25 **Abstract**

26 The contamination of water by synthetic organic molecules and trace metals is a growing
27 challenge, in spite of the enormous research efforts being made in the field of water treatment.
28 In this study, reduced graphene oxide-copper sulphide (rGO-CuS) nanocomposites of different
29 rGO/CuS (2/1, 1/1, 1/2) molar ratios were fabricated *via* a facile one-step hydrothermal method.
30 The nanocomposite materials, named hereafter as 2rGO-CuS, rGO-CuS and rGO-2CuS, were
31 characterized using various analytical techniques, including X-ray diffraction (XRD), Raman
32 spectroscopy, transmission electron microscopy (TEM), energy dispersive X-ray (EDX)
33 spectroscopy, X-ray photoelectron spectroscopy (XPS) and UV–visible spectrophotometry.
34 The photocatalytic performance of the nanocomposites was assessed under visible light
35 irradiation ($\lambda > 420$ nm) for the simultaneous photocatalytic reduction of Cr(VI) and phenol
36 degradation. It was found that rGO-2CuS achieved a remarkable enhancement of the
37 photocatalytic activity among the prepared nanocomposites for the degradation of phenol and
38 reduction of Cr(VI). Therefore, the simultaneous photocatalytic phenol degradation and Cr(VI)
39 reduction over rGO-2CuS sample was further investigated. The experimental results revealed
40 that rGO-2CuS catalyst maintained good degradation efficacy of mixed pollutants after 6 runs
41 and dissolved oxygen was found to be essential to promote Cr(VI) reduction and phenol
42 degradation. A detailed photocatalytic activity under visible light irradiation mechanism was
43 proposed based on quenching experiments and fluorescence measurements.

49

50 **1. Introduction**

51 Photocatalysts are nowadays increasingly used to treat environmental problems, in
52 particular excessive discharges of industrial waste water. Industrial wastewater is often loaded
53 with traces of toxic metal ions (e.g., Cr(VI), Cd(II), As(V)), Hg(II)) as well as with harmful
54 organic pollutants (e.g., organic dyes, polychlorinated biphenyls, phenol...) at the same time
55 [1-3]. Among the metal ions, hexavalent chromium, Cr(VI), is a highly toxic and non-
56 biodegradable pollutant, which can cause different health problems such as cancer pulmonary
57 congestions, and liver damage. Owing to its high toxicity, Cr(VI) has been classified as a
58 priority pollutant by the United States Environmental Protection Agency (USEPA) and many
59 other countries [4, 5]. Therefore, several methods have been developed for Cr(VI) removal,
60 including ion exchange, chemical precipitation, adsorption and membrane separation
61 techniques [6, 7]. Currently, the reduction of Cr(VI) to Cr(III) using photocatalysis is
62 considered to be the most promising approach, as it reduces the highly toxic Cr(VI) to less
63 harmful Cr(III), a trace element necessary for human beings [8]. On the other hand, organic
64 pollutants like phenolic compounds are major pollutants of the aquatic environment with
65 carcinogenic and mutagenic characters, causing a risk to human health [9, 10].

66 Hence, the development of catalysts for the simultaneous removal of organic pollutants and
67 metal ions from wastewater represents an appealing approach. The strategy consists of using
68 semiconductor catalysts, which upon light irradiation, the photogenerated electron-hole pairs
69 are consumed separately in the corresponding oxidation and reduction half-reactions. This
70 process not only prevents the recombination of the electron-hole pairs, but also improves the
71 photocatalytic efficiency [11, 12].

72 Although semiconductors such TiO₂, ZnO and their nanocomposites have been used for the
73 simultaneous Cr(VI) reduction and phenol oxidation [11, 13-15], these photocatalytic processes
74 have been conducted under UV light irradiation due to the wide band gaps of TiO₂ and ZnO,

75 which hinders their widespread application. To overcome this limitation and extend
76 photocatalyst absorption to the visible range, coupling TiO₂ with other semiconductor materials
77 has been adopted as an effective strategy. For instance, TiO₂/Co-g-C₃N₄ [16], Tb_xO_y loaded
78 TiO₂-oriented nanosheets [17], N-doped TiO₂-carbon composite fibres [18], Cu-doped TiO₂
79 nanoparticles modified with 8-hydroxyquinoline [19], carbon nitride loaded into titanium
80 incorporated SBA-15 mesoporous silica (Ti-SBA15-CN) [10], and CdS/TiO₂ [20] have been
81 successfully applied for simultaneous removal of metal ions and organic pollutants. For a more
82 efficient use of visible light, various narrow-band gap semiconductor photocatalysts, such as
83 BiVO₄ [21], bismuth oxyiodide/reduced graphene oxide/bismuth sulphide (BiOI/rGO/Bi₂S₃)
84 [22], PANI-sensitized g-C₃N₄/ZnFe₂O₄ heterostructure [23], AgI(β)/Bi₂O₃(β)- Bi₂O₂CO₃
85 composite [24], and Au-Pd nanoparticles loaded on g-C₃N₄/MCM-41 [25] have been
86 investigated for this photochemical process. Nevertheless, it is well-established that some of
87 these photocatalysts have certain disadvantages such as photo-corrosion and instability.
88 Therefore, it is important to develop highly efficient and robust photocatalysts for the
89 simultaneous treatment of mixed pollutants.

90 A huge effort has been devoted to the development of visible light photocatalysts to
91 maximize the use of clean, safe and abundant solar energy. In recent years, transition metal
92 dichalcogenide (TMD) nanostructures have drawn enormous attention, owing to their
93 outstanding electronic and optical properties as well as their wide applications in different
94 fields, including energy conversion devices, photocatalysis, photovoltaics, biosensors, etc. [26-
95 28]. Among them, the non-toxic, cheap and *p*-type semiconductor copper sulphide (CuS)
96 exhibits excellent luminescence and photochemical properties with a narrow band gap (1.2–
97 2.2 eV), which is dependent on the CuS crystalline phase. CuS can harvest efficiently photons
98 in the visible absorption window and thus makes it an interesting semiconductor for
99 photocatalytic processes [2, 29]. However, the catalytic activity of CuS is not satisfactory due

100 to its poor absorption and low separation efficiency of photogenerated electron-hole pairs along
101 with its anti-photo-corrosion stability. Therefore, improving the photo-activity and
102 photostability of CuS remains a challenge and a priority for practical application in the
103 environmental field [30, 31].

104 Graphene-based materials have received a great deal of attention. Currently, constructing
105 heterostructures between semiconductors and graphene can reduce the possibility of electron-
106 hole pair recombination to further improve the photocatalytic performance [32, 33]. Due to the
107 presence of electronic interactions and the charge equilibrium between semiconductor materials
108 and graphene sheets, the potential of the conduction band of the materials is reduced, resulting
109 in an increase in the photoinduced electron migration efficiency and a negative shift in the
110 Fermi level of the materials [34, 35]. In addition, graphene acting as a carrier could enhance the
111 degree of dispersion of the original samples to provide more reactive sites, which would lead
112 to increased photocatalytic activity [34].

113 In the present study, we report a facile and practical strategy for the synthesis of reduced
114 graphene oxide-copper sulphide (rGO-CuS) composites by a one-step hydrothermal approach.
115 Their catalytic activities are systematically investigated for the simultaneous photocatalytic
116 reduction of Cr(VI) and oxidation of phenol to seek enhanced performance. In order to better
117 understand the synergistic effect between Cr(VI) reduction and oxidation of phenol, systematic
118 experiments were performed, including control experiments to reveal the roles of Cr(VI),
119 phenol and rGO-CuS in the oxidation and reduction processes. The effects of the initial
120 concentration of the substrates, pH and active oxygen species in the degradation process were
121 investigated experimentally and the photocatalytic degradation mechanism was therefore
122 proposed.

123

124

125 **2. Experimental section**

126 **2.1. Synthesis of catalysts**

127 The preparation of the rGO-CuS nanocomposites (2rGO-CuS, rGO-CuS and rGO-2CuS) was
128 carried out by an easy hydrothermal method in a one-step process. To 40 mL of Milli-Q (MQ)
129 water was added 40 mg of graphene oxide (GO) powder. A homogeneous solution was prepared
130 by ultrasonic (464 W, 35 Hz) irradiation for 2 h. To this solution was added 20, 40 or 80 mg of
131 copper sulphate (CuSO_4) under magnetic stirring to obtain a solution (a). Then 25 mg of
132 thiourea was dissolved in 25 mL of MQ water to obtain a solution (b). Solutions (a) and (b)
133 were mixed together and transferred into a 100 mL Teflon-lined autoclave and heated at 110
134 °C for 14 h. The suspensions of the obtained mixtures 2rGO-CuS, rGO-CuS and rGO-2CuS
135 were centrifuged at 8000 rpm for 20 min for efficient separation from supernatant, washed
136 repeatedly with MQ water and ethanol, and finally dried in a vacuum oven at room temperature
137 for 12 h. For comparison, the pure CuS was synthesized by the similar experimental process in
138 absence of GO powder. Similarly, rGO was prepared in absence of CuS precursors under the
139 same hydrothermal process.

140 **2.2. Photocatalytic activity test**

141 The photocatalytic activities of the products were tested for the reduction of Cr(VI) under
142 visible light irradiation. For all photocatalytic tests, a 50 mL aqueous solution containing a
143 certain amount of Cr(VI) ($\text{K}_2\text{Cr}_2\text{O}_7$) and 0.5 g L^{-1} of the catalyst in absence or presence of
144 phenol was prepared. The pH of the suspension was adjusted by using 0.1 M HCl or 0.1 M
145 NaOH solution. The resulting suspension was ultrasonicated for 1 min and magnetically stirred
146 for 0.5 h in the dark to ensure adsorption–desorption equilibrium.

147 The aqueous solution was irradiated under stirring at room temperature in air through with a
148 cut off filter ($\lambda > 420 \text{ nm}$, to suppress the light with wavelength shorter than 420 nm) using a
149 visible fiber lamp (Spot Light Source 400–700 nm, L9566-03, Hamamatsu, Japan). The

150 intensity of the light was measured using a PM600TM Laser Fiber Power Meter (Coherent Inc,
151 USA) and was determined as being 0.4 W cm^{-2} . During the visible light irradiation, about 2 mL
152 of the suspension was taken from the reaction cell at given time intervals, and then centrifuged
153 to remove the photocatalyst particles. The concentration of Cr(VI) was determined by the
154 diphenylcarbazide (DPC) method [15]. The absorbance of sample solutions was measured
155 using UV-vis spectrophotometry at 540 nm after full color development. The concentration of
156 phenol was measured by a HPLC system. Additionally, the total Cr content was also determined
157 by ICP-AES.

158 **2.3. Hydroxyl radical ($\cdot\text{OH}$) formation measurement**

159 The formation of $\cdot\text{OH}$ radicals in presence of rGO, CuS, 2rGO-CuS, rGO-CuS and rGO-2CuS
160 under visible light illumination was monitored by using terephthalic acid (TA) as the
161 fluorescence probe. It is known that TA reacts with $\cdot\text{OH}$ in basic solution to generate 2-
162 hydroxyterephthalic acid (TAOH), which fluoresces at approximately 426 nm upon excitation
163 at 312 nm [36]. In a typical process, 0.5 g/L of nanocomposite were dispersed in an aqueous
164 solution (3 mL) containing $5 \times 10^{-4} \text{ M}$ TA and $2 \times 10^{-3} \text{ M}$ NaOH in a spectrometric quartz
165 cuvette. The mixed solution was stirred in the dark for 10 min. After irradiation under the visible
166 light, the reaction solution was centrifuged to remove the sample particles. The filtrate was
167 analyzed using a PL spectrophotometer.

168

169 **3. Results and discussion**

170 **3.1. Characterization**

171 The phase composition and crystal structure of the CuS and CuS-rGO nanocomposites were
172 studied with X-ray diffraction (XRD) (**Fig. 1** and **Fig. S1**). The presence of sharp diffraction
173 peaks evidences that the as-obtained products are crystalline. The XRD patterns of CuS and
174 CuS-rGO nanocomposites comprise several peaks at 10.8° , 21.7° , 27.1° , 27.6° , 29.2° , 31.7° ,

175 32.7°, 38.8°, 43.2°, 44.3°, 47.8°, 52.7°, 57.1° and 59.3° ascribed to the (002), (004), (100),
176 (101), (102), (103), (006), (105), (106), (008), (110), (108), (202) and (116) diffraction planes,
177 respectively [37]. All the diffraction peaks can be perfectly indexed as hexagonal covellite CuS
178 (space group: $P63|mmc$), which are in good agreement with the JCPDS no. 78-2391, with cell
179 parameters $a=3.796 \text{ \AA}$ and $c=16.36 \text{ \AA}$. The absence of GO diffraction peak and the appearance
180 of broad diffraction peak at $\sim 22.4^\circ$ in the XRD patterns of CuS-rGO nanocomposites indicates
181 the effective reduction of GO to rGO [38]. The XRD patterns reveal that the products were
182 devoid of any detectable impurities or any other phases. Moreover, the addition of GO did not
183 affect the crystal orientation of the CuS nanocomposites.

184 Raman spectroscopy is a powerful and non-destructive technique for investigating the
185 structural nature of carbon-based materials such as graphene [39, 40]. **Figure S2** depicts the
186 Raman spectra of GO, rGO, CuS and rGO-CuS nanocomposites. The Raman spectrum of GO
187 exhibits two main characteristic peaks, the D band at $\sim 1368 \text{ cm}^{-1}$ attributed to defects and
188 disorder in the hexagonal graphitic layers, and the G band at $\sim 1589 \text{ cm}^{-1}$ ascribed to the
189 vibration of sp^2 carbon atoms in the 2D hexagonal lattice. Similarly, the Raman spectrum of
190 rGO comprises the characteristic D and G bands at respectively 1368 and 1589 cm^{-1} .
191 Meanwhile, the Raman spectrum of the CuS displays a strong and sharp band at $\sim 468 \text{ cm}^{-1}$
192 assigned to the S-S stretching mode of A_{1g} symmetry of CuS with a hexagonal structure [41,
193 42]. For rGO-CuS nanocomposites, all the Raman spectra consist of the D and G bands of rGO
194 along with the peak of CuS. It is important to notice a red-shift of the D and G bands to 1353
195 and 1584 cm^{-1} , respectively, indicating the high ability for recovery of the hexagonal network
196 of carbon atom and the presence of charge transfer between rGO and CuS [42].
197 The intensity ratio of the D and G bands (I_D/I_G) for rGO-2CuS increases to 1.31 (**Table S1**), as
198 compared to 0.85 recorded for GO. These observations further confirm the formation of new

199 and smaller sp^2 domains and testifies the reduction of GO to rGO during the hydrothermal
200 reaction [40]. The results are in good agreement with XRD patterns.

201 Transmission electron microscopy (TEM) and selected area electron diffraction (SAED)
202 were further performed to assess the mesoporous structure and morphology of CuS and rGO-
203 2CuS nanocomposite. **Figure 2a** depicts the TEM image of rGO-2CuS nanocomposite. It can
204 be seen that all rGO sheets are densely decorated with a large quantity of small nanoparticles,
205 and the rGO sheets in the composite are made of a few layers of graphene sheets. A close look
206 at these nanoparticles reveals that they are randomly distributed on the surface with size ranging
207 from 20 to 30 nm, as shown in **Figure 2c**. The HRTEM image, conducted on the scattered
208 nanosheets, is displayed in **Figure 2b**. The regular spacing of the clear lattice planes is
209 calculated to be 0.305 nm, which is consistent with the d spacing for the (1 0 2) crystal plane of
210 hexagonal phase of CuS [2]. Furthermore, the selected area electron diffraction (SAED) pattern
211 demonstrated the growth of single crystals of CuS (**Fig. 2d**). Thus, these results are in good
212 agreement with XRD analysis.

213 In addition, the corresponding EDX plot is shown in **Figure S3**. It clearly confirms the
214 presence of Cu, S, and C elements with an atomic ratio of elemental copper and sulfur of
215 approximately 1:1 (other peaks originate from the substrate used). This result indicates that
216 individual CuS nanoparticles are well anchored onto the graphene sheets during the
217 hydrothermal synthesis and prevent the restacking of rGO sheets during the reduction process.

218 The chemical composition of the rGO-2CuS composite was further confirmed by X-ray
219 photoelectron spectroscopy (XPS) analysis (**Fig. S4**). The XPS survey spectrum in **Figure S4a**
220 clearly shows the peaks of Cu_{2p} , S_{2p} , O_{1s} , and C_{1s} [2, 42]. The O_{1s} and C_{1s} originate from rGO.
221 **Figure S4b** displays the core level spectrum of the Cu_{2p} , comprising two peaks at 933.75 and
222 953.54 eV, which can be appropriately curve-fitted with four bands. The peaks at 933.75 and
223 952.25 eV are assigned respectively to $Cu_{2p_{3/2}}$ and $Cu_{2p_{1/2}}$ of Cu^+ , while the peaks at 935.75 and

224 954.38 eV are attributed to the characteristic peaks of $\text{Cu}_{2p_{3/2}}$ and $\text{Cu}_{2p_{1/2}}$ of Cu^{2+} , in accordance
225 with the literature data [43]. The Auger line of Cu (Cu LMM) at 568.4 eV is the typical binding
226 energy value of CuS [42, 44]. Also, the two weak shake-up satellite lines at 943.0 eV and
227 962.6 eV indicate the presence of the paramagnetic chemical state of Cu^{2+} [2, 42, 44]. In the
228 case of S_{2p} region (**Fig. S4c**), the deconvolution of the S_{2p} spectrum leads to two main doublets
229 at (161.5, 163.8 eV) and (164.6, 165.4 eV), that are typical values for metal sulphides and can
230 be attributed to sulphide and disulphide, respectively [43]. Moreover, the peaks at (166.4,
231 168.13 eV) and (168.97, 170.11 eV) are assigned to polysulfides, sulfate or thiosulfate (SO_4^{2-}
232 or $\text{S}_2\text{O}_3^{2-}$) due to some surface oxidation [43]. The core level C_{1s} spectrum of the rGO-2CuS
233 composite can be curve-fitted with three Gaussian peaks (**Fig. S4d**). The peak centered at 284.4
234 eV is attributed to the conjugated sp^2 -type C=C bonding in graphitic structure and the other two
235 peaks located at 285.0 and 288.7 eV are ascribed to C-C and C=O, respectively [39, 45].
236 Overall, the XPS data suggest that rGO-2CuS is well formed.

237 **Figure S5a** displays the UV-vis absorption spectra of the synthesized rGO, CuS and
238 CuS-rGO composites dispersed in water. The rGO exhibits an absorption peak at 245 nm, which
239 can be assigned to the π - π^* transition of aromatic C-C bonds along with a band at 410 nm due
240 to the n - π^* transition of C=O bonds [39]. The UV-vis absorption spectrum of pure CuS displays
241 a characteristic covellite CuS-like absorption band in the near-IR region due to inter-band
242 transitions between valence and unoccupied states [2, 42, 45]. The strong absorption in the
243 visible range holds promise for the potential application of CuS-based materials in
244 photocatalytic processes. Following the introduction of rGO, the absorbance of rGO-CuS
245 composites increased throughout the spectrum compared to the CuS sample as a result of the
246 absorption effect of rGO and the quantum effect of CuS. Moreover, it can be seen that a larger
247 blue absorption profile has occurred, which might be attributed to quantum confinement [46].

248 The optical band gap was calculated using Eq. (1) by plotting $(\alpha h\nu)^2$ vs. $(\alpha\nu)$, where ‘ α ’ is the
249 absorption coefficient, ‘ $h\nu$ ’ is the photon energy, ‘ A ’ is a constant, ‘ E_g ’ is the band gap and ‘ n ’
250 depends on the type of band gap of the semiconductor (for a direct gap, $n = 1/2$, while for an
251 indirect band gap, $n = 2$).

$$(\alpha h\nu)^n = A (\alpha\nu - E_g) \quad (1)$$

252
253 A plot of $(\alpha h\nu)^2$ vs. $(h\nu)$ gives a line whose interception on the energy axis corresponds to the
254 energy band gap. According to the above equation and based on a direct transition, as shown in
255 **Fig. S5b**, the calculated optical band gap of pure CuS was 2.13 eV. Upon hybridization with
256 rGO, the optical band gap of rGO-CuS nanocomposites changed from 2.06 to 1.96 eV when
257 GO content increased from 1 to 2. These band gaps are higher than the bulk value, which could
258 be due to quantum confinement in the small crystalline CuS nanostructures.

259 **3.2. Photocatalytic performance**

260 **3.2.1. Photocatalytic reduction of Cr(VI)**

261 The photocatalytic performance of the rGO-CuS nanocomposites (0.5 g/L) was examined
262 for the reduction of Cr(VI) (20 mg/L) aqueous solution as a toxic heavy metal pollutant. As
263 shown in **Figure 3**, no reduction occurred in absence of light or photocatalyst alone, indicating
264 that the reaction was mainly due to photocatalysis. The slight decrease of the Cr(VI) absorption
265 (~15%) after 30 min in the dark was ascribed to metal ion adsorption on the catalyst surface.

266 Under visible-light irradiation, rGO alone achieved a very weak performance for the
267 photocatalytic Cr(VI) reduction. CuS revealed high photoreduction activity of Cr(VI) to Cr(III)
268 with complete reduction after 70 min. Interestingly, the performance of CuS for Cr(VI)
269 photoreduction was improved through hybridization with rGO. Indeed, it could be seen that the
270 time for the complete reaction was reduced to 60 and 50 min in the presence of rGO-CuS and
271 rGO-2CuS, respectively. This contrasts with 2rGO-CuS catalyst for which a decrease of the

272 photocatalytic activity was observed (80% reduction after 70 min, as compared to 100%
273 achieved by CuS alone under otherwise identical experimental conditions). This decreased
274 activity can be ascribed to the reduced amount of CuS within 2rGO-CuS. All together, these
275 findings suggest that the visible light-induced photocatalytic activity of CuS nanoparticles can
276 be enhanced through hybridization with rGO, which is most likely due to increased efficiency
277 of light absorption and enhanced electron-hole separation of rGO-CuS nanocomposites [47].

278 **3.2.2. Effect of light intensity**

279 The influence of light intensity on Cr(VI) photoreduction process was investigated for light
280 intensity ranging from 0.1 to 0.5 W/cm² (**Fig. S6**). It was found that the photoreduction kinetics
281 were significantly affected by the light intensity; decreasing of the light intensity from 0.4 to
282 0.1 W/cm² led to a clear decrease of the reduction rate from 100 to 85% after 70 min. In contrast,
283 increasing the light intensity to 0.5 W/cm² had no effect on Cr(VI) reduction rate. Therefore,
284 the optimal irradiation intensity of visible light was fixed at 0.4 W/cm².

285 **3.2.3. Effect of pH on photoreduction of Cr(VI)**

286 The pH of the solution is a critical parameter in the photocatalytic process. The reduction
287 of Cr(VI) at different initial pH values is summarized in **Figure S7**. The kinetic of Cr(VI)
288 photoreduction increased slightly after 50 min of visible light illumination upon decreasing the
289 initial pH value from 5.8 (the pH of the initial solution) to 2.5, whereas only 66.3% and 33.7%
290 of Cr(VI) were photocatalytically removed at pH 7 and 8.5 within the same period, respectively.
291 The effect of the acidified pH is consistent with the reported results [10, 15].

292 The dominant chromium species in the solution at pH 2.5 is HCrO₄⁻ or Cr₂O₇²⁻ [5, 10].
293 Under these conditions, the photocatalyst surface can be highly protonated and thus leads to a
294 strong electrostatic attraction towards the main species in solution. The pH could significantly
295 influence the reduction of Cr(VI) to Cr(III) and a decrease in pH could increase the reduction
296 kinetics of Cr(VI) [5, 48]. Moreover, Cr(III) could form Cr(OH)₃ which could precipitate on

297 the surface of the photocatalyst at high pH solution, covering the activity sites of the catalysts
298 [8, 48].

299 **3.2.4. Synergistic effect of phenol on Cr(VI) photoreduction**

300 It has been previously reported in the literature that the coexistence of metal-organic
301 pollutants may enhance the photocatalytic reduction of Cr(VI) [10, 49]. In this work, the
302 influence of variable initial phenol concentration on the reduction of 20 mg/L Cr(VI) over rGO-
303 2CuS (0.5 g/L) was investigated (**Fig. 4a**). In the presence of phenol, the complete
304 photoreduction time of Cr(VI) was reduced from 50 to 20 min when the Cr(VI)/phenol ratio
305 was increased to 1:2, suggesting that the presence of phenol could improve Cr(VI) removal by
306 acting as a scavenger of photo-generated holes. It can be seen that upon increasing the
307 Cr(VI)/phenol ratio to 1:3, the time required to reach full reduction of Cr(VI) increased. This is
308 maybe due to an increase in intermediates adsorbed on the rGO-2CuS nanocomposite surface
309 with the increase in phenol concentration, which could cover the active sites of the catalyst [15].

310 **3.2.5. Effect of Cr(VI) on phenol photodegradation**

311 To assess the influence of Cr(VI) on phenol degradation, an aqueous solution of phenol (20
312 g/L), rGO-2CuS (0.5 g/L) and Cr(VI) (10 g/L) was irradiated under visible light for different
313 time intervals. It could be observed that the extent of phenol degradation also increased greatly
314 until complete degradation after 20 min of irradiation, following the addition of phenol/Cr(VI)
315 (1:2), as shown in **Figure 4b**. Furthermore, the improvement of phenol degradation indicates
316 that Cr(VI) is an efficient scavenger of photo-generated electrons, which is similar to the
317 observation reported in the literature [50, 51]. The results confirmed the synergistic effect
318 between Cr(VI) reduction and phenol oxidation.

319 The performance of the developed photocatalyst is comparable to and even better than that
320 achieved by the most photocatalysts described in the literature for the simultaneous Cr(VI)
321 photoreduction and phenol degradation (**Table S2**).

322 3.2.6. Kinetic study

323 The modeling of the kinetic data with an appropriate kinetic model allows to determine the
324 apparent rate constant and the order of reaction of the photocatalytic process. It is well-
325 established that the rate (r) of a photocatalytic reaction for a single component can be defined
326 using equation (2) [50, 52]:

$$327 \quad r = \ln\left(\frac{C}{C_0}\right) \approx -kKt = -k_{app} \quad (2)$$

329 where C_0 is the initial concentration, C is the concentration of reactant, t is time, k is the rate
330 constant of reaction, and k_{app} is the apparent rate constant.

332 Although this pseudo first-order rate equation has been extensively used in the literature for
333 modeling photocatalytic kinetic data, it is based on the Langmuir classical isothermal model,
334 which assumes a homogeneous surface. However, the surface of a catalyst is rarely
335 homogeneous and several studies have been carried out in this regard suggested the possibility
336 to use modified Langmuir–Freundlich isotherm (an isotherm for adsorption onto heterogeneous
337 surface from liquid phase), Equation 3 [52].

$$338 \quad \ln\left(\frac{C}{C_0}\right) = -k_{app}[cat]^\alpha t \quad (3)$$

339 where the plot of $\ln(C/C_0)$ versus t should give a line with a slope of $-k_{app}[cat]^\alpha$.

340 The determination of the order of reaction (α) is made by the methods introduced recently in
341 refs. [52, 53]. By plotting the normalized concentration (C/C_0) versus normalized time scale (t
342 $[cat]^\alpha$) at different concentrations of catalyst, the reaction order can be determined.

343 To study the kinetics of the photoreduction of Cr(VI) and phenol, the curves of $\ln(C/C_0)$ vs.
344 time were plotted at different conditions (**Fig. S8**). All plots are linear, confirming the pseudo
345 first-order reaction under the investigated experimental conditions. The obtained values of k_{app}
346 are summarized in **Tables S3** and **S4**.

347 3.27. Analysis of by-products of Cr(VI) and phenol

348 In order to better understand the photocatalytic process, the total residual concentration of
349 Cr ions after photocatalytic reduction was assessed by ICP-AES. The experiment was carried

350 out by visible light irradiation of a mixture of Cr(VI) (20 mg/L), phenol (20 mg/L) and GO-
351 2CuS (0.5 mg/L) at pH 5.8 (**Fig. 5**). After 20 min of irradiation, a concentration of 0.015 mg/L
352 of residual Cr(VI) ions was measured. This is far below the maximum allowable concentrations
353 of 0.25 mg/L for industrial wastewater and 0.05 mg/L for drinking water [1, 50, 54].

354 Furthermore, XPS analysis was used to study the chemical states of the Cr species adsorbed
355 on the catalyst surface after the photoreaction (**Fig. S9**). In the high-resolution spectrum of the
356 Cr_{2p}, the peaks located at 586.9 and 576.7 eV corresponding respectively to the 2p_{3/2} and 2p_{1/2}
357 orbitals are attributed to Cr(III) [2, 55]. These results also confirm that rGO-2CuS
358 nanocomposite is not only capable of simultaneously reducing Cr(VI) and oxidizing phenol,
359 but also of removing Cr ions by adsorption [10, 15].

360 To investigate further the mechanism of phenol degradation using rGO-2CuS
361 nanocomposite, the generated intermediate products were identified using high-performance
362 liquid chromatography (HPLC). The results of HPLC (**Fig. S10**) revealed that two main
363 intermediates identified as hydroquinone (7.4 min) and 1,4-benzoquinone (10.9 min) were
364 formed. Their identification by HPLC was done based on their retention time, as compared to
365 standard chemicals (**Fig. S11**). These by-products are formed following •OH radical addition to
366 the benzenic ring of phenol to yield hydroquinone and its subsequent oxidation to 1,4-
367 benzoquinone. It is not excluded that other by-products, derived from the ring-opening such as
368 short-chain acids, are also generated during the photochemical degradation of phenol over rGO-
369 2CuS [9]. However, the products derived from the opening of the benzene ring could not be
370 identified by HPLC. Instead, approximately 95% of the phenol was mineralized in 20 min (**Fig.**
371 **S12**), suggesting that the phenol was not only decomposed into small organic compounds, but
372 even mineralized into inorganic carbonaceous forms.

373 **3.2.8. Stability of rGO-2CuS photocatalyst**

374 Durability plays a key role in photocatalysis. Therefore, the repeatability and stability of the
375 photocatalyst were investigated. **Figures S13** and **S14** depict the performance of the recycled
376 rGO-2CuS nanocomposite for the mixed Cr(VI)/phenol system under visible light irradiation.
377 The photocatalyst was recovered by centrifugation after each cycle to regenerate the
378 photocatalyst and reused in the next cycle without any additional treatment. As can be observed,
379 even after 5 photocatalytic cycles, the photoreduction efficiency of Cr(VI) and phenol oxidation
380 were as high as 92% and 88%, respectively, and no significant loss of photocatalytic activity
381 can be seen during the cycling experiments. Furthermore, to demonstrate the stability of the
382 rGO-2CuS, XRD analysis of the used photocatalyst was performed (data not shown). The results
383 revealed that no significant changes took place in the XRD patterns before and after the cycling
384 test, indicating that the catalyst exhibits good visible-light photocatalytic stability.

385 **3.2.9. Mechanism of the photocatalytic activity**

386 **Figure 6** displays the photocatalytic conversion rates of Cr(VI) and phenol over rGO-2CuO
387 in the presence of different radical scavengers under visible light (> 420 nm) irradiation for 20
388 min. For reaction under N_2 ambient conditions, before the start of the experiments, the reaction
389 solution was purged with high-purity N_2 ($> 99.999\%$) for 1 h to remove dissolved O_2 as much
390 as possible, and continued to purge N_2 through the photocatalytic process. The recorded rates
391 of Cr(VI) reduction (**Fig. 6a**) and phenol degradation (**Fig. 6b**) in the mixed reaction system
392 were higher in ambient air than in ambient N_2 . This could be due to the major role of O_2 in the
393 photocatalytic reaction process, through the reaction of dissolved O_2 with photogenerated
394 electrons to produce the $O_2^{\cdot-}/\cdot OOH$ superoxide radicals [8, 51]. In the case of Cr(VI) reduction,
395 the suppression effect was more evident, it is ca. 60% Cr(VI) reduction after 40 min irradiation
396 in N_2 gas ambient compared with 100% reduction achieved in air after 20 min photoreaction.
397 This can be attributed to important roles of O_2 in the photocatalytic reaction process. Besides,
398 it has been reported that $O_2^{\cdot-}$ can reduce Cr(VI) to Cr(III) [56, 57]. Thus, in this study, $O_2^{\cdot-}$ may

399 also tend to reduce Cr(VI) during the photocatalytic reaction process. However, Cr(VI) can also
400 be reduced in the absence of O₂, as illustrated in **Figure 6a**. This indicates that CB electrons
401 from rGO-2CuS also contribute to the reduction of Cr(VI). While the purging effect of N₂ on
402 phenol degradation is less obvious, suggesting that the phenol could be degraded by valence
403 band (VB) holes when photogenerated electrons were scavenged by Cr(VI) in mixed
404 Cr(VI)/phenol system. In the presence of Cr(VI), conduction band (CB) electron scavenging
405 and electron-hole separation are enhanced, increasing the rate of phenol degradation, as shown
406 in **Figure 6b**.

407 In **Figure 6a**, introduction of 1 mM EDTA-Na₂, a hole scavenger, leads to a decrease in the
408 photoreduction activity of Cr(VI). Furthermore, when the reaction process was carried out
409 under N₂ ambient, Cr(VI) reduction decreased to higher extent than in the presence of EDTA-
410 Na₂ only. This could be attributed to the decreased electron transportation of the O₂/O₂^{•-}
411 mediated reduction in the absence of dissolved oxygen. Besides, it was previously reported that
412 Cr(VI) could be reduced by either photogenerated electrons or other active species [56, 57].
413 The O₂^{•-} is generated from the dissolved oxygen and photo-generated electrons of the rGO-
414 2CuS under irradiation, and could then be transformed into H₂O₂ and/or hydroxyl radical ([•]OH)
415 in water. Potentially, the O₂/O₂^{•-} mediator not only improves the electron transfer for CB to
416 Cr(VI), but also promotes the formation of [•]OH from H₂O per photogenerated hole [56].

417 In this study, in the event that the CB position of a semiconductor is more negative than the
418 reduction potential of O₂/O₂^{•-}, trapping of photogenerated electrons with molecular oxygen is
419 possible to produce O₂^{•-} and the photocatalytic reduction is also enhanced by effective
420 consumption of photogenerated holes in this mixed photocatalytic process [51, 56].

421 The photocatalytic activity of phenol degradation with the addition of EDTA-Na₂ was also
422 examined (**Fig. 6b**). The results revealed that when EDTA-Na₂ was introduced into the reaction
423 system, it caused a rapid deactivation of the rGO-2CuS photocatalyst and the degradation

424 efficiency of phenol was decreased from 100% to 56% after 20 min visible light irradiation.
425 The result clearly indicates that the phenol degradation mainly relies on the photogenerated
426 holes [8, 58]. It is also observed that the photodegradation efficiency in air is higher than that
427 in ambient N₂. This can be attributed to dissolved oxygen, which promotes oxidation. However,
428 the effect of dissolved oxygen was not so obvious in the presence of EDTA-Na₂, indicating that
429 h⁺ are the most important reactive species for phenol oxidation.

430 In the photocatalytic reaction, the hydroxyl radical ([•]OH) is considered to be the most
431 important active group. Thus, a study of [•]OH radical formation can provide a quantitative index
432 to estimate the number of charge carriers actually implicated in phenol degradation. It is well-
433 established that the terephthalic (TA) fluorescence method is a very sensitive technique used to
434 detect the amount of [•]OH produced and whose increase implies an improvement in
435 photocatalytic efficiency. The method relies on the reaction of TA with [•]OH to generate a
436 fluorescent TAOH (maximum emission at ~426 nm) [36, 50]. From **Figure S15a**, the rGO-
437 2CuS nanocomposite showed a considerably higher amount of [•]OH production than CuS. This
438 outcome is in good accordance with the results of photodegradation of phenol.

439 From the results of the experiments, we suggest a plausible mechanism for the
440 photocatalytic reduction of Cr(VI) and oxidation of phenol over rGO-2CuS. Under visible light
441 irradiation, rGO-2CuS could generate electrons and holes. Following this, the electrons in the
442 CB of the rGO-2CuS in the ambient air are scavenged by O₂ to generate O₂^{•-} and migrate to
443 Cr(VI) to reduce it. Meanwhile, the photogenerated holes left behind in the VB could produce
444 [•]OH from H₂O. H₂O₂ could be produced by superoxide radical and H⁺. Besides, O₂^{•-} not only
445 could induce organics oxidation, but also could promote the Cr(VI) reduction by a two-step
446 O₂^{•-} mediated indirect reduction process [56]. In addition, due to the high oxidation efficiency
447 of H₂O₂, its existence would inevitably lead to the oxidation of reduced chromium to Cr(VI).
448 The existence of H₂O₂ in the catalytic system was highlighted by the absorption peak of o-

449 tolidine at 446 nm in the UV-vis spectrum [51, 59]. From **Figure S15b**, as the intensity of the
 450 absorption peak decreases, the H₂O₂ content of the simple solution of Cr(VI) and phenol
 451 decreases compared to that of the water under visible light irradiation. In case the Cr(VI)/phenol
 452 combined system, almost no H₂O₂ could be observed, suggesting that phenol degradation could
 453 be effective in consuming H₂O₂ and inhibiting oxidation of the lower valence states of
 454 chromium to improve Cr(VI) reduction activity [51]. Moreover, the photogenerated holes and
 455 various active oxidants, such as H₂O₂, [•]OH and O₂^{•-}, could oxidize phenol. During this
 456 photocatalytic reaction system, Cr(VI) acts as an electron acceptor, which can react with the
 457 photogenerated CB electrons; and meanwhile, phenol acts as an electron donor, which can react
 458 with the photoexcited holes. Both processes can enhance the separation rate of the
 459 photogenerated electron holes, resulting in much more CB electrons for Cr(VI) reduction and
 460 VB holes for phenol oxidation.

461 The above results show the synergistic effect of mixed Cr(VI)/phenol system. The
 462 generation of photogenerated electron-hole pairs, radicals and the reaction process can be
 463 summarized according to the following equations:

464

465 Therefore, based on the results and analysis of the experiments, a plausible mechanism was
466 proposed and illustrated in **Figure 7**.

467

468 **4. Conclusion**

469 In conclusion, rGO/CuS composites of different rGO/CuS weight (2/1, 1/1, 1/2) ratios were
470 fabricated *via* a facile one-step method and their photocatalytic activity in the reduction of
471 Cr(VI) was studied under visible light irradiation. The rGO-2CuS nanocomposite exhibited a
472 significantly high photocatalytic activity under visible light irradiation. In the Cr(VI)/phenol
473 mixed reaction solution, rGO-2CuS displayed enhanced photocatalytic activity for the
474 simultaneous photocatalytic reduction of Cr(VI) and oxidation of phenol. Cycling experiments
475 revealed that the prepared rGO-2CuS presents high stability. The phenol degradation, which
476 effectively consumes H_2O_2 , $\text{O}_2^{\cdot-}$, $\cdot\text{OH}$ and holes, not only promotes separation of
477 photogenerated electrons and holes, but also increases chromium reduction in Cr(VI)/phenol
478 systems. The detailed reaction mechanism for the photocatalytic reduction of Cr(VI) and
479 oxidation of phenol over rGO-2CuS was proposed. The highly effective photoactivity and high
480 stability properties effectively remove a large number of organic pollutants in aqueous systems,
481 which can potentially be applied in the photocatalytic field.

682 **Figure captions**

683 **Figure 1:** X-ray diffraction patterns of pure CuS and rGO-2CuS nanocomposite.

684 **Figure 2:** (a) Typical TEM images, (b) HRTEM image (inset is the high magnification TEM
685 image of rGO-2CuS), (c) HRTEM image showing lattice planes, and (d) selected area electron
686 diffraction (SAED) pattern of rGO-2CuS.

687 **Figure 3:** Photocatalytic reduction of Cr(VI) (20 mg/L) over rGO-CuS (0.5 g/L) under visible
688 light irradiation ($\lambda > 420$ nm).

689 **Figure 4:** (a) Photocatalytic reduction efficiencies of Cr(VI) (20 mg/L) in presence and absence
690 of phenol (10 mg/L) at different ratios, (blank test: reduction of Cr(VI) in presence of phenol
691 (ratio 1:2) without catalyst). (b) Photocatalytic degradation of phenol (20 mg/L) in presence
692 and absence of Cr(VI) (10 mg/L) at different ratios, (blank test: degradation of phenol in
693 presence of Cr(VI) (ratio 1:2) without catalyst); rGO-2CuS=0.5 g/L, pH = 5.8, visible light.

694 **Figure 5:** (a) Efficiency of removal of Cr, Cr(VI)+Cr(III) in the coexisting Cr(VI)-phenol
695 system, (b) Distribution of the intermediates during the degradation process of phenol.

696 **Figure 6:** (a) Cr(VI) reduction and (b) phenol degradation in presence of different scavengers
697 and various ambient conditions under visible light irradiation. Reaction conditions: catalyst
698 loading = 0.5 g/L, [phenol]=20 mg/L, [Cr(VI)]=20 mg/L, pH= 5.8, T = 25°C.

699 **Figure 7:** Schematic illustration for the synergistic photocatalysis of Cr(VI) reduction and
700 phenol degradation over rGO-2CuS catalyst.
