}(x, \xi), \tag{101} \]

\[ \lambda_1(x) F^{12}_{\xi}(x, \xi) - \lambda_2(\xi) F^{12}(x, \xi) = \lambda_2'(\xi) F^{12}(x, \xi) - c_1(x) F^{22}(x, \xi), \tag{102} \]

\[ \lambda_2(x) F^{21}_{\xi}(x, \xi) - \lambda_1(\xi) F^{21}(x, \xi) = \lambda_1'(\xi) F^{21}(x, \xi) + c_2(x) F^{11}(x, \xi), \tag{103} \]

\[ \lambda_2(x) F^{22}_{\xi}(x, \xi) + \lambda_2(\xi) F^{22}(x, \xi) = -\lambda_2'(\xi) F^{22}(x, \xi) + c_2(x) F^{12}(x, \xi). \tag{104} \]

with the boundary conditions

\[ F^{11}(L, \xi) = \kappa F^{21}(L, \xi), \tag{105} \]

\[ F^{12}(x, x) = -\frac{c_1(x)}{\lambda_1(x) + \lambda_2(x)}, \tag{106} \]

\[ F^{21}(x, x) = \frac{c_2(x)}{\lambda_1(x) + \lambda_2(x)}, \tag{107} \]

\[ F^{22}(L, \xi) = \frac{1}{\kappa} F^{12}(L, \xi). \tag{108} \]

The injection gains are, for all \( x \) in \([0, L]\),

\[ r(x) = \lambda_2(0) F^{12}(x, 0) - \left(1 - \frac{L}{K_1}\right) \lambda_1(0) F^{11}(x, 0), \tag{109} \]

\[ s(x) = \lambda_2(0) F^{22}(x, 0) - \left(1 - \frac{L}{K_1}\right) \lambda_1(0) F^{21}(x, 0). \tag{110} \]

The kernels \( F^{11}(x, \xi), F^{12}(x, \xi), F^{21}(x, \xi) \) and \( F^{22}(x, \xi) \) are the solutions to the kernel equations (101)-(108). The well-posedness of the solutions to kernel equations (101)-(108) is guaranteed by the Theorem A.1 in [18] in the triangular domain \( \Delta_2 \) following a coordinate change \( (x, \xi) \mapsto (L - \xi, L - x) \).

Based on the reversibility of the backstepping transformation, it is straightforward to prove the iISS of the error system (95)-(98) in the \( L^2 \) sense through studying the stability of the target system (35)-(39). Let

\[ \bar{\eta}(t) = \int_0^t \tilde{e}_2(0, \tau) \, d\tau + L_1^{-1} q_2 \beta(t). \tag{111} \]

the following theorem concerning the iISS of the error system (95)-(98) implies that the state estimates go to the real values as time goes on.

**Theorem 2 (iISS of Error System)** Under the assumptions of Theorem 1, consider the system (95)-(98), and the functions \( r \) and \( s \) respectively determined by (109) and (110), where \( F^{11}(x, 0), F^{12}(x, 0), F^{21}(x, 0) \) and \( F^{22}(x, 0) \) (\( x \) in \([0, L]\)) are obtained
Theorem 3 (iISS of Closed-loop System) Under the assumptions of Theorem 1, for any \((\bar{e}_1(\cdot, 0), \bar{e}_2(\cdot, 0), \bar{e}_3(\cdot, 0), \bar{e}_4(\cdot, 0))^T\) in \(L^2((0, L); \mathbb{R}^4)\) in \(\mathbb{R}\), the observer-based output feedback controller (113) makes the equilibrium of the system (26)-(34) and (32)-(30) and the error system (95)-(98) integral input-to-state stable in the \(L^2\) sense, that is there exists positive constants \(\Omega_3, b_3\) such that along the solution to (26)-(34), for any \(\bar{p}\) such that \(\bar{p} \in \mathcal{L}^2[0, \infty)\), it holds, for all \(t \in [0, \infty)\),

\[
\int_0^t \left( \dot{\bar{e}}_1^2(x, t) + \dot{\bar{e}}_2^2(x, t) \right)^{\frac{1}{2}} \, dt + \int_0^L \left( \bar{e}_1^2(x, t) + \bar{e}_2^2(x, t) \right) \, dx + L\eta^2(t) \leq \Omega_3 e^{-\theta t} \left[ \int_0^L \left( \dot{\bar{e}}_1^2(x, 0) + \dot{\bar{e}}_2^2(x, 0) \right)^{\frac{1}{2}} \, dx + L\eta^2(0) \right] + b_3 \int_0^t \bar{p}^2(s) \, ds. \tag{114}
\]

Proof The following candidate Lyapunov function is proposed,

\[
W = W_1 + W_2. \tag{115}
\]
where

\[
W_1 = \int_0^L \begin{bmatrix} e_1(x,t) \\ e_2(x,t) \\ \eta(t) \end{bmatrix}^T P_1(x) \begin{bmatrix} e_1(x,t) \\ e_2(x,t) \\ \eta(t) \end{bmatrix} dx, \quad (116)
\]

\[
W_2 = \int_0^L \begin{bmatrix} \tilde{e}_1(x,t) \\ \tilde{e}_2(x,t) \\ \tilde{\eta}(t) \end{bmatrix}^T P_2(x) \begin{bmatrix} \tilde{e}_1(x,t) \\ \tilde{e}_2(x,t) \\ \tilde{\eta}(t) \end{bmatrix} dx, \quad (117)
\]

with

\[
P_j(x) = \begin{bmatrix} \frac{P_1}{\lambda_1(x)} e^{-\mu x} & 0 & 0 \\ 0 & \frac{P_2}{\lambda_2(x)} e^{\mu x} & 0 \\ 0 & 0 & \frac{P_4}{\lambda_4(x)} e^{\mu x} \end{bmatrix}, \quad j = 1, 2, \quad \text{for all } x \in (0, L). \quad (118)
\]

From Theorem 1 and the invertibility and linearity of the backstepping transformation, for the system (26)-(34) and (32)-(30), there exist positive constants \( p_{11}, p_{12}, p_{14}, C, a_1, b \) and a constant \( p_{13} \) such that

\[
\dot{W}_1 \leq -\theta W_1 + a_1 \dot{\beta}^2(\cdot), \quad (119)
\]

and

\[
\int_0^L \left( e_1^2(x,t) + e_2^2(x,t) \right) dx + L\eta^2(t) \leq Ce^{-\theta t} \left( \int_0^L \left( e_1^2(x,0) + e_2^2(x,0) \right) dx + L\eta^2(0) \right) + b \int_0^t \dot{\beta}^2(s) ds. \quad (120)
\]

From Theorem 2, the iISS of the error system (95)-(98) guarantees exact estimation of the state \( e_1 \) and \( e_2 \) of the system (26)-(30) under the assumptions of Theorem 1, i.e., there exist positive constants \( p_{21}, p_{22}, p_{24}, a_2 \) and a constant \( p_{23} \) such that

\[
\dot{W}_2 \leq -\theta W_2 + a_2 \dot{\beta}^2(\cdot), \quad (121)
\]

and (112) hold.

According to the separation principle, and the inequalities (119)-(121), the Lyapunov function \( \dot{W} \) for the output feedback closed-loop system consisting of the original system (26)-(34) and (32)-(30) and the error system (95)-(98) satisfies

\[
\dot{W} = \dot{W}_1 + \dot{W}_2 \leq -\theta W + (a_1 + a_2) \dot{\beta}^2(\cdot). \quad (122)
\]

Then for \( \Omega_3 \geq \max \{ \Omega_2, C \}, b_3 = b + b_2 \), one can derive the following result from (112) and (120),

\[
\int_0^L \left( e_1^2(x,t) + e_2^2(x,t) \right) dx + L\eta^2(t) + \int_0^L \left( \tilde{e}_1^2(x,t) + \tilde{e}_2^2(x,t) \right) dx + L\tilde{\eta}^2(t) 
\]

\[
\leq \Omega_3 e^{-\theta t} \left( \int_0^L \left( e_1^2(x,0) + e_2^2(x,0) \right) dx + L\eta^2(0) + \int_0^L \left( \tilde{e}_1^2(x,0) + \tilde{e}_2^2(x,0) \right) dx + L\tilde{\eta}^2(0) \right) + b_3 \int_0^t \dot{\beta}^2(s) ds. \quad (123)
\]
Therefore, it is proved that with the control law (113), the equilibrium \( \varepsilon_1 \equiv \varepsilon_2 \equiv 0 \) of the system (26)-(34) and (32)-(30) is integral input-to-state stable in the \( L^2 \) sense.

5  |  **OPTIMAL CONTROLLER AND NUMERICAL STUDIES**

5.1  |  **Optimal controller**

From (114), the maximal value of \( \theta \) implies the highest rate of the exponential convergence of closed-loop system. In order to seek the optimal control law \( U(t) \) in (113), the following optimization problem for the maximal \( \theta \) can be considered to derive the optimal value of \( k_i \):

\[
\max \theta \\
\text{subject to } \mu, \theta, p_1, p_2, p_4, q_3, q_4 > 0, \text{ and (40)-(50) for all } x \in [0, L].
\]

(124)

Checking the constraints above, ask to deal with the matrix inequalities that are not directly numerically tackled due to the products between unknown parameters. The parameters \( k_i, \mu, \theta, m \) can be given through line search methods, and the other variables \( p_1, p_2, p_3, p_4 \) can be derived by solving linear matrix inequalities (LMIs). We discretize the spatial variable \( x \) on the domain \([0, L]\) to solve infinite LMIs.

5.2  |  **Simulations**

In order to demonstrate the performance of the proposed controller (113) in stabilizing the system (26)-(30) around the equilibrium, numerical simulations are done in this section. Given \( \bar{p}(t), \omega^*(x), v^*(x) \), compute controller for the linearized system and simulate the nonlinear model. For simulations, we illustrate by rush hour the traffic demand \( \bar{p}(t) \) serving as an exogenous variable for traffic flow model that varies on time scales.

For numerical simulations, the traffic parameters of a local road section under consideration are chosen as in [13]:

\( L = 1 \text{ km}, \nu_f = 150 \text{ km/h}, \rho_m = 200 \text{ veh./km}, \tau = 60 \text{ s}, \bar{p}(t) = 420e^{-10t} \text{ (veh./h)}, t \in [0, \infty) \). The steady state is chosen as
\( \rho^*(x) = 120 - 0.5x \) (veh./km), \( v^*(x) = 70 - 0.5x \) (km/h), \( x \in [0, L] \) which leads to the characteristic speeds \( \lambda_1 = 70 - 0.5x \), and \( \lambda_2 = 20 + 0.125x, x \in [0, L] \), then \( q_1 = -0.2857, q_2 = 0.0107, q_3 = 1, q_4 = 1, \kappa = 2.2487 \). The initial conditions are defined as

\[
\rho(x, 0) = \rho^*(x) + 0.5 \sin 4\pi x, \\
v(x, 0) = v^*(x) + 1.8 \cos 4\pi x.
\]

Solving (124) by using Matlab, Figure 2 shows the relation between maximal \( \theta \) and parameter \( k_i \). It is checked in this figure that the larger \( k_i \) is, the larger is \( \theta_{\text{max}} \) given by (124). This figure can be used to compute the best performance, given an amplitude constraint on \( k_i \). Choosing the control gain \( k_i = 35 \) in (89) and (113), \( \mu = 0.6, \) and \( m = 0.1, \) we get \( \theta = 7, p_1 = 10.6524, p_2 = 15.966, p_3 = 0.0059, p_4 = 564.0186, \) so that (40)-(50) hold. The integral tuning parameter is set \( L_i = 5 \) in (98), and using the method described and the code attached in Appendix F.2 of [27], the values of kernels \( G_{11}, G_{12}, G_{21}, G_{22} \) at \( x = 0 \) are derived from numerical computation of the kernel equations (81)-(88) and the values of \( F_{11}, F_{12}, F_{21}, F_{22} \) at \( x = 0 \) are obtained from the numerical computation of (101)-(108). Different from the previous research giving the explicit formula of backstepping transformations that can be used to deduce the explicit solutions of kernels, the numerical solutions of kernels in the general formation of backstepping transformations can be derived using [27].

The iISS of the error system can be seen in Figure 3. The evolution of the output feedback controller \( U(t) \) given by (113) is given in Figure 4. In Figure 5, the state of the closed-loop system with the output feedback control converges.
to zero steady state. This numerical result is consistent with Theorem 3. Figure 6 gives the numerical simulations of the nonlinear ARZ traffic model in closed loop with the controller that is computed with the linearized model. It is obvious that the designed observer-based output feedback controller for the linearized ARZ traffic system stabilizes the nonlinear system in the same way.

6 | CONCLUSION

The stabilization of the nonlinear Aw-Rascle-Zhang (ARZ) congestion traffic flow model with an unknown perturbation at the upstream boundary was considered in this paper. A full-state feedback controller was designed to stabilize the linear part of the nonlinear ARZ model. By designing an exponentially convergent observer which only needs to measure the upstream boundary state, an output state feedback controller and the iISS were achieved. Only the upstream inlet vehicles velocity was measured for the design of control law and the unpredicted perturbation was rejected by designing proper injection gains of the observer.

With the same method, some related problems could be considered. Instead of the congested regime, the free-flow regime will be studied in the future research work. Moreover, it could be a great help to apply our approach to
some other models or other balance laws rather than the traffic flow model. The method also can be used for other hyperbolic systems with more than two eigenvalues. We may also investigate the observer-based output feedback control for nonlinear systems.
